THE GENERICITY THEOREM FOR THE ESSENTIAL DIMENSION OF TAME STACKS

GIULIO BRESCIANI AND ANGELO VISTOLI

Abstract. Let $X$ be a regular tame stack. If $X$ is locally of finite type over a field, we prove that the essential dimension of $X$ is equal to its generic essential dimension, this generalizes a previous result of P. Brosnan, Z. Reichstein and the second author. Now suppose that $X$ is locally of finite type over a 1-dimensional local noetherian domain $R$ with fraction field $K$ and residue field $k$. We prove that $\text{ed}_k X_k \leq \text{ed}_K X_K$ if $X \to \text{Spec} R$ is smooth and $\text{ed}_k X_k \leq \text{ed}_K X_K + 1$ in general.

1. Introduction, and the statement of the main theorem

Let $k$ be a field, $X \to \text{Spec} k$ an algebraic stack, $\ell$ an extension of $k$, $\xi \in X(\ell)$ an object of $X$ over $\ell$. If $k \subseteq L \subseteq \ell$ is an intermediate extension, we say, very naturally, that that $L$ is a field of definition of $\xi$ if $\xi$ descends to $L$. The essential dimension $\text{ed}_k \xi$, which is either a natural number or $+\infty$, is the minimal transcendence degree of a field of definition of $\xi$. If $X$ is of finite type then $\text{ed}_k \xi$ is always finite.

This number $\text{ed}_k \xi$ is a very natural invariant, which measures, essentially, the number of independent parameters that are needed for defining $\xi$. The essential dimension $\text{ed}_k X$ of $X$ is the supremum of the essential dimension of all objects over all extensions of $k$ (if $X$ is empty then $\text{ed}_k X$ is $-\infty$). This number is the answer to the question “how many independent parameters are needed to define the most complicated object of $X$?”. For example, this is a very natural question for the stack $\mathcal{M}_g$ of smooth projective curves of genus $g$.

Essential dimension was introduced for classifying stacks of finite groups in [BR97], with a rather more geometric language. Since then it has been actively investigated by many mathematicians. It has been studied for classifying stacks of positive dimensional algebraic group starting from [Rei00], and for more general classes of geometric and algebraic objects in [BRV07]. See [BF03, BRV11, Rei10, Mer13] for an overview of the subject.

Suppose that $X$ is an integral algebraic stack which is locally of finite type over $k$. We can define the generic essential dimension $\text{ged}_k X$ (see [BRV11] Definition 3.3) as the supremum of all $\text{ed}_k \xi$ taken over all $\xi \in X(\ell)$ such that the associated morphism $\xi : \text{Spec} \ell \to X$ is dominant. For example, if $X$ has finite inertia and $X \to M$ is its moduli space, then $M$ is an integral scheme over $K$; if $k(M)$ is its field of rational functions, the pullback $X_{k(M)} \to \text{Spec} k(M)$ is a gerbe (the generic
gerbe of $X$), and
\[ \text{ged}_k X = \text{ed}_{k(M)} X_{k(M)} + \dim M. \]
So, if a generic object of $X$ has trivial automorphism group, then
\[ \text{ged}_k X = \dim M = \dim X. \]

P. Brosnan, Z. Reichstein and the second author proved two results linking $\text{ed}_k X$ and $\text{ed}_{k(M)} X_{k(M)}$.

1. The genericity theorem (see [BRV07, BRV18, BRV11, RV13]) says that if $X$ is a smooth integral tame Deligne–Mumford stack over $k$, then $\text{ed}_k X = \text{ged}_k X$.

2. If $R$ is a DVR with quotient field $K$ and residue field $k$, and $X \to \text{Spec} R$ is a finite tame étale gerbe, then $\text{ed}_k X_k \leq \text{ed}_K X_K$. This was proved in [BRV11, BRV18] (the proof in the first paper did not work when $R$ had mixed characteristics).

(1) plays a pivotal role in the calculation of the essential dimension of many stacks of geometric interest, such as stacks of smooth or stable curves, stacks of principally polarized abelian varieties [BRV11], coherent sheaves on smooth curves [BDH18], quiver representations [Sca20] and polarized K3 surfaces [Gao20].

In this paper we extend both these results to weakly tame stacks, in a somewhat more general form.

