#### Abstract

A family $\mathcal{P}$ of subgraphs of $G$ is called a path cover (resp. a path partition) of $G$ if $\bigcup_{P \in \mathcal{P}} V(P)=V(G)$ (resp. $\left.\dot{\bigcup}_{P \in \mathcal{P}} V(P)=V(G)\right)$ and every element of $\mathcal{P}$ is a path. The minimum cardinality of a path cover (resp. a path partition) of $G$ is denoted by $\operatorname{pc}(G)($ resp. $\operatorname{pp}(G))$. In this paper, we characterize the forbidden subgraph conditions assuring us that $\operatorname{pc}(G)(\operatorname{or} \operatorname{pp}(G))$ is bounded by a constant. Our main results introduce a new Ramsey-type problem.

Key words and phrases. path cover number, path partition number, forbidden subgraph, Ramsey number

AMS 2020 Mathematics Subject Classification. 05C38, 05C55.

## 1 Introduction

All graphs considered in this paper are finite, simple, and undirected. For terms and symbols not defined in this paper, we refer the reader to [2].

Let $G$ be a graph. Let $V(G)$ and $E(G)$ denote the vertex set and the edge set of $G$, respectively. For a vertex $x \in V(G)$, let $N_{G}(x)$ denote the neighborhood of $x$ in $G$; thus $N_{G}(x)=\{y \in V(G): x y \in E(G)\}$. For a subset $X$ of $V(G)$, let $N_{G}(X)=\left(\bigcup_{x \in X} N_{G}(x)\right) \backslash X$, and let $G[X]$ (resp. $\left.G-X\right)$ denote the subgraph of $G$ induced by $X$ (resp. $V(G) \backslash X$ ). Let $\alpha(G)$ denote the independence number of

[^0]$G$, i.e., the maximum cardinality of an independent set of $G$. Let $K_{n}, P_{n}$ and $K_{1, n}$ denote the complete graph of order $n$, the path of order $n$ and the star of order $n+1$, respectively. For two positive integers $n_{1}$ and $n_{2}$, the Ramsey number $R\left(n_{1}, n_{2}\right)$ is the minimum positive integer $R$ such that any graph of order at least $R$ contains a clique of cardinality $n_{1}$ or an independent set of cardinality $n_{2}$.

For two graphs $G$ and $H, G$ is said to be $H$-free if $G$ contains no induced copy of $H$. For a family $\mathcal{H}$ of graphs, a graph $G$ is said to be $\mathcal{H}$-free if $G$ is $H$-free for every $H \in \mathcal{H}$. In this context, the members of $\mathcal{H}$ are called forbidden subgraphs. For two families $\mathcal{H}_{1}$ and $\mathcal{H}_{2}$ of graphs, we write $\mathcal{H}_{1} \leq \mathcal{H}_{2}$ if for every $H_{2} \in \mathcal{H}_{2}$, there exists $H_{1} \in \mathcal{H}_{1}$ such that $H_{1}$ is an induced subgraph of $H_{2}$. The relation " $\leq$ " between two families of forbidden subgraphs was introduced in [7]. Note that if $\mathcal{H}_{1} \leq \mathcal{H}_{2}$, then every $\mathcal{H}_{1}$-free graph is also $\mathcal{H}_{2}$-free.

Let $\mathcal{A}$ be a family of graphs. A family $\mathcal{P}$ of subgraphs of $G$ is called an $\mathcal{A}$-cover of $G$ if $\bigcup_{P \in \mathcal{P}} V(P)=V(G)$ and each element of $\mathcal{P}$ is isomorphic to a graph belonging to $\mathcal{A}$. Note that some elements of an $\mathcal{A}$-cover of $G$ might have common vertices. An $\mathcal{A}$-cover $\mathcal{P}$ of $G$ is called an $\mathcal{A}$-partition of $G$ if the elements of $\mathcal{P}$ are pairwise vertexdisjoint. A $\left\{P_{i}: i \geq 1\right\}$-cover (resp. a $\left\{P_{i}: i \geq 1\right\}$-partition) of $G$ is called a path cover (resp. a path partition) of $G$. Since $\{G[\{x\}]: x \in V(G)\}$ is a path partition of $G$ (and so a path cover of $G$ ), the minimum cardinality of a path cover (or a path partition) of any graph is well-defined. The value $\min \{|\mathcal{P}|: \mathcal{P}$ is a path cover of $G\}$ (resp. $\min \{|\mathcal{P}|: \mathcal{P}$ is a path partition of $G\}$ ), denoted by $\operatorname{pc}(G)$ (resp. $\operatorname{pp}(G)$ ), is called the path cover number (resp. the path partition number) of $G$. It is trivial that $\mathrm{pc}(G) \leq \operatorname{pp}(G)$. Since a graph $G$ has a Hamiltonian path if and only if $\mathrm{pp}(G)=1$, the decision problem for the path partition number is a natural generalization of the Hamiltonian path problem. In fact, it has been widely studied in, for example, [13-17]. Throughout this paper, we implicitly use the following fact.

Fact 1.1 Let $G$ be a graph, and let $\left\{X_{1}, X_{2}, \ldots, X_{m}\right\}$ be a partition of $V(G)$. Then $\operatorname{pc}(G) \leq \sum_{1 \leq i \leq m} \operatorname{pc}\left(G\left[X_{i}\right]\right)$ and $\operatorname{pp}(G) \leq \sum_{1 \leq i \leq m} \operatorname{pp}\left(G\left[X_{i}\right]\right)$.

In this paper, we focus on the following conditions concerning a family $\mathcal{H}$ of forbidden subgraphs:
(A1) There exists a constant $c_{1}=c_{1}(\mathcal{H})$ such that $\mathrm{pc}(G) \leq c_{1}$ for every connected $\mathcal{H}$-free graph $G$.
(A2) There exists a constant $c_{2}=c_{2}(\mathcal{H})$ such that $\operatorname{pp}(G) \leq c_{2}$ for every connected $\mathcal{H}$-free graph $G$.

Our main aim is to characterize the finite families $\mathcal{H}$ of connected graphs satisfying (A1) or (A2).

Figure 1: Graphs $K_{m}^{*}, F_{m, n}^{(1)}, F_{m, n}^{(2)}, F_{m, n}^{(3)}$ and $F_{m, n}^{(4)}$

Let $m$ and $n$ be two positive integers. We define five graphs which will be used as forbidden subgraphs in our main result (see Figure (1).

- Let $K_{m}^{*}$ denote the graph with $V\left(K_{m}^{*}\right)=\left\{x_{i}, y_{i}: 1 \leq i \leq m\right\}$ and $E\left(K_{m}^{*}\right)=$ $\left\{x_{i} x_{j}: 1 \leq i<j \leq m\right\} \cup\left\{x_{i} y_{i}: 1 \leq i \leq m\right\}$.
- Let $A:=\left\{x_{1}, x_{2}\right\} \cup\left\{y_{i}: 1 \leq i \leq m\right\} \cup\left\{z_{i}: 1 \leq i \leq n\right\}$. We define four graphs as follows:
- Let $F_{m, n}^{(1)}$ denote the graph on $A$ such that $E\left(F_{m, n}^{(1)}\right)=\left\{x_{1} x_{2}, x_{1} y_{1}, x_{1} z_{1}\right\} \cup$ $\left\{y_{i} y_{i+1}: 1 \leq i \leq m-1\right\} \cup\left\{z_{i} z_{i+1}: 1 \leq i \leq n-1\right\}$.
- Let $F_{m, n}^{(2)}$ is the graph obtained from $F_{m, n}^{(1)}$ by adding the edge $y_{1} z_{1}$.
- Let $F_{m, n}^{(3)}$ denote the graph on $A$ such that $E\left(F_{m, n}^{(3)}\right)=\left\{x_{1} y_{1}, x_{1} z_{1}, x_{2} y_{1}, x_{2} z_{1}\right\} \cup$ $\left\{y_{i} y_{i+1}: 1 \leq i \leq m-1\right\} \cup\left\{z_{i} z_{i+1}: 1 \leq i \leq n-1\right\}$.
- Let $F_{m, n}^{(4)}$ is the graph obtained from $F_{m, n}^{(3)}$ by adding the edge $y_{1} z_{1}$.

