SHIFT-IN Variant HOMOGENEOUS CLASSES OF RANDOM FIELDS

ENKELEJD HASHORVA

Abstract: Let $\|\cdot\| : \mathbb{R}^d \mapsto [0, \infty)$ be a 1-homogeneous continuous map and let $T = \mathbb{R}^l$ or $T = \mathbb{Z}^l$ with $d, l$ positive integers. For a given $\mathbb{R}^d$-valued random field (rf) $Z(t), t \in T$, which satisfies $\mathbb{E}\{\|Z(t)\|^\alpha\} \in [0, \infty)$ for all $t \in T$ and some $\alpha > 0$ we define a class of rf’s $\mathbb{K}^+_{\alpha}[Z]$ related to $Z$ via certain functional identities. In the case $T = \mathbb{R}^l$ the elements of $\mathbb{K}^+_{\alpha}[Z]$ are assumed to be quadrant stochastically continuous. If $B^h Z \in \mathbb{K}^+_{\alpha}[Z]$ for any $h \in T$ with $B^h Z(\cdot) = Z(\cdot - h), h \in T$, we call $\mathbb{K}^+_{\alpha}[Z]$ shift-invariant. This paper is concerned with the basic properties of shift-invariant $\mathbb{K}^+_{\alpha}[Z]$’s. In particular, we discuss functional equations that characterise the shift-invariance and relate it with spectral tail and tail rf’s introduced in this article for our general settings. Further, we investigate the class of universal maps $\mathbb{U}$, which is of particular interest for shift-representations. Two applications of our findings concern max-stable rf’s and their extremal indices.

Key words: homogeneous classes of random fields; shift-invariant classes of random fields; quadrant stochastic continuity; extremal index; lattices;

1. Introduction

This paper investigates basic properties of certain classes of separable and measurable $E$-valued rf's which are related to a given $E$-valued rf $Z(t), t \in T$ defined on a complete probability space $(\Omega, \mathcal{F}, \mathbb{P})$. For simplicity we shall consider $E = \mathbb{R}^d$, extensions to $E$ a linear normed space which is also a Polish space with a metric generating its norm are possible but will not be considered here. We set $T = \mathbb{R}^d$ or $T = \mathbb{Z}^l$ with $d$ and $l$ two positive integers. If $T = \mathbb{R}^l, l = 1$ we shall assume that all rf’s below are stochastic continuous from the right, which can be generalised when $l > 1$ to quadrant stochastic continuity, see Definition 2.2 below.

Hereafter $\Omega_T$ stands for the set of all separable $\mathbb{R}^d$-valued rf’s which are quadrant stochastically continuous defined on complete probability spaces, not necessarily the same as $(\Omega, \mathcal{F}, \mathbb{P})$. In view of Lemma A.1 all rf’s in $\Omega_T$ have a separable and measurable version. Hence in the following $Z \in \Omega_T$ will be simply assumed to be separable and measurable. Particular interesting instances for the elements of $\Omega_T$ are rf’s with generalised càdlàg sample paths and the discrete ones ($T = \mathbb{Z}^l$).

We are interested in certain classes of rf’s from $\Omega_T$ related to a given $Z \in \Omega_T$ via

i) some given constant $\alpha > 0$;

ii) a 1-homogeneous continuous map $\|\cdot\| : \mathbb{R}^d \mapsto [0, \infty)$.

In particular, for $Z \in \Omega_T$ we shall assume that $\mathbb{E}\{\|Z(t_0)\|^\alpha\} \in (0, \infty)$ for some $t_0 \in T$ and

\[
(1.1) \quad \mathbb{E}\left\{\sup_{t \in [-a,a] \cap T} \|Z(t)\|^\alpha\right\} < \infty, \quad \forall a \in (0, \infty).
\]

Clearly, if $T = \mathbb{Z}^l$, then (1.1) is satisfied if $\mathbb{E}\{\|Z(t)\|^\alpha\} < \infty$ for all $t \in T$.

We shall focus next on rf’s $\tilde{Z} \in \Omega_T$ defined on complete probability spaces $(\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}})$ that satisfy the following functional identity

\[
(1.2) \quad \tilde{\mathbb{E}}\{\|\tilde{Z}(h)\|^\alpha F(\tilde{Z}/\|\tilde{Z}(h)\|)\} = \mathbb{E}\{\|Z(h)\|^\alpha F(Z/\|Z(h)\|)\}, \quad \forall h \in T, \forall F \in \mathcal{H},
\]

with $\mathcal{H}$ the class of all maps $F : D \mapsto \mathbb{R}$ and all maps $F : D \mapsto [0, \infty]$ which are $\mathcal{B}/\mathcal{B}([0, \infty])$-measurable, with $D = E^T$ equipped with the product $\sigma$-field $\mathcal{B}$. In our notation $\mathcal{B}(V)$ stands for the Borel $\sigma$-field of some topological space $V$.

For notational simplicity hereafter we shall write $\mathbb{P}$ and $\mathbb{E}$ instead of $\tilde{\mathbb{P}}$ and $\tilde{\mathbb{E}}$, respectively.

**Definition 1.1.** $K^+_{\alpha}[Z]$ with representer $Z$ consists of rf’s $\tilde{Z} \in \Omega_T$ that satisfy (1.1), (1.2) and

\[
(1.3) \quad \mathbb{P}\left\{\sup_{t \in T} \|\tilde{Z}(t)\| > 0\right\} = 1.
\]

Further assume that $Z \in K^+_{\alpha}[Z]$.

Clearly, if $S$ is a rv independent of $Z$, then $SZ \in K^+_{\alpha}[Z]$, provided that $\mathbb{E}\{S^\alpha\} \in (0, \infty)$. The class $K^+_{\alpha}[Z]$ is very tractable, if additionally to $Z$ it contains its deterministic shifts $B^h Z$ for all $h \in T$, where $B^h Z(\cdot) = Z(\cdot - h), h \in T$. This leads to the following definition:

**Definition 1.2.** $K^+_{\alpha}[Z]$ is shift-invariant if for some $\tilde{Z} \in K^+_{\alpha}[Z]$

\[
(1.4) \quad B^h \tilde{Z} \in K^+_{\alpha}[Z], \quad \forall h \in T.
\]
It follows easily that if $K_\alpha^+[Z]$ is shift-invariant, then (1.4) holds for all $\tilde{Z} \in K_\alpha^+[Z]$. Hence in particular

$$\mathbb{E}\{\|Z(t)\|^\alpha\} = \mathbb{E}\{\|Z(0)\|^\alpha\} \in (0, \infty), \quad t \in \mathcal{T}.$$ 

Clearly, if $Z$ is stationary satisfying both (1.1) and (1.3), then it generates a shift-invariant $K_\alpha^+[Z]$. Interestingly, the shift-invariance property is not implied only by the stationarity of $Z$, see Example 3.5 below. Moreover, in the particular case that $Z$ has càdlàg sample paths, then the shift-invariance of $K_\alpha^+[Z]$ is equivalent with the shift-invariance of the tail measure determined by $Z$, see Remark 4.5 below.

Define the probability measure

$$\hat{P}(A) = \frac{1}{\mathbb{E}\{\|Z(0)\|^\alpha\}} \mathbb{E}\{\|Z(0)\|^\alpha \mathbb{1}(A)\}, \quad \forall A \in \mathcal{F},$$

with $\mathbb{1}(A)$ the indicator function of some set $A$ and let hereafter $R$ be an $\alpha$-Pareto random variable (rv) on $(\Omega, \mathcal{F}, \mathbb{P})$ being independent of all other random elements.

For a shift-invariant $K_\alpha^+[Z]$ we shall show that $Z/\|Z(0)\|$ and $RZ/\|Z(0)\|$ under $\hat{P}$, called spectral tail and tail rf, respectively, can be alternatively utilised to study the properties of $K_\alpha^+[Z]$. Tail and spectral tail rf’s are initially introduced in [1, 2] in the study of regular variation of stationary time series. As shown recently in [3], $Y(t), t \in \mathbb{Z}^l$ is a tail rf if and only if (iff) it is an exceedance stationary process.

In order to work with both spectral tail and tail rf’s in the settings of quadratic stochastically continuous rf’s (so far only càdlàg processes or $\mathcal{T}$ countable has been considered, see e.g., [2, 4–6]), the functional equation (1.2) should hold for a larger class of maps $F$ that include the integral functional

$$F_I(f) : f \mapsto \int_{\mathcal{T}} \|f(t)\| \lambda(dt),$$

with $f(t), t \in \mathbb{R}^l$ measurable $\mathbb{R}^d$-valued functions and $\lambda$ the Lebesgue measure on $\mathcal{T} = \mathbb{R}^l$; such an extension is stated in (3.2) below. We shall denote by $D(\mathbb{R}^l, \mathbb{R}^d)$ the space of càdlàg functions $f : \mathbb{R}^l \mapsto \mathbb{R}^d$, see [7–10] for details. Dropping the càdlàg assumptions on $Z$ leads to several challenges including:

i) Numerous functionals of interest including $F_I$ defined in (1.6) are not measurable, invalidating thus the application of (1.2) for those functionals;

ii) In the general settings of this paper, the relation between $M(K) = \sup_{t \in K} \|Z(t)\|$ and the sojourn time $L_u(K) = \int_K \mathbb{1}(\|Z(t)\| > u) \lambda(dt), u \in \mathbb{R}$, where $K$ is some hypercube in $\mathbb{R}^l$ is not clear, while for $Z$ with càdlàg sample paths $\mathbb{P}\{M(K) > u\} = 1$ implies $\mathbb{P}\{L_u(K) > 0\} = 1$;

iii) Important properties of $K_\alpha^+[Z]$ when $Z$ has càdlàg sample paths or $\mathcal{T} = \mathbb{Z}^l$ are retrieved by studying the corresponding tail measure $\nu_Z$ defined in Remark 4.5 below. The latter can be characterised by Lipschits maps when $\|\cdot\|$ is a norm as shown in [6, 10]. For $Z$ with non-càdlàg sample paths such a characterisation is not available.

Both i)-iii) indicate that already results derived in [6, 11] for càdlàg rf’s and their corresponding tail measures do not imply any of our findings of this paper.

In the first part of this contribution we shall discuss basic properties of $K_\alpha^+[Z]$’s and give characterisations in terms of functional equations. Then we focus on shift-invariant $K_\alpha^+[Z]$’s presenting results that extend previous findings concerned with the case $\mathcal{T} = \mathbb{Z}^l$ or $\mathcal{T} = \mathbb{R}^l$ and $Z$ with sample paths in $D(\mathbb{R}^l, \mathbb{R}^d)$ published.
In the investigation of shift-invariant $\mathbb{K}^+_\alpha[Z]$’s several maps including anchoring and shift-involutions play a crucial role, which is not surprising in view of [2, 3, 15]. We shall show that also of particular importance are certain maps belonging to some class $\mathcal{U}$ of universal maps. Their study is important for the investigation of shift-representations in [16].

Below is a short summary of some new findings of this contribution:

i) Eq. (1.2) is shown to hold for a large class of maps $F$ including $F_I$ defined in (1.6);

ii) Tail and spectral tail rf’s are defined for general rf’s in $\Omega_T$ dropping the càdlàg sample path assumption in [6, 10] and the restriction that $T$ is countable imposed in [2, 5, 13, 14, 17]. Moreover, we do not assume that $\|z\| = 0$ iff $z = 0 \in \mathbb{R}^l$ as in [14] or $\|\cdot\|$ is a norm as in the aforementioned papers.

iii) Characterisations of shift-invariant classes of rf’s are derived. We retrieve known results for càdlàg rf’s, while our results are new for the case of rf’s with sample paths in $D(\mathbb{R}^l, \mathbb{R}^d), l > 1$ and also when $\|\cdot\|$ is not a norm. In particular, all the findings related to full rank lattices and additive subgroups of $T$ are all new. Moreover, even in the case $T = \mathbb{Z}^l$ we derive some new results, for instance representation (7.11) and extend existing results removing restrictions on $\|\cdot\|$;

iv) We derive interesting properties of shift-invariant universal maps belonging to $\mathcal{U}$. In particular, we introduce (positive) shift-involutions and highlight their role in the investigation of universal maps applied to elements of shift-invariant $\mathbb{K}^+_\alpha[Z]$’s or to their spectral tail rf’s;

v) Our applications include new results for max-stable processes and their extremal indices.

Outline of the rest of the paper: Section 2 introduce lattices, some classes of maps, quadrant stochastically continuous rf’s and our notation followed by a short investigation of the properties of general classes of homogeneous rf’s in Section 3. Shift-invariant $\mathbb{K}^+_\alpha[Z]$’s are dealt with in Section 4, where we relate them with spectral tail and tail rf’s. Section 5 is dedicated to universal maps and their relations with (positive) shift-involutions and anchoring maps. In Section 6, for a given $\mathbb{K}^+_\alpha[Z]$ we define the corresponding max-stable rf and present a crucial separating property of their extremal indices in Lemma 6.2. In particular, new representations of those indices can be derived, see Remark 6.3, Item (iii). All proofs are displayed in Section 7. In Appendix A we discuss properties of quadratic stochastically continuous rf’s, concluding with some technical results in Appendix B.

2. Preliminaries

2.1. Lattices. Unless otherwise stated $\mathcal{L}$ shall denote a discrete subgroup of the additive group $T$ (called also a lattice on $T$) which has countably infinite number of elements. In several instances we shall assume that $\mathcal{L}$ has full rank, i.e., for some non-singular $l \times l$ real matrix $A$ (called base matrix) $\mathcal{L} = \{Ax, x \in T\}$, where $x$ denotes a $l \times 1$ vector. Two base matrices $A, B$ generate the same lattice on $T$ iff

$$A = BU,$$
where $U$ is a $l \times l$ real matrix with determinant $\pm 1$. Therefore, when $\mathcal{T} = \mathbb{R}^l$ the volume of the fundamental parallelepiped $\{Ax, x \in [0, 1]^l\}$ does not depend on the choice of the base matrix and is given by
\begin{equation}
\Delta(\mathcal{L}) = |\text{det}(A)| > 0.
\end{equation}

2.2. Some classes of maps. Write $\mathcal{H}_\beta, \beta \geq 0$ for the class of measurable maps $F \in \mathcal{H}$ (recall the definition of $\mathcal{H}$ in the Introduction) which are $\beta$-homogeneous, i.e., $F(cf) = c^\beta F(f)$ for all $f \in D$ and $c > 0$. Throughout this paper $g : \mathcal{T} \mapsto [0, \infty)$ is continuous such that $\sup_{t \in \mathcal{T}} g(t) > 0$.

Write $\mathcal{H}_a, a \geq 0$ for the class of maps determined for given $\Gamma_a \in \mathcal{H}_a$ by
\begin{equation}
F(f) = \frac{\Gamma_a(f)\Gamma(f)}{\mathcal{I}_\beta(g_1(f)g_2)}, \quad \mathcal{I}_\beta(f, g) = \int_{\mathcal{T}} \|f(t)\|^\beta g(t)\lambda(dt), \quad f \in D,
\end{equation}
with $\Gamma_\beta : D \mapsto [0, c], \Gamma_\beta \in \mathcal{H}_\beta$ and $c$ some positive constant, or
\begin{equation}
F(f) = \Gamma_a(f)\mathcal{I}(\mathcal{I}_\beta(g_1(f)g_2) \in A), \quad f \in D, \quad A \in \{\{0\}, (0, \infty), \{\infty\}\}.
\end{equation}
Throughout this paper $\lambda$ denotes the Lebesgue measure on $\mathbb{R}^l$ or the counting measure on $\mathbb{Z}^l$, if $\mathcal{T} = \mathbb{R}^l$ or $\mathcal{T} = \mathbb{Z}^l$, respectively. For the case that $f$ is not $\lambda$-measurable we set $F(f) = 0$.

We note in passing that the choice of $\lambda$ is important since the translation invariance of $\lambda$ is crucial when the shift-invariance property is discussed.

2.3. Involutions & anchoring maps. The important role of infargsup (or alternatively infargmax) map in extreme value theory is well-known, see e.g., [18–20]. In particular, any max-stable distribution has a representation in terms of infargsup functional as shown in [21]. Anchoring maps introduced in [2] play a crucial role in the investigation of tail rf’s. See also [2, 4, 13, 17, 22, 23] for various results concerning anchoring maps. Our definition of anchoring maps is adopt from [15], where $\mathcal{L}$ is some lattice on $\mathcal{T}$ and $\mathbb{R} = \mathbb{R} \cup \{-\infty, \infty\}$.