Tame stacks have been defined by D. Abramovich, M. Olsson and the second author in [AOV08]. They are stacks with finite inertia, whose automorphism group schemes for objects over a field are linearly reductive. In characteristic 0 these are the Deligne–Mumford stacks with finite inertia; but in positive characteristic they are not necessarily Deligne–Mumford, as there exist finite group schemes that are linearly reductive but not reduced, such as $\mu_p$ in characteristic $p$; and étale finite group schemes are linearly reductive if and only if their order is prime to the characteristic.

We define weakly tame stacks as algebraic stacks, in the sense of [LMB00], whose automorphism group schemes for objects over a field are finite and linearly reductive, but whose inertia is not necessarily finite.

**Theorem 1.1.** Let $X$ be a regular integral weakly tame stack, which is locally of finite type over a field $k$. Then
\[ \text{ed}_k X = \text{ged}_k X. \]

**Theorem 1.2.** Let $S$ be a regular, integral, and locally noetherian scheme, $X$ an integral, weakly tame stack, $X \to S$ a smooth morphism. If $s \in S$ a point with residue field $k(s)$, then
\[ \text{ed}_{k(s)} X_{k(s)} \leq \text{ged}_{k(S)} X_{k(S)}. \]

**Theorem 1.3.** Let $X$ be a regular integral weakly tame stack, which is locally of finite type over a local noetherian 1-dimensional domain $R$ with fraction field $K$ and residue field $k$. Then
\[ \text{ed}_k X_k \leq \text{ged}_K X_K + 1. \]

Theorem 1.1 generalizes (1) above. Theorem 1.2 generalizes (2) above; not because $S$ is not assumed to be the spectrum of a DVR (in fact, the general case easily reduces to this), but mostly because $X$ is not assumed to be a gerbe over $S$. 
Theorem 1.3 is, as far as we know, the first result comparing essential dimensions in mixed characteristic without smoothness assumptions. Theorem 1.2 also implies a slightly weaker version of Theorem 1.1 in which the morphism $X \to \text{Spec } k$ is assumed to be smooth.

Our approach to the proof of the genericity theorem is very different from those in the references above. The main tool is a new arithmetic valuative criterion for properness of morphisms of tame stacks (Theorem 2.1), which was proved, in a slightly weaker form, by the first author in [Bre21] in characteristic 0. The proof of the general case will appear in [BV].

2. Proofs of the theorems

Let us start with some preliminary results.

An arithmetic valuative criterion for tame algebraic stacks. A basic example of tame stacks is root stacks (see [AGV08] Appendix B2). We will need this in the following situation. Let $R$ be a DVR with uniformizing parameter $\pi$ and residue field $k \coloneqq R/(\pi)$. If $n$ is a positive integer, we will denote by $\sqrt[n]{\text{Spec } R}$ the $n$th root of the Cartier divisor $\text{Spec } k \subseteq \text{Spec } R$. It is a stack over $\text{Spec } R$, such that given a morphism $\phi: T \to \text{Spec } R$, the groupoid of liftings $T \to \sqrt[n]{\text{Spec } R}$ is equivalent to the groupoid whose objects are triples $(L, s, \alpha)$, where $L$ is an invertible sheaf on $T$, $s \in L(T)$ is a global section of $L$, and $\alpha$ is an isomorphism $L^{\otimes n} \cong \mathcal{O}_T$, such that $\alpha(s^{\otimes n}) = \phi^\sharp(\pi)$. Alternatively, $\sqrt[n]{\text{Spec } R}$ can be described as the quotient stack $[\text{Spec } R[t]/(t^n - \pi)/\mu_n]$, where the action of $\mu_n$ on $\text{Spec } R[t]/(t^n - \pi)$ is by multiplication on $t$. The morphism $\rho: \sqrt[n]{\text{Spec } R} \to \text{Spec } R$ is an isomorphism outside of $\text{Spec } k \subseteq \text{Spec } R$, while the reduced fiber $\rho^{-1}(\text{Spec } k)_{\text{red}}$ is non-canonically isomorphic to the classifying stack $\mathcal{B}_k\mu_n$.

Our version of the valuative criterion is as follows.

