**JULIA SETS AND GEOMETRICALLY FINITE MAPS OVER FINITE EXTENSIONS OF THE $p$-ADIC FIELD**

SHILEI FAN, LINGMIN LIAO, HONGMING NIE, AND YUEFEI WANG

Abstract. Let $K$ be a finite extension of the field $\mathbb{Q}_p$ of $p$-adic numbers, and $\phi \in K(z)$ be a rational map of degree at least 2. We prove that the $K$-Julia set of $\phi$ is the natural restriction of the $\mathbb{C}_p$-Julia set, provided that the critical orbits are well-behaved. Moreover, under further assumption that $\phi$ is geometrically finite, we prove that the dynamics on the $K$-Julia set of $\phi$ is a countable state Markov shift.

1. INTRODUCTION

1.1. Motivation and background. In recent decades, $p$-adic and non-archimedean dynamics have been attracting much attention. On the one hand, many $p$-adic analogues of classical complex dynamics results already appear in the literature. A Siegel’s linearization theorem for non-Archimedean fields has been presented in a paper of Herman and Yoccoz [28], and a non-Archimedean Montel’s theorem appears in a work of Hsia [29] (see also a paper of Favre, Kiwi, and Trucco [24]). Some other significant contributions in this direction arise in the Ph.D. theses of Benedetto [4] and Rivera-Letelier [39] and in Kiwi’s descriptions [34, 35] of the dynamics for lower degree rational maps. On the other hand, the ergodic aspect of the aforementioned dynamics develops intensively. The ergodic decomposition starts with an early result of Oselies and Zieschang [38], and then the $p$-adic entropy shows up in a study of Lind and Ward [37]. Later, some ergodic criteria for uniform continuous functions gather in a paper of Anashin [1]. The equilibrium measure on the related Berkovich projective line emerges in works of Baker and Rumely [2], Chambert-Loir [12], and Favre and Rivera-Letelier [25].

For a fixed prime number $p \geq 2$, denote by $\mathbb{Q}_p$ the field of $p$-adic numbers and by $\mathbb{C}_p$ the completion of an algebraic closure of $\mathbb{Q}_p$. Let $K$ be a finite extension of $\mathbb{Q}_p$. Write $\mathbb{P}^1_K$ and $\mathbb{P}^1_{\mathbb{C}_p}$ the projective lines over $K$ and $\mathbb{C}_p$, respectively. In this paper, we study rational maps $\phi \in K(z)$ as dynamical systems on $\mathbb{P}^1_K$ and on $\mathbb{P}^1_{\mathbb{C}_p}$.

The rational map $\phi$ partitions naturally the space $\mathbb{P}^1_{\mathbb{C}_p}$ into two parts: the Fatou set $F_{\mathbb{C}_p}(\phi)$ on which the iterations $\phi^n$ act equicontinuously and the Julia set $J_{\mathbb{C}_p}(\phi)$ (the complement

Key words and phrases. $p$-adic dynamics, Julia set, geometrically finite, countable state Markov chain.
of $F_{\mathbb{C}_p} (\phi)$ on which the iterations $\phi^n$ act chaotically. One main task in non-archimedean dynamics is to depict these two sets and further understand the relevant dynamics. For $F_{\mathbb{C}_p} (\phi)$, Benedetto [5] proved a no wandering domains result, and Rivera-Letelier [39] gave a classification of the Fatou components. For $J_{\mathbb{C}_p} (\phi)$, applying aforementioned Montel’s theorem, Hsia [29] obtained that $J_{\mathbb{C}_p} (\phi)$ is contained in the closure of the periodic points. Then assuming $\phi$ has a repelling periodic point, Bézivin [11] proved that $J_{\mathbb{C}_p} (\phi)$ is the closure of the repelling periodic points.

In $\mathbb{P}_K^1$, the Julia set $J_K (\phi)$ is the region on which the sequence $\{\phi^n\}_{n \geq 1}$ is not equicontinuous with respect to the spherical metric. Although $J_K (\phi)$ is a subset of $J_{\mathbb{C}_p} (\phi) \cap \mathbb{P}_K^1$ by definition, the equality of these two sets is elusive. Nevertheless, all periodic points in $J_{\mathbb{C}_p} (\phi)$ are repelling (e.g., see [6, Proposition 1.1]), which rules out a severe obstruction to preserve the consistency of the Julia points occurring in complex/real dynamics. (A precise example in the latter is the polynomial $P(z) = z^2 - z \in \mathbb{R}[z]$ acting on $\mathbb{P}_C^1$ and $\mathbb{P}_R^1$, respectively, for which the point 0 is a parabolic fixed point in $\mathbb{P}_C^1$ attracting all the nearby points in $\mathbb{P}_R^1$ and hence 0 is contained in the $\mathbb{C}$-Julia set but not in the $\mathbb{R}$-Julia set of $P$.) It is reasonable to expect an affirmative answer of the following conjecture.

**Conjecture 1.1.** Let $\phi \in K(z)$ be a rational map. Then

$$J_{\mathbb{C}_p} (\phi) \cap \mathbb{P}_K^1 = J_K (\phi).$$

If $\phi$ has degree less than 2, then Conjecture 1.1 follows immediately from the simple behavior of the iterations $\phi^n$ (see [9, Section 1.5]). In this paper, we first explore the above relation on Julia sets provided that $\phi$ has degree at least 2. We will show in Theorem 1.2 that Conjecture 1.1 holds under certain conditions on the critical orbits.

Once the Fatou and Julia sets are at our disposal, we can attempt to investigate the dynamical behaviors on such sets. In general, we may understand the dynamics by stating some fundamental properties such as the ergodicity and the linearization, but a detailed description of the behaviors for orbits seems improbable. However, this is not the case when we study the dynamics of $\phi \in K(z)$ on $\mathbb{P}_K^1$, for which, in many cases, we can employ well-known dynamical models to characterize the Fatou and Julia dynamics of $\phi$.

For the dynamics on Fatou set, Fan and the second author [16] proved a minimal decomposition result for the polynomials defined over $\mathbb{Z}_p$, and showed that the dynamics on each minimal component is topologically conjugate to an odometer. Such a decomposition also appears for other maps such as convergent power series on the integral ring of a finite extension of $\mathbb{Q}_p$ [18], rational maps over $\mathbb{Q}_p$ of degree one [13], and rational maps over $\mathbb{Q}_p$ having good reduction [14]. The first and second authors provided concrete examples of the Chebyshev polynomials on $\mathbb{Z}_2$ and the square maps on $\mathbb{Z}_p$ in [19] and [20], respectively.

For the dynamics on Julia set, a classical example is the polynomial $(z^p - z)/p$ on $\mathbb{Z}_p$, which turns out to be topologically conjugate to the full shift on the symbolic space with $p$ symbols, see [47]. This property also holds for quadratic polynomials over $\mathbb{Q}_p$, see [45]. In the paper [17], the authors proved that any $p$-adic transitive weak repeller is topologically conjugate to a subshift of finite type on an alphabet of finitely many symbols. Such $p$-adic transitive weak repellors include expanding polynomials and rational maps over $\mathbb{Q}_p$. We refer to [21] and [22] for the concrete example $az + 1/z$.

In this paper, we also study the dynamics on the Julia set for more general rational maps which are out of range of the previous work of [17]. We will prove in Theorem 1.3 that such a dynamical system can be modeled by a countable state Markov shift.

### 1.2. Statement of main results

A critical point $c \in \mathbb{P}_{\mathbb{C}_p}^1$ of $\phi$ is *wild* if $p$ divides the local degree of $\phi$ at $c$. Otherwise, we say that $c$ is *tame*. The point $c$ is *recurrent* if it is accumulated by its forward orbit under $\phi$. As we will see in Section 3.4, the inclusion of the closures of
forward orbits induces an equivalence relation on the critical points in $J_{C_p}(\phi)$ together with a partial order $\preceq$ on the resulting quotient set $M(\phi)$. Each least element in $(M(\phi), \preceq)$ is called a minimal class.

Our first result asserts that under certain assumptions on the critical orbits, the set $J_K(\phi)$ equals to the restriction of $J_{C_p}(\phi)$ on $\mathbb{P}_K^n$.

**Theorem 1.2.** Let $\phi \in K(z)$ be a rational map of degree at least 2. Suppose that

1. $\phi$ has no wild recurrent critical points in $J_{C_p}(\phi) \cap \mathbb{P}_K^n$, and
2. each minimal class in $(M(\phi), \preceq)$ has at most two representations in $J_{C_p}(\phi) \cap \mathbb{P}_K^n$.

Then

$$J_{C_p}(\phi) \cap \mathbb{P}_K^n = J_K(\phi).$$

As aforementioned, one inclusion $J_K(\phi) \subset J_{C_p}(\phi) \cap \mathbb{P}_K^n$ in Theorem 1.2 follows unconditionally from the definitions. We focus on the reverse inclusion, where the difficulty arises from the complexity of critical orbits in $J_{C_p}(\phi) \cap \mathbb{P}_K^n$. Even under the assumptions in Theorem 1.2 the argument is far from straightforward. We provide an elaborate analysis on the orbits of disks near the critical points, and deduce the conclusion, in most cases, by an argument on the existence of repelling periodic points.

We remark here on the assumptions in Theorem 1.2. The absence of wild recurrent critical points in $J_{C_p}(\phi) \cap \mathbb{P}_K^n$ guarantees a no wandering domains result and controls the ratios of diameters of certain disks. Though most of analysis works for general case, the one concerning the existence of repelling periodic points requires the restriction on the numbers of representations for the minimal classes. Loosely speaking, for each disk in a fixed sphere close to a critical point, such a restriction controls uniformly the “location” (the first critical point covered by the orbit of the disk) and the “time” (the number of iteration to cover the first critical point). Without this restriction, the “location” and the “time” may vary simultaneously, which is excluded from our arguments.

A special class of rational maps satisfying the assumptions in Theorem 1.2 is the geometrically finite maps $\phi \in K(z)$ of which every critical point in $J_{C_p}(\phi) \cap \mathbb{P}_K^n$ has a finite forward orbit. For such a map $\phi$, consider the set $C_{K_p}(\phi)$ of the critical points of $\phi$ in $J_{C_p}(\phi) \cap \mathbb{P}_K^n$, and denote by $GO_K(\text{Crit}^*_K(\phi))$ the grand orbit of $\text{Crit}^*_K(\phi)$ in $\mathbb{P}_K^n$. Following Theorem 1.2 and the invariance of $J_{C_p}(\phi)$, we conclude that $GO_K(\text{Crit}^*_K(\phi)) \subset J_K(\phi)$. Write

$$I_K(\phi) := J_K(\phi) \setminus GO_K(\text{Crit}^*_K(\phi)).$$

Our next result characterizes the dynamics of $\phi$ on $I_K(\phi)$.

**Theorem 1.3.** Let $\phi \in K(z)$ be a geometrically finite rational map of degree at least 2. Then there exist a countable state Markov shift $(\Sigma_A, \sigma)$ and a bijection $h : J_K(\phi) \to \Sigma_A$ such that $(I_K(\phi), \phi)$ is topologically conjugate to $(h(I_K(\phi)), \sigma)$ via $h$.

We mention here that if $\text{Crit}^*_K(\phi) = \emptyset$, then the shift space $\Sigma_A$ has finite states, which is a special case of a result in [17] for $p$-adic weak repellers. The presence of a critical point in $J_K(\phi)$ implies that $\phi$ is not expanding on $J_K(\phi)$. To construct the states of the Markov shift, we track the orbits of countably many open disks near critical points. To illustrate Theorem 1.3 we provide a concrete example whose Gurevich entropy on Julia set is the logarithm of an algebraic number in Section 4.

### 1.3. Strategy of the proofs.

We establish the inclusion $J_{C_p}(\phi) \cap \mathbb{P}_K^n \subset J_K(\phi)$ in Theorem 1.2 in three main steps:

1. First, we work on the points on the boundary of $J_{C_p}(\phi) \cap \mathbb{P}_K^n$ (see Lemma 3.1). The no wandering domains result (Theorem 2.13) implies that any point in $\mathbb{P}_K^n$ close to such a
boundary point is eventually mapped into a periodic component of $F_{C_p}(\phi)$, which breaks the equicontinuity.

Second, for the interior of $J_{C_p}(\phi) \cap \mathbb{P}_K^1$, we reduce to discuss the critical points in $J_{C_p}(\phi) \cap \mathbb{P}_K^1$ (see Proposition 3.4). In this process, we apply a technical lemma (Lemma 3.2) on the orbit of a disk in $\mathbb{P}_K^1$ intersecting $J_{C_p}(\phi) \cap \mathbb{P}_K^1$, where the absence of wild recurrent critical points controls the ratios of diameters for certain disks.

Last, we show that the critical points in $J_{C_p}(\phi) \cap \mathbb{P}_K^1$ are indeed contained in $J_K(\phi)$. To achieve this, we consider natural equivalence classes of critical points in $J_{C_p}(\phi)$ and further reduce our investigation to certain minimal classes (see Proposition 3.6). For each such minimal class, under the assumption on the number of representations, specially in the recurrent case, we prove two crucial results (Propositions 3.8 and 3.10) concerning the existence of repelling (pre)periodic points in desired disks. We then proceed the proof by contradiction. If there is a point contained in $J_{C_p}(\phi) \cap \mathbb{P}_K^1$ but not in $J_K(\phi)$, we verify the assumptions in the aforementioned results and obtain contradictions (see Corollaries 3.9 and 3.11).

To prove Theorem 1.3, applying the local properties of $\phi$, we obtain a cover $\mathcal{P}_0$ of $J_K(\phi)$, each of whose elements is either an open disk on which $\phi$ is bijective, or a critical point. Decompose $\mathcal{P}_0$ along the critical orbits and divide some “larger” disks into “smaller” ones so that in the resulting cover $\mathcal{P}$, an iterated image of any open set is a union of elements in $\mathcal{P}$. Considering the images of elements in $\mathcal{P}$, we obtain a natural (infinite) matrix, and then assign each point in $J_K(\phi)$ a code sequence to obtain a coding map $h$. By the inverse of $\phi$ in each open set in $\mathcal{P}$, we deduce the desired conjugacy via $h$. In particular, in the argument showing bijectivity of $h$, we apply Theorem 1.2 to treat the grand orbit of critical points.

Outline of the paper. In Section 2, we give the relevant preliminaries. In particular, we describe the local dynamics near critical points (see Proposition 2.5) in Section 2.3 and we state an invariance property of the Fatou set (see Lemma 2.8) and a no wandering domains result (see Theorem 2.13) in Sections 2.4 and 2.5.

In Section 3, we prove Theorem 1.2. We first deal with the boundary of $J_{C_p}(\phi) \cap \mathbb{P}_K^1$ in Section 3.2. Then we consider the interior of $J_{C_p}(\phi) \cap \mathbb{P}_K^1$ in Section 3.3. After that, we focus on some minimal equivalence classes in Section 3.4. Finally in Section 3.5, we establish Propositions 3.8 and 3.10 on the existence of repelling periodic points. In particular, Section 3.5.2 is the most technical part, which concerns the recurrent critical points.

Sections 4 and 5 are devoted to describing the Julia dynamics. Section 4 provides a motivation example satisfying the assumption of Theorem 1.3 which contains numerous computations. In particular, Section 4.4 gives the Gurevich entropy for this example. Finally, Section 5 covers the proof of Theorem 1.3. Section 5.1 states a reduced version of Theorem 1.3 and then Section 5.2 finishes the full general version.

Acknowledgements. The authors are grateful to the Department of Mathematics, Zhejiang University, and Shanghai Center for Mathematical Sciences, where part of this paper was written, for their hospitality. They thank Robert Benedetto for discussing the no wandering domains result. SF was partially supported by NSF of China (Grant No. 11971190) and YW was partially supported by NSF of China (Grant No. 11688101)

2. Preliminaries

In this section, we introduce some preliminaries that we will use in the rest of the paper.