We introduce below shift-involutions and positive shift-involutions, which are important for the investigation of elements of a given $\mathbb{K}_+^a[Z]$ and the corresponding spectral tail rf, respectively.

Definition 2.1. Let $\mathcal{I} : \mathcal{T} \to \mathbb{R}^d$ be $\mathcal{D}/\mathcal{B}(\mathbb{R}^d)$-measurable.

A1) For all $j \in \mathcal{L}, f \in D$ we have $\mathcal{I}(B^j f) = j = \mathcal{I}(f)$;
A2) $\mathcal{I}(f) = j \in \mathcal{L}$ implies $\|f(j)\| > \text{min}(1, \|f(0)\|)$ for all $f \in D$;
A3) $\mathcal{I}(f) = j \in \mathcal{L}$ implies $\|f(j)\| > 0$ for all $f \in D$.

Suppose that $\mathcal{I}$ satisfies A1). If $\mathcal{I}$ is 0-homogeneous it is called a shift-involution and if further A3) holds it is called a positive shift-involution. When A2) holds $\mathcal{I}$ is referred to as anchoring.

Note that the above maps are defined with respect to a given $\mathcal{L}$.

Hereafter $\prec$ stands for some total order on $\mathcal{T}$ which is shift-invariant, i.e., $i \prec j$ implies $i + k \prec j + k$ for all $i, j, k \in \mathcal{T}$; a canonical instance is the lexicographical order. Both inf and sup are taken with respect to $\prec$ and the infimum of an empty set is equal to $\infty$. As pointed out in [2], an interesting anchoring map which is not 0-homogeneous is the first exceedance functional $\mathcal{I}_{\mathcal{L}, fe}$ defined by
\begin{equation}
\mathcal{I}_{\mathcal{L}, fe}(f) = \inf\left\{ j \in \mathcal{L} : \|f(j)\| > 1 \right\}, \quad f \in D,
\end{equation}
where \( I_{\mathcal{L}, f_e}(f) = \infty \) if there are infinitely many exceedance on \( \{ j \in \mathcal{L}, j < k_0 \} \) for some \( k_0 \in \mathcal{L} \) with all components positive. Define further the inargsup map

\[
I_\mathcal{L}(f) = \inf \left( j \in \mathcal{L} : \| f(j) \| = \sup_{i \in \mathcal{L}} \| f(i) \| \right), \quad f \in \mathcal{D},
\]

which is a positive shift-involution and also anchoring.

2.4. Quadrant stochastically continuous rf’s. Let the rf \( Z(t), t \in \mathcal{T} = \mathbb{R}^l \) be defined on the complete probability space \( (\Omega, \mathcal{F}, \mathbb{P}) \). Stochastic continuity of \( Z \) at some \( t \in \mathcal{T} \) means convergence in probability \( Z(t_n) \xrightarrow{p} Z(t) \) as \( n \to \infty \) if \( \lim_{n \to \infty} t_n = t \) with \( t_n, t \in \mathcal{T}, n \in \mathbb{N} \).

The stochastic continuity can be relaxed as follows: Given \( t \in \mathcal{T} \), if \( l = 1 \) we suppose that \( Z(h) \xrightarrow{p} Z(t), t \downarrow h \) and also \( \lim_{h \uparrow t} Z(h) \) exists and is finite. The last limit is in probability and \( \xrightarrow{p} \) means convergence in probability. In this case \( Z \) is called stochastically continuous from the right at \( t \). When \( l > 1 \), we consider limits along the quadrants \( Q_i(t) \) similarly to the definition of generalised càdlàg functions, see e.g., [8]. Specifically, we assume \( \lim_{h \to t, h \in Q_i} Z(h) \) exists and is finite (limit is taken in probability) for all \( i \leq 2^l \) and \( Z(h) \xrightarrow{p} Z(t), h \to t, h \in Q_1 \) for all \( t \in \mathbb{R}^l \) with

\[
Q_j(t) = \{ s \in \mathbb{R}^l : s_i R_i t_i, i \leq l \}, \quad R_i \in \{ <, \geq \}, \quad j = 1, \ldots, 2^l,
\]

(2.4)

\[
Q_1(t) = \{ s \in \mathbb{R}^l : s_i \geq t_i, i \leq l \}.
\]

Definition 2.2. \( Z(t), t \in \mathcal{T} \) is called quadrant stochastically continuous if \( \mathcal{T} \subset \mathbb{Z}^l \) or when \( \mathcal{T} \subset \mathbb{R}^l \), then it is quadrant stochastically continuous at all points \( t \in \mathcal{T} \).

Recall that by \( \Omega_{\mathcal{T}} \) we denote the class of all rf’s defined on complete probability spaces, which are quadrant stochastically continuous. Important instances of \( Z \in \Omega_{\mathcal{T}} \) include all rf’s with càdlàg sample paths, see e.g., [10]. For second order processes and \( \mathcal{T} = [0, S] \) necessary conditions that imply the stochastic continuity of \( Z \) up to a countable set are presented in [24][Prop 2.6]. Basic properties of elements of \( \Omega_{\mathcal{T}} \) are discussed in Appendix A.

3. Homogeneous classes of rf’s

We shall fix \( \alpha > 0 \) and as in the Introduction, we denote by \( \| \cdot \| \) a 1-homogeneous continuous map \( \mathbb{R}^d \to [0, \infty) \). Canonical examples include \( \| \cdot \| \) being a norm on \( \mathbb{R}^d \) or \( \| x \| = (\sum_{i=1}^d |x_i|^\alpha)^{1/\alpha}, x \in \mathbb{R}^d \) if \( \alpha \in (0, 1) \). In this section \( Z \in \Omega_{\mathcal{T}} \) is a given quadrant stochastically continuous rf.

Definition 3.1. If \( \mathbb{E}\{\| Z(t) \|^{\alpha} \} < \infty, \forall t \in \mathcal{T} \) and \( \mathbb{E}\{\| Z(t_0) \|^{\alpha} \} \in (0, \infty) \) for some \( t_0 \in \mathcal{T} \), then \( \mathbb{K}_\alpha[Z] \) consists of all \( \tilde{Z} \in \Omega_{\mathcal{T}} \) satisfying (1.2).

We show next that condition (1.3) is satisfied for some \( \tilde{Z} \in \mathbb{K}_\alpha[Z] \).

Lemma 3.2. There exists \( \tilde{Z} \in \mathbb{K}_\alpha[Z] \) satisfying both (1.1) and (1.3). Moreover, \( \mathbb{P}\{\sup_{t \in \mathcal{D}} \| \tilde{Z}(t) \| > 0 \} = 1 \) for any countable dense subset \( \mathcal{D} \) of \( \mathcal{T} \) that contains \( t_0 \).
Remark 3.3. An implication of Lemma 3.2 is that $K_\alpha[Z] = K_\alpha[\widetilde{Z}]$ for $\widetilde{Z}$ as therein.

In the light of Remark 3.3 we can limit our investigation to elements $\tilde{Z} \in K_\alpha[Z]$ such that (1.1) and (1.3) hold, hence we shall consider below only $K_\alpha^+[Z]$ defined in the Introduction.

We present the below the main result of this section extending the functional equation (1.2) to a broader and important class of maps $F \in \mathcal{S}_0$ defined in (2.2) and (2.3), respectively. Further we justifying the labelling $\alpha$-homogeneous.

Theorem 3.4. Given a $K_\alpha^+[Z]$ we have

$$(3.1) \quad \mathbb{E}\{\|Z(h)\|^\alpha \Gamma(Z)\} = \mathbb{E}\{\|\tilde{Z}(h)\|^\alpha \Gamma(\tilde{Z})\}, \quad \forall h \in \mathcal{T}, \forall \Gamma \in \mathcal{S}_0, \forall \tilde{Z} \in K_\alpha^+[Z].$$

Further, (1.2) is equivalent with

$$(3.2) \quad \mathbb{E}\{F(Z)\} = \mathbb{E}\{F(\tilde{Z})\}, \quad \forall F \in \mathcal{S}_\alpha, \forall \tilde{Z} \in K_\alpha^+[Z].$$

Example 3.5 (Brown-Resnick $\alpha$-homogeneous class of rf’s). For $X(t) = (X_1(t), \ldots, X_d(t))$, $t \in \mathcal{T}$ a centered $\mathbb{R}^d$-valued Gaussian rf with almost surely continuous sample paths and $\max_{1 \leq i \leq d} P\{X_i(0) = 0\} = 1$ let

$$Z(t) = (\xi_1 e^{W_1(t)}, \ldots, \xi_d e^{W_d(t)}), \quad W_i(t) = X_i(t) - \alpha \text{Var}(X_i(t))/2, \quad 1 \leq i \leq d, t \in \mathcal{T},$$

where $\xi_1, \ldots, \xi_d$ are rv’s that take values $\pm 1$ being further independent of $X$. Taking $\|x\| = (\sum_{i=1}^d |x_i|^\alpha / d)^{1/\alpha}$, $x \in \mathbb{R}^d$, then $\mathbb{E}\{\|Z(t)\|^\alpha\} = 1$ for all $t \in \mathcal{T}$. In the light of [25][Cor. 6.1]

$$d\mathbb{E}\left\{\sup_{t \in [-a,a]^d} \|Z(t)\|^{\alpha}\right\} = \sum_{i=1}^d \mathbb{E}\left\{\sup_{t \in [-a,a]^d} e^{\alpha X_i(t) - \text{Var}(\alpha X_i(t))/2}\right\} < \infty, \quad \forall \alpha > 0$$

and thus $Z$ satisfies (1.1) and (1.3).

4. Shift-Invariant Homogeneous Classes, Spectral Tail and Tail RF’s

Under the settings of Section 3 we shall assume without loss of generality hereafter that

$$(4.1) \quad \mathbb{E}\{\|Z(0)\|^\alpha\} = 1.$$ 

We call $\Theta$ the local rf of $K_\alpha^+[Z]$, if $\Theta$ is the rf $Z/\|Z(0)\|$ under $\tilde{P}$ in (1.5).

Remark 4.1. If $P\{\|\Theta(0)\| > 0\} = 1$, then $\Theta \in K_\alpha^+[Z]$ and $\Theta$ is unique in the sense that if $\tilde{Z}$ is another element of $K_\alpha^+[Z]$ defined on the same probability space as $Z$ and we define $\tilde{\Theta}$ as the rf $\tilde{Z}/\|\tilde{Z}(0)\|$ under $\tilde{P}$, then $\Theta$ and $\tilde{\Theta}$ have the same law, which follows from (3.2).

In view of (1.1), the quadrant stochastic continuity of $Z$ implies the quadrant stochastic continuity of $\Theta$ and by definition since $(\Omega, \mathcal{F}, P)$ is complete, then also $(\Omega, \mathcal{F}, \tilde{P})$ is complete. For notational simplicity we shall write below $P$ instead of $\tilde{P}$.

The above discussion and Lemma A.1 leads to the following result:

Lemma 4.2. For all $\tilde{Z} \in K_\alpha^+[Z]$, any dense countable set $\mathbb{D} \subset \mathcal{T}$ is a separant for $\tilde{Z}, \|\tilde{Z}\|, \Theta, \|\Theta\|$. 

In view of (3.2) and the definition given in the Introduction a given $\mathbb{K}_\alpha^+[Z]$ is shift-invariant iff

$$E\{F(Z)\} = E\{F(B^hZ)\}, \quad \forall F \in \mathfrak{S}_\alpha, \forall h \in T, \forall Z \in \mathbb{K}_\alpha^+[Z].$$

Hereafter, a shift-invariant $\mathbb{K}_\alpha^+[Z]$ will be simply denoted by $\mathcal{K}_\alpha[Z]$. Interestingly, all $\mathcal{K}_\alpha[Z]$’s are closed under random shifting, i.e.,

$$Z_N = B^N Z \in \mathcal{K}_\alpha[Z]$$

for all $T$-valued rv’s $N$ independent of $Z$ having distribution function $P_N$, which follows by the Fubini-Tonelli theorem and (4.2). This fact is important for simulation purposes and has been proved in [26][Thm 2] for special $Z$ included in Example 3.5.

Note in passing that since $Z$ is measurable, the random shift $B^N Z$ is also a rf and it belongs to $\Omega_T$.

Unless otherwise specified, for given $Z$ with a countable dense separant $\mathbb{D}$, we shall consider shift-invariant maps $F$ with respect to $L = \mathbb{D}$ assuming further that $\mathbb{D}$ is an additive group or $L = T$. In both case we simply say that $F$ is shift-invariant.

**Example 4.3.** Consider a shift-invariant $\mathcal{K}_\alpha[Z]$ and a shift-invariant $F \in \mathfrak{S}_0$ which is non-negative. If $E\{|Z(0)|^\alpha F(Z)\} \in (0, \infty)$ by (4.2) $\mathbb{K}_\alpha^+[Z]$ with $Z = Z F(Z)$ or $\hat{Z} = Z F(Z)/F(Z) \in (0, \infty)$ is also shift-invariant.

In the following $\mathbb{D} = T$ if $T = Z^l$ and when $T = \mathbb{R}^l$, then $\mathbb{D}$ is a dense countable subset of $\mathbb{R}^l$. Write $\mathcal{P}_\mathbb{D}$ for the class of functions

$$p_N : \mathbb{D} \mapsto (0, \infty), \quad \sum_{t \in \mathbb{D}} p_N(t) < \infty.$$

If $N$ is a $\mathbb{D}$-valued rv defined on $(\Omega, \mathcal{F}, \mathbb{P})$, then we write also $p_N$ for its density function. Below $N$ is independent of any other random element defined on the same probability space as $Z$.

We state next equivalent characterisations of shift-invariants. Write $Z_\mathbb{D}(t) = Z(t), t \in \mathbb{D}$ for the restriction of $Z$ on $\mathbb{D}$ and denote the corresponding $\alpha$-homogeneous class of rf’s by $\mathbb{K}_\alpha^+[Z_\mathbb{D}]$.

**Theorem 4.4.** Suppose that $\mathbb{D}$ as above is further an additive subgroup of $T$. $\mathbb{K}_\alpha^+[Z]$ is shift-invariant iff one of the following holds:

(i) $\mathbb{K}_\alpha^+[Z_\mathbb{D}]$ is shift-invariant;

(ii) for all rv $N$ with density $p_N \in \mathcal{P}_\mathbb{D}$

$$Z_N(t) = \frac{\|Z(0)\|}{\left(\sum_{h \in \mathbb{D}} \|B^N Z(h)\|^\alpha p_N(h)\right)^{1/\alpha}} B^N Z(t) \in \mathbb{K}_\alpha^+[Z];$$

(iii) for all rv $N$ with density $p_N \in \mathcal{P}_\mathbb{D}$

$$Z_N(t) = \frac{[p_N(t)]^{1/\alpha} \mathbb{I}(\|Z(0)\| \neq 0)}{\left(\max_{h \in \mathbb{D}} p_N(h) \|B^N Z(h)\|^\alpha \sum_{h \in \mathbb{D}} \mathbb{I}(R \|B^N Z(h)/Z(0)\| > 1)p_N(h)\right)^{1/\alpha}} B^N Z(t) \in \mathbb{K}_\alpha^+[Z],$$

with $R$ an $\alpha$-Pareto rv independent of $Z$. 

Remark 4.5. Consider $D = D(\mathcal{T}, \mathbb{R}^d)$ the set of functions $f : \mathcal{T} \to \mathbb{R}^d$, with the further assumption that if $\mathcal{T} = \mathbb{R}^d$, then $D$ consists only of càdlàg functions. We equipped $D$ with the Skorohod $J_1$-topology which turns it into a Polish metric space, see e.g., [7, 8, 10]. Denote by $\mathcal{D}$ the corresponding Borel $\sigma$-field in $D$. Let $Z$ be almost surely with sample paths in $D$ satisfying (1.1), (1.3) and $\mathbb{E}\{\|Z(0)\|^\alpha\} \in (0, \infty)$. We can define an $-\alpha$-homogeneous measure $\nu_Z$ on $\mathcal{D}$ by
\begin{equation}
\nu_Z(A) = \mathbb{E}\left\{\int_0^\infty \mathbb{I}(r^{-1}Z \in A)\alpha r^{-\alpha - 1}dr\right\}, \ \forall A \in \mathcal{D}.
\end{equation}
In view of [10] $\mathbb{K}^+_\alpha[Z]$ is shift-invariant iff $\nu_Z$ is shift-invariant. Note that in [6] it is assumed further that $\|\cdot\|$ is a norm.