**Theorem 2.1.** Let $f: X \to S$ be a proper morphism of finite type where $S$ is a scheme and $X$ a tame stack, $R$ a DVR with quotient field $K$. Suppose that we have a 2-commutative square

$$
\begin{array}{ccc}
\text{Spec } K & \longrightarrow & X \\
\downarrow & & \downarrow f \\
\text{Spec } R & \longrightarrow & S
\end{array}
$$

Then there exists a unique positive integer $n$ and a representable lifting $\sqrt[n]{\text{Spec } R} \to X$, unique up to a unique isomorphism, of the given morphism $\text{Spec } R \to S$, making the diagram

$$
\begin{array}{ccc}
\text{Spec } K & \longrightarrow & X \\
\downarrow & & \downarrow \\
\sqrt[n]{\text{Spec } R} & \longrightarrow & \text{Spec } R \longrightarrow S
\end{array}
$$

2-commutative.

The proof of the theorem will appear in [BV].

**Definition 2.2.** In the situation of Theorem 2.1, we call the integer $n$ the loop index of the morphism $\text{Spec } K \to X$ at the place associated with $R \subseteq K$. If the loop index is 1, we say that $\text{Spec } K \to X$ is untangled.
Lemma 2.3. Let $R \subseteq R'$ be a weakly ramified extension of DVRs, and let $K \subseteq K'$ be the fraction fields of $R$ and $R'$ respectively. Given a diagram

$$
\begin{array}{c}
\text{Spec } K \\
\downarrow \\
\text{Spec } R
\end{array} \longrightarrow \begin{array}{c}
X \\
\downarrow f \\
S
\end{array}
$$

with the same hypotheses as in Theorem 2.1, if the composite morphism $\text{Spec } K' \to \text{Spec } K \to X$ is untangled, then $\text{Spec } K \to X$ is also untangled.

Proof. This follows immediately from the fact that if $R \subseteq R'$ is weakly unramified, then the induced morphism $\sqrt{\text{Spec } R'} \to \sqrt{\text{Spec } R}$ is representable, so that $\text{Spec } K \to X$ and Spec $K' \to X$ have the same loop index. ♠

Some easy commutative algebra. In the proof of the main theorem we will also use the following well known facts, for which we do not know a reference.

Lemma 2.4. Let $B$ be a regular local ring of dimension, $b \in m_B \setminus \{0\}$. There exists a quotient $\phi : B \to R$, where $R$ is a DVR, such that $\phi(b) \neq 0$. Furthermore, if $b \in m_B \setminus m_B^2$ we can find such a $\phi : B \to R$ with $\phi(b) \in m_R \setminus m_R^2$.

Proof. If $\dim B = 1$ then we take $B = R$. If $\dim B \geq 2$ we proceed by induction on $\dim B$; it is enough to show that there exists $c \in m_B \setminus m_B^2$ such that $b \notin (c)$, and $b \notin (c) + m_B^2$ if $b \in m_B \setminus m_B^2$.

If $b \in m_B \setminus m_B^2$ it is enough to chose $c \in m_B$ so that the images of $b$ and $c$ in $m_B/m_B^2$ are linearly independent.

In general, we know that the ring $B$ is a UFD. Let $x$ and $y$ be elements of $m_B$, whose images in $m_B/m_B^2$ are linearly independent; the elements $x + y^d$, for $d \geq 1$ are irreducible. We claim that they are pairwise not associate: this implies that only finitely many of them can divide $b$, which implies the claim.

To check this, assume that $x + y^e = u(x + y^d)$ for some $u \in B \setminus m_B$ with $e > d > 0$. Reducing modulo $(y)$ we see that $u \equiv 1 \pmod y$, while reducing modulo $(x)$ and dividing by $y^d$, which is possible because $A/(x)$ is a domain, we get $u \equiv y^{e-d} \pmod x$, and this is clearly a contradiction. ♠

Lemma 2.5. Let $A \to B$ be a local homomorphism of local noetherian regular rings with $A$ a DVR, assume that $m_A/m_A^2 \to m_B/m_B^2$ is injective. There exists a surjective homomorphism $B \to R$ such that $A \to R$ is an injective, weakly unramified extension of DVRs.

Here by weakly unramified we mean that the ramification index is 1; in other words, a uniformizing parameter of $A$ maps to a uniformizing parameter of $R$.

The proof is immediate from Lemma 2.4.