2.1. Notation. We set the following notation.
\[ K \quad \text{a finite extension of } \mathbb{Q}_p \]
\[ \pi \quad \text{a uniformizer of } K \]
\[ L \quad \text{the field } K \text{ or } \mathbb{C}_p \]
\[ \text{Crit}_{\mathbb{C}_p}(\phi) \quad \text{the set of the critical points of } \phi \text{ in } \mathbb{P}^1_{\mathbb{C}_p} \]
\[ \text{Crit}_K(\phi) \quad \text{the set of the critical points of } \phi \text{ in } \mathbb{P}^1_K \]
\[ \text{Crit}^{*}_{\mathbb{C}_p}(\phi) \quad \text{the intersection } J_{\mathbb{C}_p}(\phi) \cap \text{Crit}_{\mathbb{C}_p}(\phi) \]
\[ J_{\mathbb{C}_p}(\phi) \quad \text{the intersection } J_{\mathbb{C}_p}(\phi) \cap \mathbb{P}^1_{\mathbb{C}_p} \]
\[ F_{\mathbb{C}_p}(\phi) \quad \text{the intersection } F_{\mathbb{C}_p}(\phi) \cap \mathbb{P}^1_{\mathbb{C}_p} \]
\[ O_{\phi}(x) \quad \text{the forward orbit } \{\phi^n(x)\}_{n \geq 0} \text{ of } x \in \mathbb{P}^1_{\mathbb{C}_p} \text{ under a rational maps } \phi \in \mathbb{C}_p(z). \]

### 2.2. \textit{p}-adic disks.

Let \(| \cdot |_p\) be the natural and non-trivial \(p\)-adic absolute value associated to \(L\). For \(x \in L\) and \(r > 0\), define

\[ D_L(x, r) := \{ z \in L : |z - x|_p < r \} \text{ and } \overline{D}_L(x, r) := \{ z \in L : |z - x|_p \leq r \}. \]

We call \(D_L(x, r)\) (resp. \(\overline{D}_L(x, r)\)) an open (resp. closed) \(L\)-disk. In the projective space \(\mathbb{P}^1_L\), an open \(\mathbb{P}^1_L\)-disk is a set of form either \(D_L(z, r)\) or \(\mathbb{P}^1_L \setminus \overline{D}_L(z, r)\), and a closed \(\mathbb{P}^1_L\)-disk is a set of form either \(\overline{D}_L(z, r)\) or \(\mathbb{P}^1_L \setminus D_L(z, r)\).

Regarding \(\mathbb{P}^1_{\mathbb{C}_p}\) as \(\mathbb{C}_p \cup \{\infty\}\), we introduce the spherical metric on \(\mathbb{P}^1_{\mathbb{C}_p}\) as follows: for \(x, y \in \mathbb{C}_p\),

\[ \rho(x, y) = \frac{|x - y|_p}{\max\{|x|_p, 1\} \max\{|y|_p, 1\}} \]

and

\[ \rho(x, \infty) = \begin{cases} 1, & \text{if } |x|_p \leq 1; \\ 1/|x|_p, & \text{if } |x|_p > 1. \end{cases} \]

Note that for any \(x, y \in \mathbb{P}^1_{\mathbb{C}_p}\), the distance \(\rho(x, y) \leq 1\). Since \(\mathbb{P}^1_L \subset \mathbb{P}^1_{\mathbb{C}_p}\), for \(0 < r \leq 1\), set the disks in metric \(\rho\) as follows:

\[ D_{\mathbb{P}^1_L}(x, r) := \{ y \in \mathbb{P}^1_L : \rho(x, y) < r \} \quad \text{and} \quad \overline{D}_{\mathbb{P}^1_L}(x, r) := \{ y \in \mathbb{P}^1_L : \rho(x, y) \leq r \}. \]

Then \(D_{\mathbb{P}^1_L}(x, r)\) and \(\overline{D}_{\mathbb{P}^1_L}(x, r)\) are \(\mathbb{P}^1_L\)-disks. For a disk \(D \subset \mathbb{P}^1_L\), denote its diameter by

\[ \text{diam}(D) := \sup_{x_1, x_2 \in D} \rho(x_1, x_2). \]

For more details about the spherical metric, we refer to [9] Section 5.1.

### 2.3. \textbf{Analytic functions.}

To simplify notations, in this subsection we write \(\cdot\) for \(|\cdot|_p\), and write \(D(x, r)\) (resp. \(\overline{D}(x, r)\)) for \(D_{\mathbb{C}_p}(x, r)\) (resp. \(\overline{D}_{\mathbb{C}_p}(x, r)\)).

Let \(D \subset \mathbb{C}_p\) be a disk and pick \(x_0 \in D\), a map \(f : D \to L\) is \textit{analytic} if it can be written as a power series

\[ f(z) = \sum_{n=0}^{\infty} a_n (z - x_0)^n \in \mathbb{C}_p[[z - x_0]] \]

converging on \(D\). A point \(c \in D\) is \textit{critical} if the derivative of \(f\) at \(c\) equals 0, i.e., \(f'(c) = 0\). If \(D\) contains a critical point \(c\), we can rewrite

\[ f(z) = b_0 + \sum_{n=m}^{\infty} b_n (z - c)^n \in \mathbb{C}_p[[z - c]] \]

with \(b_m \neq 0\) for some \(m \geq 2\). We call \(m\) the \textit{local degree} of \(f\) at \(c\) and denote it by \(\text{deg}_c f\).
The following lemma shows that analytic maps are well behaved away from the critical points.

**Lemma 2.1** ([31 Chapter 3 Lemma 1.6]). Let $D \subset \mathbb{C}_p$ be a disk and let $f : D \to \mathbb{C}_p$ be an analytic map. Suppose $x_0 \in D$ is not a critical point of $f$. Then there exists $r > 0$ such that for all $2 \leq k < \infty$, 

$$\left| \frac{f^{(k)}(x_0)}{k!} \right| r^{k-1} < |f'(x_0)|$$

and for all $x, y \in D(x_0, r)$,

$$|f(x) - f(y)| = |f'(x_0)||x - y|.$$

Inspired by the above result and following [32 Definition 4.1], we define the following terminology of “scaling” for convenience.

**Definition 2.2.** An analytic map $f$ defined on a disk $D \subset \mathbb{C}_p$ is (locally) scaling (in distances) on $D(x_0, r) \subset D$ if there exists $\alpha \in |\mathbb{C}_p|$ such that for all $x, y \in D(x_0, r)$,

$$|f(x) - f(y)| = \alpha |x - y|.$$

We mention here that $f$ is scaling on $D(x_0, r)$ if and only if $f$ has Weierstrass degree 1 in the common sense. In the above definition, we call $\alpha > 0$ the scaling ratio of $f$ at $x_0$. Moreover, we say the largest disk $D(x_0, r)$ on which $f$ is scaling is the maximal scaling disk of $f$ at $x_0$, and denote it by $S_{x_0}(f)$. The following lemma asserts that $S_{x_0}(f)$ is the maximal scaling disk of $f$ at any point $x \in S_{x_0}(f)$.

**Lemma 2.3.** Under the assumptions in Lemma 2.1, if $x \in S_{x_0}(f)$, then $S_x(f) = S_{x_0}(f)$.

**Proof.** It is obvious that $S_{x_0}(f) \subset S_x(f)$. By symmetry, $S_{x_0}(f) \supset S_x(f)$. \qed

At a critical point, we have the following property on the distance of images.

**Lemma 2.4.** Let $D \subset \mathbb{C}_p$ be a disk and let $f : D \to \mathbb{C}_p$ be an analytic map. Assume $c \in D$ is a critical point with $\deg_c f = m \geq 2$. Then there exists $r > 0$ such that for all $x \in D(c, r) \subset D$,

$$|f(x) - f(c)| = \left| \frac{f^{(m)}(c)}{m!} \right| |x - c|^m.$$

**Proof.** Set

$$g(x) := \frac{f(x) - f(c)}{(x - c)^{m-1}}.$$  

Then $g(x)$ is analytic on $D$ and $g(c) = 0$. By Lemma 2.1 there exists $r > 0$ such that for all $x \in D(c, r)$,

$$|g(x) - g(c)| = |g'(c)||x - c|.$$  

Noting that $g'(c) = f^{(m)}(c)/m!$, we have

$$\left| \frac{f(x) - f(c)}{(x - c)^{m-1}} \right| = \left| \frac{f^{(m)}(c)}{m!} \right| |x - c|.$$  

Hence the conclusion follows. \qed

A critical point $c$ of $f$ is **tame** if $p \nmid \deg_c f$ and **wild** if $p \mid \deg_c f$. Lemma 2.4 asserts that $f$ is not scaling in a neighborhood of any critical point. However, the next result claims that in a small neighborhood of any tame critical point $c$, the map $f$ is scaling on the disks not containing $c$. This property fails for wild critical points, in which case, $f$ is scaling on further small disks. This distinction is an obstruction that forces us to assume the absence of wild recurrent Julia critical points in our Theorem 1.2.
Proposition 2.5. Let \( D \subset \mathbb{C}_p \) be a disk and let \( f : D \to \mathbb{C}_p \) be an analytic map. Then the
following hold.

(1) Let \( c \in D \) be a critical point of \( f \). Then there exists \( r = r_c > 0 \) such that for any \( x \in D(c, r) \) with \( x \neq c \), the
maximal scaling disk \( S_x(f) = D(x, \delta(f|x-c)|) \), where
\[
\delta_f = \begin{cases} 
1 & \text{if } c \text{ is tame,} \\
\frac{1}{p^{-\frac{1}{\rho(c,D)}}} & \text{if } c \text{ is wild.}
\end{cases}
\]

(2) If in addition, \( f \) has finitely many critical points in \( D \), then for any small \( r > 0 \), there exists \( \epsilon_r > 0 \) such that \( f \) is scaling on
\( D(x, \epsilon_r) \subset D \) for any \( x \in (D\setminus K) \setminus \bigcup_{f'(c)=0} D(c, r) \).

Proof. The statement (1) follows from [9, Lemma 11.5]. The statement (2) follows immediately
from the local compactness of \( K \) and the fact that all the critical points in \( D \setminus K \) are
uniformly away from the points in \( K \).

Note that for any point \( x \in \mathbb{P}_1^{\mathbb{C}_p} \), in local coordinates, a rational map \( \phi \in \mathbb{C}_p(z) \) is analytic
in a neighborhood of \( x \). Then Proposition 2.5 immediately implies the following result.

Corollary 2.6. Let \( \phi \in \mathbb{C}_p(z) \) be a rational map of degree at least 2. Then the following hold.

(1) Let \( c \in \mathbb{P}_1^{\mathbb{C}_p} \) be a critical point of \( \phi \). Then there exists \( 0 < r = r_c < 1 \) such that
for any \( x \in D_{\mathbb{P}_1^{\mathbb{C}_p}}(c, r) \) with \( x \neq c \), in local coordinates, the map \( \phi \) is scaling on
\( D_{\mathbb{P}_1^{\mathbb{C}_p}}(x, \delta_c \rho(x, c)) \), where \( \delta_c = 1 \) if \( c \) is tame and \( \delta_c = \frac{1}{p^{-\frac{1}{\rho(c,D)}}} \) if \( c \) is wild.

(2) For any small \( 0 < r < 1 \), there exists \( 0 < \epsilon_r < 1 \) such that, in local coordinates, \( \phi \) is scaling on
\( D_{\mathbb{P}_1^{\mathbb{C}_p}}(x, \epsilon_r) \) for any \( x \in \mathbb{P}_1^{\mathbb{C}_p} \setminus \bigcup_{c \in \text{Crit}_{\mathbb{C}_p}(\phi)} D_{\mathbb{P}_1^{\mathbb{C}_p}}(c, r) \).

For the images of disks near a wild critical point, we have the following estimates for the
ratios of diameters, which will play a crucial role in the proof of Lemma 3.2.

Corollary 2.7. Let \( \phi \in \mathbb{C}_p(z) \) be a rational function of degree at least 2. Suppose that \( c \in \text{Crit}_{\mathbb{C}_p}(\phi) \) is a wild critical point and let \( r_c > 0 \) be as in Corollary 2.6. For \( 0 < r < r_c \) sufficiently small, consider disks \( D_1 \subset D_2 \subset D_{\mathbb{P}_1^{\mathbb{C}_p}}(c, r) \). Assume \( c \notin D_2 \). Then
\[
\frac{\text{diam}(\phi(D_1))}{\text{diam}(\phi(D_2))} \begin{cases} \geq p^{-\frac{1}{\rho(c,D)}} \cdot |\deg_c \phi| & \text{if } \phi \text{ is not scaling on } D_1, \\
\geq \frac{\text{diam}(D_1)}{\rho(c,D_2)} |\deg_c \phi| & \text{if } \phi \text{ is not scaling on } D_2 \text{ but scaling on } D_1, \\
\frac{\text{diam}(D_1)}{\text{diam}(D_2)} & \text{if } \phi \text{ is scaling on } D_2.
\end{cases}
\]
Moreover, if in addition, \( c \in \mathbb{P}_1^{\mathbb{C}_p} \) and \( D_1 \cap \mathbb{P}_1^{\mathbb{C}_p} \neq \emptyset \), then for any \( \beta \in |K^X| \) with \( \beta \leq p^{-\frac{1}{\rho-1}} \),
\[
\frac{\text{diam}(\phi(D_1 \cap \mathbb{P}_1^{\mathbb{C}_p}))}{\text{diam}(\phi(D_2))} \begin{cases} \geq \beta |\deg_c \phi| & \text{if } \phi \text{ is not scaling on } D_1, \\
\geq \frac{\text{diam}(D_1)}{\rho(c,D_2)} |\deg_c \phi| & \text{if } \phi \text{ is not scaling on } D_2 \text{ but scaling on } D_1, \\
\frac{\text{diam}(D_1)}{\text{diam}(D_2)} & \text{if } \phi \text{ is scaling on } D_2.
\end{cases}
\]

Proof. We first consider the case that \( c = 0 \). Pick \( x \in D_1 \) and consider the maximal scaling
disk \( S_x(\phi) = D_{\mathbb{P}_1^{\mathbb{C}_p}}(x, p^{-\frac{1}{\rho(c,D)}} \rho(x, c)) \). It follows that \( \phi(S_x(\phi) \cap D_1) \subset \phi(D_1) \), and hence
\[
\text{diam}(\phi(S_x(\phi) \cap D_1)) \leq \text{diam}(\phi(D_1)).
\]
Hence, thus in this case, the second assertion also holds for $c$. It follows that

$$|\phi'(x)| = |a \deg c \phi||x - c|^{\deg c \phi - 1} = |a \deg c \phi|\rho(x, c)^{\deg c \phi - 1},$$

and

$$\text{diam}(\phi(D_2)) \begin{cases} \leq |a|\rho(x, c)^{\deg c \phi} & \text{if } \phi \text{ is not scaling on } D_2, \\ \geq \frac{|\deg c \phi|\text{diam}(S_x(\phi) \cap D_1)}{|\rho(x, c)|} & \text{if } \phi \text{ is not scaling on } D_2, \\ = \frac{\text{diam}(D_1)}{\text{diam}(D_2)} & \text{if } \phi \text{ is scaling on } D_2. \end{cases}$$

Then we conclude that

$$\frac{\text{diam}(\phi(D_1))}{\text{diam}(\phi(D_2))} \geq \frac{|\phi'(x)|\text{diam}(S_x(\phi) \cap D_1)}{\text{diam}(\phi(D_2))} \geq \frac{|\deg c \phi|\text{diam}(S_x(\phi) \cap D_1)}{|\rho(x, c)|}$$

if $\phi$ is not scaling on $D_2$.

Note that $\text{diam}(S_x(\phi)) = p^{-\frac{1}{p-1}}\rho(x, c)$. Then the first assertion follows immediately for $c = 0$.

In the case that $D_1 \cap \mathbb{P}^1_K \neq \emptyset$, we pick $x \in D_1 \cap \mathbb{P}^1_K$. If $\phi$ is scaling on $D_1$ in local coordinates, then $\text{diam}(\phi(D_1 \cap \mathbb{P}^1_K)) = \text{diam}(\phi(D_1))$, which implies that, in this case, the second assertion holds for $c = 0$. Now we consider the case that $\phi$ is not scaling on $D_1$. Then for any $\beta \in |K^\times|$ with $|\beta| \leq p^{-\frac{1}{p-1}}$, we have

$$D_{\beta p} (x, \beta \rho(x, c)) \subseteq S_x(\phi) \subseteq D_1.$$

Note that $\text{diam}(S_x \cap \mathbb{P}^1_K) \leq \text{diam}(S_x)$ and

$$\text{diam}(D_{\beta p} (x, \beta \rho(x, c)) \cap \mathbb{P}^1_K) = \text{diam}(D_{\beta p} (x, \beta \rho(x, c))).$$

It follows that

$$\text{diam}(\phi(D_1) \cap \mathbb{P}^1_K) \geq \text{diam}(\phi(S_x \cap \mathbb{P}^1_K)) \geq \text{diam}(\phi(D_{\beta p} (x, \beta \rho(x, c)))) = |\phi'(x)|\beta \rho(x, c).$$

Hence

$$\frac{\text{diam}(\phi(D_1) \cap \mathbb{P}^1_K)}{\text{diam}(\phi(D_2))} \geq \frac{\text{diam}(\phi(S_x \cap \mathbb{P}^1_K))}{\text{diam}(\phi(D_2))} \geq \frac{|\phi'(x)|\beta \rho(x, c)}{|a|\rho(x, c)^{\deg c \phi}}.$$

Thus in this case, the second assertion also holds for $c = 0$.