Definition 4.6. $F \in \mathcal{S}_0$ (and similarly for other maps) is shift-invariant with respect to a set $\mathcal{L} \subset \mathcal{T}$ if
\[ F(B^h f) = F(f), \ \forall f \in \mathcal{L}, \forall h \in \mathcal{L}. \]

Definition 4.7. We shall call $\Theta \in \Omega_\mathcal{T}$ a spectral tail rf if
\begin{enumerate}[label=(i), ref=(i)]
\item $\mathbb{P}\{\|\Theta(0)\| = 1\} = 1$;
\item for all $\Gamma \in \mathcal{S}_0, h \in \mathcal{T}
\end{enumerate}
\begin{equation}
\mathbb{E}\{\|\Theta(h)\|^\alpha \Gamma(\Theta)\} = \mathbb{E}\{\mathbb{I}(\|\Theta(-h)\| \neq 0)\Gamma(B^h \Theta)\};
\end{equation}
\begin{enumerate}[label=(iii), ref=(iii)]
\item for all $p_N \in \mathcal{P}_\mathcal{D}$, with $\mathcal{D}$ being further a subgroup of the additive group $\mathcal{T}$
\end{enumerate}
\begin{equation}
\sum_{t \in \mathcal{D}} \mathbb{E}\left\{\sup_{s \in [-a,a]}|rD||\Theta(s-t)|^\alpha \frac{\|\Theta(r-t)\|^\alpha p_N(r)}{\sum_{r \in \mathcal{D}}\|\Theta(r-t)\|^\alpha p_N(r)}\right\}p_N(t) < \infty, \ \forall a > 0.
\end{equation}

Corollary 4.8. Let $\Theta$ be the local rf of $\mathbb{K}^+_\alpha[Z]$ and suppose that $\mathcal{D}$ is further a subgroup of the additive group $\mathcal{T}$. If further $\Theta$ is a spectral tail rf and for all $N$ with density $p_N \in \mathcal{P}_\mathcal{D}$ and independent of $\Theta$
\begin{equation}
Z_N(t) = \frac{1}{\left(\sum_{h \in \mathcal{D}}\|B^N \Theta(h)\|^\alpha p_N(h)\right)^{1/\alpha}}B^N \Theta(t) \in \mathbb{K}^+_\alpha[Z],
\end{equation}
then $\mathbb{K}^+_\alpha[Z]$ is shift-invariant. Conversely, if $\mathbb{K}^+_\alpha[Z]$ is shift-invariant, then $\Theta$ is a spectral tail rf.

Example 4.9 (Shift-invariance of Brown-Resnick class of rf’s). Let $X$ and $Z$ be as in Example 3.5. Suppose that $\gamma_{ij}(s, t) = \text{Var}(X_i(t) - X_j(s)), s, t \in \mathcal{T}$ depends only on $t - s$ for all $s, t \in \mathcal{T}$ and all $i, j \leq d$. For all $\Gamma \in \mathcal{S}_0$ we have by Lemma B.8
\begin{equation}
d\mathbb{E}\{\|Z(h)\|^\alpha \Gamma(Z)\} = \sum_{k=1}^d \mathbb{E}\{\mathbb{e}^{\alpha X_k(h)} - \text{Var}(\alpha X_k(h))/2\Gamma(Z)\} = \sum_{k=1}^d \mathbb{E}\{\mathbb{e}^{\alpha X_k(0)} - \text{Var}(\alpha X_k(0))/2\Gamma(B^h Z)\}
\end{equation}
\begin{equation}
= \sum_{k=1}^d \mathbb{E}\{\|Z_k(0)\|^\alpha \Gamma(Z)\} = d\mathbb{E}\{\|Z(0)\|^\alpha \Gamma(B^h Z)\}
\end{equation}
for all $h \in \mathcal{T}$, hence $\mathbb{K}^+_\alpha[Z]$ is shift-invariant. The shift-invariance of $\mathbb{K}^+_\alpha[Z]$ is for $d = 1$ a direct consequence of [19] and when $X$ is a Brownian motion it follows from [27]. Now since $\|Z(0)\| = 1$ almost surely, then the local rf of $\mathbb{K}^+_\alpha[Z]$ is simply $Z$. 

Recall that $R$ with $\mathbb{P}\{R > t\} = t^{-\alpha}, t \geq 1$ is an $\alpha$-Pareto rv independent of any other element. Notably, for $Y = R\Theta$

$$
(4.7) \quad \mathbb{E}\{\Gamma(xB^hY)\mathbb{I}\{x\|Y(-h)\| > 1\}\} = x^\alpha \mathbb{E}\{\Gamma(Y)\mathbb{I}\{\|Y(h)\| > x\}\}, \quad \forall \Gamma \in \mathcal{H}, \forall h \in \mathcal{T}, \forall x > 0.
$$

This is shown in [2, 13] if $\mathcal{T} = \mathbb{Z}^l$ and [6], [10] for the case $\mathcal{T} = \mathbb{R}$ and $\mathcal{T} = \mathbb{R}^l$, respectively. In the aforementioned articles $\|\cdot\|$ is assumed to be a norm on $\mathbb{R}^l$. Using the results of [10], the case of our general $\|\cdot\|$ treated here follows.

**Definition 4.10.** We shall call $Y \in \Omega_\mathcal{T}$ a tail rf if

(i) $\mathbb{P}\{\|Y(0)\| > 1\} = 1$;

(ii) (4.7) holds for all $x > 0$;

(iii) Eq. (4.5) holds for all $p_\mathbf{N} \in \mathcal{P}_\mathbb{R}$ with $\Theta$ substituted by $Y$.

**Remark 4.11.** If $\mathcal{T} = \mathbb{Z}^l$, since by (4.4) $\mathbb{E}\{\|\Theta(h)\|^{\alpha}\} = \mathbb{P}\{\|\Theta(-h)\| \neq 0\}, h \in \mathcal{T}$, then (4.5) is satisfied and it also holds if $\Theta$ is substituted by $Y$. The case $\mathcal{T} = \mathbb{R}^l$ can be reformulated as in (4.10) below.

Tail and spectral tail rf’s are crucial for the study of stationary regularly varying time series, see [1, 4, 5, 13, 14, 28]. Hereafter $\widehat{\mathcal{Y}}$ consists of all maps $F$ defined by

$$
F = F_1F_2, \quad F_1 \in \mathcal{H}_0, \quad F_2 \in \mathcal{H}.
$$

**Corollary 4.12.** If $\Theta$ is the local rf of some shift-invariant $K_\alpha[Z]$, then $Y = R\Theta$ is a tail rf satisfying (4.7) with $\Gamma \in \widehat{\mathcal{Y}}$ instead of $\Gamma \in \mathcal{Y}$, i.e.,

$$
(4.8) \quad \mathbb{E}\{\Gamma(xB^hY)\mathbb{I}\{x\|Y(-h)\| > 1\}\} = x^\alpha \mathbb{E}\{\Gamma(Y)\mathbb{I}\{\|Y(h)\| > x\}\}, \quad \forall \Gamma \in \widetilde{\mathcal{Y}}, \forall h \in \mathcal{T}, \forall x > 0.
$$

The next result is motivated by [5][Thm 3.2] and Remark 4.5. We note in passing that (4.10) below appears for $l = 1$ and $\tau = 0$ in [6] for the càdlàg case. Our proofs for the more general setup here are not based on the characterisation of tail measures via Lipschitz maps, a property heavily used in [6].

**Theorem 4.13.** If $Y$ is a tail rf, then $\|Y(0)\|$ has an $\alpha$-Pareto distribution being independent of $\Theta = Y/\|Y(0)\|$. Moreover $\Theta$ is a spectral tail rf satisfying

$$
(4.9) \quad \int_0^\infty \mathbb{E}\{\Gamma(r\Theta)\mathbb{I}\{\|r\Theta(h)\| > 1\}\}r^{-\alpha-1}\lambda(dr) = \mathbb{E}\{\Gamma(B^hY)\mathbb{I}\{\|Y(h)\| \neq 0\}\}, \quad \forall \Gamma \in \widehat{\mathcal{Y}}, \forall h \in \mathcal{T},
$$

there exists a shift-invariant $K_\alpha[Z]$ with tail rf $Y$ and Definition 4.10, Item (iii) is equivalent with

$$
(4.10) \quad \int_{t \in [-\alpha,\alpha]}\int_{s \in [-\alpha,\alpha]} \frac{1}{\lambda(\|Y(s)\| > 1)}\lambda(ds)\lambda(dt) < \infty, \quad \forall \alpha > 0
$$

for all $\tau \in [0,\alpha]$. Conversely, if $\Theta \in \Omega_\mathcal{T}$ satisfies Definition 4.10, Item (iii) and both (4.9) and $\mathbb{P}\{\|\Theta(0)\| = 1\} = 1$ hold, then $Y = R\Theta$ is a tail rf.

**Remark 4.14.** As shown in Theorem 4.13, given a tail rf $Y$ we can construct a shift-invariant $K_\alpha^+[Z_N]$ such that its tail rf at 0 is $Y$.  

In this section $\mathcal{L} \subset \mathcal{T}$ is a discrete subgroup of the additive group $\mathcal{T}$ with countably infinite number of elements and $\mathbb{K}_0^+[\mathbf{Z}]$ is shift-invariant. The next lemma (we omit its proof) states a fundamental property of shift-invariant maps $\tilde{\mathcal{Y}}$ (recall the definition in Example 4.3). All event inclusions and equalities in the following are modulo null sets with respect to the corresponding probability measure.

**Lemma 5.1.** Let $F_1, F_2 \in \tilde{\mathcal{Y}}$ be two shift-invariant maps. If for all $\mathbb{R}^d$-valued tail rf's $\mathbf{Y} \in \Omega_T$

\begin{equation}
\mathbb{P}\{F_1(\mathbf{Y}) \in A\} = 1 \implies \mathbb{P}\{F_2(\mathbf{Y}) \in A\} = 1,
\end{equation}

where $A \in \{\{0\}, (0, \infty), \{\infty\}\}$ is non-empty, then for all tail rf $\mathbf{Y}$

\begin{equation}
\{F_1(\mathbf{Y}) \in A\} \subset \{F_2(\mathbf{Y}) \in A\}.
\end{equation}

**Remark 5.2.** Lemma 5.1 can be reformulated for $F_1, F_2 \in \tilde{\mathcal{Y}}_\alpha$ and spectral tail rf's $\Theta$. Utilising Lemma B.2 also the corresponding result for elements $\tilde{\mathbf{Z}} \in \mathbb{K}_\alpha[\mathbf{Z}]$ can be shown to hold.

**Definition 5.3.** Denote by $\mathbb{U}$ the class of maps $F \in \tilde{\mathcal{Y}}$ such that for all $F_1, F_2 \in \mathbb{U}$ and $A \in \{\{0\}, (0, \infty), \{\infty\}\}$ non-empty $\{F_1(\mathbf{Y}) \in A\} = \{F_2(\mathbf{Y}) \in A\}$ for all tail rf $\mathbf{Y} \in \Omega_T$. We call $\mathbb{U}$ the class of universal maps.

Let $A \subset \mathcal{T}$ be such that $\lambda(A) > 0$. For $f : \mathcal{T} \mapsto \mathbb{R}^d$ such that $\|f(\cdot)\|$ is $\lambda$-measurable define

$$S_A(f) = \int_A \|f(t)\|^\alpha \lambda(dt), \quad B_{A, \tau}(f) = \int_A \|f(t)\|^\tau I(\|f(t)\| \geq 1)\lambda(dt).$$

If $A = \mathcal{T}$ we write simply $S$ instead of $S_A$.

In the following a shift-involution with respect to an additive subgroup $\mathcal{L}$ of $\mathcal{T}$ with countably infinite number of elements will be denoted hereafter by $\mathcal{J}_1$, whereas $\mathcal{J}_2$ and $\mathcal{J}_3$ will denote a positive shift-involution and an anchoring map, respectively (with respect to given $\mathcal{L}$). A weak restriction introduced in [15] that we shall impose next is

\begin{equation}
\mathbb{P}\{S_L(Z) < \infty\} = \mathbb{P}\{S_L(Z) < \infty, J_1(Z) \in \mathcal{L}\}
\end{equation}

and

\begin{equation}
\mathbb{P}\{S_L(Y) < \infty\} = \mathbb{P}\{S_L(Y) < \infty, J_k(Y) \in \mathcal{L}\}, \quad k = 2, 3,
\end{equation}

which are satisfied if $\mathcal{J}_i = \mathcal{I}_L, i = 1, 2, 3$ and $\mathcal{J}_3 = \mathcal{I}_L, fe$. In the following $\|t\|_* = \sum_{i=1}^l |t_i|, t = (t_1, \ldots, t_l) \in \mathbb{R}^l$. The next lemma shows in particular that $\mathbb{U}$ contains both $S_L$ and $B_L, \tau$.

**Lemma 5.4.** Let $\mathcal{L}$ be an additive subgroup of $\mathcal{T}$ with countably infinite number of elements. If $\mathcal{J}_1$ satisfies (5.3), $\mathcal{J}_2$ satisfies (5.4) and $\mathcal{J}_3$ satisfies (5.4), where $S_L(Y)$ is substituted by $B_{L, 0}(Y)$, then

\begin{equation}
\{S_L(Z) < \infty\} = \{J_1(Z) \in \mathcal{L}\} = \left\{ \lim_{\|t\|_* \rightarrow \infty, t \in \mathcal{L}} \|Z(t)\| = 0 \right\},
\end{equation}

\begin{equation}
\{\mathcal{J}_2(Y) \in \mathcal{L}\} = \{S_L(Y) < \infty\}, \quad \{\mathcal{J}_3(Y) \in \mathcal{L}\} = \{B_L, \tau(Y) < \infty\},
\end{equation}

\begin{equation}
\{S_L(Y) < \infty\} = \left\{ \lim_{\|t\|_* \rightarrow \infty, t \in \mathcal{L}} \|Y(t)\| = 0 \right\} = \{J_L(Y) \in \mathcal{L}\} = \{B_L, \tau(Y) < \infty\},
\end{equation}

with $J_L$ equal $\mathcal{I}_L$ or $\mathcal{I}_L, fe$ and $\tau \geq 0$. 

Remark 5.5. In the literature only $\mathcal{L} = \mathbb{Z}^l$ has been considered: (5.5) can be deduced from [20][Prop 10] for $\mathcal{F}_l$ the infargmax map; for $l > 1$ the first two equalities in (5.7) have been shown in [5][Lem 3.3] when one of the events has probability 1. The claims in (5.7) and anchoring maps with $\mathcal{T} = \mathbb{Z}$ and $\tau = 0$ are shown in [4], see also [2, 5, 13–15] and [29, 30] for $\mathcal{T} = \mathbb{Z}^l, \tau = 0$. In the aforementioned contributions $\|\cdot\|$ is a norm on $\mathbb{R}^d$, which we do not assume here.

We show next that Lemma 5.4 has a natural extension for $\mathcal{L} = \mathcal{T}$ proving further the existence of two different elements in $\mathbb{U}$.

**Theorem 5.6.** Under the assumptions of Lemma 5.4 for all $\tau \geq 0$

\begin{equation}
\mathbb{P}\{S(Z) > 0\} = \mathbb{P}\{S(\Theta) > 0\} = \mathbb{P}\{B_{\mathcal{T}, \tau}(Y) > 0\} = 1.
\end{equation}

Moreover, if $\mathcal{L}$ is a full rank lattice on $\mathcal{T} = \mathbb{R}^l$

\begin{align}
\{S(\Theta) < \infty\} & = \left\{ \lim_{\|t\| \to \infty} \|\Theta(t)\| = 0 \right\} = \left\{ \int_{\mathcal{T} \in K \cap \mathcal{T}} \sup_{t} \|\Theta(t + s)\|^{\alpha} \lambda(ds) < \infty \right\} = \{\mathcal{I}(\Theta) \in \mathbb{R}^l\} \\
\{S(Z) < \infty\} & = \left\{ \lim_{\|t\| \to \infty} \|Z(t)\| = 0 \right\} = \left\{ \int_{\mathcal{T} \in K \cap \mathcal{T}} \sup_{t} \|Z(t + s)\|^{\alpha} \lambda(ds) < \infty \right\} = \{\mathcal{I}(Z) \in \mathbb{R}^l\}
\end{align}

and

\begin{align}
\{S(Z) < \infty\} & = \left\{ \lim_{\|t\| \to \infty} \|Z(t)\| = 0 \right\} = \left\{ \int_{\mathcal{T} \in K \cap \mathcal{T}} \sup_{t} \|Z(t + s)\|^{\alpha} \lambda(ds) < \infty \right\} = \{\mathcal{I}(Z) \in \mathbb{R}^l\} \\
\{S_{\mathcal{L}}(Z) < \infty\} & = \{\mathcal{S}_{\mathcal{L}}(Z) < \infty\}
\end{align}

for all compact sets $K \subset \mathbb{R}^l$, with $\mathcal{I}(f) = \mathcal{I}_f(f), f \in \mathcal{D}$ the infargsup map.