Lemma 2.6. Let $U$ be a noetherian integral regular scheme, $V \subseteq U$ a nonempty open subset, $u \in U$. There exist a morphism $f : \text{Spec } R \to U$, where $R$ is a DVR, which sends the closed point of $\text{Spec } R$ to $u$, inducing an isomorphism $k(u) \simeq R/m_R$, and the generic point into $V$.

Proof. If $u \in V$, this is clear. If not, call $I \subseteq \mathcal{O}_{U,u}$ the radical ideal of the complement of the inverse image of $V$ in $\text{Spec } \mathcal{O}_{U,u}$, take $b \in I \setminus \{0\}$, and apply Lemma 2.4. ♠
Lemma 2.7. Let $A$ be a local noetherian 1-dimensional domain with fraction field $K$, $R$ a DVR with quotient field $L$ and residue field $\ell$. Let $A \subseteq R$ be a local embedding, inducing embeddings $k \subseteq \ell$ and $K \subseteq L$. Then
\[ \text{trdeg}_k \ell \leq \text{trdeg}_K L. \]

Proof. If $A$ is a DVR, this is [BRV18, Lemma 2.1] (there it is assumed that $A \subseteq R$ is weakly unramified, but this is not in fact used in the proof). In the general case, consider the normalization $A$ of $A$ in $K$, and its localization $A'$ at the maximal ideal $m_R \cap A$. By the Krull–Akizuki theorem $A$ is a Dedekind domain, so $A'$ is a DVR.

Call $k'$ the residue field of $A'$; we have a factorization $k \subseteq k' \subseteq \ell$, and $k'$ is algebraic over $k$, so that $\text{trdeg}_k \ell = \text{trdeg}_k k'$, so the general case reduces to the case of an extension of DVRs. ♣

Lemma 2.8. Let $k$ be a field, $R$ a DVR containing $k$, with residue field $\ell$ and fraction field $K$. Assume $\text{trdeg}_k \ell < +\infty$. Then
\[ \text{trdeg}_k \ell < \text{trdeg}_K k. \]

Proof. Suppose $u_1, \ldots, u_n$ are elements of $R$ whose images in $\ell$ are algebraically independents over $k$. If $\pi$ is a uniformizing parameter for $R$, it is immediate to show that $\pi, u_1, \ldots, u_n$ are algebraically independent over $k$. ♣

The proofs. Let us proceed with the proof of the theorems. For all of them, the first step is to reduce to the case in which $X$ is tame; in other words, show that we may assume that $X$ has finite inertia. The reduction is done almost word by word as in the beginning of the proof of [BRV07, Theorem 6.1], and will be omitted here. So we can assume that $X$ is tame. The theorems are easy consequences of the following.

Let $X \to S$ be a dominant morphism locally of finite type, where $X$ is a regular integral tame stack, $S$ an integral locally noetherian scheme. Assume either that
(1) $S$ is locally of finite type over a field $k$, or
(2) $S$ has dimension 1, or
(3) $X \to S$ is smooth.

Lemma 2.9. Let $\ell$ be a field, $\xi: \text{Spec} \ell \to X$ a morphism; call $s \in S$ the image of the composite $\text{Spec} \ell \xrightarrow{\xi} X \to S$. Then $\ell$ is an extension of $k(s)$, and we can think of $\xi$ as a morphism $\text{Spec} \ell \to X_{k(s)}$. Assume that $s$ is not the generic point of $S$.
(1) If $S$ is locally of finite type over a field $k$, there exists a generalization $s' \neq s$ of $s$ such that
\[ \text{ed}_k \xi \leq \text{ed}_k X_{k(s')} . \]
(2) If $S$ has dimension 1, then
\[ \text{ed}_{k(s)} \xi \leq \text{ed}_{k(S)} X_{k(S)} + 1 . \]
(3) If $X \to S$ is smooth, there exists a generalization $s' \neq s$ of $s$ such that
\[ \text{ed}_{k(s)} \xi \leq \text{ed}_{k(s')} X_{k(s')} . \]

Proof. By [LMB08, Théorème 6.3] there exists a regular scheme $U$ and a smooth morphism $U \to X$ with a lifting $\text{Spec} k \to U$ of $\xi$; if we call $u \in U$ the image of $\text{Spec} \ell \to U$, we can replace $\ell$ with $k(u)$, and assume $\ell = k(u)$. 