In general, set $\psi(z) = z + c$ and consider the map $\phi \circ \psi$. Let $D_1 = \{x - c : x \in D_1\}$ and $D_2 = \{x - c : x \in D_2\}$. Note that

$$\frac{\text{diam}(\phi(D_1))}{\text{diam}(\phi(D_2))} = \frac{\text{diam}(\phi \circ \psi(D_1))}{\text{diam}(\phi \circ \psi(D_2))}.$$

Applying the previous argument for $\phi \circ \psi$, we obtain the conclusion. \hfill \Box

2.4. Julia sets and Fatou sets. Let $\phi \in L(z)$ be a rational map of degree at least 2. The Fatou set $F_L(\phi)$ is defined to be the subset of points in $\mathbb{P}^1_L$ having a neighborhood on which the family $\{\phi^n\}_{n \geq 0}$ of iterations is equicontinuous with respect to the spherical metric $\rho$. The Julia set $J_L(\phi)$ is the complement $\mathbb{P}^1_L \setminus F_L(\phi)$. Hence the set $F_L(\phi)$ is open while the set $J_L(\phi)$ is closed. If $L$ is algebraically closed (i.e. $L = \mathbb{C}_p$), the set $F_L(\phi)$ contains all the nonrepelling periodic points, while the set $J_L(\phi)$ contains all the repelling periodic points [6, Proposition 1.1]. Moreover, the map $\phi$ always has a nonrepelling fixed point [43, Corollary 5.19] and hence $F_L(\phi) \neq \emptyset$. In contrast, $J_L(\phi)$ could be empty. For example, if $\phi$ has good reduction, then $J_L(\phi) = \emptyset$ [43, Theorem 2.17]. In this case, both sets $F_L(\phi)$ and $J_L(\phi)$ are totally invariant.
under \( \phi \) [9 Proposition 5.10]. However, if \( L \) is not algebraically closed (i.e. \( L = K \)), the set \( F_L(\phi) \) could be empty, see [15]. In this case, even though the set \( J_L(\phi) \) is forward invariant and contains all the repelling periodic points in \( \mathbb{P}_L^1 \), the total invariance of \( J_L(\phi) \) is unclear. However, we have the following invariance away from critical points.

**Lemma 2.8.** Let \( \phi \in K(z) \) be a rational map of degree at least 2. Assume that \( x \in \mathbb{P}_K^1 \) is not a critical point of \( \phi \). Then \( x \in F_K(\phi) \) if and only if \( \phi(x) \in F_K(\phi) \).

**Proof.** By the definition of \( J_K(\phi) \), we immediately have that if \( x \in F_K(\phi) \), then \( \phi(x) \in F_K(\phi) \). Now we assume \( \phi(x) \in F_K(\phi) \). Then there exists a neighborhood \( V \subset \mathbb{P}_K^1 \) of \( \phi(x) \) such that the sequence \( \{\phi^n\}_{n \geq 1} \) is equicontinuous on \( V \). Since \( x \) is not a critical point, by Lemma 2.1 there exists a neighborhood \( U \subset \mathbb{P}_K^1 \) of \( x \) such that \( \phi \) is scaling on \( U \) and \( \phi(U) \subset V \). Hence \( \{\phi^{n+1}\}_{n \geq 1} \) is equicontinuous on \( U \). Thus \( \{\phi^n\}_{n \geq 1} \) is equicontinuous on \( U \). We conclude \( x \in F_K(\phi) \).

The following result is an immediate consequence of Lemma 2.8 that we will use repeatedly in our later argument.

**Corollary 2.9.** Let \( \phi \in K(z) \) be a rational map of degree at least 2, and let \( D \subset \mathbb{P}_p^1 \) be a disk such that \( \phi^n \) is scaling on \( D \) for some \( n \geq 1 \). Suppose \( \phi^n(D \cap \mathbb{P}_K^1) \cap J_K(\phi) \neq \emptyset \). Then \( (D \cap \mathbb{P}_K^1) \cap J_K(\phi) \neq \emptyset \).

For a rational map \( \phi \in \mathbb{C}_p(z) \), the following result asserts that any disk intersecting the Julia set has an iteration with large diameter.

**Lemma 2.10.** Let \( \phi \in \mathbb{C}_p(z) \) be a rational map of degree at least 2, and let \( D \subset \mathbb{P}_p^1 \) be a disk such that \( D \cap J_{\mathbb{C}_p}(\phi) \neq \emptyset \). Then there exists \( n_0 \geq 0 \) such that

\[
\text{diam}(\phi^{n_0}(D)) = 1.
\]

**Proof.** Suppose on the contrary that \( \text{diam}(\phi^n(D)) < 1 \) for all \( n \geq 0 \). Let \( \theta_n \in \text{PGL}(2, \mathbb{C}_p) \) be an isometry such that \( \theta_n(\phi^n(D)) \subset D_{\mathbb{C}_p}(0, 1) \). It follows from [9 Corollary 5.18] that the sequence \( \{\theta_n \circ \phi^n\}_{n \geq 0} \) is equicontinuous on \( D \) with respect to the spherical metric. Applying [9 Lemma 5.6], we obtain that \( \{\phi^n\}_{n \geq 0} \) is equicontinuous on \( D \), and hence \( D \subset F_{\mathbb{C}_p}(\phi) \), which contradicts the assumption \( D \cap J_{\mathbb{C}_p}(\phi) \neq \emptyset \).

### 2.5. Fatou components.

For a rational map \( \phi \in \mathbb{C}_p(z) \) of degree at least 2, it is possible to define the Fatou components in terms of \( D \)-components or analytic components, see [7]. However, it is more convenient for our purposes to inherit the terminologies from the Berkovich dynamics.

Let \( \mathbb{P}_{\mathbb{C}_p}^{1,\text{an}} \) be the Berkovich space over \( \mathbb{C}_p \) that is a compact, uniquely path connected, Hausdorff topological space, see [3,10,33,41]. Since \( \mathbb{P}_{\mathbb{C}_p}^1 \) can be identified with a dense subset in \( \mathbb{P}_{\mathbb{C}_p}^{1,\text{an}} \), the rational map \( \phi \) extends to a self map on \( \mathbb{P}_{\mathbb{C}_p}^{1,\text{an}} \), see [3], to abuse notation, we also call this extension \( \phi \). The Berkovich Julia set \( J_{\text{Ber}}(\phi) \) consists of the points \( \xi \in \mathbb{P}_{\mathbb{C}_p}^{1,\text{an}} \) such that for all (weak) neighborhood \( U \) of \( \xi \), the set \( \cup_{n=1}^{\infty} \phi^n(U) \) omits at most two points in \( \mathbb{P}_{\mathbb{C}_p}^1 \). The complement of \( J_{\text{Ber}}(\phi) \) is the Berkovich Fatou set \( F_{\text{Ber}}(\phi) \). For the equivalent definitions for \( J_{\text{Ber}}(\phi) \) and \( F_{\text{Ber}}(\phi) \) in terms of appropriate notions of equicontinuity or normality, we refer to [24].

Following [9 Theorem 8.3], the set \( F_{\mathbb{C}_p}(\phi) \) is a subset of \( F_{\text{Ber}}(\phi) \), more precisely, \( F_{\text{Ber}}(\phi) \cap \mathbb{P}_{\mathbb{C}_p}^1 = F_{\mathbb{C}_p}(\phi) \). Then we say a subset \( \Omega \subset F_{\mathbb{C}_p}(\phi) \) is a (Fatou) component of \( F_{\mathbb{C}_p}(\phi) \) if there exists a component \( U \) of \( F_{\text{Ber}}(\phi) \) such that \( \Omega = U \cap F_{\mathbb{C}_p}(\phi) \). In our term, a component of \( F_{\mathbb{C}_p}(\phi) \) is the union of possibly infinitely many \( D \)-components in [7].
The following result is an immediate consequence of the fact that each component of $F_{Ber}(\phi)$ is mapped onto a component of $F_{Ber}(\phi)$ by $\phi$, see [9] Proposition 8.2.

**Proposition 2.11.** Let $\phi \in \mathbb{C}_p(z)$ be a rational function of degree at least 2, and let $\Omega$ be a component of $F_{\mathbb{C}_p}(\phi)$. Pick $x \in \Omega$. Then $\phi(\Omega)$ is the component of $F_{\mathbb{C}_p}(\phi)$ containing $\phi(x)$. Moreover, $\phi^{-1}(\Omega)$ is the union of components of $F_{\mathbb{C}_p}(\phi)$ containing preimages $\phi^{-1}(x)$.

A periodic component of $F_{Ber}(\phi)$ is either attracting that contains an attracting periodic point, or indifferent that is bijective to itself under certain iteration, see [39, Section 4.4]. The components of $F_{\mathbb{C}_p}(\phi)$ inherit immediately this classification:

**Corollary 2.12.** Let $\phi \in \mathbb{C}_p(z)$ be a rational function of degree at least 2, and let $\Omega$ be a periodic connected component of $F_{\mathbb{C}_p}(\phi)$. Then $\Omega$ is either an attracting component containing an attracting periodic point, or an indifferent component mapping bijectively to itself under certain iteration.

A wandering domain is a component of $F_{\mathbb{C}_p}(\phi)$ that is not eventually periodic. In contrast to the complex setting, see [44], there exist polynomials in $\mathbb{C}[z]$ possessing wandering domains, see [8, Theorem 1.1]. However, for rational maps of degree at least 2 with algebraic coefficients, it is conjectured that such maps have no wandering domains in $\mathbb{P}^1_{\mathbb{C}_p}$, see [43, Conjecture 5.50]. This conjecture holds under the no wild recurrent Julia critical points assumption, see [5, Theorem 1.2]. For our purposes, we state the following no wandering domains result that is slightly stronger than Benedetto’s original version. The proof is a minor modification of Benedetto’s proof in [3, Theorems 1.2 and 1.3], see also [9, Section 11.3]. We omit the proof here.

**Theorem 2.13.** Let $\phi \in K(z)$ be a rational map of degree at least 2. Suppose $\phi$ has no wild recurrent critical points in $J_{\mathbb{C}_p}(\phi) \cap \mathbb{P}^1_K$. Then every component of $F_{\mathbb{C}_p}(\phi)$ that intersects with $\mathbb{P}^1_K$ is non-wandering. Moreover, there are only finitely many periodic components of $F_{\mathbb{C}_p}(\phi)$ intersecting $\mathbb{P}^1_K$.

### 2.6. Brief background of symbolic dynamics.

We now state some preliminaries of symbolic dynamics for later use. Standard references are [33] and [36].

Let $\mathcal{A}$ be a countable symbol set. Associated with the discrete topology, the set $\mathcal{A}$ is noncompact. Then the product space $\Sigma := \mathcal{A}^\mathbb{N}$ is also noncompact under the product topology. For $b_0, b_1, \ldots, b_j \in \mathcal{A}$, the cylinder set starting $b_0, b_1, \ldots, b_j$ is

$$[b_0b_1\cdots b_j] := \{a = (a_i)_{i \in \mathbb{N}} \in \Sigma : a_i = b_i \text{ for } 0 \leq i \leq j\}.$$

All the cylinder sets form a countable basis of open-closed sets. Moreover, we can define a distance between two distinct points $a = \{a_i\}_{i \in \mathbb{N}}$ and $a' = \{a'_i\}_{i \in \mathbb{N}}$ in $\Sigma$ by $\hat{\rho}(a, a') = 2^{-n}$, where $n$ is the smallest integer with $a_n \neq a'_n$. Then the metric $\hat{\rho}$ induces the same topology as the product topology.

Let $\sigma : \Sigma \to \Sigma$ be the (left-)shift. A countable $|\mathcal{A}| \times |\mathcal{A}|$, zero-one matrix $A = (A_{b_i b_j})$ induces a $\sigma$-invariant subset $\Sigma_A$ of $\Sigma$:

$$\Sigma_A = \{(b'_i) \in \Sigma : A_{b_i b_{i+1}} = 1\},$$

which is noncompact under the subspace topology. We say the system $(\Sigma_A, \sigma)$ is a countable state Markov shift defined by $A$, and call $(\Sigma_A, \sigma)$ irreducible if the matrix $A$ is irreducible, i.e., for any $b_i, b_j \in \mathcal{A}$, there exists a positive integer $\ell$ such that $(A^\ell)_{b_i b_j} > 0$.

Since the space $\Sigma_A$ is noncompact, we consider the Gurevich entropy $h_G(\Sigma_A, \sigma)$ for the system $(\Sigma_A, \sigma)$, see [26] and [27], which is the supremum of the topological entropies $h_{top}(\Sigma_A, \sigma)$ over all subsystems $(\Sigma_A', \sigma)$ formed by restricting to a finite subset of symbols in $\mathcal{A}$. If the matrix $A$ is irreducible, there is a combinatorial way to compute $h_G(\Sigma_A, \sigma)$: For any $a_{i_0} \in \mathcal{A}$,
a first-return loop of length $n \geq 1$ at $a_{i_0}$ is a path \( \{a_{i_0}, a_{i_1}, \ldots, a_{i_n}\} \) such that $a_{i_0} = a_{i_n}$, $a_{i_k} \neq a_{i_0}$ for $1 \leq k \leq n-1$ and $A_{a_{i_k} a_{i_{k+1}}} = 1$ for $0 \leq k \leq n-1$. Let $\delta_{a_{i_0}}(n)$ be the number of the first-return loops at $a_{i_0}$ of length $n$, and set

$$G_{a_{i_0}}(z) = \sum_{n \geq 1} \delta_{a_{i_0}}(n)z^n.$$ 

If $1 - G_{a_{i_0}}(z)$ has a real root $R > 0$ such that $G_{a_{i_0}}(z)$ converges and is not $1$ on $|z| < R$, then $h_G(\Sigma_A, \sigma) = -\log R$. Remark that if such an $R$ exists, then it is independent of $a_{i_0}$; see [42,46].

3. Restriction of the Julia set

In this section we prove Theorem 1.2. Let $\phi \in K(z)$ be a rational map of degree at least 2. As mentioned in Section 1 by definitions, $J_{\mathbb{C}^p}(\phi) \subset J_{\mathbb{C}_p}(\phi)$. So it suffices to show $J_{\mathbb{C}_p}(\phi) \subset J_{\mathbb{C}_p}(\phi)$. We point out that the assumption (2) of Theorem 1.2 is not required until Section 3.5.2. But we repeatedly apply the assumption (1), that is, in this section, we always make the following assumption.

**Assumption:** The map $\phi$ has no wild recurrent critical points in $J_{\mathbb{C}_p}(\phi)$.

Let $\partial J_{\mathbb{C}_p}(\phi)$ be the boundary of $J_{\mathbb{C}_p}(\phi)$ in $\mathbb{P}_K^1$, and denote by

$$\text{Int}(J_{\mathbb{C}_p}(\phi)) := J_{\mathbb{C}_p}(\phi) \setminus \partial J_{\mathbb{C}_p}(\phi)$$

the interior of $J_{\mathbb{C}_p}(\phi)$ in $\mathbb{P}_K^1$.