Remark 5.7.  
(i) If one of the events in (5.9) holds with probability 1, the claim therein and the equality with the second event in (5.10) is shown for $\mathcal{T} = \mathbb{R} = \mathcal{L}, \tau = 0$ with $Z$ having càdlàg sample paths and $\|\cdot\|$ equal to some norm on $\mathbb{R}^l$ in [6][Thm 2.8].

(ii) Related results for the case of stochastically continuous $Z$ and $\mathcal{L} = \mathcal{T}, \tau = 0$ are given in [20], recall Remark 4.5. The discrete setup $\mathcal{T} = \mathbb{Z}^l$ and $\|\cdot\|$ a norm on $\mathbb{R}^l$ is considered in several papers, see [2, 3, 5, 15, 29] and the references therein.

6. Applications

We consider in this section some implications for max-stable rf’s and extremal indices.

6.1. Max-stable rf’s. A given $\alpha$-homogeneous class of rf’s $\mathbb{K}_{\alpha}^+\{\mathcal{Z}\}$ is closely related to max-stable rf’s as shown in [31]. Assume for simplicity that $\mathbb{E}\{\|\mathcal{Z}(h)\|^{\alpha}\} = 1, h \in \mathcal{T}$ and define a max-stable rf $X(t), t \in \mathcal{T}$ with unit Fréchet marginals via its de Haan representation (e.g., [20, 32])

\begin{equation}
X(t) = \max_{i \geq 1} \Gamma_i^{-1/\alpha} \mathcal{Z}^{(i)}(t), \quad t \in \mathcal{T}.
\end{equation}

Here $\Gamma_i = \sum_{k=1}^{i} \mathcal{V}_k$ with $\mathcal{V}_k, k \geq 1$ unit exponential rv’s being independent of any other random element and $\mathcal{Z}^{(i)}$’s are independent copies of $\mathcal{Z} = \|\mathcal{Z}\|$. The rf $\mathcal{Z}$ is called a spectral rf of $X$. Note that it is possible to define also a $\mathbb{R}^d$-valued max-stable $\mathcal{X}$ by taking $\mathcal{Z}^{(i)}$ independent copies of $\mathcal{Z}$, see e.g., [33].
Max-stable rf’s are very tractable due to the explicit expression of their finite dimensional distributions, namely as shown for instance in [34]

$$-\ln \mathbb{P}\{X(t_1) \leq x_1, \ldots, X(t_n) \leq x_n\} = \mathbb{E}\left\{ \max_{1 \leq i \leq n} \frac{1}{x_i} Z^\alpha(t_i) \right\}$$

for all $t_i \in T, x_i \in (0, \infty), i \leq n$.

**Lemma 6.1.** The rf $X$ is quadrant stochastically continuous and has locally bounded sample paths. Moreover, if $\mathbb{K}_\alpha^+[Z]$ is shift-invariant, then $X$ is stationary.

The most prominent example of stationary max-stable $X$ is obtained for $Z$ as in Example 3.5, which is referred to as a Brown-Resnick max-stable rf, see e.g., [10, 26, 27, 35].

Suppose next that $\mathbb{K}_\alpha^+[Z]$ is shift-invariant. In view of [20]

$$\mathbb{P}\{S(Z) < \infty\} = 1$$

is closely related to the existence of so-called Rosiński representation of max-stable processes, see [11]. Such representations are also referred to as mixed moving maxima (M3) representation [13, 19] being closely related to dissipative/conservative decompositions, [20, 36–40]. The findings in the previous section give several other equivalent conditions for such a representation, which are considered in details in [16].

### 6.2. Extremal indices

Let $L$ be a full rank lattice on $\mathbb{R}^l$ or $L = \mathbb{R}^l$ and let $\mathbb{K}_\alpha[Z]$ be given. Define the extremal index of the stationary max-stable $X$ with spectral process $Z$ with respect to $L$ by

$$\mathbb{E}_Z^L = \lim_{n \to \infty} n^{-l} \mathbb{E}\left\{ \max_{t \in [0,n]^l \cap L} \|Z(t)\|^\alpha \right\} \in [0, \infty).$$

We drop the superscript $L$ if it is equal to $T$. The properties of $\mathbb{E}_Z$ are related to the distribution of supremum of $X$, namely utilising (6.2), (A.2) and (1.1)

$$-\ln \mathbb{P}\left\{ \sup_{t \in [0,n]^l \cap L} X(t) \leq r n^l \right\} = \frac{1}{r n^l} \mathbb{E}\left\{ \sup_{t \in [0,n]^l \cap L} \|Z(t)\| \right\} \to \frac{1}{r} \mathbb{E}_Z < \infty$$

as $n \to \infty$ for all $r > 0$. From the above, $\mathbb{E}_Z^L = 0$ is equivalent with

$$\sup_{t \in [0,n]^l \cap L} X(t)/n^l \overset{P}{\to} 0, \quad n \to \infty.$$

**Lemma 6.2.** If $L$ is a full rank lattice on $T$, then

$$\mathbb{P}\{B_{L,\tau}(Y) = \infty\} = 1 \iff \mathbb{E}_Z^L = 0 \iff \mathbb{E}_Z^T = 0 \iff \mathbb{P}\{B_{T,\tau}(Y) = \infty\} = 1$$

for all $\tau$ such that $\mathbb{E}\{|\Theta(t)|^\tau\} < \infty, \forall t \in T$.

**Remark 6.3.**

(i) If $Z$ is stochastically continuous, then $\mathbb{E}_Z^T = 0 \iff \mathbb{P}\{S(Y) = \infty\} = 1$ follows from [37, 41–43] or directly from (5.10);

(ii) If $Z$ has almost surely sample paths in $D(\mathbb{R}, \mathbb{R}^d)$ and $\|\cdot\|$ is a norm on $\mathbb{R}^d$, then the last two equivalences in (6.5) for $\tau = 0$ follow from [6][Lem 2.5, Thm 2.9] and for $L = \mathbb{Z}^l$ by [15][Thm 3.8], see also [4] for the case $L = \mathbb{Z} = T$;

(iii) Some novel representations for $\mathbb{E}_Z^L$ can be derived by combining (7.11) and (B.9), (B.10).
From the above
\[ \mathbb{P}\{S(Z) < \infty\} > 0 \Leftrightarrow B^T_Z > 0. \]

The next lemma shows an equivalent condition for \( \mathbb{P}\{S(Y) < \infty\} = 1 \) in terms of the so-called C condition introduced in [44]. The discrete case \( \mathcal{T} = \mathbb{Z}^l \) is discussed recently in [15][Lem 6], see also [2, 4, 5, 29].

**Lemma 6.4.** We have \( \mathbb{P}\{S(Z) < \infty\} = 1 \), iff for all increasing positive sequences \( a_n, r_n, n \geq 1 \) such that \( \lim_{n \to \infty} r_n \mathbb{P}\{X(0) > a_n\} = \lim_{n \to \infty} 1/r_n = 0 \) and for all \( s, v \) positive and \( \mathcal{L} \) a full rank lattice on \( \mathcal{T} \) or \( \mathcal{L} = \mathcal{T} \)
\[ \lim_{m \to \infty} \limsup_{n \to \infty} \mathbb{P}\left\{ \sup_{m \leq \sum_{i=1}^j |t_i| \leq r_n, t \in \mathcal{L}} X(t) > a_n v | X(0) > a_n s \right\} = 0. \]

7. Proofs

**Proof of Lemma 3.2** We consider for simplicity the case \( \mathcal{T} = \mathbb{R}^l \) and \( \alpha = 1 \). Let \( \mathcal{D} = \{ t_i, i \in \mathbb{N} \} \) be a dense countable subset of \( \mathbb{R}^l \) containing \( t_0 \), which is a separant for \( Z \). By Lemma A.1 it is also a separant for \( \|Z\| \) since we assume that \( \|\cdot\| \) is continuous. Since \( \mathbb{E}\{\|Z(t_i)\|\} \in [0, \infty) \) for all \( t \in \mathcal{D} \), we can find positive \( w_i \)’s such that \( w_i \mathbb{E}\{\|Z(t_i)\|\} \leq 2^{-i}, i \in \mathbb{N} \). Hence by the Fubini-Tonelli theorem, the positivity of \( w_i \)’s and the assumption that \( \mathbb{E}\{\|Z(t_0)\|^{\alpha}\} \in (0, \infty) \) we obtain
\[ 0 < \sum_{t_i \in \mathcal{D}} \mathbb{E}\{w_i \|Z(t_i)\|\} = \sum_{t_i \in \mathcal{D}} w_i \mathbb{E}\{\|Z(t_i)\|\} < \infty \]

implying that \( M = \max_{t_i \in \mathcal{D}} w_i \|Z(t_i)\| \) is a non-negative rv with \( p^* = \mathbb{P}\{M > 0\} \in (0, 1] \). Denote by \( Z^*(t), t \in \mathcal{T} \) the rf \( Z(t) \) conditioned on \( M > 0 \). Since \( Z \) is quadrant stochastically continuous rf and \( \|\cdot\| \) is continuous, then also \( Z^* \) and \( \|\tilde{Z}\| \) are quadrant stochastically continuous rf’s which we assume to be separable. Using that \( \mathcal{D} \) is a separant for \( \|Z^*\| \)
\[ \mathbb{P}\{\sup_{t \in \mathcal{T}} \|Z^*(t)\| > 0\} = \mathbb{P}\{\max_{t_i \in \mathcal{D}} \|Z^*(t_i)\| > 0\} = 1 \]
and thus (1.3) holds. Since \( \|Z(t)\| > 0 \) for some \( t \in \mathcal{D} \) implies \( M > 0 \), using further that \( \|\cdot\| \) is 1-homogeneous (set \( \tilde{Z} = p^* Z^* \))
\[ \mathbb{E}\{\|\tilde{Z}(t)\|F(\tilde{Z})\} = p^* \mathbb{E}\{\|Z^*(t)\|F(Z)\} = \mathbb{E}\{\|Z(t)\|F(Z)\} \]
holds for all \( t \in \mathcal{D}, F \in \mathcal{S}_0 \). In view of (1.1) for all \( a > 0 \)
\[ \mathbb{E}\left\{ \sup_{t \in [-a,a]^l} \|\tilde{Z}(t)\| \right\} = \mathbb{E}\left\{ \sup_{t \in [-a,a]^l} \|Z(t)\|I(M > 0) \right\} \leq \mathbb{E}\left\{ \sup_{t \in [-a,a]^l} \|Z(t)\| \right\} < \infty \]
and thus (1.1) holds for \( \tilde{Z} \). We can assume without loss of generality that \( \mathcal{D} \) is also a separant for \( \tilde{Z} \). Since both \( Z \) and \( \tilde{Z} \) are quadrant stochastically continuous, application of the dominated convergence theorem implies the validity of (7.1) for all \( t \in \mathcal{T} \) (recall that \( \mathcal{T} \) equals \( \mathcal{T} \) up to a countable set when \( \mathcal{T} = \mathbb{R}^l \)), since for some \( t_n \to t \) as \( n \to \infty \) with \( t_n \)’s in \( \mathcal{D} \) we can pass to limit in (7.1). Hence by definition, \( \tilde{Z} \in \mathcal{K}_\alpha[Z] \) and it satisfies (1.1) and (1.3) as required. \( \square \)
**Proof of Theorem 3.4** We show first (3.1), which clearly holds when $\mathcal{T}$ is countable using (4.2) since the maps involved are measurable. We shall focus therefore on the case $\mathcal{T} = \mathbb{R}^l$. Let $\beta \geq 0$ and $g : \mathcal{T} \to [0, \infty)$ be continuous such that $\sup_{t \in \mathcal{T}} g(t) > 0$. Set below

\begin{equation}
(7.2) \quad R_{k,n}(f, g) = \sum_{t \in (\mathbb{Z}^2)^l \cap [-k, k]^l} n^{-l}\|f(t)\|^\beta g(t), \quad f \in D
\end{equation}

and with $\mathcal{J}_{\beta}(f, g) = \int_{\mathcal{T}} \|f(t)\|^\beta g(t) \lambda(dt)$ define

\[ F(f) = \frac{\Gamma_0(f) \Gamma_\beta(f)}{\mathcal{J}_{\beta}(f, g)}, \quad \Gamma_0 \in \mathcal{F}_0, \Gamma_\beta \in \mathcal{F}_\beta, f \in D, \]

where $\Gamma_\beta$ is bounded. Since the definition of $\mathbb{K}_\alpha^+ [Z]$ yields

\[ \mathbb{P}\left\{ \sup_{t \in \mathcal{T}} \|Z(t)\| > 0 \right\} = \mathbb{P}\left\{ \sup_{t \in \mathcal{T}} \|\widetilde{Z}(t)\| > 0 \right\} = 1, \]

then utilising [45][Thm 2.1, Rem 2.2,iii], we obtain

\begin{equation}
(7.3) \quad \mathbb{P}\{ \mathcal{J}_{\beta}(Z, g) > 0 \} = \mathbb{P}\{ \mathcal{J}_{\beta}(\widetilde{Z}, g) > 0 \} = 1.
\end{equation}

Further, by the assumption $\Gamma_0$ is 0-homogeneous, we can assume without loss of generality that it is bounded (use dominated convergence theorem for unbounded case). Hence $\Gamma_\beta = \Gamma_0 \Gamma_\beta^*$ is bounded and thus by (7.3) $F(Z)$ is a finite rv. Clearly

\[ \mathcal{U}_{k,n}(f) = \Gamma_\beta(f) / R_{k,n}(f, g), \quad \Gamma_\beta \in \mathcal{F}_\beta, f \in D, \quad k, n > 0 \]

is a $\mathcal{G}/\mathcal{B}(\mathbb{R})$-measurable and 0-homogeneous finite map in $\mathcal{F}_0$. For all $h \in \mathcal{T}$ and all $k, n, \tau > 0$ positive and $\widetilde{Z} \in \mathbb{K}_\alpha^+ [Z]$ by (4.2)

\begin{equation}
(7.4) \quad \mathbb{E}\{\|Z(h)\|^\alpha \mathcal{U}_{k,n}(Z) \mathcal{I}(\mathcal{U}_{k,n}(Z) \leq r)\} = \mathbb{E}\{\|\widetilde{Z}(h)\|^\alpha \mathcal{U}_{k,n}(\widetilde{Z}) \mathcal{I}(\mathcal{U}_{k,n}(\widetilde{Z}) \leq r)\} < \infty.
\end{equation}

Applying Lemma A.3 (note that both $\|f\|$ and $g_k$ are bounded on $[-k, k]^l$) yields for some sequence $n_{kl}$ increasing in $l$

\[ R_{k,n_{kl}}(Z, g_k) \to \mathcal{J}_{\beta}(Z, g_k), \quad R_{k,n_{kl}}(Z, g_k) \to \mathcal{J}_{\beta}(Z, g_k), \quad g_k(t) = g(t) I(t \in [-k, k]^l) \]

as $l \to \infty$ almost surely. Hence for all $r > 0$

\[ \mathcal{U}_{k,n_{kl}}(Z) \mathcal{I}(\mathcal{U}_{k,n_{kl}}(Z) \leq r) \to \mathcal{U}_k(Z) \mathcal{I}(\mathcal{U}_k(Z) \leq r) \]

and

\[ \mathcal{U}_{k,n_{kl}}(\widetilde{Z}) \mathcal{I}(\mathcal{U}_{k,n_{kl}}(\widetilde{Z}) \leq r) \to \mathcal{U}_k(\widetilde{Z}) \mathcal{I}(\mathcal{U}_k(\widetilde{Z}) \leq r) \]

as $l \to \infty$ almost surely, where we set

\[ \mathcal{U}_k(Z) = \Gamma_\beta(Z) / \mathcal{J}_{\beta}(Z, g_k), \quad \mathcal{U}(Z) = \Gamma_\beta(Z) / \mathcal{J}_{\beta}(Z, g). \]