Our first main result is the following, which is proved in Section [2
Theorem 1.2 Let $\mathscr{H}$ be a finite family of connected graphs. Then the following hold:
(i) The family $\mathcal{H}$ satisfies (A1) if and only if $\mathcal{H} \leq\left\{K_{1, n}, K_{n}^{*}, F_{n, n}^{(1)}, F_{n, n}^{(2)}\right\}$ for an integer $n \geq 2$.
(ii) The family $\mathcal{H}$ satisfies (A2) if and only if $\mathcal{H} \leq\left\{K_{1, n}, K_{n}^{*}, F_{n, n}^{(1)}, F_{n, n}^{(2)}, F_{n, n}^{(3)}, F_{n, n}^{(4)}\right\}$ for an integer $n \geq 2$.

Our motivation derives from two different lines of research. The first one is forbidden subgraph conditions for the existence of a Hamiltonian path. Now we focus on the condition that
every connected $\mathscr{H}$-free graph (of sufficiently large order) has a Hamiltonian path
for a family $\mathcal{H}$ of connected graphs. Duffus et al. [3] proved $\mathcal{H}=\left\{K_{1,3}, K_{3}^{*}\right\}$ satisfies (11), and Faudree and Gould [5] showed that if a family $\mathcal{H}$ satisfying (1) consists of two connected graphs, then $\mathcal{H} \leq\left\{K_{1,3}, K_{3}^{*}\right\}$. Thereafter a series by Gould and Harris [10-12] characterized the families $\mathcal{H}$ of connected graphs with $|\mathcal{H}|=3$ satisfying (1). Since a graph has a Hamiltonian path if and only if its path cover number (or its path partition number) is exactly one, it is natural to study the forbidden subgraph conditions assuring us that the path cover/partition number is bounded by a constant as a next step. Our main result gives a complete solution for the problem in a sense.

Our second motivation is an analysis of gap between minimum $\mathcal{A}$-covers and minimum $\mathcal{A}$-partitions. A path cover/partition, which are main topic in this paper, is just one of examples of $\mathcal{A}$-cover/partition problems, and there also exist many other cover/partition problems. One of representative other examples is the case where $\mathcal{A}$ is the family of all stars, where we regard $K_{1}$ as one of stars. If we define the star cover number and the star partition number in the same way as $\operatorname{pc}(G)$ and $\operatorname{pp}(G)$, we can easily verify that the values are always equivalent. (Indeed, the star cover number also equals to the domination number, which is one of classical invariants in graph theory. The forbidden subgraph conditions assuring us that the domination number is bounded by a constant were characterized in [8].) On the other hand, as it is evident from Theorem 1.2, there is a gap between the path cover number and the path partition number. By Theorem 1.2, we discover that $F_{n, n}^{(3)}$ and $F_{n, n}^{(4)}$ play an important role for essential structures giving such a gap.

We also obtain an analogy of Theorem 1.2 considering a cycle cover/partition problem. A $\left\{K_{1}, K_{2}, C_{i}: i \geq 3\right\}$-cover (resp. a $\left\{K_{1}, K_{2}, C_{i}: i \geq 3\right\}$-partition) of $G$ is called a cycle cover (resp. a cycle partition) of $G$. The value $\min \{|\mathcal{P}|$ : $\mathcal{P}$ is a cycle cover of $G\}($ resp. $\min \{|\mathcal{P}|: \mathcal{P}$ is a cycle partition of $G\})$, denoted by $\mathrm{cc}(G)$ (resp. $\operatorname{cp}(G)$ ), is called the cycle cover number (resp. the cycle partition number) of $G$. Since trees (or graphs having a vertex of degree one) has no $\left\{C_{i}: i \geq\right.$ $3\}$-cover, one sometimes focuses on cycle covers/partitions of general graphs instead of $\left\{C_{i}: i \geq 3\right\}$-covers/partitions (see, for example, [4]6). In Section 3, as the second result, we characterize the families $\mathcal{H}$ of forbidden subgraphs satisfying one of the following:
(A'1) There exists a constant $c_{1}=c_{1}(\mathcal{H})$ such that $\operatorname{cc}(G) \leq c_{1}$ for every connected $\mathcal{H}$-free graph $G$.
(A'2) There exists a constant $c_{2}=c_{2}(\mathcal{H})$ such that $\mathrm{cp}(G) \leq c_{2}$ for every connected $\mathcal{H}$-free graph $G$.

Theorem 1.3 Let $\mathcal{H}$ be a family of connected graphs. Then the following are equivalent.
(i) The family $\mathcal{H}$ satisfies ( $A^{\prime} 1$ ).
(ii) The family $\mathcal{H}$ satisfies ( $A^{\prime} 2$ ).
(iii) For an integer $n \geq 2, \mathcal{H} \leq\left\{K_{1, n}, K_{n}^{*}, P_{n}\right\}$.

We conclude this section by defining a new Ramsey-type concept concerning the path cover/partition number. Let $\mathcal{H}$ be a family of graphs. The path cover Ramsey number $R^{\mathrm{pc}}(\mathcal{H})$ (resp. the path partition Ramsey number $R^{\mathrm{pp}}(\mathcal{H})$ ) is the minimum positive integer $R$ such that any connected graph $G$ with $\operatorname{pc}(G) \geq R$ (resp. $\operatorname{pp}(G) \geq R)$ contains an induced copy of an element of $\mathcal{H}$, where $R^{\mathrm{pc}}(\mathcal{H})=\infty$ (resp. $\left.R^{\mathrm{pp}}(\mathcal{H})=\infty\right)$ if such an integer does not exist. Then it follows from Theorem 1.2 that the following hold:
(P1) For a finite family $\mathcal{H}$ of connected graphs, $R^{\mathrm{pc}}(\mathcal{H})$ is a finite number if and only if $\mathcal{H} \leq\left\{K_{1, n}, K_{n}^{*}, F_{n, n}^{(1)}, F_{n, n}^{(2)}\right\}$ for an integer $n \geq 2$.
(P2) For a finite family $\mathcal{H}$ of connected graphs, $R^{\mathrm{pp}}(\mathcal{H})$ is a finite number if and only if $\mathcal{H} \leq\left\{K_{1, n}, K_{n}^{*}, F_{n, n}^{(1)}, F_{n, n}^{(2)}, F_{n, n}^{(3)}, F_{n, n}^{(4)}\right\}$ for an integer $n \geq 2$.

Note that $R^{\mathrm{pc}}(\mathcal{H})=2$ if and only if $R^{\mathrm{pp}}(\mathcal{H})=2$. As we mentioned above, it is known that $R^{\mathrm{pc}}\left(\left\{K_{1,3}, K_{3}^{*}\right\}\right)=2$ and the study of triples $\left\{H_{1}, H_{2}, H_{3}\right\}$ of connected graphs with $R^{\text {pc }}\left(\left\{H_{1}, H_{2}, H_{3}\right\}\right)=2$ is completed. Since the $K_{1,3}$-freeness tends to give an important structure to many Hamiltonian properties, one might be interested in a relationship between such new Ramsey-type values and $K_{1,3}$-freeness. Here we focus on the values $R^{\mathrm{pc}}(\mathcal{H})$ and $R^{\mathrm{pp}}(\mathcal{H})$ for the case where $\mathcal{H}$ contains $K_{1,3}$. Note that for positive integers $m$ and $n$ with $m+n \geq 3$, all of $F_{m, n}^{(1)}, F_{m, n}^{(3)}$ and $F_{m, n}^{(4)}$ contain $K_{1,3}$ as an induced copy. Thus if $K_{1,3} \in \mathcal{H}$, then

$$
R^{\mathrm{pc}}(\mathcal{H})=R^{\mathrm{pc}}\left(\mathcal{H} \backslash\left\{F_{m, n}^{(1)}, F_{m, n}^{(3)}, F_{m, n}^{(4)}: m \geq 1, n \geq 1, m+n \geq 3\right\}\right)
$$

and

$$
R^{\operatorname{pp}}(\mathcal{H})=R^{\operatorname{pp}}\left(\mathcal{H} \backslash\left\{F_{m, n}^{(1)}, F_{m, n}^{(3)}, F_{m, n}^{(4)}: m \geq 1, n \geq 1, m+n \geq 3\right\}\right) .
$$

Considering (P1) and (P2), we leave the following open problem which will be a next interesting target on this concept for readers.

Problem 1 For positive integers $p, q$ and $r$ with $p \geq 3$ and $q+r \geq 4$ and for a family $\mathcal{H}$ of graphs with $\mathcal{H} \leq\left\{K_{1,3}, K_{p}^{*}, F_{q, r}^{(2)}\right\}$, determine the value $R^{\mathrm{pc}}(\mathcal{H})$ and $R^{\mathrm{pp}}(\mathcal{H})$.

## 2 Proof of Theorem 1.2

### 2.1 The "if" parts of Theorem 1.2

In this subsection, we prove the following theorem, which implies that the "if" parts of Theorem 1.2 hold.