3.1. Critical distances. We state the following quantities on the distances concerning critical orbits for later use. For each $c \in \text{Crit}_{\mathbb{C}_p}(\phi)$, fix an $r_c > 0$ satisfying Corollary 2.6 (1). We set

\[
\begin{align*}
    r_1 &:= \min \{r_c : c \in \text{Crit}_{\mathbb{C}_p}(\phi)\}, \\
    r_2 &:= \min \{\rho(c, \text{Crit}_{\mathbb{C}_p}(\phi) \setminus \{c\}) : c \in \text{Crit}_{\mathbb{C}_p}(\phi)\}, \\
    r_3 &:= \min \left\{\rho \left(\overline{\text{O}_p(c)}, \text{Crit}_{\mathbb{C}_p}(\phi) \setminus \overline{\text{O}_p(c)}\right) : c \in \text{Crit}_{\mathbb{C}_p}(\phi)\right\}, \\
    r_4 &:= \min \{\rho(c, J_{\mathbb{C}_p}(\phi)) : c \in \text{Crit}_{\mathbb{C}_p}(\phi) \cap F_{\mathbb{C}_p}(\phi)\}, \quad \text{and} \\
    r_5 &:= \min \{\rho(c, \mathbb{P}_K^1) : c \in \text{Crit}_{\mathbb{C}_p}(\phi) \setminus \text{Crit}_K(\phi)\}.
\end{align*}
\]

Due to the finiteness of $\text{Crit}_{\mathbb{C}_p}(\phi)$, the closedness of the closure $\overline{\text{O}_p(c)}$ and $J_{\mathbb{C}_p}(\phi)$, and the compactness of $\mathbb{P}_K^1$, each of the above quantities is strictly positive. Thus

$$r_* := \min\{r_1, r_2, r_3, r_4, r_5\} > 0.$$ 

3.2. Points in $\partial J_{\mathbb{C}_p}(\phi)$. The following result, whose proof combines the classification result (Corollary 2.12) and the no wandering domains result (Theorem 2.13), asserts that $\partial J_{\mathbb{C}_p}(\phi) \subset J_K(\phi)$.

**Lemma 3.1.** If $x \in \partial J_{\mathbb{C}_p}(\phi)$, then $x \in J_K(\phi)$.

**Proof.** Since $x \in \partial J_{\mathbb{C}_p}(\phi)$, for any small neighborhood $V \subset \mathbb{P}_K^1$ of $x$, the set $V \cap F_{\mathbb{C}_p}(\phi)$ is non-empty. By Theorem 2.13 for each $y \in V \cap F_{\mathbb{C}_p}(\phi)$, there exists an integer $m \geq 0$ such that $\phi^m(y) \in \mathbb{P}_K^1$ lies in a periodic component of $F_{\mathbb{C}_p}(\phi)$. Again by Theorem 2.13 the map $\phi$ has finitely many periodic components of $F_{\mathbb{C}_p}(\phi)$ intersecting $\mathbb{P}_K^1$, and by Corollary 2.12
the periodic components of $F_{C_p}(\phi)$ are either attracting or indifferent. Then there exists a constant $\epsilon > 0$ such that for all $y \in V \cap F_{C_p}^K(\phi)$,

$$\sup_{i \geq 0} \rho(\phi^i(x), \phi^i(y)) > \epsilon.$$  

This means that $x \in J_K(\phi)$. \hfill \Box

3.3. Reduction to critical points. In this subsection, we show that in order to establish $J_{C_p}^K(\phi) \subset J_K(\phi)$, it only requires to treat the critical points in $J_{C_p}^K(\phi)$. We first state the following characterization of the orbit of a disk intersecting $J_{C_p}^K(\phi)$.

**Lemma 3.2.** Let $D \subset \mathbb{P}_1$ be a disk such that $D \cap J_{C_p}^K(\phi) \neq \emptyset$. Then at least one of the following holds.

1. There exists $n_0 \geq 0$ such that
   $$\phi^{n_0}(D) \cap \text{Crit}_K(\phi) \neq \emptyset.$$

2. There exists $\epsilon_* > 0$, independent of $D$, such that
   $$\sup_{n \geq 1} \text{diam}(\phi^n(D)) \geq \epsilon_*.$$

**Proof.** Pick $0 < r < r_*$ and let $\epsilon_r > 0$ be as in Corollary 2.6 (2). Shrinking $\epsilon_r$ if necessary, we can assume that $0 < \epsilon_r < r$. Consider the disk $D' \subset \mathbb{P}_1$ such that $D \subset D'$ and \(\text{diam}(D') = \text{diam}(D)\). Then the assumption $D \cap J_{C_p}^K(\phi) \neq \emptyset$ implies $D' \cap J_{C_p}(\phi) \neq \emptyset$. Thus $\mathbb{P}_1 \setminus \bigcup_{n \geq 1} \phi^n(D')$ contains at most one point (see [9, Theorem 5.19]). Since $\phi$ has at least two distinct critical points in $\text{Crit}_{C_p}(\phi)$, the set $\bigcup_{n \geq 1} \phi^n(D')$ intersects $\text{Crit}_{C_p}(\phi)$. Hence there exists a smallest $\ell \geq 0$ such that $\phi$ is not scaling on $\phi^\ell(D')$. It follows that

$$\text{diam}(\phi^\ell(D)) = \text{diam}(\phi^\ell(D')).$$  \hfill (3.1)

Now suppose that the statement (1) does not hold and show that the statement (2) holds. By the choice of $\ell$, we have

$$\phi^\ell(D') \cap \text{Crit}_K(\phi) = \emptyset.$$  

If $\phi^\ell(D')$ contains a critical point $c \in \text{Crit}_{C_p}(\phi)$, then $c \in \text{Crit}_{C_p}(\phi) \setminus \text{Crit}_K(\phi)$. Since $\phi^\ell(D') \cap \mathbb{P}_1^K \neq \emptyset$, by the choice of $r_*$ and \hbox{[3.1]}, we conclude

$$\text{diam}(\phi^\ell(D)) = \text{diam}(\phi^\ell(D')) > r_*.$$  \hfill (3.2)

If $\phi^\ell(D') \cap D_{\mathbb{P}^1_{C_p}}(c, r) = \emptyset$ for all $c \in \text{Crit}_{C_p}(\phi)$, since $\phi$ is not scaling on $\phi^\ell(D')$, we obtain

$$\text{diam}(\phi^\ell(D)) = \text{diam}(\phi^\ell(D')) \geq \epsilon_r.$$  \hfill (3.3)

To proceed the argument, assume

$$\phi^\ell(D') \cap \text{Crit}_{C_p}(\phi) = \emptyset \quad \text{but} \quad \phi^\ell(D') \cap D_{\mathbb{P}^1_{C_p}}(c', r) \neq \emptyset$$

for some $c' \in \text{Crit}_{C_p}(\phi)$. It follows that

$$\phi^\ell(D') \subset D_{\mathbb{P}^1_{C_p}}(c', r).$$  \hfill (3.4)

Moreover, we have the following claim on the critical point $c'$.

**Claim 1.** The critical point $c' \in J_{C_p}^K(\phi)$ is wild.
We first show $c' \in J_{C_p}^{K}(\phi)$. Suppose otherwise. Then
\[ c' \in \big( \text{Crit}_{C_p}(\phi) \setminus \text{Crit}_K(\phi) \big) \bigcup F^K_{C_p}(\phi). \]
Since $D \cap J_{C_p}^{K}(\phi) \neq \emptyset$ and $\phi^c$ is scaling on $D'$, we obtain $\phi^c(D') \cap J_{C_p}^{K}(\phi) \neq \emptyset$. Hence by the choice of $r_*$, $D^p_{p^k} (c', r) \cap J_{C_p}^{K}(\phi) = \emptyset$, which contradicts (3.4). Now we show $c'$ is wild. Suppose on the contrary, that $c'$ is tame. By Corollary 3.6 (1) and the choice of $c_0$, we obtain $c' \in \phi^c(D')$, which contradicts the assumption $\phi^c(D') \cap \text{Crit}_{C_p}(\phi) = \emptyset$. Thus the claim holds.

Since $\phi$ is not scaling on $\phi^c(D')$, by Corollary 3.7 there exists $\beta \in |K^x|$ with $0 < \beta \leq p^{-\frac{1}{p-1}}$ such that
\[ \frac{\text{diam}(\phi^{c+1}(D))}{\text{diam}(\phi^{c+1}(D'))} \geq \beta |\deg c_0|_{p} \epsilon_r. \]

By Claim 1, let $W_\phi(c') = \{c_0 = c', c_1, \ldots, c_{k_0}\}$ be the set of wild critical points in $\overline{O_\phi(c')} \subset J_{C_p}^{K}(\phi)$. The no wild recurrent critical points assumption implies that each point in $W_\phi(c')$ is non-recurrent. Then we have the following claim on the lower bound of the diameter of certain iterated images of $D'$ and $D$.

**Claim 2.** There exists $c' \geq 0$ such that $\text{diam}(\phi^{c'}(D')) \geq \epsilon_r$ and
\[ \text{diam}(\phi^c(D)) \geq \beta \left( p^{-\frac{1}{p-1}} \right)^{k_0} \prod_{i=0}^{k_0} |\deg c_i|_p \epsilon_r. \]

Note that $D' \cap J_{C_p}(\phi) \neq \emptyset$. By Lemma 2.10 there exists a smallest $c' \geq 0$ such that
\[ \text{diam}(\phi^{c'}(D')) \geq \epsilon_r. \] (3.5)
If $0 \leq c' \leq c$, since $\phi^c$ is scaling on $D'$, by (3.1), we conclude
\[ \text{diam}(\phi^c(D)) = \text{diam}(\phi^{c'}(D')) \geq \epsilon_r > \beta \left( p^{-\frac{1}{p-1}} \right)^{k_0} \prod_{i=0}^{k_0} |\deg c_i|_p \epsilon_r. \]

Thus in this case, the claim holds immediately. Now we work on the case that $c' > c$. Relabeling the points in $W_\phi(c')$ with $c_0 = c'$ and applying Corollary 3.6 (1), there exist $0 \leq j_0 \leq k_0$ and $c = c_0 \leq c_1 < c_2 < \ldots < c_{j_0-1}$ such that $\phi^{c_i}(D') \supsetneq D^p_{p^k} (c_i, r)$ and $\phi^{c_{j_0}+1}(D')$ is scaling on $\phi^{c_{j_0}+1}(D')$. It follows that if $\ell_j+1 < i \leq \ell_{j_0}$ for some $1 \leq j \leq j_0-1$, or if $\ell_{j_0}+1 < i \leq c'$, then
\[ \frac{\text{diam}(\phi^{c_i}(D))}{\text{diam}(\phi^{c_{i}+1}(D'))} = \frac{\text{diam}(\phi^{c_{j_0}+1}(D))}{\text{diam}(\phi^{c_{j_0}+1}(D'))}. \] (3.6)
Moreover, letting $D'_j \subset \mathbb{P}_{C_p}$ be the disk such that $\phi^{c_i}(D) \subset D'_j$ and $\text{diam}(D'_j) = \text{diam}(\phi^{c_i}(D))$, if $\phi$ is scaling on $D'_j$ but not on $\phi^{c_i}(D')$, by Corollary 2.7, we have
\[ \frac{\text{diam}(\phi^{c_{j_0}+1}(D))}{\text{diam}(\phi^{c_{j_0}+1}(D'))} \geq \frac{\text{diam}(\phi^{c_{j_0}+1}(D))}{\rho(c_j, \phi^{c_i}(D'))} \deg c_j \phi|_p. \] (3.7)
Let $0 \leq j_1 \leq j_0$ be the largest integer such that $\phi$ is not scaling on $D'_j$. Then by Corollary 2.7
\[ \frac{\text{diam}(\phi^{c_{j_0}+1}(D))}{\text{diam}(\phi^{c_{j_0}+1}(D'))} \geq \beta |\deg c_{j_1}|_p \phi|_p. \] (3.8)
If $j_1 = j_0$, it follows from (3.5) (3.6) and (3.8) that
\[
\text{diam}(\phi''(D)) \geq \beta |\text{deg}_{c_{j_1}} \phi_p| \cdot \text{diam}(\phi''(D')) \geq \beta |\text{deg}_{c_{j_1}} \phi_p| \epsilon_r. \quad (3.9)
\]
If $0 \leq j_1 < j_0$, since $\phi$ is not scaling on $\phi^{j_1+1}(D')$, by (3.8) and Corollary 2.6 (1),
\[
\text{diam}(\phi^{j_1+1}(D)) \geq \beta |\text{deg}_{c_{j_1+1}} \phi_p| \cdot \text{diam}(\phi^{j_1+1}(D'))
\]
\[
\geq \beta |\text{deg}_{c_{j_1}} \phi_p| \cdot p^{-\frac{1}{p-1}} \rho(c_{j_1+1}, \phi^{j_1+1}(D')). \quad (3.10)
\]
Then the combination of (3.7) and (3.10) implies
\[
\frac{\text{diam}(\phi^{j_1+1}(D))}{\text{diam}(\phi^{j_1+1}(D'))} \geq \beta |\text{deg}_{c_{j_1}} \phi_p| \cdot p^{-\frac{1}{p-1}} \cdot |\text{deg}_{c_{j_1+1}} \phi_p|.
\]
Inductively, we have
\[
\frac{\text{diam}(\phi''(D))}{\text{diam}(\phi''(D'))} \geq \beta \left( p^{-\frac{1}{p-1}} \right)^{j_0-j_1} \prod_{i=j_1}^{j_0} |\text{deg}_{c_i} \phi_p| \geq \beta \left( p^{-\frac{1}{p-1}} \right)^{k_0} \prod_{i=0}^{k_0} |\text{deg}_{c_i} \phi_p|. \quad (3.11)
\]
Thus combining (3.5) and (3.11), we obtain Claim 2.

Finally, we set
\[
\epsilon_* := \beta \left( p^{-\frac{1}{p-1}} \right)^{2\text{deg} \phi - 2} \prod_{c \in \text{Crit}_{c_p}(\phi)} \text{deg}_{c} \phi_p \epsilon_r < \epsilon_r. \quad (3.12)
\]
Combining (3.2), (3.3) and Claim 2, we conclude that the statement (2) holds. This completes
the proof.

Remark 3.3. Consider the disk $D$ in Lemma 3.2 and $\epsilon_* > 0$ in (3.12). Let $D' \subset \mathbb{P}^1_{c_p}$ be the disk containing $D$ with $\text{diam}(D') = \text{diam}(D)$. If $D' \cap \text{Crit}_{c_p}(\phi) = \emptyset$ and $\sup_{n \geq 1} \text{diam}(\phi^n(D)) < \epsilon_*$, then by Lemma 3.2, there exists a smallest integer $n_0 \geq 1$ such that $\phi^{n_0}(D) \cap \text{Crit}_K(\phi) \neq \emptyset$. Pick $c \in \phi^{n_0}(D) \cap \text{Crit}_K(\phi)$. Then by Corollary 2.6 (1), there exists a disk $D_1 \subset D$ such that $c \in \phi^{n_0}(D_1)$ and $\phi^{n_0}$ is scaling on $D_1$, where $D_1' \subset D'$ is the disk containing $D_1$ with $\text{diam}(D_1') = \text{diam}(D_1)$.

For a point $x \in \mathbb{P}^1_{c_p}$, denote by
\[
C_\phi(x) := \overline{\operatorname{O}_\phi(x)} \cap \text{Crit}_{c_p}(\phi)
\]
the set of critical points in the closure of the forward orbit of $x$. The following result allows us to only work on the critical points.

**Proposition 3.4.** For $x \in J_{c_p}^K(\phi)$, if $C_\phi(x) \subset J_K(\phi)$, then $x \in J_K(\phi)$. In particular, if
\[
\text{Crit}_K^*(\phi) \subset J_K(\phi),
\]
then $J_{c_p}^K(\phi) \subset J_K(\phi)$.

**Proof.** By Lemma 3.1, it suffices to consider the case that $x \in \text{Int}(J_{c_p}^K(\phi))$. Suppose, on the contrary that $x \in F_K(\phi)$. Since $F_K(\phi)$ and $\text{Int}(J_{c_p}^K(\phi))$ are open, there exists $r > 0$ such that
\[
D_{\mathbb{P}^1_K}(x, r) \subset F_K(\phi) \cap \text{Int}(J_{c_p}^K(\phi)).
\]
Now for any $y \in D_{\mathbb{P}^1_K}(x, r)$ with $y \neq x$, set $s_y = \rho(x, y)$ and consider the disk $D_y := D_{\mathbb{P}^1_K}(y, s_y)$. By Lemma 3.2, we have two cases:

1. There exists $n_y \geq 0$ such that $\phi^{n_y}(D_y) \cap \text{Crit}_K(\phi) \neq \emptyset$. 

3.4. Equivalence classes for Julia critical points. In this subsection, we define an equivalence relation on \( \text{Crit}_c(p, \phi) \) and then show under a natural partial order, certain restriction on the minimal elements in the resulting equivalence classes validates the inclusion (3.13).