\[ \text{ed}_k \xi \leq \text{ed}_k X_{k(s')} . \]

(2) If $S$ has dimension 1, then
\[ \text{ed}_{k(s)} \xi \leq \text{ed}_{k(S)} X_{k(S)} + 1 . \]
(3) If $X \to S$ is smooth, there exists a generalization $s' \neq s$ of $s$ such that
\[ \text{ed}_{k(s)} \xi \leq \text{ed}_{k(s')} X_{k(s')} . \]

Proof. By [LMB08, Théorème 6.3] there exists a regular scheme $U$ and a smooth morphism $U \to X$ with a lifting $\text{Spec} k \to U$ of $\xi$; if we call $u \in U$ the image of $\text{Spec} \ell \to U$, we can replace $\ell$ with $k(u)$, and assume $\ell = k(u)$. 

\[ \text{ed}_k \xi \leq \text{ed}_k X_{k(s')} . \]

(2) If $S$ has dimension 1, then
\[ \text{ed}_{k(s)} \xi \leq \text{ed}_{k(S)} X_{k(S)} + 1 . \]
(3) If $X \to S$ is smooth, there exists a generalization $s' \neq s$ of $s$ such that
\[ \text{ed}_{k(s)} \xi \leq \text{ed}_{k(s')} X_{k(s')} . \]
In cases (1) and (2), we call $V$ the inverse image of $S \setminus \{s\}$ in $U$, and we construct a morphism $\Spec R \to U$ as in Lemma 2.6 such that the composition $\Spec R \to S$ maps the generic point to a generalization $s' \neq s$ of $s$.

In case (3) $X \to S$ is smooth, so $U \to S$ is also smooth, and $S$ is regular; in this case we start by choosing a point $s'$ in $S$ such that $s \in \{s'\}$, and $\mathcal{O}_{\{s'\}, s}$ is a DVR. Then we apply Lemma 2.6 to the embedding $\mathcal{O}_{\{s'\}, s} \subseteq \mathcal{O}_{U', u}$, where $U'$ is the inverse image of $\{s'\}$ in $U$, and obtain a morphism $\Spec R \to U$ such that the composition $\Spec R \to S$ maps the generic point to $s'$ and $\mathcal{O}_{\{s'\}, s} \subseteq R$ is weakly unramified.

Let $M$ be the moduli space of $X$, with the resulting factorization $X \to M \to S$. Let $K$ be the fraction field of $R$; there exists an intermediate extension $k(s') \subseteq K_1 \subseteq K$ with

$$\trdeg_{k(s')} K_1 \leq \ed_{k(s')} X_{k(s')}$$

and a factorization $\Spec K \to \Spec K_1 \to X$. Write $R_1 = R \cap K_1$; clearly $K_1 \not\subseteq R$, so that $R_1$ is a DVR; call $\ell_1 \subseteq \ell$ its residue field. The composite $\Spec R \to M$ factors through $\Spec R_1$, and we get a commutative diagram

$$\begin{array}{ccc}
\Spec K & \longrightarrow & \Spec K_1 \\
\downarrow & & \downarrow \\
\Spec R & \longrightarrow & \Spec R_1 \\
\downarrow & & \downarrow \\
M & \longrightarrow & S
\end{array}$$

By Theorem 2.1 since $X \to M$ is proper then there exists an integer $n$ and a representable extension

$$\sqrt[n]{\Spec R_1} \to X$$

of the morphism $\Spec K_1 \to X$. Since $X \to S$ is separated, the diagram

$$\begin{array}{ccc}
\sqrt[n]{\Spec R} & \longrightarrow & \sqrt[n]{\Spec R_1} \\
\downarrow & & \downarrow \\
\Spec R & \longrightarrow & \Spec R_1 \\
\downarrow & & \downarrow \\
M & \longrightarrow & S
\end{array}$$

commutes. If we chose a lifting $\Spec \ell \to \sqrt[n]{\Spec R}$ of the embedding $\Spec \ell \subseteq \Spec R$ we obtain a factorization

$$\Spec \ell \to \left(\Spec \ell_1 \times_{\Spec R_1} \sqrt[n]{\Spec R}\right)_{\text{red}} = B_{\ell_1, \mu_n} \to X$$