Theorem 2.1 Let $n \geq 2$ be an integer. Then the following hold:
(i) There exists a constant $c_{1}=c_{1}(n)$ depending on $n$ only such that $\mathrm{pc}(G) \leq c_{1}$ for every connected $\left\{K_{1, n}, K_{n}^{*}, F_{n, n}^{(1)}, F_{n, n}^{(2)}\right\}$-free graph $G$.
(ii) There exists a constant $c_{2}=c_{2}(n)$ depending on $n$ only such that $\mathrm{pp}(G) \leq c_{2}$ for every connected $\left\{K_{1, n}, K_{n}^{*}, F_{n, n}^{(1)}, F_{n, n}^{(2)}, F_{n, n}^{(3)}, F_{n, n}^{(4)}\right\}$-free graph $G$.

The following lemma is well-known (or it is also obtained from a result on digraph by Gallai and Milgram [9]). So many readers can skip are advised to skip the proof.

Lemma 2.2 For a graph $G, \operatorname{pc}(G) \leq \operatorname{pp}(G) \leq \alpha(G)$.
Proof. Since a path partition of $G$ is also a path cover of $G$, we have $\mathrm{pc}(G) \leq \operatorname{pp}(G)$.
Let $\mathcal{P}$ be a path partition of $G$ with $|\mathcal{P}|=\operatorname{pp}(G)$, and write $\mathcal{P}=\left\{Q_{i}: 1 \leq i \leq\right.$ $\operatorname{pp}(G)\}$. For each $i$ with $1 \leq i \leq \operatorname{pp}(G)$, let $x_{i}$ be an endvertex of $Q_{i}$. If $x_{i} x_{j} \in E(G)$ for some $1 \leq i<j \leq \operatorname{pp}(G)$, then the graph $Q$ obtained from $Q_{i}$ and $Q_{j}$ by joining the edge $x_{i} x_{j}$ is a path, and hence $\mathcal{P}^{\prime}=\left(\mathcal{P} \backslash\left\{Q_{i}, Q_{j}\right\}\right) \cup\{Q\}$ is a path partition of $G$ with $\left|\mathcal{P}^{\prime}\right|=\operatorname{pp}(G)-1$, which contradicts the definition of the path partition number. Thus $\left\{x_{i}: 1 \leq i \leq \operatorname{pp}(G)\right\}$ is an independent set of $G$, and hence $\operatorname{pp}(G) \leq \alpha(G)$.

Lemma 2.3 Let $n \geq 2$ and $\alpha \geq 1$ be integers. Let $G$ be a $\left\{K_{1, n}, K_{n}^{*}\right\}$-free graph, and let $X$ be a subset of $V(G)$ with $\alpha(G[X]) \leq \alpha$. Then $\alpha\left(G\left[N_{G}(X)\right]\right) \leq(n-$ 1) $R(n, \alpha+1)-1$.

Proof. By way of contradiction, we suppose that there exists a subset $Y$ of $N_{G}(X)$ such that $Y$ is an independent set of $G$ and $|Y|=(n-1) R(n, \alpha+1)$. Take a subset $X_{0}$ of $X$ with $Y \subseteq N_{G}\left(X_{0}\right)$ so that $\left|X_{0}\right|$ is as small as possible. If $\left|X_{0}\right| \leq$ $R(n, \alpha+1)-1$, then $\frac{|Y|}{\left|X_{0}\right|} \geq \frac{(n-1) R(n, \alpha+1)}{R(n, \alpha+1)-1}>n-1$, and hence there exists a vertex $x_{0} \in X_{0}$ with $\left|N_{G}\left(x_{0}\right) \cap Y\right| \geq n$, which contradicts the $K_{1, n}$-freeness of $G$. Thus $\left|X_{0}\right| \geq R(n, \alpha+1)$. Since $\alpha\left(G\left[X_{0}\right]\right) \leq \alpha(G[X]) \leq \alpha$, this implies that there exists

Figure 2: Path $P$ and sets $X_{i}$ and $Y$
a subset $X_{1}$ of $X_{0}$ such that $X_{1}$ is a clique of $G$ and $\left|X_{1}\right|=n$. By the minimality of $X_{0},\left(N_{G}(x) \cap Y\right) \backslash N_{G}\left(X_{0} \backslash\{x\}\right) \neq \emptyset$ for every $x \in X_{0}$. For each $x \in X_{0}$, let $y_{x} \in\left(N_{G}(x) \cap Y\right) \backslash N_{G}\left(X_{0} \backslash\{x\}\right)$. Then $X_{1} \cup\left\{y_{x}: x \in X_{1}\right\}$ induces a copy of $K_{n}^{*}$ in $G$, which contradicts the $K_{n}^{*}$-freeness of $G$.

In the remainder of this subsection, we fix an integer $n \geq 2$ and a connected $\left\{K_{1, n}, K_{n}^{*}, F_{n, n}^{(1)}, F_{n, n}^{(2)}\right\}$-free graph $G$. Set $n_{0}=\max \left\{\left\lceil\frac{n^{2}-n-2}{2}\right\rceil, n\right\}$. Take a longest induced path $P$ of $G$, and write $P=u_{1} u_{2} \cdots u_{m}$. Let $X_{0}=\left\{u_{i}: 1 \leq i \leq n_{0}\right.$ or $m-$ $\left.n_{0}+1 \leq i \leq m\right\}$ and $Y=N_{G}\left(V(P) \backslash X_{0}\right) \backslash\left(X_{0} \cup N_{G}\left(X_{0}\right)\right)$. Note that if $|V(P)| \leq 2 n_{0}$, then $X_{0}=V(P)$ and $Y=\emptyset$. We further remark that $N_{G}(y) \cap V(P) \subseteq\left\{u_{i}\right.$ : $\left.n_{0}+1 \leq i \leq m-n_{0}\right\}$ for every $y \in Y$ (and in the remainder of this subsection, we frequently use the fact without mentioning). For each $i$ with $n_{0}+1 \leq i \leq m-n_{0}$, let $Y_{i}=\left\{y \in Y: \min \left\{j: n_{0}+1 \leq j \leq m-n_{0}, y u_{j} \in E(G)\right\}=i\right\}$. Now we recursively define the sets $X_{i}(i \geq 1)$ as follows: Let $X_{1}=N_{G}\left(X_{0}\right) \backslash V(P)$, and for $i$ with $i \geq 2$, let $X_{i}=N_{G}\left(X_{i-1}\right) \backslash\left(V(P) \cup Y \cup\left(\cup_{1 \leq j \leq i-1} X_{j}\right)\right)$ (see Figure (2). Then $X_{1} \cap Y=\emptyset$ and $X_{1} \cup Y=N_{G}(V(P))$.

Lemma 2.4 We have $X_{2 n_{0}}=\emptyset$.
Proof. Suppose that $X_{2 n_{0}} \neq \emptyset$. Let $x_{2 n_{0}} \in X_{2 n_{0}}$. Then we can recursively take a vertex $x_{2 n_{0}-i} \in N_{G}\left(x_{2 n_{0}-i+1}\right) \cap X_{2 n_{0}-i}$ for $i$ with $1 \leq i \leq 2 n_{0}$. Note that $x_{0}=u_{k}$ for some $k$ with $1 \leq k \leq n_{0}$ or $m-n_{0}+1 \leq k \leq m$. By symmetry, we may assume that $1 \leq k \leq n_{0}$. Under this condition, we choose $k$ so that $k$ is as large as possible. Since $x_{0} x_{1} \cdots x_{2 n_{0}}$ is an induced path of $G$ having $2 n_{0}+1$ vertices, it follows from the maximality of $P$ that $|V(P)| \geq 2 n_{0}+1$. In particular, $V(P) \backslash X_{0} \neq \emptyset$.

Figure 3: An example for $s=5$

If $N_{G}\left(x_{1}\right) \cap\left(V(P) \backslash X_{0}\right)=\emptyset$, then $x_{2 n_{0}} x_{2 n_{0}-1} \cdots x_{1} u_{k} u_{k+1} \cdots u_{m-n_{0}}$ is an induced path of $G$ having $2 n_{0}+m-n_{0}-k+1(\geq m+1)$ vertices, which contradicts the maximality of $P$. Thus $N_{G}\left(x_{1}\right) \cap\left(V(P) \backslash X_{0}\right) \neq \emptyset$.