For \( c_1, c_2 \in \text{Crit}_c^*(p, \phi) \), define \( c_1 \sim c_2 \) if \( c_1 \in \overline{\mathcal{O}(c_2)} \) and \( c_2 \in \overline{\mathcal{O}(c_1)} \). It follows that \( \sim \) is an equivalence relation. Set
\[
\mathcal{M}(\phi) := \text{Crit}_c^*(p, \phi)/\sim,
\]
and let \( Q : \text{Crit}_c^*(p, \phi) \to \mathcal{M}(\phi) \) be the quotient map. For two classes \([c], [c'] \in \mathcal{M}(\phi)\), we define a partial order \( \preceq \) as follows: \([c] \preceq [c'] \) if \( \overline{\mathcal{O}(c)} \subseteq \overline{\mathcal{O}(c')} \), and \([c] \prec [c'] \) if \( \overline{\mathcal{O}(c)} \subset \overline{\mathcal{O}(c')} \). A class \([c] \in \mathcal{M}(\phi)\) is minimal if \( (\mathcal{M}(\phi), \preceq) \) contains no other element less than \([c] \).

Example 3.5. Suppose that \( \text{Crit}_c^*(p, \phi) = \{c_0, c_1, c_2, c_3\} \) satisfy the following: \( \{c_0, c_1, c_2, c_3\} \subset \overline{\mathcal{O}(c_0)}, \{c_1, c_2\} \subset \overline{\mathcal{O}(c_1)}, \{c_1, c_2\} \subset \overline{\mathcal{O}(c_2)}, \) and \( \{c_3\} \subset \overline{\mathcal{O}(c_3)} \). Then \( [c_2] = [c_1] \preceq [c_0] \) and \([c_3] \preceq [c_0] \). Moreover, \( Q^{-1}([c_0]) = \{c_0, c_1, c_2, c_3\} \).

Note that if \( c \in \text{Crit}_K^*(p, \phi) \), then \( \overline{\mathcal{O}(c)} \subset J_K^p(\phi) \). It follows that if \( c' \in \text{Crit}_c^*(p, \phi) \) with \( c' \sim c \), then \( c' \in \text{Crit}_K^*(p, \phi) \), and hence all the representations of \([c] \) are in \( \text{Crit}_K^*(p, \phi) \). The following result concerning the minimal classes provides a sufficient condition for the inclusion (3.13).

Proposition 3.6. Suppose that for any minimal class \([c] \in \mathcal{M}(\phi)\) with \( c \in \text{Crit}_K^*(p, \phi) \), we have \( c \in J_K(\phi) \). Then \( \text{Crit}_K^*(p, \phi) \subset J_K(\phi) \).

Proof. Pick \( c_0 \in \text{Crit}_K^*(p, \phi) \). By Lemma 3.1, it suffices to consider the case that \( c_0 \in \text{Int}(J_K^p(\phi)) \). Pick \( r > 0 \) such that \( D_{p\overline{1}}(c_0, r) \subset \text{Int}(J_K^p(\phi)) \). Now for any \( x \in D_{p\overline{1}}(c_0, r) \) with \( x \neq c_0 \), set \( s_x = \rho(x, c_0) \) and consider the disks \( D_{p\overline{1}}(x, s_x) \subset D_{p\overline{1}}(c_0, r) \). By Lemma 3.2, we have two cases:

1. There exists \( n_0 \geq 0 \) such that
   \[ \phi^{n_0}(D_{p\overline{1}}(x, s_x)) \cap \text{Crit}_K(\phi) \neq \emptyset. \]

2. There exists \( \epsilon_\ast > 0 \), independent of \( x \), such that
   \[ \sup_{n \geq 0} \text{diam}\left(\phi^n(D_{p\overline{1}}(x, s_x))\right) \geq \epsilon_\ast. \]
If the case (2) occurs for infinitely many distinct disks \( D_{p_k^1}(x,s_x) \), by the definition of Julia set, we conclude \( c_0 \in J_K(\phi) \).

Now shrinking \( r \) if necessary, we assume that for any disk \( D_{p_k^1}(x,s_x) \), the case (1) occurs but the case (2) does not occur. Pick such a disk \( D_{p_k^1}(x_0,s_{x_0}) \) and take \( n_0 \) to be the smallest integer in the case (1) for \( D_{p_k^1}(x_0,s_{x_0}) \). Then there in fact exists \( c_1 \in C_\phi(c_0) \) such that

\[
\phi^{n_0} \left( D_{p_k^1}(x_0,s_{x_0}) \right) \cap \text{Crit}_K(\phi) = \{c_1\}.
\]

Considering the small disks near \( c_1 \) and applying the above argument repeatedly, we eventually reach a set \( \{c_0,c_1,\cdots,c_k\} \subset \text{Crit}_K(\phi) \) satisfying the following:

(i) for \( 0 \leq j \leq k-1 \), the point \( c_{j+1} \in C_\phi(c_j) \) and \( [c_k] \) is minimal in \( M(\phi) \); and

(ii) for \( 0 \leq j \leq k-1 \), there exist integer \( n_j \geq 1 \) and disk \( D_j := D_{p_k^1}(x_j,s_{x_j}) \) with \( x_j \neq c_j \) sufficiently close to \( c_j \) and \( s_{x_j} = \rho(x_j,c_j) \) such that

(a) \( c_{j+1} \in \phi^{n_j}(D_j) \),

(b) \( \phi^{n_j-1} \) is scaling on \( \phi(D_j) \) if \( n_j > 1 \), and

(c) \( D_{j+1} \subset \phi^{n_j}(D_j) \).

By the assumption in the statement, \( c_k \in J_K(\phi) \). Then Corollary 2.9 and Remark 3.3 imply that \( D_{k-1} \cap J_K(\phi) \neq \emptyset \). Inductively, we conclude

\[
D_{p_k^1}(x_0,s_{x_0}) \cap J_K(\phi) \neq \emptyset.
\]

Since we can take \( x_0 \) arbitrarily close to \( c_0 \), by the closedness of \( J_K(\phi) \), we obtain \( c_0 \in J_K(\phi) \). Hence the conclusion follows. \( \square \)

3.5. Critical points in minimal conjugacy class. Now pick \( c \in \text{Crit}_K^*(\phi) \) such that \( [c] \in M(\phi) \) is a minimal class. Under the assumptions in Theorem 1.2, this subsection is devoted to proving that \( c \in J_K(\phi) \), which verifies the assumption in Proposition 3.6. If \( c \in \partial J_{p_k^1}(\phi) \), then by Lemma 3.1 we have \( c \in J_K(\phi) \). In what follows, we assume that \( c \in \text{Int}(J_{p_k^1}(\phi)) \). Recall the quantity \( r_\ast \) from Section 3.1. Fix a small \( 0 < r < r_\ast \) and pick an \( \epsilon \) satisfying Corollary 2.6 (2). Then set \( \epsilon_r' := \min\{r,\epsilon_r\} \) and define \( \epsilon_0 := \min\{\epsilon'/p,\epsilon_\ast\} \), where \( \epsilon_\ast \) is a fixed constant satisfying Lemma 3.2. Moreover, shrinking \( \epsilon_0 \) if necessary, we can assume

\[
\phi \left( D_{p_k^1}(c,\epsilon_0) \right) \neq p_{k^1}^1.
\]

3.5.1. Non-recurrent case. Fix the notations as above. We consider the case that the critical point \( c \) is non-recurrent.

**Proposition 3.7.** If the critical point \( c \) is non-recurrent, then \( c \in J_K(\phi) \).

**Proof.** Suppose, on the contrary that \( c \in F_K(\phi) \). Since \( c \in \text{Int}(J_{p_k^1}(\phi)) \), consider a disk \( D_{p_k^1}(c,\delta) \subset \text{Int}(J_{p_k^1}(\phi)) \cap F_K(\phi) \). By the equicontinuity, shrinking \( \delta > 0 \) if necessary, we can assume that for all \( n \geq 0 \),

\[
\text{diam} \left( \phi^n(D_{p_k^1}(c,\delta)) \right) < \epsilon_0.
\]

Pick an arbitrary \( x \in D_{p_k^1}(c,\delta) \) with \( x \neq c \), and set \( s_x = \rho(x,c) \). For the disk \( D(x) := D_{p_k^1}(x,s_x) \subset D_{p_k^1}(c,\delta) \), by the choice of \( \epsilon_0 \), the orbit of \( D(x) \) disjoins the critical points. Then it follows from Lemma 3.2 that

\[
\sup_{n \geq 1} \text{diam} \left( \phi^n(D(x)) \right) \geq \epsilon_\ast,
\]

which contradicts (3.15) since \( \epsilon_0 \leq \epsilon_\ast \). Hence the conclusion follows. \( \square \)
3.5.2. Recurrent case. Now we work on the case that \( c \) is recurrent. By the no wild recurrent critical points assumption, the critical point \( c \) is tame. Let \( c' \in \text{Crit}_K'(\phi) \) be any critical point such that \([c'] = [c]\). If \( c' \in \partial J_K^c(\phi) \), by Lemma 3.1 and the forward invariance and closedness of \( J_K(\phi) \), we have \( c \in J_K(\phi) \). Thus for the remainder of this section, we assume that \( c' \in \text{Int}(J_K^c(\phi)) \) for all such \( c' \). Consider \( 0 < \delta < \epsilon_0 \) such that for all aforementioned \( c' \), the disk \( D_{\mathbb{P}_c}(c', \delta) \subset \text{Int}(J_K^c(\phi)) \). Moreover, for \( x \in D_{\mathbb{P}_c}(c', \delta) \) with \( x \neq c' \), set \( s_x = \rho(x, c') \), let \( D(x) := D_{\mathbb{P}_c}(x, s_x) \subset D_{\mathbb{P}_c}(c', \delta) \) and \( \overline{D}(x) := \overline{D_{\mathbb{P}_c}(x, s_x)} \), denote \( D_{\mathbb{P}_c}(x) := D_{\mathbb{P}_c}(x, s_x) \) and \( \overline{D_{\mathbb{P}_c}}(x, s_x) \) the corresponding disks in \( \mathbb{P}_c \), and write

\[
S_K(x) := \{ y \in D_{\mathbb{P}_c}(c', \delta) : s_y = s_x \}
\]

the sphere near \( c' \) containing \( x \).

We first show a result concerning the existence of the repelling periodic points, which will imply that \( c \in J_K(\phi) \) in the case that \( Q^{-1}([c]) = \{c\} \).

**Proposition 3.8.** Pick \( x \in D_{\mathbb{P}_c}(c, \delta) \) with \( x \neq c \). Assume that there exists a smallest \( n := n_x \geq 0 \) such that \( \phi^n(D(x)) \cap \text{Crit}_K(\phi) \neq \emptyset \). If

\[
\phi^n(D(x)) \cap \text{Crit}_K(\phi) = \{c\}
\]

and for all \( 1 \leq m \leq n \),

\[
diam(\phi^m(\overline{D(x)})) < \epsilon_0,
\]

then \( D(x) \) contains a repelling periodic point of \( \phi \) with period \( n \).

**Proof.** To ease notations, write \( D := D(x) \) and \( \overline{D} := \overline{D(x)} \). Consider the disks \( D_{\mathbb{P}_c} := D_{\mathbb{P}_c}(x) \) and \( \overline{D_{\mathbb{P}_c}} := \overline{D_{\mathbb{P}_c}(x)} \) in \( \mathbb{P}_c \). Let \( n_0 = 0 \) and inductively define \( n_{j-1} < n_j \leq n \) to be the smallest integer such that \( c \in \phi^{n_j}(\overline{D_{\mathbb{P}_c}}) \). By \(3.16\), there exists \( j_0 \geq 1 \) such that \( n_{j_0} = n \). The existence of repelling periodic points in \( D(x) \) is a consequence of the following claim.

**Claim 3.** For \( 1 \leq j \leq j_0 \), the following hold.

\begin{enumerate}
  \item \( c \notin \phi^{n_{j-1}}(D_{\mathbb{P}_c}) \).
  \item \( \phi^{n_{j-1}+1}(\overline{D_{\mathbb{P}_c}}) \neq \mathbb{P}_c \).
  \item \( \phi^{n_{j-1}-1} \) is scaling on \( \phi^{n_{j-1}+1}(\overline{D_{\mathbb{P}_c}}) \).
  \item \( \phi^{n_{j}} \) is scaling on \( D_{\mathbb{P}_c} \).
  \item \( \text{diam}(\phi^{n_{j}}(\overline{D_{\mathbb{P}_c}})) = \text{diam}(\phi^{n_{j}}(\overline{D})) < \epsilon_0 \) if \( j_0 > 1 \).
\end{enumerate}

We proceed the proof of Claim 3 by induction. For \( j = 1 \), the statement (a) follows immediately and the statement (b) follows from \(3.14\). We begin to show the statements (c)–(e) for \( j = 1 \). Noting that there is no open disk in \( \phi(\overline{D_{\mathbb{P}_c}}) \) containing \( \phi(\overline{D}) \), we obtain

\[
diam(\phi(\overline{D_{\mathbb{P}_c}})) = diam(\phi(\overline{D})).
\]

Then by \(3.16\) and \(3.17\), the map \( \phi \) is scaling on \( \phi(\overline{D_{\mathbb{P}_c}}) \). Let \( 1 \leq i_1 \leq n_1 - 1 \) be the largest integer such that \( \phi^{i_1} \) is scaling on \( \phi(\overline{D_{\mathbb{P}_c}}) \). If \( i_1 \neq n_1 - 1 \), then by \(3.18\), we have

\[
diam(\phi^{i_1+1}(\overline{D_{\mathbb{P}_c}})) = \text{diam}(\phi^{i_1+1}(\overline{D}))
\]

but

\[
diam(\phi^{i_1+2}(\overline{D_{\mathbb{P}_c}})) > \text{diam}(\phi^{i_1+2}(\overline{D}))
\]

However, by \(3.16\), \(3.17\) and \(3.19\), the map \( \phi \) is scaling on \( \phi^{i_1+1}(\overline{D_{\mathbb{P}_c}}) \), which implies that

\[
diam(\phi^{i_1+2}(\overline{D_{\mathbb{P}_c}})) = \text{diam}(\phi^{i_1+2}(\overline{D}))
\]

This contradicts \(3.20\). Hence \( i_1 = n_1 - 1 \) and \( \phi^{n_1-1} \) is scaling on \( \phi(\overline{D_{\mathbb{P}_c}}) \). Thus the statement (c) holds for \( j = 1 \). Since by Corollary 2.6 (1), the map \( \phi \) is scaling on \( D_{\mathbb{P}_c} \), we in fact have

\[
diam(\phi^{n_1}(\overline{D_{\mathbb{P}_c}})) = \text{diam}(\phi^{n_1}(\overline{D})) = \ldots = \text{diam}(\phi^{n_{j_0}}(\overline{D})) < \epsilon_0
\]

for all \( n_{j_0} \leq n \), as desired.
that \( \phi^n \) is scaling on \( D_{C_p} \), and hence the statement (d) holds for \( j = 1 \). Applying (3.16), (3.17), (3.18) and the statement (c) for \( j = 1 \), we obtain the statement (e) for \( j = 1 \).

If \( j_0 = 1 \), then we are done. If \( j_0 > 1 \), we do the induction step. We assume that the statements (a)–(e) hold for \( j = k < j_0 \) and we show that the statements (a)–(e) hold for \( j = k + 1 \). For the statement (a), if \( c \in \text{int}(D_{C_p}) \), then \( c \in \text{int}(D_{C_p}) \). Thus the statement (c) holds for \( j = k + 1 \). For the statement (b), since \( \phi^{n_k+n_k-1} \) is scaling on \( \phi^{n_k+n_k-1}(D_{C_p}) \), it follows that \( \phi^{n_k+n_k-1}(D_{C_p}) \neq \mathbb{P}^1_{C_p} \). Moreover, noting that \( \text{diam}(\phi^{n_k+n_k-1}(D_{C_p})) < \epsilon_0 \) and \( c \in \phi^{n_k+n_k-1}(D_{C_p}) \), by (3.22), we have \( \phi^{n_k+n_k-1}(D_{C_p}) \neq \mathbb{P}^1_{C_p} \). Hence the statement (b) holds for \( j = k + 1 \).