Consequently, taking $n = n_{kl}, l \geq 1$ as in Theorem 3.4 and letting $l \to \infty$ and then $k \to \infty$ in (7.4)

\begin{equation}
(7.5) \quad \mathbb{E}\{\|Z(h)\|^\alpha \mathcal{U}(Z) \mathcal{I}(\mathcal{U}(Z) \leq r)\} = \mathbb{E}\{\|\widetilde{Z}(h)\|^\alpha \mathcal{U}(\widetilde{Z}) \mathcal{I}(\mathcal{U}(\widetilde{Z}) \leq r)\} < \infty,
\end{equation}

where we used the dominated convergence theorem and almost surely

\[ I(Z, g_k) \to \mathcal{J}_{\beta}(Z, g) > 0, \quad \mathcal{J}_{\beta}(\widetilde{Z}, g_k) \to \mathcal{J}_{\beta}(\widetilde{Z}, g) > 0, \quad k \to \infty. \]
almost surely and also \( J(\tilde{Z}) \) is also a separant for \( \tilde{Z} \). By the choice of \( p(t) \)'s and since (1.3) holds for all elements of \( \mathbb{K}_\alpha[Z] \)

\[
J(Z) = \sum_{t \in \mathcal{D}} p(t)\|Z(t)\|^{\alpha} \in (0, \infty)
\]

almost surely and also \( J(\tilde{Z}) \in (0, \infty) \) almost surely. Consequently, \( J(\tilde{Z})/J(\tilde{Z}) \) and \( J(Z)/J(Z) \) are finite and positive almost surely. Hence applying the Fubini-Tonelli theorem and (3.2) for all \( F \in \mathcal{S}_\alpha \) we obtain

\[
\mathbb{E}\{F(Z)\} = \mathbb{E}\left\{ \frac{J(Z)}{J(\tilde{Z})} F(Z) \right\} = \sum_{h \in \mathcal{D}} \mathbb{E}\{\|Z(h)\|^\alpha F(Z)/J(\tilde{Z})\} p(h) = \sum_{h \in \mathcal{D}} \mathbb{E}\{\|Z(h)\|^\alpha F(Z)/J(\tilde{Z})\} p(h) = \mathbb{E}\left\{ F(\tilde{Z}) \sum_{h \in \mathcal{D}} \|Z(h)\|^\alpha p(h)/J(\tilde{Z}) \right\} = \mathbb{E}\{F(\tilde{Z})\}.
\]

We show next that \( \tilde{Z} \) satisfies (1.1). Taking \( F(f) = \sup_{t \in \mathcal{D}[[-a,a]^{n}} \|f(t)\|^\alpha, a > 0 \) for any \( f \in \mathcal{D} \) we have that \( F \in \mathcal{S}_\alpha \). By Lemma A.1, the continuity of \( \|\cdot\| \) implies that \( \mathcal{D} \) is a separant for both \( \|\tilde{Z}\| \) and \( \|Z\| \). Hence by the previous claim for all \( a > 0 \)

\[
\mathbb{E}\left\{ \sup_{t \in [-a,a]^{n} \cap T} \|\tilde{Z}(t)\|^\alpha \right\} = \mathbb{E}\left\{ \sup_{t \in [-a,a]^{n} \cap \mathcal{D}} \|\tilde{Z}(t)\|^\alpha \right\} = \mathbb{E}\{F(\tilde{Z})\} = \mathbb{E}\{F(Z)\} = \mathbb{E}\left\{ \sup_{t \in [-a,a]^{n} \cap T} \|Z(t)\|^\alpha \right\} < \infty,
\]

where the last inequality is consequence of (1.1) establishing the proof. 

\( \square \)

**Proof of Theorem 4.4** \( \mathbb{K}_\alpha^+[Z] \) is shift-invariant \( \iff (i) \): If \( \mathbb{K}_\alpha^+[Z] \) is shift-invariant, then by definition for all \( \tilde{Z} \in \mathbb{K}_\alpha^+[Z] \) we have that \( B^h \tilde{Z} \in \mathbb{K}_\alpha^+[Z] \), hence for all \( \tilde{Z} \in \mathbb{K}_\alpha^+[Z] \) by (3.1)

(7.6) \[
\mathbb{E}\{\|Z(h)\|^\alpha F(Z)\} = \mathbb{E}\{\|\tilde{Z}(0)\|^\alpha F(B^h \tilde{Z})\}, \quad \forall h \in \mathcal{D}, \forall F \in \mathcal{S}_0
\]

and thus Item (i) follows. Assume next that \( \mathbb{K}_\alpha^+[Z] \) is shift-invariant and thus

\[
\mathbb{E}\{\|Z(h)\|^\alpha F(Z)/\|Z(h)\|)\} = \mathbb{E}\{\|\tilde{Z}(0)\|^\alpha F(B^h \tilde{Z}/\|\tilde{Z}(0)\|)\}, \quad \forall h \in \mathcal{D}, \forall F \in \mathcal{H}.
\]

In order to show that \( \mathbb{K}_\alpha^+[Z] \) is shift-invariant, we need to prove the above functional identity for \( Z, \tilde{Z} \) instead of \( Z_B, \tilde{Z}_B \), i.e., since \( F \) is measurable and can be approximated by simple functions, it suffices to show that for all \( F(f) = I((f(t_1), \ldots, f(t_n)) \in A) \) with \( A \in \mathcal{B}(\mathbb{R}^n) \) and \( t_i \)'s belong to \( T \)

(7.7) \[
\mathbb{E}\{\|Z(h)\|^\alpha F(Z(t_1)/\|Z(0)\|, \ldots, Z(t_n)/\|Z(h)\|)\} = \mathbb{E}\{\|\tilde{Z}(0)\|^\alpha F(B^h \tilde{Z}(t_1)/\|\tilde{Z}(0)\|, \ldots, B^h \tilde{Z}(t_n)/\|\tilde{Z}(0)\|)\}
\]
for all $F \in \mathcal{H}$, which clearly holds if $t_i$'s and $h$ belong to $\mathbb{D}$ by the shift-invariance of $K^+_\alpha[Z_\mathbb{D}]$. Note that $t_i - h \in \mathbb{D}$ since $\mathbb{D}$ is an additive subgroup of $\mathcal{T}$. For general $t_i$’s and $h$, since $\mathbb{D}$ is dense in $\mathcal{T}$ we can find $t_{ki}, h_k \in \mathbb{D}, k \in \mathbb{N}$ such that

$$
\lim_{k \to \infty} t_{ki} = t_i \in \mathcal{T}, \ 1 \leq i \leq n, \ \lim_{k \to \infty} h_k = h,
$$

where the limit is along $Q_1(t_i), Q_1(h)$ quadrants, respectively (see (2.4) for definition of the quadrant).

Using then dominated convergence theorem, since both $Z$ and $\tilde{Z}$ are quadrant stochastically continuous, the function $||\cdot||$ is continuous and by (1.1), (3.2)

$$
\mathbb{E}\left\{ \sup_{t \in [-a,a] \cap \mathcal{T}} \|Z(t)\|^\alpha \right\} = \mathbb{E}\left\{ \sup_{t \in [-a,a] \cap \mathcal{T}} \|\tilde{Z}(t)\|^\alpha \right\} < \infty, \ \forall \alpha \in (0, \infty)
$$

passing to limit in (7.7) as $k \to \infty$ establishes the claim.

(i) $\implies$ (ii): If follows easily that $S = \sum_{h \in \mathbb{D}} \|B^N Z(h)\| p_N(h)$ is positive and finite almost surely since

$$
\mathbb{P}\{\sup_{t \in \mathbb{D}} \|Z(t)\| > 0\} = 1.
$$

Hence for all rv $N$ with density $p_N \in \mathcal{P}_\mathbb{D}$

$$
Z_N = \frac{\|Z(0)\|}{\left( \sum_{h \in \mathbb{D}} \|B^N Z(h)\| p_N(h) \right)^{1/\alpha}} B^N Z
$$

is well-defined and belongs to $\Omega_\mathcal{T}$. By the assumption and the fact that $\mathbb{D}$ is dense it follows that (4.2) holds for all $h \in \mathbb{D}$ and all $F \in \mathcal{H}_\alpha$. Next, given $F \in \mathcal{H}_\alpha$, since $N$ is independent of $Z$ using (4.2) for the derivation of the third last equality we obtain

$$
\mathbb{E}\{F(Z_N)\} = \mathbb{E}\left\{ \sum_{h \in \mathbb{D}} \|Z(0)\|^\alpha \frac{1}{\sum_{t \in \mathbb{D}} \|B^h Z(t)\|^\alpha p_N(t)} F(B^h Z)p_N(h) \right\}
$$

$$
= \sum_{h \in \mathbb{D}} \mathbb{E}\{\Gamma(B^h Z)\} p_N(h)
$$

$$
= \sum_{h \in \mathbb{D}} \mathbb{E}\{\Gamma(Z)\} p_N(h)
$$

$$
= \mathbb{E}\left\{ F(Z) \sum_{h \in \mathbb{D}} \frac{\|Z(h)\|^\alpha p_N(h)}{\sum_{t \in \mathbb{D}} \|Z(t)\|^\alpha p_N(t)} \right\}
$$

$$
= \mathbb{E}\{F(Z)\},
$$

hence $Z_N \in K^+_\alpha[Z]$.

(ii) or (iii) $\implies$ (i): Clearly, if $Z_N \in K^+_\alpha[Z]$ for all $\mathbb{D}$-valued rv $N$ with positive density $p_N(t) > 0, t \in \mathbb{D}$, then it follows easily that $B^h Z_N \in K^+_\alpha[Z]$ for all $h \in \mathbb{D}$ implying that $K^+_\alpha[Z_\mathbb{D}]$ is shift-invariant.

$K^+_\alpha[Z]$ is shift-invariant $\implies$ (iii): Using that if $\mathbb{P}\{\|Y(0)\| > 1\} = 1, \|Y(t)\|$ has the same law as $R\|\Theta(t)\|$ and $\mathbb{E}\{\|\Theta(t)\|^\alpha\} = \mathbb{P}\{\|\Theta(-t)\| \neq 0\} \leq 1$ for all $t \in \mathcal{T}$ it follows that

$$
S_h = \sum_{t \in \mathbb{D}} \mathbb{I}(\|B^h Y(t)\| > 1) p_N(t) \in (0, \infty), \quad M_h = \max_{t \in \mathbb{D}} [p_N(t)]^{1/\alpha} \|B^h Y(t)\| \in ([p_N(h)]^{1/\alpha}, \infty)
$$

almost surely for all $h \in \mathbb{D}$, where $p_N(t) > 0, t \in \mathbb{D}$ is the density of $N$. Clearly $p_N$ is bounded and by the independence of $N$ and $Y$ it follows that $S_N$ and $M_N$ are almost surely positive and finite. Hence $Z_N$
specified by (iii) is well-defined. By the assumption we have that (4.7) holds. For all \( F \in \mathcal{H}_0 \), \( v \in \mathbb{D} \) since \( N \) is independent of \( Z \) and the definition of \( Y \) we have

\[
\mathbb{E}\{\|Z_N(v)\|^\alpha F(Z_N)\} = \mathbb{E}\left\{F(B^N Y)p_N(v)\frac{\|B^N Y(v)\|^\alpha}{M_N^\alpha S_N}\right\} = \sum_{h \in \mathbb{D}} \mathbb{E}\left\{F(B^h Y)p_N(h)p_N(v)\frac{\|B^h Y(v)\|^\alpha}{M_h^\alpha S_h}\right\} = \sum_{h \in \mathbb{D}} \mathbb{E}\left\{F(B^h Y)p_N(h)\frac{p_N(v)}{M_h^\alpha S_h} \int_0^\infty \mathbb{I}(r\|B^h Y(v)\| > 1)\alpha r^{-\alpha-1}dr\right\} = \sum_{h \in \mathbb{D}} \mathbb{E}\left\{F(B^h Y)p_N(h)\frac{\sum_{t \in \mathbb{D}} \mathbb{I}(\|B^h Y(t)\| > r)p_N(t)}{\sum_{t \in \mathbb{D}} \mathbb{I}(\|B^h Y(t)\| > s)p_N(t)} \int_0^\infty \mathbb{I}(\|B^h Y(h)\| > r)\alpha r^{-\alpha-1}dr\right\} = \int_0^\infty \mathbb{E}\left\{F(B^h Y)\sum_{h \in \mathbb{D}} \mathbb{P}_N(h)\mathbb{I}(\|p_N(v)\|^{1/\alpha} \|B^h Y(h)\| > sM_v, 1 > s)\right\} \alpha s^{-\alpha-1}ds = \mathbb{E}\{\|Z(v)\|^\alpha F(Z)\},
\]

where the last equation follows from (4.7) and since for all \( v \in \mathbb{D} \)

\[
M_v \geq \max_{t \in \mathbb{D}} [p_N(t)]^{1/\alpha} \|B^h Y(t)\| \geq [p_N(v)]^{1/\alpha} \|B^h Y(h)\|
\]

almost surely. Hence

\[
\mathbb{E}\{\|Z_N(v)\|^\alpha F(Z_N)\} = \mathbb{E}\{\|Z(v)\|^\alpha F(Z)\}
\]

holds also for \( v \in \mathbb{D} \). It follows that this holds also for all \( v \in \mathcal{T} \) using that \( Z \in \Omega_T \) (this implies by Lemma A.1 that for all \( v \in \mathcal{T} \) we can find \( v_n \in \mathbb{D} \) such that \( \lim_{n \to \infty} v_n = v \) and \( \|Z(v_n)\| \to \|Z(v)\| \) in probability as \( n \to \infty \)) and (1.1) holds. Consequently, by definition \( Z_N \in \mathbb{K}^+_\alpha[Z] \), establishing the proof. \( \Box \)

**Proof of Corollary 4.8** Let \( \mathbb{D} \) be a countable dense set of \( \mathcal{T} \) which is a subgroup of the additive group \( \mathcal{T} \). Since \( \mathbb{P}\{\|\Theta(0)\| = 1\} = 1 \), then almost surely

\[
b(B^N \Theta) = \sum_{r \in \mathbb{D}} \|B^N \Theta(r)\|^{\alpha} p_N(r) \in (0, \infty)
\]

and thus \( Z_N \) is well-defined. Since by the assumption \( Z_N \in \mathbb{K}^+_\alpha[Z] \), by Theorem 4.4, item (i) the claim follows if we show

\[
(7.8) \quad \mathbb{E}\{\|Z_N(h)\|^\alpha F(Z_N)\} = \mathbb{E}\left\{F(B^h \Theta)\right\}, \quad \forall F \in \mathcal{S}_0, h \in \mathbb{D}.
\]

In view of (4.4) using the Fubini-Tonelli theorem for any \( F \in \mathcal{S}_0, h \in \mathbb{D} \)

\[
\mathbb{E}\{\|Z_N(h)\|^\alpha F(Z_N)\} = \sum_{y \in \mathbb{D}} \mathbb{E}\left\{\|B^h \Theta(h)\|^\alpha \|B^h \Theta(y)\|^\alpha \frac{F(B^h \Theta)}{b(B^h \Theta)}\right\} p_N(y) =: \sum_{y \in \mathbb{D}} \mathbb{E}\{\|\Theta(h - y)\|^\alpha G(B^h \Theta)\} p_N(y) = \sum_{y \in \mathbb{D}} \mathbb{E}\{G(B^h \Theta)\} \mathbb{I}(\|\Theta(y - h)\| > 0) p_N(y)
\]
where we used the fact that $\Theta$ is a spectral tail process to derive the third equality above, hence (7.8) holds. The converse follows from (4.2) and Theorem 4.4, Item (ii).

\[ \square \]

**Proof of Corollary 4.12** The claim is consequence of Theorem 4.4, Corollary 4.8 and (4.7).

**Proof of Theorem 4.13** From (4.8) it follows that $\|\Theta(0)\| = R$ is $\alpha$-Pareto rv and $\Theta = Y/\|Y(0)\|$ is independent of $R$. Hence in view of (4.8) and 1-homogeneity of $\|\cdot\|$ for all $F \in \mathcal{F}$, $\forall h \in T$, $x > 0$

\[
\int_{x}^{\infty} \mathbb{E}\{F(\Theta)\mathbb{I}(\|r\Theta(h)\| > 1)\} \alpha r^{-\alpha - 1} \lambda(dr) = \mathbb{E}\{\mathbb{I}(\|Y(-h)\| > x) F(B^h Y)\},
\]

hence letting $x \downarrow 0$ by the monotone convergence theorem (4.9) follows. For all $F \in \mathcal{F}$, $\forall h \in T$ by (4.8) and the Fubini-Tonelli theorem we have using $Y = R\Theta$ and $\mathbb{P}\{\|\Theta(0)\| = 1\} = 1$

\[
\mathbb{E}\{\|\Theta(h)\|^\alpha F(\Theta)\} = \mathbb{E}\{\|Y(h)\|^\alpha F(Y)\} = \int_{0}^{\infty} r^\alpha \mathbb{E}\left\{ \frac{F(rY)}{\|rY(0)\|^\alpha} \mathbb{I}(\|r\|Y(h)\| > 1) \right\} \alpha r^{-\alpha - 1} dr = \int_{0}^{\infty} r^{2\alpha} \mathbb{E}\left\{ \frac{F(B^h Y)}{\|Y(-h)\|^\alpha} \mathbb{I}(\|Y(-h)\| > r) \right\} \alpha r^{-\alpha - 1} dr = \mathbb{E}\left\{ \frac{F(B^h Y)}{\|Y(-h)\|^\alpha} \int_{0}^{\infty} r^\alpha \alpha r^{-\alpha - 1} dr \right\} = \mathbb{E}\left\{ F(B^h \Theta) \mathbb{I}(\|\Theta(-h)\| \neq 0) \right\},
\]

hence $\Theta$ is a spectral tail rf.