Now we consider an operation recursively defining integers $j_{1}, j_{2}, \ldots$ with $1 \leq$ $j_{p} \leq m(p \geq 1)$ and $j_{1}<j_{2}<\cdots$ as follows (see Figure (3): Let $j_{1}=\min \{j: 1 \leq$ $\left.j \leq m, x_{1} u_{j} \in E(G)\right\}$. For $p \geq 2$, we assume that the integer $j_{p-1}$ has defined. If $\left\{j: j_{p-1}+2 \leq j \leq m, x_{1} u_{j} \in E(G)\right\} \neq \emptyset$, we let $j_{p}=\min \left\{j: j_{p-1}+2 \leq j \leq\right.$ $\left.m, x_{1} u_{j} \in E(G)\right\}$; otherwise, we finish the operation. Let $S=\left\{u_{j_{p}}: p \geq 1\right\}$, and set $s=|S|$. Let $j^{*}=\max \left\{j: 1 \leq j \leq m, x_{1} u_{j} \in E(G)\right\}$. Note that $j^{*} \in\left\{j_{s}, j_{s}+1\right\}$. Since $j_{p} \geq j_{p-1}+2, S$ is an independent set of $G$. Since $G$ is $K_{1, n}$-free and $\left\{x_{1}, x_{2}\right\} \cup S$ induces a copy of $K_{1, s+1}$ in $G$, we have $s+1 \leq n-1$.

For the moment, suppose that $s=1$. Since $N_{G}\left(x_{1}\right) \cap\left\{u_{j}: 1 \leq j \leq n_{0}\right\} \neq \emptyset$ and $N_{G}\left(x_{1}\right) \cap\left(V(P) \backslash X_{0}\right) \neq \emptyset$, this forces $N_{G}\left(x_{1}\right)=\left\{u_{n_{0}}, u_{n_{0}+1}\right\}$. Then

$$
\left\{x_{1}, x_{2}, u_{n_{0}}, u_{n_{0}-1}, \ldots, u_{n_{0}-n+1}, u_{n_{0}+1}, u_{n_{0}+2}, \ldots, u_{n_{0}+n}\right\}
$$

induces a copy of $F_{n, n}^{(2)}$ in $G$, which is a contradiction. Thus $s \geq 2$.
Let $Q_{1}=u_{1} u_{2} \cdots u_{j_{1}}$ and $Q_{s+1}=u_{j^{*}} u_{j^{*}+1} \cdots u_{m}$ be subpaths of $P$. For $p$ with $2 \leq p \leq s$, let $Q_{p}=u_{j_{p-1}+2} u_{j_{p-1}+3} \cdots u_{j_{p}}$ be a subpath of $P$. Then $V(P) \backslash$ $\left(\bigcup_{1 \leq p \leq s+1} V\left(Q_{p}\right)\right)=\left\{u_{j_{p}+1}: 1 \leq p \leq s-1\right\}$, and hence

$$
\begin{aligned}
2 n_{0}+1 & \leq|V(P)| \\
& =\left|V(P) \backslash\left(\bigcup_{1 \leq p \leq s+1} V\left(Q_{p}\right)\right)\right|+\left|\bigcup_{1 \leq p \leq s+1} V\left(Q_{p}\right)\right| \\
& \leq(s-1)+\sum_{1 \leq p \leq s+1}\left|V\left(Q_{p}\right)\right| \\
& =\sum_{1 \leq p \leq s+1}\left(\left|V\left(Q_{p}\right)\right|+1\right)-2 .
\end{aligned}
$$

This implies that $\sum_{1 \leq p \leq s+1}\left(\left|V\left(Q_{p}\right)\right|+1\right) \geq 2 n_{0}+3 \geq 2\left\lceil\frac{n^{2}-n-2}{2}\right\rceil+3 \geq n^{2}-n+1$. If $\left|V\left(Q_{p}\right)\right| \leq n-1$ for all $p$ with $1 \leq p \leq s+1$, then $n^{2}-n+1 \leq \sum_{1 \leq p \leq s+1}\left(\left|V\left(Q_{p}\right)\right|+1\right) \leq$ $(s+1) n \leq(n-1) n$, which is a contradiction. Thus $\left|V\left(Q_{q}\right)\right| \geq n$ for some $q$ with $1 \leq q \leq s+1$.

Note that $\left|N_{G}\left(x_{1}\right) \cap V\left(Q_{q}\right)\right|=1$. Write $N_{G}\left(x_{1}\right) \cap V\left(Q_{q}\right)=\left\{u_{j}\right\}$. If $q \neq s+1$, then $j \in\left\{j_{p}: 1 \leq p \leq s\right\}$; otherwise, $j=j^{*}\left(\in\left\{j_{s}, j_{s+1}\right\}\right)$. Since $u_{j}$ is an endvertex of $Q_{q}$, there exists a subpath $Q$ of $Q_{q}$ such that $u_{j}$ is an endvertex of $Q$ and $|V(Q)|=n$. Since $|S| \geq 2$, we can take a vertex $v \in S$ as follows: If $q \neq s+1$, let $v \in S \backslash\left\{u_{j}\right\}$; otherwise (i.e., $j=j^{*}$ ), let $v=u_{j_{1}}$. Then by the definition of $Q_{p}(1 \leq p \leq s+1)$, $N_{G}(v) \cap V\left(Q_{q}\right)=\emptyset$. Since $2 n_{0} \geq 2 n \geq n+1$, the vertices $x_{i}$ with $2 \leq i \leq n+1$ have been defined, and hence this implies that $\left\{x_{1}, v, x_{2}, x_{3}, \ldots, x_{n+1}\right\} \cup V(Q)$ induces a copy of $F_{n, n}^{(1)}$ in $G$, which is a contradiction.

Lemma 2.5 Let $i$ be an integer with $n_{0}+1 \leq i \leq m-n_{0}$, and let $y \in Y_{i}$. Then the following hold:
(i) If $y u_{i+1} \notin E(G)$, then $N_{G}(y) \cap V(P)=\left\{u_{i}, u_{i+2}\right\}$.
(ii) We have $Y_{m-n_{0}}=\emptyset$.
(iii) If $G$ is $F_{n, n}^{(3)}$-free, then $y u_{i+1} \in E(G)$.

Proof.
(i) Suppose that $y u_{i+1} \notin E(G)$ and $N_{G}(y) \cap V(P) \neq\left\{u_{i}, u_{i+2}\right\}$. Let $k=\max \{j$ : $\left.n_{0}+1 \leq j \leq m-n_{0}, y u_{j} \in E(G)\right\}$. If $k=i$ (i.e., $N_{G}(y) \cap V(P)=\left\{u_{i}\right\}$ ), then

$$
\left\{u_{i}, y, u_{i-1}, u_{i-2}, \ldots, u_{i-n}, u_{i+1}, u_{i+2}, \ldots, u_{i+n}\right\}
$$

induces a copy of $F_{n, n}^{(1)}$ in $G$, which is a contradiction. Since $y u_{i+1} \notin E(G)$ and $N_{G}(y) \cap V(P) \neq\left\{u_{i}, u_{i+2}\right\}$, this forces $k \geq i+3$. Then

$$
\left\{u_{i}, u_{i+1}, u_{i-1}, u_{i-2}, \ldots, u_{i-n}, y, u_{k}, u_{k+1}, \ldots, u_{k+n-2}\right\}
$$

induces a copy of $F_{n, n}^{(1)}$ in $G$, which is a contradiction.
(ii) By (i), if there exists a vertex $y \in Y_{m-n_{0}}$, then it follows that $y u_{m-n_{0}+1} \in E(G)$ or $N_{G}(y) \cap V(P)=\left\{u_{m-n_{0}}, u_{m-n_{0}+2}\right\}$, and in particular, $N_{G}(y) \cap X_{0} \neq \emptyset$, which contradicts the definition of $Y$. Thus we have $Y_{m-n_{0}}=\emptyset$.
(iii) Suppose that $G$ is $F_{n, n}^{(3)}$-free and $y u_{i+1} \notin E(G)$. Then it follows from (i) that $N_{G}(y) \cap V(P)=\left\{u_{i}, u_{i+2}\right\}$, and hence

$$
\left\{y, u_{i+1}, u_{i}, u_{i-1}, \ldots, u_{i-n+1}, u_{i+2}, u_{i+3}, \ldots, u_{i+n+1}\right\}
$$

induces a copy of $F_{n, n}^{(3)}$ in $G$, which is a contradiction.

Lemma 2.6 We have $V(G)=V(P) \cup N_{G}(V(P)) \cup\left(\bigcup_{2 \leq i \leq 2 n_{0}-1} X_{i}\right)$.