Since \( \text{diam}(\phi^{n_k+n_k-1}(D_{C_p})) = \text{diam}(\phi^{n_k+n_k-1}(D)) < \epsilon_0 \) and \( c \in \phi^{n_k+n_k-1}(D) \), as in (3.18),

\[
\text{diam}(\phi^{n_k+n_k-1}(D_{C_p})) = \text{diam}(\phi^{n_k+n_k-1}(D)).
\]

Moreover, by (3.16) and (3.17), the map \( \phi \) is scaling on \( \phi^{n_k+n_k-1}(D_{C_p}) \). Let \( 0 \leq k+1 \leq n_k - n_k - 1 \) be the largest integer such that \( \phi^{k+1} \) is scaling on \( \phi^{k+1}(D_{C_p}) \). If \( i_1 \neq n_k + n_k - 1 \), then by (3.21), it follows that

\[
\text{diam}(\phi^{n_k+i_k+1}(D_{C_p})) = \text{diam}(\phi^{n_k+i_k+1}(D)),
\]

but

\[
\text{diam}(\phi^{n_k+i_k+1+2}(D_{C_p})) > \text{diam}(\phi^{n_k+i_k+1+2}(D)).
\]

However, by (3.16), (3.17) and (3.22), the map \( \phi \) is scaling on \( \phi^{n_k+i_k+1+2}(D_{C_p}) \), which implies

\[
\text{diam}(\phi^{n_k+i_k+1+2}(D_{C_p})) = \text{diam}(\phi^{n_k+i_k+1+2}(D)).
\]

This contradicts (3.23). Hence \( i_1 = n_k - n_k - 1 \) and \( \phi^{n_k+n_k-1} \) is scaling on \( \phi^{n_k+n_k-1}(D_{C_p}) \). Thus the statement (c) holds for \( j = k + 1 \).

By Corollary 2.6 (1), since \( \text{diam}(\phi^{n_k+n_k-1}(D_{C_p})) < \epsilon_0 \), the statement (a) for \( j = k + 1 \) implies that \( \phi \) is scaling on \( \phi^{n_k+n_k-1}(D_{C_p}) \). Moreover, the statement (c) for \( j = k + 1 \) implies that \( \phi^{n_k+n_k-1} \) is scaling on \( \phi^{n_k+n_k-1}(D_{C_p}) \). It follows that \( \phi^{n_k+n_k-1} \) is scaling on \( \phi^{n_k+n_k-1}(D_{C_p}) \). Since \( \phi^{n_k} \) is scaling on \( D_{C_p} \), the statement (d) holds for \( j = k + 1 \). Combining the statement (c) for \( j = k + 1 \) and (3.21), we obtain

\[
\text{diam}(\phi^{n_k+n_k-1}(D_{C_p})) = \text{diam}(\phi^{n_k+n_k-1}(D)).
\]

Then the statement (e) for \( j = k + 1 \) follows immediately from (3.17) and (3.24). Therefore, Claim 3 holds.

We continue to show that \( D \) contains a repelling periodic point of \( \phi \). From the statements (b) and (c) for \( j = j_0 \) in Claim 3, we conclude that \( \phi^{n_k}(D_{C_p}) \neq \mathbb{P}^1_{C_p} \). It follows that

\[
\text{diam}(\phi^{n_k}(D_{C_p})) = \text{diam}(\phi^{n_k}(D_{C_p})).
\]

Note that

\[
\frac{\text{diam}(D)}{\text{diam}(D_{C_p})} = |\pi|.
\]

Then the statement (d) for \( j = j_0 \) in Claim 3 implies that

\[
\frac{\text{diam}(\phi^{n_k}(D))}{\text{diam}(\phi^{n_k}(D_{C_p}))} = |\pi|.
\]

Since \( c \in J_{C_p}(\phi) \) and \( c \in D \cap \phi^{n_k}(D) \subset D_{C_p} \cap \phi^{n_k}(D_{C_p}) \), it follows that \( D_{C_p} \subseteq \phi^{n_k}(D_{C_p}) \). Hence by (3.25),

\[
\text{diam}(D_{C_p}) < \text{diam}(\phi^{n_k}(D_{C_p})).
\]
Combining \([3.26]\), \([3.27]\) and \([3.28]\), we obtain
\[
\text{diam}(D) = |\pi|\text{diam}(D_{C_p}) < |\pi|\text{diam}(\phi^n(D_{C_p})) = \text{diam}(\phi^n(D)).
\]
Hence
\[
\text{diam}(\overline{D}) \leq \text{diam}(\phi^n(D)). \tag{3.29}
\]
Again since \(c \in \overline{D} \cap \phi^n(D)\), it follows from \([3.29]\) that \(\overline{D} \subset \phi^n(D)\), and hence \(D \subset \phi^n(D)\).

Then by the statement (d) for \(j = j_0\) in Claim 3, the map \(\phi\) has a repelling periodic point \(x \in D\). By the choice of \(n\), the point \(x\) is of period \(n\). \(\square\)

**Corollary 3.9.** If \(Q^{-1}([c]) = \{c\}\) and \(c\) is recurrent, then \(c \in J_K(\phi)\).

**Proof.** Suppose, on the contrary that \(c \in F_K(\phi)\). Shrinking \(\delta\) if necessary, we assume \(D_{p_1}^\phi(c, \delta) \subset F_K(\phi)\). Moreover, by the equicontinuity, for all \(m \geq 0\), we can assume
\[
\text{diam}(\phi^m(D_{p_1}^\phi(c, \delta))) < \epsilon_0.
\]

Pick an arbitrary \(x \in D_{p_1}^\phi(c, \delta)\) with \(x \neq c\) and consider \(D(x)\). Then \(D(x) \subset \text{Int}(J_K(\phi))\). If the orbit of \(D(x)\) intersects \(\text{Crit}_K(\phi)\), by the choice of \(\epsilon_0\), we have that \(c\) is the unique point in the intersection. Proposition 3.8 implies that \(D(x)\) contains a repelling periodic point of \(\phi\). Since \(D(x) \subset F_K(\phi)\), the orbit of \(D(x)\) must disjoint \(\text{Crit}_K(\phi)\). However, noting that \(D(x) \subset \text{Int}(J_K(\phi))\), by Lemma 3.2 we deduce that there exists \(\epsilon_* > 0\), independent of \(x\) such that
\[
\sup_{n \geq 1} \text{diam} \phi^n(D(x)) \geq \epsilon_*.
\]
This implies \(c \in J_K(\phi)\) which hence contradicts the assumption \(c \in F_K(\phi)\). \(\square\)

Now we consider the case that \(Q^{-1}([c]) = \{c, c_1\}\) with \(c \neq c_1\). Again, we first show a result concerning the existence of repelling periodic points.

**Proposition 3.10.** Pick \(x \in D_{p_1}^\phi(c, \delta)\) with \(x \neq c\). Suppose that

1. for any \(y \in S_K(x)\), there exists a smallest \(n_y \geq 1\) such that \(\phi^{n_y}(D(y)) \cap \text{Crit}_K(\phi) \neq \emptyset\);
2. for all \(y \in S_K(x)\), \(\phi^{n_y}(D(y)) \cap \text{Crit}_K(\phi) = \{c_1\}\); and
3. for any \(y \in S_K(x)\) and all \(1 \leq m \leq n_y\), \(\text{diam}(\phi^m(\overline{D(y)})) < \epsilon_0\).

Then the following hold.

(i) If there exists \(y_0 \in S_K(x)\) such that \(n_{y_0} \neq n_x\), then \(D(x) \cup D(y_0)\) contains a repelling preperiodic point of \(\phi\).

(ii) If \(n_y = n_x\) for all \(y \in S_K(x)\), picking \(z \in D_{p_1}^\phi(c_1, \epsilon_0)\) with \(s_z = |\pi|\text{diam}(\phi^{n_z}(D_{C_p}(x)))\), we further assume that

(a) for any \(w \in S_K(z)\), there exists a smallest \(n_w \geq 1\) such that \(\phi^{n_w}(D(w)) \cap \text{Crit}_K(\phi) \neq \emptyset\);
(b) for all \(w \in S_K(z)\), \(\phi^{n_w}(D(w)) \cap \text{Crit}_K(\phi) = \{c\}\); and
(c) for any \(w \in S_K(z)\) and all \(1 \leq m \leq n_w\), \(\text{diam}(\phi^m(\overline{D(w)})) < \epsilon_0\).

Then if \(\phi^{n_w}(D_{C_p}(x)) = \phi^{n_z}(D_{C_p}(z))\) and \(n_w = n_z\) for all \(w \in S_K(z)\), we have that for any \(y \in S_K(x)\), the disk \(D(y)\) contains a repelling periodic point.

**Proof.** If there exists \(y_0 \in S_K(x)\) such that \(n_{y_0} \neq n_x\), without loss of generality, we may assume that \(n_{y_0} > n_x\). Observe \(c_1 \in \phi^{n_x}(D(x))\). Then, by the assumption (3), \(\phi^{n_x}(D(x)) \subset D_{p_1}^\phi(c_1, \epsilon_0)\), and we have that \(c_1 \notin \phi^{n_x}(D(y_0)) \subset D_{p_1}^\phi(c_1, \epsilon_0)\) but \(c_1 \in \phi^{n_{y_0} - n_x}(\phi^{n_x}(D(x)))\).

Note that by the choice of \(\epsilon_0\) and the assumption (3), the map \(\phi^{n_{y_0} - n_x}\) is scaling on the smallest disk in \(p_{c_1}^{n_x}\) containing \(\phi^{n_x}(D(y_0))\). Then \(\phi^{n_x}(D(y_0))\) contains a repelling periodic point of \(\phi\) with period \(n_{y_0} - n_x\). Since \(\phi^{n_x}\) is scaling on \(D_{C_p}(y_0)\), Corollary 2.9 implies that \(D(y_0)\) contains a repelling preperiodic point of \(\phi\), and hence the statement (i) holds.
Now we show the statement (ii). Note that by Corollary 2.6 (1) and (3.14),
\[
\operatorname{diam}(\phi(D(x))) = \operatorname{diam}(\phi(D_{C_p}(x))) = \operatorname{diam}(\phi(D_{C_\ell}(x))).
\] (3.30)
By the assumption (3) and (3.30), we have \(\phi(D_{C_\ell}(x)) \neq \mathbb{P}^1_{C_\ell}\). The choice of \(\epsilon_0\) and the assumption (3) imply that \(\phi^{n_{x}-1}\) is scaling on \(\phi(D_{C_\ell}(x))\) and hence \(\phi^{n_{x}}(D_{C_\ell}(x)) \neq \mathbb{P}^1_{C_\ell}\).

For \(y \in S_K(x)\), consider the disks \(\overline{D}^{(1)}(y) := D_{p_1K'}(y, |\pi|s_y)\) and \(\overline{D}^{(1)}(y) := D_{p_1C_{p_1}}(y, |\pi|s_y)\), and also set \(\overline{D}^{(1)}(c) := D_{p_1C_{p_1}}(c, |\pi|s_x)\). We conclude that
\[
\frac{\operatorname{diam}\left(\phi^{n_{x}}(\overline{D}^{(1)}(y))\right)}{\operatorname{diam}\left(\phi^{n_{x}}(D_{C_p}(y))\right)} = |\pi|,\] (3.31)
and
\[
\frac{\operatorname{diam}\left(\phi^{n_{x}}(\overline{D}^{(1)}(c))\right)}{\operatorname{diam}\left(\phi^{n_{x}}(D_{C_p}(y))\right)} = |\pi|^{\deg \phi}.\] (3.32)

If \(\phi^{n_{x}}(D_{C_\ell}(x)) = \phi^{n_{x}}(D_{p_1C_{p_1}}(c, s_x))\), then \(c_1 \in \phi^{n_{x}}(D_{p_1C_{p_1}}(c, s_x))\). From the assumption (2) and the assumption \(n_y = n_x\), we deduce that \(c_1 \in \phi^{n_{x}}(\overline{D}^{(1)}(y))\). By (3.31) and (3.32),
\[
\phi^{n_{x}}(\overline{D}^{(1)}(c)) \subset \phi^{n_{x}}(\overline{D}^{(1)}(y)).\] (3.33)
Moreover, by the choice of \(z\) and by combining with (3.31), we have
\[
\operatorname{diam}\left(\phi^{n_{x}}(\overline{D}^{(1)}(y))\right) = s_z.
\]
If further \(n_w = n_z\) for all \(w \in S_K(z)\), then \(c \in \phi^{n_{w}+n_z}(\overline{D}^{(1)}(y))\). Moreover,
\[
\overline{D}^{(1)}_{C_p}(y) \subset \phi^{n_{w}+n_z}(\overline{D}^{(1)}_{C_p}(y)).\] (3.34)
Indeed, otherwise, if \(\phi^{n_{w}+n_z}(\overline{D}^{(1)}_{C_p}(y)) \subset \overline{D}^{(1)}_{C_p}(y)\), then \(\phi^{n_{w}+n_z}(\overline{D}^{(1)}_{C_p}(y)) \subset \overline{D}^{(1)}_{C_p}(c)\), and hence by (3.33), we obtain \(\phi^{n_{w}+n_z}(\overline{D}^{(1)}_{C_p}(c)) \subset \overline{D}^{(1)}_{C_p}(c)\), which implies that \(\overline{D}^{(1)}_{C_p}(c) \subset F_{C_p}(\phi)\) contradicting the assumption \(c \in J_{C_p}(\phi)\).

By (3.34), we first consider the case that \(\overline{D}^{(1)}_{C_p}(y) = \phi^{n_{w}+n_z}(\overline{D}^{(1)}_{C_p}(y))\). If \(c \in \phi^{n_{w}+n_z}(\overline{D}^{(1)}_{C_p}(c))\), then by (3.33), we have \(\phi^{n_{w}+n_z}(\overline{D}^{(1)}_{C_p}(c)) \subset \overline{D}^{(1)}_{C_p}(y)\), and hence \(\phi^{n_{w}+n_z}(\overline{D}^{(1)}_{C_p}(c)) \subset \overline{D}^{(1)}_{C_p}(c)\), which also contradicts the assumption \(c \in J_{C_p}(\phi)\). If \(c \not\in \phi^{n_{w}+n_z}(\overline{D}^{(1)}_{C_p}(c))\), then by the assumptions (b) and (c), we have
\[
\frac{\operatorname{diam}\left(\phi^{n_{w}+n_z}(\overline{D}^{(1)}_{C_p}(c))\right)}{\operatorname{diam}\left(\phi^{n_{w}+n_z}(\overline{D}^{(1)}_{C_p}(y))\right)} = |\pi|^{\deg \phi}.\] (3.35)
It follows that there exists \(y_0 \in S_K(x)\) such that
\[
\phi^{n_{w}+n_z}(\overline{D}^{(1)}_{C_p}(c)) \subset \overline{D}^{(1)}_{C_p}(y_0) \subset \overline{D}^{(1)}_{C_p}(x).\] (3.36)
Inductively, by (3.36), for any \(k \geq 1\), we conclude that
\[
\phi^{k(n_{w}+n_z)}(\overline{D}^{(1)}_{C_p}(c)) \subset \overline{D}^{(1)}_{C_p}(x),
\]
which implies that
\[
\phi^{n_{w}+n_z}(\overline{D}^{(1)}_{C_p}(c)) \subset F_{C_p}(\phi).\] (3.37)
However, noting $\overline{D}(x) \subset D_{K^1}(c, \delta) \subset J_{K^p}(\phi)$ and $\phi^{n_x+n_z}(\overline{D}_{K^p}(c)) \cap \mathbb{P}_K^1 \neq \emptyset$ since $c \in \mathbb{P}_K^1$, by (3.36), we obtain
\[ \phi^{n_x+n_z}(\overline{D}_{K^p}(c)) \cap J_{K^p}(\phi) \neq \emptyset, \]
which contradicts (3.37).

We now consider the case that $\overline{D}_{K^p}(y) \subset \phi^{n_x+n_z}(\overline{D}_{K^p}(y))$. Then by the assumptions (b), (c) and Corollary 2.6 (1), for any $w \in S_K(z)$,
\[ \overline{D}_{K^p}(y) \subset \phi^n(D_{K^p}(w)). \]
Since by the assumptions (2), (3) and Corollary 2.6 (1), the map $\phi^n$ is scaling on $\overline{D}_{K^p}(y)$, considering the disks $\overline{D}_{K^p}(y') := D_{K^p}(y', |\pi|s_y)$ for $y' \in \overline{D}_{K^p}(y)$ with $\rho(y, y') = |\pi|s_y$, we have that $\phi^n$ maps all except one such disks to maximal disks in $S_K(z)$. Pick such a disk $\overline{D}_{K^p}(y')$ that is mapped to $S_K(z)$ by $\phi^n$. It follows that $\phi^{n_x+n_z}$ is scaling on $\overline{D}_{K^p}(y')$. By (3.38),
\[ \overline{D}_{K^p}(y') \subset \overline{D}_{K^p}(y) \subset \phi^{n_x+n_z}(\overline{D}_{K^p}(y')). \]
and hence setting $D^{(1)}(y') := D_{K^p}(y') \cap \mathbb{P}_K^1$, we conclude
\[ D^{(1)}(y') \subset \phi^{n_x+n_z}(D^{(1)}(y')). \]
It follows that $D^{(1)}(y')$ contains a periodic point of $\phi$.