We show next that $\mathbb{K}_\alpha^+ [Z]$ with $Z = Z_N$ given by

\[
Z_N(t) = \frac{[p_N(t)]^{1/\alpha}}{\left( \max_{h \in \mathbb{R}^l} p_N(h) \|B^N Y(h)\|^\alpha \int_{\mathbb{R}^l} \|B^N Y(h)\|^\tau \mathbb{I}(\|B^N Y(h)\| > 1)p_N(h)\lambda (dh) \right)^{1/\alpha} B^N Y(t)}
\]

is a shift-invariant $\alpha$-homogeneous class of rf’s, where $N$ with density $p_N(t) > 0$, $t \in \mathbb{R}^l$ is independent of $Y$ and $\tau \in [0, \alpha]$. Define in the following

\[
(7.9) \quad M_t(Y) = \max_{h \in \mathbb{R}^l} [p_N(h)]^{1/\alpha} \|B^t Y(h)\|, \quad S_t(Y) = \int_{\mathbb{R}^l} \|B^t \Theta(h)\|^\tau \mathbb{I}(\|B^t Y(h)\| > 1)p_N(h)\lambda (dh).
\]

Since $\|Y(0)\| > 1$ almost surely, then clearly $M_t > [p_N(t)]^{1/\alpha}$ almost surely. Non-trivial conclusion is that $S_t > 0$ almost surely, which follows thanks to [45][Thm 2.1, Rem 2.2,iii)]. By the assumption on $\tau$ and the fact that necessarily $\lim_{\|h\| \to \infty} p_N(t) = 0$

\[
(7.10) \quad M_t(Y) \in ([p_N(t)]^{1/\alpha}, \infty), \quad S_t(Y) \in (0, \infty), \quad t \in T.
\]

The shift-invariance follows with the same arguments as in the proof of Theorem 4.4,(iii) and we omit the details. In view of Lemma B.3 we have that $Z$ satisfies (1.1) is equivalent with (4.10).

Next, if the converse holds, then $Y$ is a tail rf from Corollary 4.12 and thus the proof is complete. \[ \square \]
PROOF OF LEMMA 5.4 By the assumption that $Z$ satisfies (5.4) we have

$$\{0 < S_L(Z) < \infty\} \subset \{J_1(Z) \in L\}$$

almost surely. From (B.6) $\{J_1(Z) \in L\} \subset \{0 < S_L(Z) < \infty\}$ follows. Taking $J_1$ equal to the infargsup functionals $I_L$ establish thus (5.5). Similarly, the claims of the two other equalities in (5.6) follow. Next since $K \cap L$ has only finite number of elements for every compact $K \subset \mathbb{R}^l$, then

$$\{0 < S_L(\Theta) < \infty\} \subset \left\{\lim_{\sum_{i=1}^l t_i \to \infty, t \in L} \|\Theta(t)\| = 0\right\} \subset \{0 < B_{L,\tau}(Y) < \infty\}$$

modulo null sets. Since by Lemma B.7 $0 < B_{L,\tau}(Y) < \infty$ implies $M_L(Y) < \infty$ almost surely, applying (B.10) with $F(Y) = S_L(\Theta)/[M_L(Y)]^\alpha$ we also have

$$\{0 < B_{L,\tau}(Y) < \infty\} \subset \{0 < S_L(\Theta) < \infty\}$$

modulo null sets. Since further $\|Y(0)\| = \|R\Theta(0)\| = R\|\Theta(0)\| = R > 1$ almost surely and $\|\cdot\|$ is 1-homogeneous, then

$$\{B_{L,0}(Y) < \infty\} \subset \{I_{L,f}(Y) \in L\}.$$ 

The reverse implication follows from (B.8), hence

$$\left\{\lim_{\sum_{i=1}^l t_i \to \infty, t \in L} \|\Theta(t)\| = 0\right\} \subset \{I_L(Y) \in L\},$$

establishing the proof. □

PROOF OF THEOREM 5.6 From Lemma 4.2 and the continuity of $\|\cdot\|$ we have that $Z, \Theta, Y$ and $\|Z\|, \|Y\|, \|\Theta\|$ are stochastically continuous. Since further

$$P\left\{\sup_{t \in T} \|Z(t)\| > 0\right\} = P\left\{\sup_{t \in T} \|\Theta(t)\| > 1\right\} = P\left\{\sup_{t \in T} \|Y(t)\| > 1\right\} = 1,$$

then (5.8) follows from [45][Thm 2.1, Rem 2.2,iii]).

Assume next that $P\{S(Z) < \infty\} = 1$. Since $q_0 = 1$, then Lemma B.2 yields

$$q_1 = P\{0 < S(\Theta) < \infty\} = 1.$$

As in the proof of Theorem 4.4 we have that

$$Z_N = \frac{\|Z(0)\|}{(p_N(N)S(Z))]^{1/\alpha}}B_N \in K_0[Z],$$

where $N$ is a $T$-valued rv with density function $p_N(t) > 0, t \in T$ being further independent of $Z$. Hence Theorem 3.4 implies

$$E\left\{\sup_{t \in [-a,a] \cap T} \|Z_N(t)\|^\alpha\right\} < \infty, \forall a \in (0, \infty)$$

and thus for all $a \in (0, \infty)$

$$\{S(\Theta) < \infty\} = \left\{\int_T \sup_{t \in [-a,a] \cap T} \|\Theta(t+s)\|^\alpha \lambda(ds) < \infty\right\}$$

implying that

$$q_2 := P\left\{\int_T \sup_{t \in [-a,a] \cap T} \|\Theta(t+s)\|^\alpha \lambda(ds) < \infty\right\} = P\left\{\lim_{\sum_{i=1}^l |t_i| \to \infty} \|\Theta(t)\| = 0\right\} = q_3 = 1.$$
Clearly, $q_3 = 1$ implies
\[ q_4 := P\{I(\Theta) \in R^1\} = P\{B_{T,\tau}(Y) < \infty\} =: q_5 = 1. \]

In view of (6.5), Lemma 5.1 and Remark 5.2 \{B_{T,\tau}(Y) < \infty\} = \{B_{C,\tau}(Y) < \infty\}. Moreover, by Lemma B.7 \{B_{T,\tau}(Y) < \infty\} \subset \{S(\Theta) < \infty\}, hence both (5.9) and (5.10) hold. The proof of (5.11) and (5.12) follows with the same arguments using Lemma B.2 and Remark 5.2.

**Proof of Lemma 6.1** If $K_0^+[Z]$ is shift-invariant, then the stationarity of $X$ follows from [21][Thm 6.9, take $L = B^{-1}$ therein]. By (1.1) if $s \to t$ along $Q_i(t)$ as $n \to \infty$, where $Q_i$ is a quadrant of $t \in T$, then the quadrant stochastic continuity of $\|Z\|$ we have the convergence in probability $\|Z(s)\|^\alpha P \to Y^\alpha$ as $s \to t$, where $Y = \|Z(t)\|$ if $i = 1$ and for other indices $i$ we have that $Y$ is non-negative such that $E\{Y^\alpha\} < \infty$, which is consequence of (1.1) and dominated convergence theorem. Using again (1.1), by (6.2)
\[ X_{s_1,s_2}^\vee = (X(s_1), X(s_2)) \to (V,V) = V^\vee \]
in distribution as $s_1, s_2 \to t$, where $V$ has the same distribution as $X(t)$ if $i = 1$.

Clearly, $X(s) \overset{P}{\to} V$ as $s \to t$ implies that $X_{s_1,s_2}^\vee$ converges in distribution to $V^\vee$ as $s_1, s_2 \to t$. Also the converse holds, see e.g., [46][Lem 1.3.1]. Indeed, if $X_{s_1,s_2}^\vee$ converges in distribution to $V^\vee$ as $s_1, s_2 \to t$, then as in [47][p. 408] for given $\varepsilon > 0$
\[ \limsup_{n \to \infty} P\{X_{s_1,s_2}^\vee \not\in \Delta_\varepsilon\} \leq P\{V \not\in \Delta_\varepsilon\} = 0, \quad s_1, s_2 \to t, \]
where $\Delta_\varepsilon = \{(x,y) \in R^2 : |x - y| < \varepsilon\}$. Hence $X$ is quadrant stochastically continuous. 

**Proof of Lemma 6.2** First note that $B_C^+[Z]$ exists and is finite which follows from the shift-invariance of $K_0[Z]$ and the subadditivity of supremum functional, see also [11]. We show next that if $L$ is a full rank lattice on $T$ or $L = T$, then
\[ B_C^+[Z] = \frac{1}{\Delta(L)} E\left\{ \frac{1}{\int_{T} \|\Theta(s)\|\tau(\|Y(s)\| > 1)\lambda(ds)} \right\} < \infty \]
for all $\tau \in R$ such that $E\{\|\Theta(t)\|\tau\} < \infty, \forall t \in T$ (this holds in particular if $\tau \in [0,\alpha]$). In our notation $\Delta(\mathbb{R}^l) = 1$ and if $L$ is a full rank lattice on $T$, then $\Delta(L) = |\det(A)| > 0$ as in (2.1), where $A$ is a non-singular base matrix of the lattice $L$ i.e., $L = \{Ax, x \in \mathbb{Z}^l\}$.

In view of (B.3) for all $S > 0$ by the translation invariance of the measure $\lambda(\cdot)$ and the Fubini-Tonelli theorem
\[ \infty > E\left\{ \sup_{t \in [0,S]} \|Z(t)\|^\alpha \right\} = \int_{t \in [0,S]} E\left\{ \frac{1}{\int_{s \in [0,S]} \|\Theta(s-t)\|\tau(\|Y(s-t)\| > 1)\lambda(ds)} \right\} \lambda(dt) = S^l \int_{t \in [0,1]} E\left\{ \frac{1}{\int_{s+t \in [0,S]} \|\Theta(s)\|\tau(\|Y(s)\| > 1)\lambda(ds)} \right\} \lambda(dt), \]
hence by the monotone convergence theorem and since $\|\Theta(0)\| = 1$ almost surely
\[ \lim_{S \to \infty} S^{-p}E\left\{ \sup_{t \in [0,S]} \|Z(t)\|^\alpha \right\} = E\left\{ \frac{1}{\int_{T} \|\Theta(s)\|\tau(\|Y(s)\| > 1)\lambda(ds)} \right\} < \infty. \]
Consider next $\mathcal{L}$ a full rank lattice on $\mathbb{R}^l$. We can transform $\mathcal{L}$ linearly to $\mathbb{Z}^l$ and thus the hypercube $[0,n]^l$ is transformed to a parallelepiped say $K_n$ with volume $n^l/\Delta(\mathcal{L})$ implying

$$
\lim_{n \to \infty} n^{-l} \sum_{i \in [0,n] \cap \mathcal{L}} 1 = \frac{1}{\Delta(\mathcal{L})} > 0.
$$

As above with $\lambda$ the counting measure on $\mathcal{T}$, for all $0 > \varepsilon$

$$
\mathbb{E} \left\{ \sup_{t \in [0,S] \cap \mathcal{L}} \| Z(t) \|^\alpha \right\} \geq \int_{s \in \mathcal{L}(S \setminus (1-\varepsilon)S) \cap \mathcal{L}} \mathbb{E} \left\{ \frac{1}{\| \Theta(s) \|^{\tau}} \mathbb{I}(\| Y(t-s) \| > 1) \right\} \lambda(ds) =: C_\varepsilon.
$$

implying for any $\varepsilon \in (0,1)$

$$
\int_{t \in [0,S] \cap \mathcal{L}} \| \Theta(s) \|^{\tau} \mathbb{I}(\| Y(t-s) \| > 1) \lambda(dt) \to \int_{\mathcal{L}} \| \Theta(s) \|^{\tau} \mathbb{I}(\| Y(t-s) \| > 1) \lambda(dt)
$$
as $S \to \infty$ almost surely for any $s \in [-\varepsilon S, \varepsilon S]$, we obtain by monotone convergence theorem

$$
\lim_{\varepsilon \downarrow 0} \lim_{S \to \infty} S^{-l} A_\varepsilon = \mathbb{E} \left\{ \frac{1}{\| \Theta(s) \|^{\tau}} \mathbb{I}(\| Y(t) \| > 1) \right\} \lim_{\varepsilon \downarrow 0} \lim_{S \to \infty} \int_{s \in \mathcal{L}(S \setminus (1-\varepsilon)S) \cap \mathcal{L}} \lambda(ds)
$$

Since further

$$
\mathbb{E} \left\{ \sup_{t \in [0,S] \cap \mathcal{L}} \| Z(t) \|^\alpha \right\} \leq C_\varepsilon + \int_{s \in ([0,S] \setminus (1-\varepsilon)S) \cap \mathcal{L}} \lambda(ds),
$$

then the formula for $\mathbb{B}_Z^c$ follows. It implies that $\mathbb{B}_Z^c = 0$ iff

$$
\mathbb{P}\{B_{\mathcal{L},\tau}(Y) = \infty\} = 1
$$

and thus the first equivalence in (6.5) is clear.

Suppose next that $\mathbb{P}\{B_{\mathcal{L},\tau}(Y) = \infty\} = 1$ for some $\tau \geq 0$. By Lemma 5.4 $\mathbb{P}\{B_{\mathcal{L},0}(Y) = \infty\} = 1$. Since for all $n \in \mathbb{N}$ we have that $\mathbb{P}\{B_{2^{-n}\mathcal{L},0}(Y) = \infty\} = 1$ and since $2^{-n}\mathcal{L}$ is a full rank lattice on $\mathbb{R}^l$, then by the first equivalence and (B.1) we have that $\mathbb{B}_{Z}^c = 0$ which is equivalent with $\mathbb{P}\{B_{2^{-n}\mathcal{L},0}(Y) = \infty\} = 1$. If the latter holds, then since $\mathbb{B}_{Z}^c \leq \mathbb{B}_{Z} = 0$, then $\mathbb{B}_{Z} = 0$, hence (6.5) follows. 