Proof. Suppose that $V(G) \neq V(P) \cup N_{G}(V(P)) \cup\left(\bigcup_{2 \leq i \leq 2 n_{0}-1} X_{i}\right)$. Since $G$ is connected, there exists a vertex $z \in V(G) \backslash\left(V(P) \cup N_{G}(V(P)) \cup\left(\bigcup_{2 \leq i \leq 2 n_{0}-1} X_{i}\right)\right)$ adjacent to a vertex $y \in V(P) \cup N_{G}(V(P)) \cup\left(\bigcup_{2 \leq i \leq 2 n_{0}-1} X_{i}\right)$ in $G$. By Lemma 2.4 and the definition of $X_{i}$ and $Y$, this implies that $y \in Y$. Let $i$ be the integer such that $y \in Y_{i}$. Then by Lemma 2.5(ii), $n_{0}+1 \leq i \leq m-n_{0}-1$. Let $k=\max \{j$ : $\left.n_{0}+1 \leq j \leq m-n_{0}, y u_{j} \in E(G)\right\}$. By Lemma 2.5(i), $k \geq i+1$. If $k=i+1$, then

$$
\left\{y, z, u_{i}, u_{i-1}, \ldots, u_{i-n+1}, u_{i+1}, u_{i+2}, \ldots, u_{i+n}\right\}
$$

induces a copy of $F_{n, n}^{(2)}$ in $G$; if $k \geq i+2$, then

$$
\left\{y, z, u_{i}, u_{i-1}, \ldots, u_{i-n+1}, u_{k}, u_{k+1}, \ldots, u_{k+n-1}\right\}
$$

induces a copy of $F_{n, n}^{(1)}$ in $G$. In either case, we obtain a contradiction.

Now we recursively define the values $\alpha_{i}(i \geq 0)$ as follows: Let $\alpha_{0}=2\left\lceil\frac{n_{0}}{2}\right\rceil$, and for $i$ with $i \geq 1$, let $\alpha_{i}=(n-1) R\left(n, \alpha_{i-1}+1\right)-1$.

Lemma 2.7 For an integer $i$ with $i \geq 0, \alpha\left(G\left[X_{i}\right]\right) \leq \alpha_{i}$.
Proof. We proceed by induction on $i$. If $|V(P)| \leq 2 n_{0}$, then $G\left[X_{0}\right]$ equals to $P$, and hence $\alpha\left(G\left[X_{0}\right]\right)=\alpha(P)=\left\lceil\frac{|V(P)|}{2}\right\rceil \leq n_{0} \leq \alpha_{0}$; if $|V(P)| \geq 2 n_{0}+1$, then $G\left[X_{0}\right]$ consists of two components each of which is a path of order $n_{0}$, and hence $\alpha\left(G\left[X_{0}\right]\right)=$ $2\left\lceil\frac{n_{0}}{2}\right\rceil=\alpha_{0}$. In either case, we have $\alpha\left(G\left[X_{0}\right]\right) \leq \alpha_{0}$. Thus we may assume that $i \geq 1$, and suppose that $\alpha\left(G\left[X_{i-1}\right]\right) \leq \alpha_{i-1}$. Since $X_{i} \subseteq N_{G}\left(X_{i-1}\right)$, it follows from Lemma 2.3 that $\alpha\left(G\left[X_{i}\right]\right) \leq \alpha\left(G\left[N_{G}\left(X_{i-1}\right)\right]\right) \leq(n-1) R\left(n, \alpha_{i-1}+1\right)-1=\alpha_{i}$, as desired.

Note that the value $\sum_{1 \leq i \leq 2 n_{0}-1} \alpha_{i}$ is a constant depending on $n$ only. Thus, considering Lemmas 2.2, 2.6 and 2.7, it suffices to show that

- $\operatorname{pc}(G[V(P) \cup Y])$ is bounded by a constant depending on $n$ only, and
- if $G$ is $\left\{F_{n, n}^{(3)}, F_{n, n}^{(4)}\right\}$-free, then $\operatorname{pp}(G[V(P) \cup Y])$ is bounded by a constant depending on $n$ only.

Hence the following lemma completes the proof of Theorem 2.1.

Lemma 2.8 (i) We have $\operatorname{pc}(G[V(P) \cup Y]) \leq \max \{3 n-6,1\}$.
(ii) If $G$ is $\left\{F_{n, n}^{(3)}, F_{n, n}^{(4)}\right\}$-free, then there exists a Hamiltonian path of $G[V(P) \cup Y]$, i.e., $\operatorname{pp}(G[V(P) \cup Y])=1$.

Proof. If $Y=\emptyset$, then $P$ is a Hamiltonian path of $G[V(P) \cup Y]$, and hence pc $(G[V(P) \cup$ $Y])=\operatorname{pp}(G[V(P) \cup Y])=1$. Thus we may assume that $Y \neq \emptyset$. By Lemma 2.5(ii), $Y_{m-n_{0}}=\emptyset$.

We first prove (i). Fix an integer $i$ with $n_{0}+1 \leq i \leq m-n_{0}-1$. Let $Y_{i, 1}=\left\{y \in Y_{i}:\right.$ $\left.y u_{i+1} \in E(G)\right\}$ and $Y_{i, 2}=Y_{i} \backslash Y_{i, 1}$. Then by Lemma2.5(i), $N_{G}(y) \cap V(P)=\left\{u_{i}, u_{i+2}\right\}$ for all $y \in Y_{i, 2}$. Let $j \in\{1,2\}$. If there exists an independent set $U \subseteq Y_{i, j}$ of $G$ with $|U|=n-1$, then $\left\{u_{i-1}, u_{i}\right\} \cup U$ induces a copy of $K_{1, n}$ in $G$, which is a contradiction. Thus $\alpha\left(G\left[Y_{i, j}\right]\right) \leq n-2$. Since $Y \neq \emptyset$, i.e., $Y_{p, q} \neq \emptyset$ for some $p$ and $q$ with $n_{0}+1 \leq p \leq m-n_{0}-1$ and $q \in\{1,2\}$, this implies that $n \geq 3$. By Lemma 2.2, there exists a path partition $\mathcal{P}_{i, j}=\left\{Q_{i, j}^{(1)}, Q_{i, j}^{(2)}, \ldots, Q_{i, j}^{\left(s_{i, j}\right)}\right\}$ of $G\left[Y_{i, j}\right]$ with $s_{i, j} \leq n-2$, where $\mathcal{P}_{i, j}=\emptyset$ and $s_{i, j}=0$ if $Y_{i, j}=\emptyset$. For an integer $t$ with $1 \leq t \leq n-2$, if $t \leq s_{i, j}$, let $R_{i, j}^{(t)}$ be the path $u_{i} v Q_{i, j}^{(t)} w u_{i+j}$, where $\{v, w\}$ is the set of endvertices of $Q_{i, j}^{(t)}$; otherwise, let $R_{i, j}^{(t)}$ be the path between $u_{i}$ and $u_{i+j}$ on $P$ (i.e., $R_{i, 1}^{(t)}=u_{i} u_{i+1}$ and $R_{i, 2}^{(t)}=u_{i} u_{i+1} u_{i+2}$ ). We define the value $\xi_{2}$ (resp. $\xi_{3}$ ) with $\xi_{2}=m-n_{0}$ or $\xi_{2}=m-n_{0}-1$ (resp. $\xi_{3}=m-n_{0}-1$ or $\xi_{3}=m-n_{0}$ ) according as $m$ is odd or even. Let
$R_{1}^{(t)}=u_{1} u_{2} \cdots u_{n_{0}+1} R_{n_{0}+1,1}^{(t)} u_{n_{0}+2} R_{n_{0}+2,1}^{(t)} u_{n_{0}+3} \cdots u_{m-n_{0}-1} R_{m-n_{0}-1,1}^{(t)} u_{m-n_{0}} u_{m-n_{0}+1} \cdots u_{m}$, $R_{2}^{(t)}=u_{1} u_{2} \cdots u_{n_{0}+1} R_{n_{0}+1,2}^{(t)} u_{n_{0}+3} R_{n_{0}+3,2}^{(t)} u_{n_{0}+5} \cdots u_{\xi_{2}-2} R_{\xi_{2}-2,2}^{(t)} u_{\xi_{2}} u_{\xi_{2}+1} \cdots u_{m}$, and $R_{3}^{(t)}=u_{1} u_{2} \cdots u_{n_{0}+2} R_{n_{0}+2,2}^{(t)} u_{n_{0}+4} R_{n_{0}+4,2}^{(t)} u_{n_{0}+6} \cdots u_{\xi_{3}-2} R_{\xi_{3}-2,2}^{(t)} u_{\xi_{3}} u_{\xi_{3}+1} \cdots u_{m}$.