Thus the statement (ii) holds and this completes the proof. \qed

**Corollary 3.11.** If $Q^{-1}([c]) = \{c, c_1\}$ and $c \neq c_1$, then $c \in J_K(\phi)$.

**Proof.** Suppose, on the contrary that $c \in F_K(\phi)$. It follows that $c_1 \in F_K(\phi)$; for otherwise, $\mathcal{O}_\phi(c_1) \subset J_K(\phi)$ and hence $c \in J_K(\phi)$, which is a contradiction. Shrinking $\delta$ if necessary, we can assume $D_{K^1}(c, \delta) \cup D_{K^1}(c_1, \delta) \subset F_K(\phi)$. Moreover, by the equicontinuity, for all $m \geq 0$, we can also assume that
\[ \text{diam}(\phi^m(D_{K^1}(c, \delta))) + \text{diam}(\phi^m(D_{K^1}(c_1, \delta))) < \varepsilon_0. \]
Applying Lemma 3.2 Propositions 3.8 and 3.10 and switching $c$ and $c_1$ if necessary, we only need to dispose of the case that for all $x \in D_{K^1}(c, \delta)$ with $x \neq c$, one has

1. the assumptions (1)–(3) in Proposition 3.10 hold;
2. $n_y = n_x$ for all $y \in S_K(x)$;
3. $\phi^{n_z}(D_{K^p}(x)) \neq \phi^{n_z}(D_{K^p}(c, s_x))$;
4. $\phi^{n_z}(D_{K^p}(c)) \subset D_{K^p}(c_1, \delta)$; and
5. there exists a smallest integer $\ell \geq 1$ such that
   a. $\phi^{n_x+\ell}(D_{K^p}(c, s_x)) \cap \text{Crit}_{K^p}(\phi) \neq \emptyset$;
   b. $\phi^{n_x+\ell}(D_{K^p}(c, s_x)) \cap \text{Crit}_{K^p}(\phi) = \{c\}$; and
   c. $c \notin \phi^{n_x+\ell}(D_{K^p}(x))$.

Indeed, in all other cases, we have that either $D_{K^1}(c, \delta)$ contains a repelling (pre)periodic point or $\sup_{n \geq 0} \{\phi^n(D(x))\} \geq \min\{\epsilon_0, \delta\}$, which contradicts the assumption $D_{K^1}(c, \delta) \subset F_K(\phi)$.

It follows that
\[ \rho(\phi^{n_x+\ell}(c), \phi^{n_x+\ell}(x)) > \rho(c, x). \]
Considering the forward orbit of $D(x)$ in $D(c, \delta)$ and repeatedly applying the above argument, we eventually obtain

$$
\sup_{n \geq 1} \rho(\phi^n(c), \phi^n(x)) > \delta.
$$

Hence $\{\phi^n\}_{n \geq 1}$ is not equicontinuous at $c$ in $\mathbb{P}^1_K$, which contradicts the assumption $c \in F_K(\phi)$. \hfill \Box

**Proof of Theorem 1.2.** Theorem 1.2 immediately follows from Lemma 3.1, Propositions 3.4, 3.6, 3.7, Corollaries 3.9 and 3.11. \hfill \Box

4. A FIRST EXAMPLE

In this section, consider $f : \mathbb{P}^1_{\mathbb{Q}_2} \to \mathbb{P}^1_{\mathbb{Q}_2}$ given by

$$
f(x) = \frac{9}{4}x(x - 1)^2.
$$

As we will see in Section 4.1, the polynomial $f$ is postcritically finite, each of whose critical critical points is eventually periodic. We prove that Theorem 1.3 holds for $f$. The argument sheds light on the proof of Theorem 1.3 in the next section.

**Remark 4.1.** In [30, Section 4], Ingram classified the cubic postcritically finite complex polynomials with rational coefficients into seven conjugacy classes. Since these polynomials are of rational coefficients, we can regard them as polynomials from $\mathbb{P}^1_{\mathbb{Q}_p}$ to itself. It turns out that for $p \geq 3$, these polynomials possess no Julia critical points, and up to conjugacy, the above $f$ is the unique such polynomial whose corresponding 2-adic Julia set contains a critical point.

Our main goal in this section is to prove the following result. Recall the notations from Section 1 and write $I(f) := I_{\mathbb{Q}_2}(f) = J_{\mathbb{Q}_2}(f) \setminus \text{GO}_{\mathbb{Q}_2}(1)$ for simplicity.

**Theorem 4.2.** Let $f$ be as above. Then there exist a countable state Markov shift $(\Sigma_A, \sigma)$ and a bijection $h : J_{\mathbb{Q}_2}(f) \to \Sigma_A$ such that $I(f)$ is topologically conjugate to $(h(I(f)), \sigma)$ via $h$.

In Section 4.1 we describe the orbit of disks in $\mathbb{Q}_2$ under $f$ and depict the Julia and Fatou sets of $f$. In Section 4.2 we illustrate the orbit of disks on $\mathbb{Q}_2$ under $f$ in terms of tree of closed disks. Then we prove Theorem 4.2 in Section 4.3. The proof contains exact scaling ratios of the iterations of $f$. However, we remark that when we deal with the general case in Section 5 we do not require those ratios precisely. To help readers catch the idea of the proof of Theorem 1.3 all details for $f$ will be given. Finally, we compute the Gurevich entropy of $f$ in Section 4.4. It turns out that this entropy is the logarithm of an algebraic number.

To ease notations, in this section, we write $|\cdot|$ for the absolute value on $\mathbb{Q}_2$ and write $F(f)$, $J(f)$ and $\text{GO}(1)$ for the Fatou set $F_{\mathbb{Q}_2}(f)$, the Julia set $J_{\mathbb{Q}_2}(f)$ and the grand orbit $\text{GO}_{\mathbb{Q}_2}(1)$, respectively. We begin with the determination of the Julia and Fatou sets of $f$.

4.1. Julia and Fatou sets of $f$. First note that the fixed point $\infty \in F(f)$. Further, $\{\infty\}$ is totally $f$-invariant, we thus need only focus on the dynamics in $\mathbb{Q}_2$. Note also that the fixed points of $f$ are $0$ and $1/3$ and the critical points of $f$ are $1$ and $1/3$. Moreover, both of the critical points are wild. Observe that $1/3$ is contained in $F_{\mathbb{Q}_2}(f)$, and hence in $F(f)$. The point $0$ is a repelling fixed point with multiplier $9/4$, and hence $0 \in J(f)$. The critical point $1$ is mapped to $0$ by $f$. It follows that $1 \in J_{\mathbb{Q}_2}(f) \cap \mathbb{Q}_2$, and $J_{\mathbb{Q}_2}(f) \cap \mathbb{Q}_2$ contains no recurrent critical points. By Theorem 1.2 we have $1 \in J(f)$. Moreover, we can define a component of $F(f)$ to be the restriction of a component of $F_{\mathbb{Q}_2}(f)$ to $\mathbb{Q}_2$.

To characterize the Julia dynamics, we first consider the Fatou set. Recall that the ring of integers of $\mathbb{Q}_2$ is $\mathbb{Z}_2 := \{x \in \mathbb{Q}_2 : |x| \leq 1\}$. For a point $a \in F(f)$, denote by $\Omega_a$ the component
of $F(f)$ containing $a$. We also denote by $\Omega_\infty$ the basin of $\infty$ for $f$, that is, the set of points in $\mathbb{Q}_2$ whose orbits diverge to $\infty$.

**Lemma 4.3.** The Fatou component $\Omega_\infty$ contains $\mathbb{Q}_2 \setminus \mathbb{Z}_2$.

**Proof.** For $x \in \mathbb{Q}_2$ with $|x| > 1$, we have
\[
|f(x)| = 4|x||(x-1)^2| = 4|x^3| > |x|.
\]
It follows that $\mathbb{Q}_2 \setminus \mathbb{Z}_2 \subset \Omega_\infty$. \qed

Now we concentrate our attention on $\mathbb{Z}_2$. Note that
\[
\mathbb{Z}_2 = 2\mathbb{Z}_2 \cup (1 + 2\mathbb{Z}_2) = 4\mathbb{Z}_2 \cup (2 + 4\mathbb{Z}_2) \cup (1 + 4\mathbb{Z}_2) \cup (1 + 2 + 4\mathbb{Z}_2).
\]
The dynamics on the disks $2 + 4\mathbb{Z}_2$ and $1 + 2 + 4\mathbb{Z}_2$ are quite simple:

**Lemma 4.4.** The disks $2 + 4\mathbb{Z}_2$ and $1 + 2 + 4\mathbb{Z}_2$ are in $F(f)$. More precisely,

1. $2 + 4\mathbb{Z}_2 \subset \Omega_\infty$; and
2. $1 + 2 + 4\mathbb{Z}_2 \subset \Omega_{1/3}$.

**Proof.** For the statement (1), pick $x \in 2 + 4\mathbb{Z}_2$. We have $|f(x)| = 4|x| > 1$. Hence by Lemma 4.3, we conclude that $f(2 + 4\mathbb{Z}_2) \subset \Omega_\infty$. Hence $2 + 4\mathbb{Z}_2 \subset \Omega_\infty$.

For the statement (2), note that
\[
\frac{1}{3} = 1 + 2 + 2^3 + 2^5 + \cdots \in 1 + 2 + 4\mathbb{Z}_2.
\]
Pick an arbitrary point $x \in 1 + 2 + 4\mathbb{Z}_2$. Then $3(1-x)/2 \in 1 + 2\mathbb{Z}_2$. Writing $3(1-x)/2 = 1 + y$ with $y \in 2\mathbb{Z}_2$, we have
\[
\left|f(x) - \frac{1}{3}\right| = \left|\frac{9}{4}x(1-x)^2 - \frac{1}{3}\right| = \left|x(\frac{3}{2}(1-x))^2 - \frac{1}{3}\right| = \left|x + 2xy + xy^2 - \frac{1}{3}\right| \leq \left|x - \frac{1}{3}\right|.
\]
Hence $1 + 2 + 4\mathbb{Z}_2 \subset \Omega_{1/3}$. \qed

Now we analyze the orbit of the disks in $4\mathbb{Z}_2$ and $1 + 4\mathbb{Z}_2$, which allows us to construct a subshift on an alphabet of countably many symbols in Section 4.3. We begin with the disk $4\mathbb{Z}_2$.

**Proposition 4.5.** The map $f$ is scaling on $4\mathbb{Z}_2$ with scaling ratio 4. Moreover, for $n \geq 1$ and $a,b \in \{0,1\}$, the following hold:

1. $f(2^{n+1}\mathbb{Z}_2) = 2^{n-1}\mathbb{Z}_2$;
2. $f(2^{n+1} + 2^n\mathbb{Z}_2) = 2^{n-1} + 2^n\mathbb{Z}_2$;
3. $f(2^{n+1} + a2^n + 2^n\mathbb{Z}_2) = 2^{n-1} + a2^n + 2^n\mathbb{Z}_2$; and
4. $f(2^{n+1} + a2^n + b2^n + 2^n\mathbb{Z}_2) = 2^{n-1} + a2^n + b2^n + 2^n\mathbb{Z}_2$.

**Proof.** Observe that
\[
|f(x) - f(y)| = 4|(x^3 - 2x^2 + x) - (y^3 - 2y^2 + y)| = 4|x - y||x^2 + y^2 + xy - 2(x - y) + 1|.
\]
Then for $x,y \in 4\mathbb{Z}_2$,
\[
|f(x) - f(y)| = 4|x - y|.
\]
Thus any disk contained in $4\mathbb{Z}_2$ is mapped to a disk with radius multiplied by 4. Then the statement (1) follows immediately. Direct computation shows
\[
|f(2^{n+1} + a2^n + b2^n + 2^n\mathbb{Z}_2) - (2^{n-1} + a2^n + b2^n + 1)| = 2^n + 2.
\]
Hence, the statements (2) to (4) hold. \qed

The following corollary gives more details of the orbits of the disks in $4\mathbb{Z}_2$.

**Corollary 4.6.** For $n \geq 1$, the following hold:
Then the statement (2) holds.

Direct computations show that

\[ \left| r \right| \]

By Lemma 2.1, it suffices to pick

\[ r \]

Proposition 4.7. For

\[ f \]

For any point \( x \) of \( S_0(f) \), the image \( f(D) \) is also a disk since the map \( f \) is scaling on \( D \) with scaling ratio \( |f'(x_0)| \).

**Proposition 4.7.** For \( n \geq 1 \), the following hold:

1. \( f(2^n + 2^nZ_2) = 2^{n-2} + 2^{n+1}Z_2 \), in particular,
2. \( f(2^n + 2^nZ_2) = \{1\} \bigcup \bigcup_{m \geq 2} ((1 + 2^{m+1} + 2^{m+3}Z_2) \cup (1 + 2^{m+1} + 2^{m+2} + 2^{m+3}Z_2)) \);
3. \( f(2^{n+1} + 2^{n+2}Z_2) = 2^{n-1} + 2^nZ_2 \), in particular,
4. \( f(2^n + 2^nZ_2) = 2^{n-2} + 2^n + 2^{n+1}Z_2 \);
5. \( f(2^n + 2^nZ_2) = 2^{n+1} + 2^nZ_2 \), in particular,
6. \( f^n(2^n + 2^nZ_2) = 1 + 2 + 2^nZ_2 \).

Then by Lemmas 4.3 and 4.4, the second assertions of the statements (3) and (4) hold.

Proof. The statements (1), (2) and the first assertions of the statements (3), (4) follow immediately from Proposition 4.7. For the remaining assertions, by induction, we have

\[ f^{n+1}(2^{n+1} + 2^{n+2}Z_2) = (2^{-1} + Z_2) \subset Q_2 \setminus Z_2, \]

and

\[ f^n(2^n + 2^nZ_2) = 1 + 2 + 2^nZ_2. \]

On the disk \( 1 + 4Z_2 \), the dynamics is more subtle since the image of a disk is not necessary a disk. However, by Lemma 2.1, for any point \( x_0 \in 1 + 4Z_2 \) with \( x_0 \neq 1 \) and \( x_0 \neq 1/3 \), there is a maximal scaling disk \( S_{x_0}(f) \) of \( x_0 \). Then for any disk \( D \subset S_{x_0}(f) \), the image \( f(D) \) is also a disk since the map \( f \) is scaling on \( D \) with scaling ratio \( |f'(x_0)| \).

**Proposition 4.7.** For \( n \geq 1 \), the following hold:

1. \( f(1 + 2^nZ_2) \subset 2^{n-2}Z_2; \)
2. \( f(1 + 2^nZ_2) = 2^{n+1} + 2^{n+2}Z_2 \), in particular, \( f \) is scaling on \( 1 + 2^{n+1} + 2^{n+2}Z_2 \) with scaling ratio \( 2^{-n} \); and
3. \( f(1 + 2^nZ_2) = 2^{n+1} + 2^{n+2}Z_2 \), in particular, \( f \) is scaling on \( 1 + 2^{n+1} + 2^{n+2} + 2^{n+3}Z_2 \) with scaling ratio \( 2^{-n} \).

Proof. For the statement (1), pick \( x \in 1 + 2^nZ_2 \). Then \( |x| = 1 \) and \( |x - 1| \leq 2^{-n} \). Hence

\[ |f(x)| = 4|x||x - 1|^2 \leq 2^{-2n+2}, \]

and the conclusion follows.