**Proof of Lemma 6.4** In view of Theorem 5.6 $\mathbb{P}\{\mathcal{S}(Y) < \infty\} = 1$ is equivalent with $\| Z(t) \| \to 0$ and $\| \Theta(t) \| \to 0$ and $\sum_{i=1}^l |t_i| \to \infty$, $t = (t_1, \ldots, t_l) \in \mathcal{L}$ almost surely. Assume for simplicity $\alpha = 1$. Utilising the first equality in (6.4) and dominated convergence theorem we have for any $m, s, v$ positive and $a_n, r_n, n \geq 1$ such that $\lim_{n \to \infty} 1/r_n = \lim_{n \to \infty} r_n \mathbb{P}\{X(0) > a_n\} = \lim_{n \to \infty} r_n/a_n = 0$

$$
1 = \lim_{n \to \infty} \max_{m \leq \sum_{i=1}^l |t_i| \leq r_n, t \in \mathcal{L}} \mathbb{P}\{ X(t) > a_n s, X(0) > a_n v \}
$$

$$
= v \lim_{n \to \infty} a_n \max_{m \leq \sum_{i=1}^l |t_i| \leq r_n, t \in \mathcal{L}} \mathbb{P}\{ X(t) \leq a_n s, X(0) > a_n v \}
$$

$$
= v \max_{s \to \infty} \mathbb{E} \left\{ \max_{m \leq \sum_{i=1}^l |t_i| \leq r_n, t \in \mathcal{L}} \| Z(t) \|, \| Z(0) \| / s / v \right\} - \max_{m \leq \sum_{i=1}^l |t_i| \leq r_n, t \in \mathcal{L}} \| Z(t) \|\right\}
$$
\[ \frac{v}{s} \mathbb{E}\{\|Z(0)\|s/v}\} = 1, \quad m \to \infty, \]

hence (6.6) follows. Conversely, as above

\[
1 - \lim_{n \to \infty} \mathbb{P}\left\{ \max_{m \leq \sum_{i=1}^{l}|t_i|, t \in \mathcal{L}} X(t) > a_n s, X(0) > a_n v \right\}
= \frac{v}{s} \mathbb{E}\left\{ \max_{m \leq \sum_{i=1}^{l}|t_i|, t \in \mathcal{L}} \|Z(t)\|, \|Z(0)\|s/v - \max_{m \leq \sum_{i=1}^{l}|t_i|, t \in \mathcal{L}} \|Z(t)\| \right\} I(\|Z(0)\| > 0)
= \frac{v}{s} \mathbb{E}\left\{ \max\left(0, \frac{s}{v} - \max_{m \leq \sum_{i=1}^{l}|t_i|, t \in \mathcal{L}} \|\Theta(t)\| \right) \right\}
\]

and (6.6) taking \( s = v > 0 \) we have

\[
\lim_{m \to \infty} \mathbb{E}\left\{ \max\left(0, 1 - \max_{m \leq \sum_{i=1}^{l}|t_i|, t \in \mathcal{L}} \|\Theta(t)\| \right) \right\} = 1,
\]

which is equivalent with convergence in probability (since the integrand is bounded)

\[
\max\left(0, 1 - \max_{m \leq \sum_{i=1}^{l}|t_i|, t \in \mathcal{L}} \|\Theta(t)\| \right) \to 1, \quad m \to \infty
\]

and the above is equivalent with the almost sure convergence \( \|\Theta(t)\| \to 0 \) as \( \sum_{i=1}^{l} |t_i| \to \infty \) with \( t = (t_1, \ldots, t_l) \in \mathcal{L} \) establishing the proof. \( \square \)

**Appendix A. Basic properties of \( Z \in \Omega_T \)**

Examples of \( Z \in \Omega_T \) include all rf’s with generalised càdlàg sample paths, see e.g., [10]. For second order processes and \( \mathcal{T} = [0, T] \) necessary conditions that imply that \( Z \) is stochastically continuous up to a countable set are presented in [24][Prop 2.6].

We are interested on versions of \( Z \) which are both separable and jointly measurable. Our definition of separability is the same as strong separability given in [48][Def. 9.2.3]. Here \( \mathcal{T} \) is equipped with the usual topology. The separant of \( Z \) is a dense countable subset \( \mathbb{D} \subset \mathcal{T} \), which is denoted by \( \mathcal{T}^\ast \) in the aforementioned definition.

We call the rf \( Z(t), t \in \mathcal{T} \) (jointly) measurable, if \( Z(t, \omega) : \mathcal{T} \times \Omega \to \mathbb{R} \) is measurable \( \sigma(\mathcal{B}(\mathcal{T}) \times \mathcal{F})/\mathcal{B}(\mathbb{R}) \) measurable, where \( \sigma(\mathcal{B}(\mathcal{T}) \times \mathcal{F}) \) is the smallest \( \sigma \)-field on \( \mathcal{T} \times \Omega \) generated by the product of \( \mathcal{B}(\mathcal{T}) \) and \( \mathcal{F} \). Further \( \sigma(\mathcal{B}(\mathcal{T}) \times \mathcal{F}) \) stands for the completion of \( \sigma(\mathcal{B}(\mathcal{T}) \times \mathcal{F}) \) with respect to \( \lambda \times \mathbb{P} \).

**Lemma A.1.** If \( Z \in \Omega_T \), then there exists a set \( T_0 \in \mathcal{T} \) of countable hyperplanes such that \( Z \) is stochastically continuous on \( \mathcal{T} \setminus T_0 \) and there exists a separable and measurable version of \( Z \) and \( \|Z\| \) defined on \( (\Omega, \mathcal{F}, \mathbb{P}) \). Further any dense countable set \( \mathbb{D} \) is a separant for both \( Z \) and \( \|Z\| \).

**Proof of Lemma A.1** If \( l = 1 \) the set \( T_0 \) being countable is shown in [49][p. 177] and the measurability in [49][Rem 2°, p. 179]. Using the fact that convergence in probability is metrizable, the existence of \( T_0 \) follows as the corresponding result for generalised càdlàg functions, see [50][Prop 2.1]. Hence the existence of separable and measurable version follows from [51][Thm 1, p. 171]. Let \( Z \) be that version and denote by \( \mathbb{D} \) a separant for \( Z \). Since \( \|\cdot\| \) is continuous, then the measurability of \( \|Z\| \) follows. Further, a direct application of [48][Prop 9.2.3] yields that \( \|Z\| \) is separable with separant \( \mathbb{D} \).
If $Z$ is stochastically continuous, then any dense subset of $\mathbb{R}^l$ is a separant for $Z$ follows from [51][Thm 5, p. 169]. Utilising the proof of the aforementioned theorem, taking instead of the spheres $S$ therein with center $x$ the intersection $S \cap Q_1(x)$ with $Q_1(x)$ the quadrant of $x$ defined in (2.4), it follows that also for the more general setup that $Z$ is quadrant stochastically continuous we have that any dense subset of $\mathbb{R}^l$ is a separant for $Z$, hence the claim follows. □

Lemma A.2. Let $K = [a, b]^l, a < b$ and denote by $||\cdot||_*$ a norm on $T$. If $Z \in \Omega_T$ with separant $D$, then we have the convergence in probability

(A.1) \[ \max_{t \in D_n} Z(t) \xrightarrow{p} \sup_{t \in K} Z(t), \quad n \to \infty, \]

where $D_n = \{t_{nk} \in D \cap K, 1 \leq k \leq k_n\}, n \in \mathbb{N}$ is a sequence of subsets with finite number of elements satisfying $\lim_{n \to \infty} \sup_{t \in K \cap D} \inf_{1 \leq k \leq k_n} ||t - t_{nk}||_* = 0$.

Further, we can find $\bar{D}_n$ with finite number of elements such that with $\bar{K} = [a, b]^l$

(A.2) \[ \max_{t \in \bar{D}_n} Z(t) \xrightarrow{p} \sup_{t \in K} Z(t), \quad n \to \infty. \]

Proof of Lemma A.2 By the separability we have that $\sup_{t \in K} Z(t)$ is almost surely equal to $\sup_{t \in K \cap D} Z(t)$. The claim follows now by the quadrant stochastic continuity of $Z$ with similar arguments as in [49][p. 176 Continuity Separation Thm].

We can proceed similarly for $\bar{K} = [a, b]^l$ to show (A.2). For this case, by Lemma A.1, there are countable number of points on $\bar{K} \setminus K$ where $Z$ is not stochastically continuous. These points we can include in $D$ and show the claim with similar arguments as that for (A.1).

The next lemma is stated without proof.

Lemma A.3. If $Z \in \Omega_T, g_1 : \mathbb{R}^d \mapsto [0, \infty)$ is a Borel measurable locally bounded function and $g_2 : T \mapsto [0, \infty)$ is continuous, then

\[ I(g_1(Z), g_2) = \int_{[-k,k]^l} g_1(Z(t))g_2(t)\lambda(dt) \]

is a rv such that for any given $k > 0$ there exists some increasing sequence $n_{l,k}, l \geq 1$ (that can depend on $k$) such that $\hat{R}_{n_k}(g_1(Z), g_2) \to I(g_1(Z), g_2)$ as $l \to \infty$ almost surely, where

\[ \hat{R}_n(g_1(f), g_2) = \frac{1}{n^l} \sum_{t \in (Z/2^n)^l} g_1(f(t))g_2(t), \quad f \in D. \]

Appendix B. Auxiliary results

Let hereafter $K_\alpha[Z]$ be a given shift-invariant $\alpha$-homogeneous class of rf’s and $\Theta, Y$ it spectral and tail rf’s, respectively. The next claim is a consequence of (4.2) and is based on similar calculations as in [52][Thm 1]. Recall that $||\cdot|| : \mathbb{R}^d \to [0, \infty)$ is a 1-homogeneous continuous function.

Proposition B.1. If $T = \mathbb{R}^l$ and $L$ is a full rank lattice on $\mathbb{R}^l$, then

\[ \lim_{n \to \infty} \lim_{S \to \infty} S^{-l}E \left\{ \sup_{t \in [0,S]^l} ||Z(t)||^\alpha - \sup_{t \in [0,S]^l \cap 2^{-n}L} ||Z(t)||^\alpha \right\} = 0. \]
Moreover, with $\Delta(L)$ defined in (2.1) we have

\[
\lim_{n \to \infty} \frac{\mathbb{E}^{2^{-n}L}}{2^{-n}2^{-n} \Delta(L)} = \mathbb{E}^{Z^l} \in [0, \infty).
\]

**Proof of Proposition B.1** Assume for simplicity that $S$ is a positive integer, $L_n = 2^{-n}Z^l, n \in \mathbb{N}$ and set

\[
K_i = \times_{k=1}^i [i_k, i_k+1) = [i, i+1), i \in Z^l, \quad K_0 = \times_{k=1}^1 [0, 1).
\]

For all $n$ sufficiently large and any $i \in Z^l$ we have that $L_n \cap K_i$ is non-empty. Note further that $L_n$ is a full rank lattice for any $n \in \mathbb{N}$ and $\mathbb{D} = \cup_{n \geq 1} L_n$ is a countable dense subset of $\mathcal{T}$ and thus by Lemma 4.2 it is a separant for $Z$. Set below

\[
a(K) = \sup_{t \in K} \|Z(t)\|^{\alpha}, \quad K \subset \mathcal{T}.
\]

From (4.2) and (1.1) for all $n$ large we obtain

\[
\mathbb{E}\{a(K_0 \cap L_n)\} = \mathbb{E}\{a(K_i \cap L_n)\} < \infty, \quad \mathbb{E}\{a(K_0)\} = \mathbb{E}\{a(K_i)\} < \infty, \quad \forall i \in Z^l
\]

since $i \in L_n$ and $L_n$ is an additive group. Consequently, we have for some positive integer $S$

\[
\mathbb{E}\left\{a([0, S]^l)\right\} - \mathbb{E}\left\{a([0, S]^l \cap L_n)\right\}
\]

\[
\begin{align*}
&= \mathbb{E}\left\{\max_{i \in [0, S-1]^l \cap Z^l} a(K_i) - \max_{i \in [0, S-1]^l \cap Z^l} a(K_i \cap L_n)\right\} \\
&\leq \mathbb{E}\left\{\max_{i \in [0, S-1]^l \cap Z^l} [a(K_i) - a(K_i \cap L_n)]\right\} \\
&\leq \sum_{i \in [0, S-1]^l \cap Z^l} \mathbb{E}\{[a(K_i) - a(K_i \cap L_n)]\}
\end{align*}
\]

\[
= S^l \mathbb{E}\{a(K_0) - a(K_0 \cap L_n)\}.
\]

In view of Lemma A.2 we have the convergence in probability

\[
M_n = \sup_{t \in K_0 \cap L_n} \|Z(t)\| \xrightarrow{p} \sup_{t \in K_0} \|Z(t)\|, \quad n \to \infty.
\]

Since $M_n, n \geq 1$ is increasing in $L$ it follows that $M_n^a \to M^a$ almost surely as $n \to \infty$. Using (1.1), the non-negativity of $M_n, n \geq 1$ and its monotonicity it follows that the above convergence holds almost surely. Hence by the dominated convergence theorem which is justified by (1.1)

\[
\lim_{n \to \infty} \mathbb{E}\{a(K_0) - a(K_0 \cap L_n)\} = 0
\]

and thus the proof follows from (7.11). \qed

**Lemma B.2.** For all $F \in \mathcal{F}_0$ being non-negative the following are equivalent:

(i) $\mathbb{E}\{F(Z)\} = 0$;

(ii) $\mathbb{E}\{F(B^hZ)\} = 0$ for all $h \in \mathcal{T}$;

(iii) $\mathbb{E}\{F(\Theta)\} = 0$.

If $F$ is also bounded by 1, then the above equivalences holds with 0 substituted by 1.
**Proof of Lemma B.2** Let $\mathbb{D}$ be a countable dense subset of $\mathcal{T}$ and let $p_N \in \mathcal{P}_\mathbb{D}$. By (1.3) and Lemma A.1 $\mathbb{P}\{\sup_{t \in \mathbb{D}}\|Z(t)\| > 0\} = 1$. Hence almost surely

(B.2) \[
\sum_{t \in \mathbb{D}}\|Z(t)\|^\alpha p_N(t) > 0.
\]

(i) $\implies$ (ii): Since $F$ is non-negative, then when (i) holds, $F(Z) = 0$ almost surely. Using (4.2) for all $h \in \mathcal{T}$ and

\[ E\left\{ F(B^hZ) \sum_{t \in \mathbb{D}}\|Z(t)\|^\alpha p_N(t) \right\} = \sum_{t \in \mathbb{D}} E\left\{ F(B^hZ)\|B^hZ(h + t)\|^\alpha p_N(t) \right\} = \sum_{t \in \mathbb{D}} E\{\|Z(h + t)\|^\alpha F(Z)\} p_N(t) = 0. \]

Consequently, by (B.2) $F(B^hZ) = 0$ follows.

(ii) $\implies$ (iii): The fact that $F$ is 0-homogeneous yields

\[ E\{F(\Theta)\} = E\{\|Z(0)\|^\alpha F(Z/\|Z(0)\|)\} = E\{\|Z(0)\|^\alpha F(Z)\} = 0 \]

and thus (iii) holds.

(iii) $\implies$ (i): By the shift-invariance of $\mathbb{K}^+_{\mathcal{T}}[Z]$ (using (4.2) to derive the last equality below)

\[ 0 = \sum_{t \in \mathbb{D}} E\{F(B^t\Theta)\} p_N(t) = \sum_{t \in \mathbb{D}} E\{\|Z(0)\|^\alpha F(B^tZ)\} p_N(t) = E\left\{ F(Z) \sum_{t \in \mathbb{D}}\|Z(t)\|^\alpha p_N(t) \right\}, \]

hence (B.2) implies (i).

Next, if $E\{F(Z)\} = 1$ we have that $\bar{F} = 1 - F \in \mathcal{S}_0$ and $E\{\bar{F}(Z)\} = 0$, which by the above is equivalent with $E\{\bar{F}(\Theta)\} = 1$, hence the proof is complete. \hfill \Box

**Lemma B.3.** If $K \subset \mathbb{Z}^l$ have finite number of elements and $\lambda$ is the counting measure on $\mathbb{Z}^l$ or $\lambda$ is the Lebesgue measure on $\mathcal{T} = \mathbb{R}^l$ and $K = [-a, a]^l \cap \mathcal{T}, a > 0$, then

(B.3) \[
E\left\{ \sup_{t \in K}\|\mathcal{T}(t)\|^\alpha \right\} = \int_{\mathcal{T}} E\left\{ \frac{1}{|K\|} \mathbb{I}\{\|\Theta(s - t)\|^\tau\|Y(s - t)\| > 1\}\lambda(ds) \right\} \lambda(dt) \in [0, \infty)
\]

for all $\tau \in \mathbb{R}$ such that $E\{\|\Theta(t)\|^\tau\} < \infty, \forall t \in \mathcal{T}$, where $Y = R\Theta$.