Then we easily verify that $\left\{R_{a}^{(t)}: a \in\{1,2,3\}, 1 \leq t \leq n-2\right\}$ is a path cover of $G[V(P) \cup Y]$ having cardinality at most $3(n-2)$, which proves (i).

Next we prove (ii). Suppose that $G$ is $\left\{F_{n, n}^{(3)}, F_{n, n}^{(4)}\right\}$-free. We start with the following claim.

Claim 2.1 For an integer $i$ with $n_{0}+1 \leq i \leq m-n_{0}-1,\left\{u_{i}, u_{i+1}\right\} \cup Y_{i}$ is a clique of $G$.

Proof. Suppose that there exist two vertices $y, y^{\prime} \in\left\{u_{i}, u_{i+1}\right\} \cup Y_{i}$ with $y y^{\prime} \notin E(G)$. By the definition of $Y_{i}$ and Lemma 2.5(iii), every vertex in $Y_{i}$ is adjacent to both $u_{i}$ and $u_{i+1}$ in $G$. Thus $y, y^{\prime} \in Y_{i}$. Recall that $N_{G}(Y) \cap V(P) \subseteq\left\{u_{j}: n_{0}+1 \leq j \leq\right.$ $\left.m-n_{0}\right\}$. Let $k=\max \left\{j: n_{0}+1 \leq j \leq m-n_{0}, N_{G}\left(u_{j}\right) \cap\left\{y, y^{\prime}\right\} \neq \emptyset\right\}$. We may assume that $y u_{k} \in E(G)$. Note that $k \geq i+1$. If $k=i+1$, then

$$
\left\{y, y^{\prime}, u_{i}, u_{i-1}, \ldots, u_{i-n+1}, u_{i+1}, u_{i+2}, \ldots, u_{i+n}\right\}
$$

induces a copy of $F_{n, n}^{(4)}$ in $G$, which is a contradiction. Thus $k \geq i+2$. If $y^{\prime} u_{k} \in E(G)$, then

$$
\left\{y, y^{\prime}, u_{i}, u_{i-1}, \ldots, u_{i-n+1}, u_{k}, u_{k+1}, \ldots, u_{k+n-1}\right\}
$$

induces a copy of $F_{n, n}^{(3)}$ in $G$; if $y^{\prime} u_{k} \notin E(G)$, then

$$
\left\{u_{i}, y^{\prime}, u_{i-1}, u_{i-2}, \ldots, u_{i-n}, y, u_{k}, u_{k+1}, \ldots, u_{k+n-2}\right\}
$$

induces a copy of $F_{n, n}^{(1)}$ in $G$. In either case, we obtain a contradiction.

For an integer $i$ with $n_{0}+1 \leq i \leq m-n_{0}-1$, it follows from Claim 2.1 that there exists a Hamiltonian path $R_{i}$ of $G\left[\left\{u_{i}, u_{i+1}\right\} \cup Y_{i}\right]$ with the endvertices $u_{i}$ and $u_{i+1}$. Then

$$
u_{1} u_{2} \cdots u_{n_{0}+1} R_{n_{0}+1} u_{n_{0}+2} R_{n_{0}+2} u_{n_{0}+3} \cdots u_{m-n_{0}-1} R_{m-n_{0}-1} u_{m-n_{0}} u_{m-n_{0}+1} \cdots u_{m}
$$

is a Hamiltonian path of $G\left[V(P) \cup\left(\bigcup_{n_{0}+1 \leq i \leq m-n_{0}-1} Y_{i}\right)\right](=G[V(P) \cup Y])$, as desired.

### 2.2 The "only if" parts of Theorem 1.2

Let $s \geq 2$ and $t \geq 3$ be integers, and let $Q_{i}=u_{i}^{(1)} u_{i}^{(2)} \cdots u_{i}^{(t)}(1 \leq i \leq s)$ be $s$ pairwise vertex-disjoint paths. We define four graphs.

- Let $H_{s, t}^{(1)}$ be the graph obtained from the union of the paths $Q_{1}, \ldots, Q_{s}$ by adding $2(s-1)$ vertices $v_{i}, w_{i}(1 \leq i \leq s-1)$ and $3(s-1)$ edges $v_{i} w_{i}, v_{i} u_{i}^{(t)}, v_{i} u_{i+1}^{(1)}(1 \leq$ $i \leq s-1$ ).
- Let $H_{s, t}^{(2)}$ be the graph obtained from $H_{s, t}^{(1)}$ by adding $s-1$ edges $u_{i}^{(t)} u_{i+1}^{(1)}(1 \leq i \leq$ $s-1)$.
- Let $H_{s, t}^{(3)}$ be the graph obtained from the union of the paths $Q_{1}, \ldots, Q_{s}$ by adding $2(s-1)$ vertices $v_{i}, w_{i}(1 \leq i \leq s-1)$ and $4(s-1)$ edges $v_{i} u_{i}^{(t)}, v_{i} u_{i+1}^{(1)}, w_{i} u_{i}^{(t)}, w_{i} u_{i+1}^{(1)}(1 \leq$ $i \leq s-1)$.
- Let $H_{s, t}^{(4)}$ be the graph obtained from $H_{s, t}^{(3)}$ by adding $s-1$ edges $u_{i}^{(t)} u_{i+1}^{(1)}(1 \leq i \leq$ $s-1$ )

Lemma 2.9 We have $\operatorname{pc}\left(H_{s, t}^{(1)}\right)=\operatorname{pc}\left(H_{s, t}^{(2)}\right)=\left\lceil\frac{s+1}{2}\right\rceil$.
Proof. Note that $u_{1}^{(1)}, u_{s}^{(t)}, w_{i}(1 \leq i \leq s-1)$ have degree one in $H_{s, t}^{(2)}$. Since a path contains at most two vertices of degree at most one, $\operatorname{pc}(G) \geq\left\lceil\frac{l}{2}\right\rceil$ for every graph $G$ where $l$ is the number of the vertices of $G$ having degree one. In particular, we have

$$
\begin{equation*}
\operatorname{pc}\left(H_{s, t}^{(2)}\right) \geq\left\lceil\frac{s+1}{2}\right\rceil . \tag{2}
\end{equation*}
$$

If $s$ is odd, let

$$
\mathcal{P}=\left\{H_{s, t}^{(1)}-\left\{w_{j}: 1 \leq j \leq s-1\right\}, w_{2 i-1} v_{2 i-1} u_{2 i}^{(1)} Q_{2 i} u_{2 i}^{(t)} v_{2 i} w_{2 i}: 1 \leq i \leq \frac{s-1}{2}\right\}
$$

if $s$ is even, let
$\mathcal{P}=\left\{H_{s, t}^{(1)}-\left\{w_{j}: 1 \leq j \leq s-1\right\}, H_{s, t}^{(1)}\left[\left\{w_{s-1}\right\}\right], w_{2 i-1} v_{2 i-1} u_{2 i}^{(1)} Q_{2 i} u_{2 i}^{(t)} v_{2 i} w_{2 i}: 1 \leq i \leq \frac{s-2}{2}\right\}$.
Then we verify that $\mathcal{P}$ is a path cover of $H_{s, t}^{(1)}$ with $|\mathcal{P}|=\left\lceil\frac{s+1}{2}\right\rceil$. Furthermore, since $H_{s, t}^{(1)}$ is a spanning subgraph of $H_{s, t}^{(2)}$, a path cover of $H_{s, t}^{(1)}$ is also a path cover of $H_{s, t}^{(2)}$, and hence $\mathrm{pc}\left(H_{s, t}^{(2)}\right) \leq \mathrm{pc}\left(H_{s, t}^{(1)}\right) \leq\left\lceil\frac{s+1}{2}\right\rceil$. This together with (2) leads to the desired conclusion.