of $\xi$. Since the essential dimension of $B_{\ell_1, \mu_n}$ over $\ell_1$ is at most 1, we get that

$$\ed_{k(s)} \xi \leq \trdeg_{k(s)} \ell_1 + 1.$$ 

If $S$ is locally of finite type over a field $k$, then by Lemma 2.8 applied to $R_1/k$ we obtain

$$\trdeg_{k(s)} \ell_1 + 1 \leq \trdeg_{k(s')} K_1 + 1$$

$$\leq \trdeg_{k(s')} K_1 + \trdeg_k k(s') - \trdeg_k k(s);$$

Since $\ed_k \xi = \ed_{k(s)} \xi + \trdeg_k k(s)$ and $\ed_k X_{k(s')} = \ed_{k(s')} X_{k(s')} + \trdeg_k k(s')$, we obtain the thesis.

If $S$ has dimension 1, then $s'$ is the generic point and by Lemma 2.7 applied to the embedding $\mathcal{O}_{S, s} \subseteq R_1$ we obtain the desired inequality

$$\trdeg_{k(s)} \ell_1 + 1 \leq \trdeg_{k(S)} K_1 + 1 \leq \ed_{k(S)} X_{k(S)} + 1.$$
If $X \to S$ is smooth, then $\mathcal{O}_{\{s\}, x}$ is a DVR and $R$ is weakly unramified over it, and since $\mathcal{O}_{\{s\}, x} \subseteq R_1 \subseteq R$ then $R$ is weakly unramified over $R_1$, too. We can thus assume that $n = 1$, by Lemma 2.3, so that $\mathcal{O}_{t, \mu_n} = \mathcal{O}_\ell$, and by Lemma 2.7 applied to the embedding $\mathcal{O}_{\{s\}, x} \subseteq R_1$ we get

$$\operatorname{ed}_k(s) \xi \leq \operatorname{trdeg}_{k(s)}(\ell_1) \leq \operatorname{trdeg}_{k(s)}(\ell_1) K_1 \leq \operatorname{ed}_k(s') X_{k(s')}$$

as claimed.

$\diamondsuit$

The proof of Theorem 1.1. We apply the above to the case in which $S = M$ is the moduli space of $X$. Let $\xi : \operatorname{Spec} \ell \to X$ be a morphism; we need to show that $\operatorname{ed}_k(\ell) \leq \operatorname{gcd}_k X$. Call $s \in M$ the image of $\xi$; if $s$ is the generic point of $M$, the result follows immediately.

If not, by induction on the codimension of $\{s\}$ in $M$ we may assume that the inequality holds for all morphisms $\operatorname{Spec} \ell' \to X$, such that the codimension of the closure of the image $s' \in M$, which equals $\dim M - \operatorname{trdeg}_k k(s')$, is less than the codimension of $\{s\}$. In particular, this holds for morphisms as above, such that $s'$ is a generalization of $s$ different from $s$.

From Lemma 2.9 we get a generalization $s' \neq s$ of $s$ and an inequality

$$\operatorname{ed}_k(s) \xi \leq \operatorname{ed}_k(s') X_{k(s')}.$$  

By inductive hypothesis, $\operatorname{ed}_k X_{k(s')} \leq \operatorname{gcd}_k X$, hence we conclude.

$\Box$

The proof of Theorem 1.2. By Theorem 1.1 applied to $X_{k(S)} \to \operatorname{Spec} k(S)$, it enough to prove that $\operatorname{ed}_k X_{k(S)} \leq \operatorname{ed}_k X_{k(S)}$ for any $s \in S$. Once again we proceed by induction on the codimension of $\{s\}$ in $S$, the case of codimension 0 being obvious. If this is positive, given a morphism $\operatorname{Spec} \ell \to X_{k(s)}$, Lemma 2.9 gives us a generalization $s'$ of $s$ with $\operatorname{ed}_k(s) \leq \operatorname{ed}_k(s') X_{k(s')}$, and the theorem follows.

The proof of Theorem 1.3. By Theorem 1.1 applied to $X_K \to \operatorname{Spec} K$, it enough to prove the inequality $\operatorname{ed}_K X_K \leq \operatorname{ed}_K X_K + 1$, which follows immediately from Lemma 2.9.