**Proof of Lemma B.3** The case $\Theta$ has càdlàg sample paths is easier and follows along the lines of [6]. The proof for the general case requires some technical modification, we omit the details. \hfill \Box

$\mathbb{P}\{A; B\}$ instead of $\mathbb{P}\{A\|B\}$ in the following and set for given non-negative weights $w_i, i \in \mathcal{L}$

\[ \mathcal{A}_k(f) = \sum_{i \in \mathcal{L}} w_i \mathbb{I}(\mathcal{J}_k(f) = i), \quad k = 1, 2, 3 \]

and note that for $w_i = 1, i \in \mathcal{L}$ we simply have

\[ \mathcal{A}_k(f) = \mathbb{I}(\mathcal{J}_k(f) \in \mathcal{L}). \]

**Lemma B.4.** Let $\mathcal{L}$ be a subgroup of $\mathcal{T}$ with countably infinite number of elements. For all shift-involutions $\mathcal{J}_1$, all positive shift-involutions $\mathcal{J}_2$ and all $F \in \mathcal{H}_0$ shift-invariant with respect to $\mathcal{L}$

(B.4) \[
E\{\|Z(0)\|^\alpha F(Z); \mathcal{A}_1(Z)\} = E\left\{ \sum_{i \in \mathcal{L}} w_i\|B^iZ(0)\|^\alpha F(B^iZ); \mathcal{J}_1(Z) = 0 \right\}
\]
\( \mathbb{E} \{ F(\Theta); A_2(\Theta) \} = \mathbb{E} \left\{ \sum_{i \in \mathcal{L}} w_i \| B^i \Theta(0) \|^\alpha F(B^i \Theta); J_2(\Theta) = 0 \right\} \)

and

\( \mathbb{P} \{ S_{\mathcal{L}}(Z) = \infty, J_1(Z) \in \mathcal{L} \} = \mathbb{P} \{ S_{\mathcal{L}}(\Theta) = \infty, J_1(\Theta) \in \mathcal{L} \} = 0. \)

**Proof of Lemma B.4** Since \( J_1 \) is a shift-involution and thus \( 0 \)-homogeneous, utilising the shift-invariance of \( \mathcal{K}_\alpha[Z] \), for all \( F \in \mathcal{H}_0 \) the Fubini-Tonelli theorem implies

\[
\mathbb{E} \left\{ \sum_{s \in \mathcal{L}} w_s \| B^s Z(0) \|^\alpha F(B^s Z); J_1(Z) = 0 \right\} = \sum_{s \in \mathcal{L}} w_s \mathbb{E} \{ \| B^s Z(0) \|^\alpha F(B^s Z); J_1(Z) = 0 \} \\
= \sum_{s \in \mathcal{L}} w_s \mathbb{E} \{ \| Z(0) \|^\alpha F(Z) \| J_1(B^{-s} Z) = 0 \} \\
= \mathbb{E} \{ \| Z(0) \|^\alpha F(Z) \sum_{s \in \mathcal{L}} w_s \| J_1(\Theta) = s \} \\
= \mathbb{E} \{ \| Z(0) \|^\alpha \} \mathbb{E} \{ F(\Theta); A_1(\Theta) \},
\]

which proves (B.4). Since \( \mathcal{L} \) has countably infinite number of elements, then \( F(Z) = \mathbb{I}(S_{\mathcal{L}}(Z) = \infty) \) is shift-invariant with respect to \( \mathcal{L} \). From the above taking \( w_i = 1, i \in \mathcal{L} \)

\[
\mathbb{E} \{ S_{\mathcal{L}}(Z) F(Z); J_1(Z) = 0 \} = \mathbb{E} \{ F(\Theta); J_1(\Theta) \in \mathcal{L} \} = \mathbb{P} \{ S_{\mathcal{L}}(\Theta) = \infty, J_1(\Theta) \in \mathcal{L} \} = 0.
\]

The last equality follows since \( \mathbb{E} \{ S_{\mathcal{L}}(Z) F(Z); J_1(Z) = 0 \} \in \{ 0, \infty \} \). In view of Lemma B.2

\[
\mathbb{P} \{ S_{\mathcal{L}}(Z) = \infty, J_1(Z) \in \mathcal{L} \} = 0,
\]

hence (B.6) follows. Next, if \( J_2 \) is a positive shift-involution, then using that \( \Theta \) is a spectral tail rf by the Fubini-Tonelli theorem, for any \( F \in \mathcal{H}_0 \)

\[
\mathbb{E} \left\{ \sum_{s \in \mathcal{L}} w_s \| B^s \Theta(0) \|^\alpha F(B^s \Theta); J_2(\Theta) = 0 \right\} = \sum_{s \in \mathcal{L}} w_s \mathbb{E} \{ \| B^s \Theta(0) \|^\alpha F(B^s \Theta); J_2(\Theta) = 0 \} \\
= \sum_{s \in \mathcal{L}} w_s \mathbb{E} \{ F(\Theta) \| J_2(\Theta) = 0 \} \mathbb{I}(\| B^{-s} \Theta(0) \| \neq 0) \\
= \sum_{s \in \mathcal{L}} w_s \mathbb{E} \{ F(\Theta) \| J_2(\Theta) + s = s \} \\
= \mathbb{E} \{ F(\Theta); \sum_{s \in \mathcal{L}} w_s J_2(\Theta) = s \} \\
= \mathbb{E} \{ F(\Theta); A_2(\Theta) \},
\]

where the second equality follows since by the assumption \( \mathbb{I}(\| B^{-s} f \| \neq 0) \in \mathcal{H}_0 \) and the fact that \( \Theta \) is a spectral tail rf, whereas the third equality follows by the assumption that \( J_2 \) is a positive shift-invariant involution which yields \( J_2(\Theta) = k \) implies \( \| \Theta(k) \| \neq 0 \) almost surely for any \( k \in \mathcal{L} \). Hence (B.4) follows and thus the proof is complete. \( \square \)
Lemma B.5. Under the setup of Lemma B.4 if \( \mathcal{J}_3 \) is an anchoring map, then for all \( F \in \mathcal{H} \) shift-invariant with respect to \( \mathcal{L} \) and all \( \tau \geq 0 \)

\[
\mathbb{E}\{\|Y(0)\|\| F(Y); \mathcal{A}_3(\Theta)\} = \mathbb{E}\left\{\sum_{i \in \mathcal{L}} w_i \|B^i Y(0)\|\| F(\mathcal{J}_3(Y) = 0)\right\}
\]

and

\[
\mathbb{P}\{\mathcal{B}_{\mathcal{L},\tau}(Y) = \infty, \mathcal{J}_3(Y) \in \mathcal{L}\} = 0.
\]

Remark B.6. (i) If \( \mathcal{L} = \mathcal{T} = \mathbb{Z}^d \) and \( \mathcal{J}_3(Y) \in \mathcal{T} \) almost surely and \( \| \cdot \| \) is a norm on \( \mathbb{R}^d \), then (B.7) reduces to [2][Prop 3.6];

(ii) If \( \mathbb{E}\{\|Z(0)\|^\alpha\} = 1 \) and \( \mathcal{J}_k, k \leq 3 \) are as in Lemma B.4 and Lemma B.5, then for all \( F \in \mathcal{H}_\alpha \) shift-invariant with respect to \( \mathcal{L} \)

\[
\mathbb{E}\left\{\frac{F(\Theta)}{\mathcal{S}_\mathcal{L}(\Theta)}\right\} = \mathbb{E}\{F(Z); \mathcal{J}_1(Z) = 0\} = \mathbb{E}\{F(\Theta); \mathcal{J}_2(\Theta) = 0\} = \mathbb{E}\{F(\Theta); \mathcal{I}_\mathcal{L}(Y) = 0\},
\]

with \( \Theta(t) = \Theta(t) / \sup_{t \in \mathcal{L}} \|\Theta(t)\| \) and for any \( F \in \mathcal{H}_\alpha \) shift-invariant with respect to \( \mathcal{L} \) and all \( \tau \geq 0 \)

\[
\mathbb{E}\left\{\sum_{i \in \mathcal{L}} w_i \|Y(0)\|^\tau F(Y) \right| \|\| Y(i)\|>1\right\} = \mathbb{E}\{F(Y); \mathcal{J}_3(Y) = 0\},
\]

where we interpret \( \infty / \infty \) as 0.

Proof of Lemma B.5 Using the Fubini-Tonelli theorem we obtain by (4.7) for any \( F \in \mathcal{H} \) and \( \mathcal{J}_3 \) an anchoring functional

\[
\mathbb{E}\left\{\sum_{i \in \mathcal{L}} w_i \|B^i Y(0)\|\| F(\mathcal{J}_3(Y) = 0)\right\}
\]

\[
= \sum_{i \in \mathcal{L}} w_i \mathbb{E}\{\|Y(-i)\| > 1\|B^i Y(0)\|^\tau F(B^i Y); \mathcal{J}_3(Y) = 0\}
\]

\[
= \sum_{i \in \mathcal{L}} w_i \mathbb{E}\{\|Y(i)\| > 1\|Y(0)\|^\tau F(\mathcal{J}_3(B^{-i} Y) = 0\}
\]

\[
= \sum_{i \in \mathcal{L}} w_i \mathbb{E}\{\|Y(0)\|^\tau F(\mathcal{J}_3(B^{-i} Y) = 0\}
\]

\[
= \sum_{i \in \mathcal{L}} w_i \mathbb{E}\{\|Y(0)\|^\tau F(\mathcal{J}_3(Y) = i\}
\]

\[
= \mathbb{E}\left\{\|Y(0)\|^\tau F(\mathcal{J}_3(Y) = \mathcal{A}_3(Y)\}
\]

and thus (B.7) follows. We have that \( F(Y) = \mathbb{I}(\mathcal{B}_{\mathcal{L},\tau}(Y) = \infty) \) is shift-invariant with respect to \( \mathcal{L} \) since \( \mathcal{L} \) is a subgroup of the additive group \( \mathcal{T} \). By the assumption \( \mathcal{L} \) has infinite number of elements and the above \( \mathbb{P}\{\mathcal{B}_{\mathcal{L},\tau}(Y) = \infty, \mathcal{J}_3(Y) \in \mathcal{L}\} = 0 \) establishing the proof. \( \square \)
Lemma B.7. Suppose that \( \mathbb{P}\{B_{L,T}(Y) < \infty\} > 0 \). If \( L \) is as in Lemma B.4 or \( L = T \), then \( \mathbb{P}\{B_{L,T}(Y) < \infty, M_L(Y) = \infty\} = 0 \) and for all \( \tau \in [0, \alpha] \)

\[
E\left\{ \frac{\|Y(0)\|^\ast S_L(Y)}{[M_L(Y)]^\alpha B_{L,T}(Y)} \right\} = 1.
\]

Proof of Lemma B.7 For all \( z \in (0, 1] \) almost surely

\[
B_{L,T}(zY) \leq B_{L,T}(Y) \leq B_{L,T}(z^{-1}Y).
\]

Further since \( \|Y\| \) is quadrant stochastically continuous, then from [45][Thm 2.1, Rem 2.2,iii)] \( M_L(Y) > 1/z \) implies \( B_{L,T}(zY) > 0 \) almost surely for all \( z > 0 \). Hence since also \( \mathbb{P}\{B_{L,T}(Y) > 0\} = 1 \) as shown in (5.8), for all \( z \in (0, 1] \) by (B.12) and the Fubini-Tonelli theorem

\[
E\left\{ \frac{1}{B_{L,T}(Y)} I\{B_{L,T}(Y) < \infty, M_L(Y) = \infty\} \right\} 
\leq E\left\{ \frac{B_{L,T}(zY)}{B_{L,T}(zY) \mathbb{E}\{B(Y) < \infty, M_L(Y) > 1/z\}} I\{B(Y) < \infty, M_L(Y) > 1/z\} \right\} 
= \int_T E\left\{ \frac{\|Y(0)\|^\ast}{B_{L,T}(zY) B_{L,T}(zY)} I\{z M_L(Y) > 1, z \|Y(t)\| > 1\} \right\} \lambda(dt)
= z^\alpha \int_T E\left\{ \frac{\|Y(-t)\|^\ast}{B_{L,T}(z^{-1}Y) B_{L,T}(Y)} I\{\|Y(-t)\| > z\} \right\} \lambda(dt)
= z^\alpha E\left\{ \frac{\|B_{L,T}(z^{-1}Y) < \infty\}}{B_{L,T}(z^{-1}Y) B_{L,T}(Y)} \int_T \|Y(0)\|^\ast I\{\|Y(-t)\| > z\} \lambda(dt) \right\}
= z^\alpha E\left\{ \frac{1}{B_{L,T}(Y)} \right\}
< \infty,
\]

where the last inequality follows from (4.10). Consequently, letting \( z \to 0 \) implies

\( \{B_{L,T}(Y) < \infty\} \subset \{M_L(Y) < \infty\} \).

Using the latter implication, by the Fubini-Tonelli theorem and (4.7) taking \( L = T \) (note that \( M_L(Y) > 1 \) almost surely)

\[
E\left\{ \frac{\|Y(0)\|^\ast S_L(Y)}{[M_L(Y)]^\alpha B_{T,T}(Y)} \right\} = \int_T E\left\{ \frac{\|Y(0)\|^\ast \|Y(t)\|^\ast}{[M_L(Y)]^\alpha B_{T,T}(Y)} \right\} \lambda(dt)
= \int_T \int_0^\infty E\left\{ \frac{\|Y(0)\|^\ast I\{\|Y(t)\| > 1\}}{[M_L(Y)]^\alpha B_{T,T}(Y)} \right\} \alpha s^{-\alpha - 1} ds \lambda(dt)
= \int_T \int_0^\infty E\left\{ \frac{\|Y(-t)\|^\ast I\{\|Y(-t)\| > s\}}{[M_L(Y)]^\alpha B_{T,T}(s^{-1}Y)} \right\} \alpha s^{-\alpha - 1} ds \lambda(dt)
= \int_T \int_0^\infty E\left\{ \frac{\|Y(-t)/(M_L(Y)s)\|^\ast I\{\|Y(-t)/M_L(Y)s\| > s\}}{B_{T,T}((M_L(Y)s)^{-1}Y)} \right\} \alpha s^{-\alpha - 1} ds \lambda(dt)
= \int_0^1 E\left\{ \int_T \frac{\|Y(-t)/(M_L(Y)s)\|^\ast I\{\|Y(-t)/M_L(Y)s\| > s\}}{B_{T,T}((M_L(Y)s)^{-1}Y)} \lambda(dt) \right\} \alpha s^{-\alpha - 1} ds
\]
establishing (B.11) if \( \mathcal{L} = \mathcal{T} \). The case \( \mathcal{L} \) is a subgroup of the additive group \( \mathcal{T} \) with countably finite elements follows from (B.9) and (B.10). □

**Lemma B.8.** If \( X(t) = (X_1(t), \ldots, X_d(t)), t \in \mathcal{T} \) is a \( \mathbb{R}^l \)-valued Gaussian process and let \( (Y, X(t)), t \in \mathcal{T} \) be jointly Gaussian with \( v = \text{Var}(Y) > 0 \) defined on a probability space \( (\Omega, \mathcal{F}, \mathbb{P}) \). The law of \( X \) under the probability measure \( \hat{\mathbb{P}}_v(A) = \mathbb{E}\{e^{Y - v/2}I(A)\} \), \( A \in \mathcal{F} \) is the same as that of \( X + C \) under \( \mathbb{P} \), where

\[
C(t) = (\text{Cov}(X_1(t), Y), \ldots, \text{Cov}(X_d(t), Y)), \quad t \in \mathcal{T}.
\]

Proof of Lemma B.8 The claim of this lemma is well-known, we give few details below. Given \( t_1, \ldots, t_n \in \mathcal{T} \) we calculate the df \( W = (X(t_1), \ldots, X(t_n)) \) under \( \hat{\mathbb{P}}_v \) by exponential tilting of \( (X(t_1), \ldots, X(t_n)) \) with respect to \( Y \). It is well-known that exponential tilting of multivariate Gaussian df is again a multivariate Gaussian, see for instance [21][Lem 6.1]. The only thing that changes under the exponential tilting is the trend which can be calculated as in the afore-mentioned lemma for each component separately, hence the proof is complete.

We sketch next an alternative proof. First note that for any \( k \times 1 \) real matrix \( M \) and all \( B \in \mathcal{B}(\mathbb{R}^k), k \geq 1 \)

\[
\mathbb{E}\{e^{Y - v/2}I(MY \in B)\} = \hat{\mathbb{P}}_v\{MY + Mv \in B\}.
\]

Since we can write \( W = W - MY + MY \) where \( W - MY, MY \) are independent Gaussian random vector with \( M \) a \( nd \times 1 \) real matrix which can be determined explicitly, then by the above identity and the independence of both random vectors, for all \( B \in \mathcal{B}(\mathbb{R}^{nd}) \)

\[
\mathbb{E}\{e^{Y - v/2}I(W \in B)\} = \hat{\mathbb{P}}_v\{W - MY + MY + Mv \in B\} = \hat{\mathbb{P}}_v\{W + Mv \in B\}.
\]

Hence the proof follows by calculating \( M \) explicitly. □