Lemma 2.10 We have $\operatorname{pp}\left(H_{s, t}^{(3)}\right)=\operatorname{pp}\left(H_{s, t}^{(4)}\right)=s$.
Proof. We first prove that

$$
\begin{equation*}
\operatorname{pp}\left(H_{s, t}^{(4)}\right) \geq s \tag{3}
\end{equation*}
$$

Let $\mathcal{P}$ be a path partition of $H_{s, t}^{(4)}$. It suffices to show that $|\mathcal{P}| \geq s$. For each $i$ with $1 \leq i \leq s$, let $R_{i}$ be the unique element of $\mathcal{P}$ containing $u_{i}^{(2)}$. We remark that $R_{i}$ might equal to $R_{j}$ for some $1 \leq i<j \leq s$. Let $I=\left\{i: 1 \leq i \leq s-1, R_{i}=R_{i+1}\right\}$, and write $I=\left\{i_{1}, i_{2}, \ldots, i_{h}\right\}$ with $i_{1}<i_{2}<\ldots<i_{h}$ where $h=0$ if $I=\emptyset$. For integers $i$ and $i^{\prime}$ with $1 \leq i<i^{\prime} \leq s$, any paths of $H_{s, t}^{(4)}$ joining $u_{i}^{(2)}$ and $u_{i^{\prime}}^{(2)}$ contain every vertex in $\left\{u_{j}^{(2)}: i<j<i^{\prime}\right\}$. This implies that if $R_{i}=R_{i^{\prime}}$ with $1 \leq i<i^{\prime} \leq s$, then $i^{\prime}-i+1$ paths $R_{j}\left(i \leq j \leq i^{\prime}\right)$ are equal. In particular, we have $\left|\left\{R_{i}: 1 \leq i \leq s\right\}\right|=s-h$.

Fix an integer $l$ with $1 \leq l \leq h$. Then for every path $R$ of $H_{s, t}^{(4)}$ joining $u_{i_{l}}^{(2)}$ and $u_{i_{l}+1}^{(2)}$, we easily verify that

- $\left\{u_{i_{l}}^{(t)}, u_{i_{l}+1}^{(1)}\right\} \subseteq V(R)$, and
- $v_{i_{l}} \notin V(R)$ or $w_{i_{l}} \notin V(R)$.

Since $v_{i_{l}} w_{i_{l}} \notin E\left(H_{s, t}^{(4)}\right)$, this implies that there exists an element $R_{i_{l}}^{\prime}$ of $\mathcal{P}$ such that either $V\left(R_{i_{l}}^{\prime}\right)=\left\{v_{i_{l}}\right\}$ or $V\left(R_{i_{l}}^{\prime}\right)=\left\{w_{i_{l}}\right\}$. Therefore

$$
\begin{aligned}
|\mathcal{P}| & \geq\left|\left\{R_{i}: 1 \leq i \leq s\right\} \cup\left\{R_{i_{j}}^{\prime}: 1 \leq j \leq h\right\}\right| \\
& =\left|\left\{R_{i}: 1 \leq i \leq s\right\}\right|+\left|\left\{R_{i_{j}}^{\prime}: 1 \leq j \leq h\right\}\right| \\
& =(s-h)+h \\
& =s
\end{aligned}
$$

which proves (3).
Since

$$
\mathcal{P}^{\prime}=\left\{H_{s, t}^{(3)}-\left\{w_{j}: 1 \leq j \leq s-1\right\}, H_{s, t}^{(3)}\left[\left\{w_{i}\right\}\right]: 1 \leq i \leq s-1\right\}
$$

is a path partition of $H_{s, t}^{(3)}$ with $\left|\mathcal{P}^{\prime}\right|=s$. Furthermore, since $H_{s, t}^{(3)}$ is a spanning subgraph of $H_{s, t}^{(4)}$, a path partition of $H_{s, t}^{(3)}$ is also a path partition of $H_{s, t}^{(4)}$, and hence $\operatorname{pp}\left(H_{s, t}^{(4)}\right) \leq \operatorname{pp}\left(H_{s, t}^{(3)}\right) \leq s$. This together with (3) leads to the desired conclusion.

Now we prove the following proposition, which gives the "only if" parts of Theorem 1.2

Proposition 2.11 Let $\mathcal{H}$ be a finite family of connected graphs.
(i) If $\mathcal{H}$ satisfies (A1), then $\mathcal{H} \leq\left\{K_{1, n}, K_{n}^{*}, F_{n, n}^{(1)}, F_{n, n}^{(2)}\right\}$ for an integer $n \geq 2$.
(ii) If $\mathcal{H}$ satisfies (A2), then $\mathcal{H} \leq\left\{K_{1, n}, K_{n}^{*}, F_{n, n}^{(1)}, F_{n, n}^{(2)}, F_{n, n}^{(3)}, F_{n, n}^{(4)}\right\}$ for an integer $n \geq 2$.

Proof. Since $\mathcal{H}$ is a finite family, the value $p=\max \{|V(H)|: H \in \mathcal{H}\}$ is welldefined. If $p \leq 2$, then the desired conclusions trivially hold. Thus we may assume that $p \geq 3$.

We first suppose that $\mathcal{H}$ satisfies (A1), and show that (i) holds. There exists a constant $c_{1}=c_{1}(\mathcal{H})$ such that $\operatorname{pc}(G) \leq c_{1}$ for every connected $\mathcal{H}$-free graph $G$. Since $\operatorname{pc}\left(K_{1,2 c_{1}+1}\right)=c_{1}+1$ and $\operatorname{pc}\left(K_{2 c_{1}+1}^{*}\right)=c_{1}+1$, neither $K_{1,2 c_{1}+1}$ nor $K_{2 c_{1}+1}^{*}$ is $\mathcal{H}$-free. This implies that

$$
\begin{equation*}
\mathcal{H} \leq\left\{K_{1,2 c_{1}+1}, K_{2 c_{1}+1}^{*}\right\} \tag{4}
\end{equation*}
$$

For each $i \in\{1,2\}$, it follows from Lemma 2.9 that $\operatorname{pc}\left(H_{2 c_{1}, p}^{(i)}\right)=\left\lceil\frac{2 c_{1}+1}{2}\right\rceil=c_{1}+1$, and hence $H_{2 c_{1}, p}^{(i)}$ is not $\mathcal{H}$-free, i.e., $H_{2 c_{1}, p}^{(i)}$ contains an induced subgraph $A_{i}$ isomorphic to an element of $\mathcal{H}$. Since $\left|V\left(A_{i}\right)\right| \leq p$, we have

- $\left|\left\{j: 1 \leq j \leq 2 c_{1}, V\left(A_{i}\right) \cap V\left(Q_{j}\right) \neq \emptyset\right\}\right| \leq 2$, and
- $\left|\left\{j: 1 \leq j \leq 2 c_{1}-1, V\left(A_{i}\right) \cap\left\{v_{j}, w_{j}\right\} \neq \emptyset\right\}\right| \leq 1$.

This implies that $A_{i}$ is an induced copy of $F_{p, p}^{(i)}$, and hence

$$
\begin{equation*}
\mathcal{H} \leq\left\{F_{p, p}^{(1)}, F_{p, p}^{(2)}\right\} \tag{5}
\end{equation*}
$$

Let $n=\max \left\{2 c_{1}+1, p\right\}$. Then by (4) and (5), $\mathcal{H} \leq\left\{K_{1, n}, K_{n}^{*}, F_{n, n}^{(1)}, F_{n, n}^{(2)}\right\}$, which proves (i).

Next we suppose that $\mathcal{H}$ satisfies (A2), and show that (ii) holds. There exists a constant $c_{2}=c_{2}(\mathcal{H})$ such that $\operatorname{pp}(G) \leq c_{2}$ for every connected $\mathcal{H}$-free graph $G$. Since $\operatorname{pp}(G) \geq \operatorname{pc}(G)$ for all graphs $G, \mathcal{H}$ also satisfies (A1). Hence by (i), there exists an integer $m \geq 2$ such that

$$
\begin{equation*}
\mathcal{H} \leq\left\{K_{1, m}, K_{m}^{*}, F_{m, m}^{(1)}, F_{m, m}^{(2)}\right\} \tag{6}
\end{equation*}
$$

For each $i \in\{3,4\}$, it follows from Lemma 2.10 that $\operatorname{pp}\left(H_{c_{2}+1, p}^{(i)}\right)=c_{2}+1$, and hence $H_{c_{2}+1, p}^{(i)}$ is not $\mathcal{H}$-free, i.e., $H_{c_{2}+1, p}^{(i)}$ contains an induced subgraph $B_{i}$ isomorphic to an element of $\mathcal{H}$. Since $\left|V\left(B_{i}\right)\right| \leq p$, we have

- $\left|\left\{j: 1 \leq j \leq c_{2}+1, V\left(B_{i}\right) \cap V\left(Q_{j}\right) \neq \emptyset\right\}\right| \leq 2$, and
- $\left|\left\{j: 1 \leq j \leq c_{2}, V\left(B_{i}\right) \cap\left\{v_{j}, w_{j}\right\} \neq \emptyset\right\}\right| \leq 1$.

This implies that $B_{i}$ is an induced copy of $F_{p, p}^{(i)}$, and hence

$$
\begin{equation*}
\mathcal{H} \leq\left\{F_{p, p}^{(3)}, F_{p, p}^{(4)}\right\} . \tag{7}
\end{equation*}
$$

Let $n^{\prime}=\max \{m, p\}$. Then by (6) and (77), $\mathcal{H} \leq\left\{K_{1, n^{\prime}}, K_{n^{\prime}}^{*}, F_{n^{\prime}, n^{\prime}}^{(1)}, F_{n^{\prime}, n^{\prime}}^{(2)}, F_{n^{\prime}, n^{\prime}}^{(3)}, F_{n^{\prime}, n^{\prime}}^{(4)}\right\}$, which proves (ii).

## 3 Proof of Theorem 1.3

In this section, we prove Theorem 1.3. We start with the following lemma, which is an analogy of Lemma 2.2.

Lemma 3.1 For a graph $G, \operatorname{cp}(G) \leq R(\alpha(G)+1, \alpha(G)+1)-1$.
Proof. Let $\mathcal{P}$ be a cycle partition of $G$ with $|\mathcal{P}|=\operatorname{cp}(G)$, and write $\mathcal{P}=\left\{Q_{i}: 1 \leq\right.$ $i \leq \operatorname{cp}(G)\}$. By way of contradiction, suppose that $\operatorname{cp}(G) \geq R(\alpha(G)+1, \alpha(G)+1)$. For each integer $i$ with $1 \leq i \leq \operatorname{cp}(G)$, we define vertices $x_{i}$ and $y_{i}$ of $Q_{i}$ as follows: If either $Q_{i} \simeq K_{2}$ or $Q_{i}$ is a cycle, let $x_{i}$ and $y_{i}$ be vertices of $Q_{i}$ with $x_{i} y_{i} \in E\left(Q_{i}\right)$; if $Q_{i} \simeq K_{1}$, let $x_{i}=y_{i}=u$ where $u$ is the unique vertex of $Q_{i}$. For integers $i$ and $j$ with $1 \leq i<j \leq \operatorname{cp}(G)$, if $\left\{x_{i} x_{j}, y_{i} y_{j}\right\} \subseteq E(G)$, then we easily verify that there exists a spanning subgraph $Q$ of $G\left[V\left(Q_{i}\right) \cup V\left(Q_{j}\right)\right]$ such that either $Q \simeq K_{2}$ or $Q$ is a cycle, and hence $\mathcal{P}^{\prime}=\left(\mathcal{P} \backslash\left\{Q_{i}, Q_{j}\right\}\right) \cup\{Q\}$ is a cycle partition of $G$ with $\left|\mathcal{P}^{\prime}\right|=\operatorname{cp}(G)-1$, which contradicts the definition of the cycle partition number. Thus if $x_{i} x_{j} \in E(G)$, then $y_{i} y_{j} \notin E(G)$.

Let $K$ be the complete graph on $\{1,2, \ldots, \operatorname{cp}(G)\}$, and color all edges of $K$ by red or blue as follows: For integers $i$ and $j$ with $1 \leq i<j \leq \operatorname{cp}(G)$, if $x_{i} x_{j} \notin E(G)$, we color the edge $i j$ of $K$ by red; if $x_{i} x_{j} \in E(G)$ and $y_{i} y_{j} \notin E(G)$, we color the edge $i j$ of $K$ by blue. Since $|V(K)|=\operatorname{cp}(G) \geq R(\alpha(G)+1, \alpha(G)+1)$, there exists a monochromatic clique $I$ of $K$ with $|I|=\alpha(G)+1$. If $I$ is a red clique of $K$, then $\left\{x_{i}: i \in I\right\}$ is an independent set of $G$; if $I$ is a blue clique of $K$, then $\left\{y_{i}: i \in I\right\}$ is an independent set of $G$. In either case, we obtain a contradiction.

The following lemma was implicitly proved in [1]. (To keep the paper selfcontained, we give its proof.)

Lemma 3.2 (Choi et al. [1]) Let $n \geq 2$ be an integer. There exists a constant $c=c(n)$ depending on $n$ only such that $\alpha(G) \leq c$ for every connected $\left\{K_{1, n}, K_{n}^{*}, P_{n}\right\}$ free graph $G$.

Proof. Let $x$ be a vertex of $G$, and for an integer $i$ with $i \geq 0$, let $X_{i}$ be the set of vertices $y$ of $G$ such that the distance between $x$ and $y$ in $G$ is exactly $i$. Note that $X_{0}=\{x\}$ and $X_{1}=N_{G}(x)$. Since $G$ is $P_{n}$-free, $X_{i}=\emptyset$ for all $i \geq n-1$. Since $G$ is connected, this implies that

$$
\begin{equation*}
V(G)=\bigcup_{0 \leq i \leq n-2} X_{i} \tag{8}
\end{equation*}
$$

We recursively define the values $\alpha_{i}(i \geq 0)$ as follows: Let $\alpha_{0}=1$, and for $i$ with $i \geq 1$, let $\alpha_{i}=(n-1) R\left(n, \alpha_{i-1}+1\right)-1$.

We prove that

$$
\begin{equation*}
\alpha\left(G\left[X_{i}\right]\right) \leq \alpha_{i} \text { for an integer } i \text { with } 0 \leq i \leq n-2 \tag{9}
\end{equation*}
$$

We proceed by induction on $i$. Since $\alpha\left(G\left[X_{0}\right]\right)=1=\alpha_{0}$, we may assume that $i \geq 1$ and $\alpha\left(G\left[X_{i-1}\right]\right) \leq \alpha_{i-1}$. Since $X_{i} \subseteq N_{G}\left(X_{i-1}\right)$, it follows from Lemma 2.3 that $\alpha\left(G\left[X_{i}\right]\right) \leq \alpha\left(G\left[N_{G}\left(X_{i-1}\right)\right]\right) \leq(n-1) R\left(n, \alpha_{i-1}+1\right)-1=\alpha_{i}$, as desired.

By (18) and (9), we have $\alpha(G) \leq \sum_{0 \leq i \leq n-2} \alpha\left(G\left[X_{i}\right]\right) \leq \sum_{0 \leq i \leq n-2} \alpha_{i}$. Since the value $\sum_{0 \leq i \leq n-2} \alpha_{i}$ is a constant depending on $n$ only, we obtain the desired conclusion.

Proof of Theorem 1.3. By the definition of cycle cover and cycle partition, "(ii) $\Longrightarrow$ (i)" clearly holds.

We show that "(iii) $\Longrightarrow$ (ii)" holds. Let $n \geq 2$ be an integer, and let $c=c(n)$ be the constant as in Lemma 3.2. It suffices to show that there exists a constant $c_{1}=$ $c_{1}(n)$ depending on $n$ only such that $\operatorname{cp}(G) \leq c_{1}$ for every connected $\left\{K_{1, n}, K_{n}^{*}, P_{n}\right\}-$ free graph $G$. By the definition of $c(n)$, we have $\alpha(G) \leq c$. This together with Lemma 3.1 leads to $\operatorname{cp}(G) \leq R(\alpha(G)+1, \alpha(G)+1)-1 \leq R(c+1, c+1)-1$. Since $R(c+1, c+1)-1$ is a constant depending on $n$ only, we obtain the desired conclusion.

Finally, we show that "(i) $\Longrightarrow$ (iii)" holds, which completes the proof of Theorem 1.3. Suppose that a family $\mathcal{H}$ of connected graphs satisfies (A'1). Then there exists a constant $c_{1}=c_{1}(\mathcal{H})$ such that $\operatorname{cc}(G) \leq c_{1}$ for every connected $\mathcal{H}_{-}$ free graph $G$. Since $\operatorname{cc}\left(K_{1, c_{1}+1}\right)=c_{1}+1, \operatorname{cc}\left(K_{c_{1}+1}^{*}\right)=c_{1}+1$ and $\operatorname{cc}\left(P_{2 c_{1}+1}\right)=$ $\left\lceil\frac{2 c_{1}+1}{2}\right\rceil=c_{1}+1$, none of $K_{1, c_{1}+1}, K_{c_{1}+1}^{*}$ and $P_{2 c_{1}+1}$ is $\mathcal{H}$-free. This implies that $\mathcal{H} \leq\left\{K_{1, c_{1}+1}, K_{c_{1}+1}^{*}, P_{2 c_{1}+1}\right\}$, and hence $\mathcal{H} \leq\left\{K_{1,2 c_{1}+1}, K_{2 c_{1}+1}^{*}, P_{2 c_{1}+1}\right\}$, which leads (iii).