For the statement (2), pick \( x_0 \in 1 + 2^nZ_2 \). We calculate the scaling disk \( S_{x_0}(f) \) of \( x_0 \). Consider the Taylor series of \( f \) near \( x_0 \):

\[ f(x) - f(x_0) = f'(x_0)(x - x_0) + \frac{f''(x_0)}{2}(x - x_0)^2 + \frac{f'''(x_0)}{6}(x - x_0)^3. \]

By Lemma 2.1, it suffices to pick \( r_{x_0} > 0 \) such that

\[ \left| \frac{f''(x_0)}{2} \right| r_{x_0} < |f'(x_0)| \quad \text{and} \quad \left| \frac{f'''(x_0)}{6} \right| r_{x_0}^2 < |f'(x_0)|. \]

Direct computations show that \( |f'(x_0)| = 2^{-n} \), \( |f''(x_0)| = 2 \), and \( |f'''(x_0)| = 2 \). Hence \( r_{x_0} < 2^{-(n+2)} \). Therefore, \( S_{x_0}(f) = D(x_0, 2^{-(n+3)}) \). It follows that for any \( x \in S_{x_0}(f) \),

\[ |f(x) - f(x_0)| = |f'(x_0)||x - x_0| = 2^{-n}|x - x_0|. \]

Note that

\[ f(1 + 2^{n+1}) = 2^{2n} + 2^{2n+3} + 2^{3n+1} + 2^{3n+4}. \]

Then the statement (2) holds.
For the statement (3), pick $y_0 \in 1 + 2^{n+1} + 2^{n+2} + 2^{n+3} \mathbb{Z}_2$. Again by Lemma 2.1, we have $S_{y_0}(f) = D(y_0, 2^{-(n+3)})$. Direct computations give us
\[ |f(1 + 2^{n+1} + 2^{n+2}) - 2^{2n}| = 2^{-(2n+4)}. \]
Then the statement (3) holds. \qed

**Corollary 4.8.** The Fatou component $\Omega_{1/3}$ is $1 + 2 + 4\mathbb{Z}_2$.

**Proof.** It follows immediately from Lemma 4.4 and Proposition 4.7. \qed

Now we can characterize the Julia set $J(f)$. Lemmas 4.3 and 4.4 imply that $J(f)$ is contained in $4\mathbb{Z}_2 \cup (1 + 4\mathbb{Z}_2)$. In fact, we have the following proposition.

**Proposition 4.9.** The Julia set of $f$ is
\[ J(f) = \bigcap_{n \geq 1} f^{-n}(4\mathbb{Z}_2 \cup (1 + 4\mathbb{Z}_2)). \]

**Proof.** If $x \notin \bigcap_{n \geq 1} f^{-n}(4\mathbb{Z}_2 \cup (1 + 4\mathbb{Z}_2))$, then there exists $n_0 \geq 0$ such that
\[ f^{n_0}(x) \notin (Q_2 \setminus \mathbb{Z}_2) \cup (2 + 4\mathbb{Z}_2) \cup (1 + 2 + 4\mathbb{Z}_2). \]
By Lemmas 4.3 and 4.4, we conclude that $x \in F(f)$. Hence $J(f) \subseteq \bigcap_{n \geq 1} f^{-n}(4\mathbb{Z}_2 \cup (1 + 4\mathbb{Z}_2))$.

Conversely, pick $y \in \bigcap_{n \geq 1} f^{-n}(4\mathbb{Z}_2 \cup (1 + 4\mathbb{Z}_2))$. For any disk $D := D_Q(y, r)$, we claim that \( \{ f^k \}_{k \geq 1} \) is not equicontinuous on $D$. To ease notations, set
\[ W_0 := \bigcup_{n \geq 1} (1 + 2^{n+1} + 2^{n+3}\mathbb{Z}_2), \quad W_1 := \bigcup_{n \geq 1} (1 + 2^{n+1} + 2^{n+2} + 2^{n+3}\mathbb{Z}_2). \]
Shrinking $D$ if necessary, let $k_0 \geq 0$ be the smallest integer such that $f^{k_0}(D) \subseteq W_0$ or $f^{k_0}(D) \subseteq W_1$. If there is no such $k_0$, then by Proposition 4.5 and Corollary 4.6, we have $y \in \text{GO}_{Q_2}(1)$, which implies $y \notin J_{C_2}(f)$, and hence by Theorem 1.2, $y \notin J(f)$. Now, inductively define $k_i > k_{i-1}$ to be the smallest positive integer such that $f^{k_i}(D) \subseteq W_0$ or $f^{k_i}(D) \subseteq W_1$. By Propositions 4.5 and 4.7, there exists $m_i \geq 1$ such that the scaling ratio of $f$ on $f^{k_i}(D)$ is $2^{-m_i}$, and hence the scaling ratio of $f^{k_{i+1} - k_i - 1}$ on $f^{k_i+1}(D)$ is $4^{m_i}$. In fact, the relation between $k_i$ and $m_i$ is $m_i = k_{i+1} - k_i - 1$. Hence $\text{diam}(f^{k_i}(D)) = 2^{m_1 + m_2 + \cdots + m_{i-1}} \cdot 4^{m_i}r$. Since $m_i \geq 1$, there are only finitely many such $k_i$. Again by Propositions 4.5 and 4.7, there exists $\ell > \max\{ k_i : i \geq 0 \}$ such that $f^\ell(D) \cap (1 + 4\mathbb{Z}_2) \neq \emptyset$. Then $f^\ell(D)$ contains 1. Hence $D$ contains an $\ell$-th pre-image of 1. Since $1 \in J(f)$, by Lemma 2.8, $D \cap J(f) \neq \emptyset$. Thus the claim holds, and hence $y \notin J(f)$. \qed

**Corollary 4.10.** The Fatou set of $f$ is
\[ F(f) = \bigcup_{n \geq 0} f^{-n}(\Omega_\infty \cup \Omega_{1/3}). \]

In particular, any component of $F(f)$ is eventually mapped to $\Omega_\infty$ or $\Omega_{1/3}$.

**Proof.** Pick $x \in F(f)$. Suppose that $x \notin \bigcup_{n \geq 0} f^{-n}(\Omega_\infty \cup \Omega_{1/3})$. Then by Lemmas 4.3 and 4.4 for any $n \geq 0$, we have $f^n(x) \in 4\mathbb{Z}_2 \cup (1 + 4\mathbb{Z}_2)$. Proposition 4.9 implies that $x \notin J(f)$, which is a contradiction. Hence $x \in \bigcup_{n \geq 0} f^{-n}(\Omega_\infty \cup \Omega_{1/3})$.

For the other direction, if $x \in \bigcup_{n \geq 0} f^{-n}(\Omega_\infty \cup \Omega_{1/3})$, then there exists $n_0 \geq 0$ such that $f^{n_0}(x) \in \Omega_\infty \cup \Omega_{1/3}$. We claim that $x \in F(f)$. If, to the contrary, $x \in J(f)$, then from the portrait of the critical points of $f$ we know that $f^i(x)$ is not a critical point for $0 \leq i \leq n_0 - 1$. Hence, by Lemma 2.8, $f^{n_0}(x) \in J(f)$, which is impossible since $f^{n_0}(x) \in \Omega_\infty \cup \Omega_{1/3} \subseteq F(f)$. \qed
4.2. The tree of closed disks. To illustrate Corollary 4.6 and Proposition 4.7, we use the tree of closed disks. Let $\mathcal{T}$ be the space of closed disks in $\mathbb{Q}_2$ with radii in the value group $|\mathbb{Q}_2^\times|$. Since for any two closed disks in $\mathbb{Q}_2^2$, either they are disjoint or one contains the other, the inclusion gives an order relation on $\mathcal{T}$. We assign an undirected edge $[A, B]$ for the two elements $A$ and $B$, if $B$ is the smallest element in $\mathcal{T}$ that is larger than $A$. Then the space $\mathcal{T}$ admits a tree structure. The ends of the tree $\mathcal{T}$ are points in $\mathbb{P}^1_{\mathbb{Q}_2}$. Denote by $\partial \mathcal{T}$ the set of the ends and define $\mathcal{T} := \mathcal{T} \cup \partial \mathcal{T}$. For such trees in a more general setting, we refer to Section 1.2.

Since $\mathbb{Q}_2$ is not algebraically closed, the polynomial $f$ does not induce a well-defined map on $\mathcal{T}$. However, after removing countably many elements in $\mathcal{T}$, there is a well-defined map on the corresponding complement. By Lemma 4.3, we now focus on the closed disks in $\mathbb{Z}_2$. Let $\mathcal{T}_0 \subset \mathcal{T}$ be the set of closed disks in $\mathbb{Z}_2$ and let $\mathcal{T}_1 \subset \mathcal{T}$ be the set of closed disks in $1 + 2\mathbb{Z}_2$ removing the ones containing the critical point $1/3$. Denote by $\partial \mathcal{T}_0$ and $\partial \mathcal{T}_1$ the sets of ends for $\mathcal{T}_0$ and $\mathcal{T}_1$, respectively. Let $\mathcal{T}_0 := \mathcal{T}_0 \cup \partial \mathcal{T}_0$ and $\mathcal{T}_1 := \mathcal{T}_1 \cup \partial \mathcal{T}_1$.

Then the polynomial $f$ induces a well-defined map

$$F : \mathcal{T}_0 \cup \mathcal{T}_1 \to \mathcal{T}.$$ 

To view Corollary 4.6 and Proposition 4.7 from the map $F$, for $n \geq 1$, we define

$$A_n := 2^{2n} + 2^{2n+3}\mathbb{Z}_2,$$

$$A'_n := 2^{2n} + 2^{2n+2} + 2^{2n+3}\mathbb{Z}_2,$$

$$B_n := 1 + 2^{n+1} + 2^{n+3}\mathbb{Z}_2,$$

$$B'_n := 1 + 2^{n+1} + 2^{n+2} + 2^{n+3}\mathbb{Z}_2.$$ 

Then under $F$, we have the following portrait (see Figure 1):

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{portrait.png}
\caption{The portrait of $A_n$, $A'_n$, $B_n$ and $B'_n$ under $F$.}
\end{figure}

4.3. Proof of Theorem 4.2. We first establish several lemmas to relate the Julia dynamics of $f$ to the symbolic dynamics. Recall the notations from Section 1.2. Set

$$\begin{cases}
\alpha_n := A_n \cap J(f), \\
\alpha'_n := A'_n \cap J(f), \\
\beta_n := B_n \cap J(f), \\
\beta'_n := B'_n \cap J(f), \\
\alpha_\infty := \{0\}, \\
\beta_\infty := \{1\}.
\end{cases}$$

Let

$$A := \{\alpha_\infty, \beta_\infty, \alpha_1, \alpha'_1, \beta_1, \beta'_1, \ldots, \alpha_n, \alpha'_n, \beta_n, \beta'_n, \ldots\}.$$
Define the matrix $A = (A_{\gamma, \gamma_j})_{\gamma, \gamma_j \in A}$ by

$$A_{\gamma, \gamma_j} = \begin{cases} 1 & \text{if } \gamma_j \subset f(\gamma_i), \\ 0 & \text{otherwise.} \end{cases}$$

From Section 4.2, we know that

1. if $\gamma_i \neq \alpha_1, \alpha'_1$, then there is a unique $\gamma_j \in A$ such that $A_{\gamma, \gamma_j} = 1$;
2. if $\gamma_i = \alpha_1$, we have $A_{\gamma, \gamma_j} = 1$ if and only if $\gamma_j = \beta_\infty, \beta_n$ or $\beta'_n$ for some $n \geq 2$; and
3. if $\gamma_i = \alpha'_1$, then $A_{\gamma, \gamma_j} = 1$ if and only if $\gamma_j \in \{\beta_1, \beta'_1\}$.

Let $(\Sigma_A, \sigma)$ be the corresponding subshift on the alphabet $A$ defined by $A$. From Section 4.1, the set $A$ is a partition of $J(f)$. Thus we immediately obtain an element in $\Sigma_A$ for each point $x \in J(f)$:

**Lemma 4.11.** For each $x \in J(f)$, there is a unique sequence $(\gamma_j)_{j \geq 0} \in \Sigma_A$ such that $f^j(x) \in \gamma_j$.

We say that the sequence in Lemma 4.11 is the **code sequence** of $x$. Consider the coding map

$$h : J(f) \to \Sigma_A,$$

sending $x$ to its code sequence. The next result claims that the map $h$ is a bijection.

**Lemma 4.12.** For any $(\gamma_j)_{j \geq 0} \in \Sigma_A$, there is a unique point $x \in J(f)$ such that the code sequence of $x$ is $(\gamma_j)_{j \geq 0}$.

To prove Lemma 4.12 we first define the sequence $\{T_{\gamma_i, \gamma_{j+1}}\}_{j \geq 0}$ of inverse maps along $\{\gamma_j\}_{j \geq 0}$:

$$T_{\gamma_j \gamma_{j+1}} : \gamma_{j+1} \to \gamma_j$$

satisfying $f \circ T_{\gamma_j \gamma_{j+1}} = id_{\gamma_{j+1}}$. By Propositions 4.5 and 4.7, if $\gamma_j \in \{\alpha_1, \alpha'_1, \ldots\}$, the inverse map $T_{\gamma_j \gamma_{j+1}}$ is scaling with scaling ratio $1/4$; and if $\gamma_j \in \{\beta_n, \beta'_n\}$, the map $T_{\gamma_j \gamma_{j+1}}$ is scaling with scaling ratio $2^n$.

Now we can prove Lemma 4.12.

**Proof of Lemma 4.12.** Pick a sequence $\{y_j\}_{j \geq 0} \subset J(f)$ such that $y_j \in \gamma_j$. Define

$$x_j := T_{\gamma_0 \gamma_1} \circ \cdots \circ T_{\gamma_{j-1} \gamma_j}(y_j).$$

If there exists $j_0 \geq 0$ such that $\gamma_{j_0} = \alpha_\infty$, then $\gamma_j = \alpha_\infty$ for all $j \geq j_0$. Hence in this case, $x_j$ converges. Now we assume that $\gamma_j \neq \alpha_\infty$ for all $j \geq 0$. Let $0 \leq i_0 < i_1 < \cdots < i_k(j) \leq j - 1$ be all integers such that $\gamma_{i_\ell} \subset 1 + 4\mathbb{Z}_2$ for $1 \leq \ell \leq k(j)$. Note that $k(j) \to \infty$, as $j \to \infty$. To ease notations, set $k = k(j)$. Rewrite

$$x_j = T_{\gamma_0 \gamma_1} \circ \cdots \circ T_{\gamma_{i_0} \gamma_{i_1} \cdots \gamma_{i_k(j) \gamma_{i_{k+1}(j)}} \cdots \circ T_{\gamma_{j-1} \gamma_j}(y_j).$$

By Propositions 4.5 and 4.7 for any $0 \leq \ell \leq k - 1$, the map $T_{\gamma_{i_\ell} \gamma_{i_{\ell+1}}} \circ \cdots \circ T_{\gamma_{i_{k(j)-1} \gamma_{i_{k(j)+1}}}}$ is scaling with scaling ratio no more than $1/2$. Moreover, for $0 \leq i \leq i_0 - 1$, the map $T_{\gamma_i \gamma_{i+1}}$ is scaling with scaling ratio $1/4$. Hence

$$|x_{j+m} - x_j| \leq \frac{1}{2^k} \left| T_{\gamma_{i_{k(j)}} \gamma_{i_{k(j)+1}}} \circ \cdots \circ T_{\gamma_{i_{k(j)-1} \gamma_{i_{k(j)+1}}}(y_{j+m})} - T_{\gamma_{i_{k(j)+1}}} \circ \cdots \circ T_{\gamma_{j-1} \gamma_j}(y_j) \right|.$$ 

By Proposition 4.9 we have $\gamma_k \subset J(f) \subset \mathbb{Z}_2$. It follows that

$$|x_{j+m} - x_j| \leq \frac{1}{2^k}.$$ 

Hence $\{x_j\}_{j \geq 0}$ is a Cauchy sequence. Set

$$x := \lim_{j \to \infty} x_j.$$
Since the scaling ratio of $T_{\gamma, \gamma+1}$ is in the value group $|Q_2|$, all $x_j \in Q_2$. Therefore, the point $x \in Q_2$.

Observe that $x$ is independent of the choice of $\{y_j\}_{j \geq 0}$. Indeed, for any other sequence $\{y'_j\}_{j \geq 0} \subset J(f)$ with $y'_j \in \gamma_j$, let

$$x'_j := T_{\gamma_0, \gamma_1} \circ \cdots \circ T_{\gamma_{j-1}, \gamma_j}(y'_j).$$

Then

$$|x'_j - x_j| \leq \frac{1}{2k} |T_{\gamma_0, \gamma_1} \circ \cdots \circ T_{\gamma_{j-1}, \gamma_j}(y_j) - T_{\gamma_0, \gamma_1} \circ \cdots \circ T_{\gamma_{j-1}, \gamma_j}(y'_j)|$$

Again, noting that $\gamma_k \subset J(f) \subset Z_2$, we have $|x'_j - x_j| \to 0$, as $j \to 0$.

Obviously, $x \in J(f)$ and the code sequence of $x$ is $\{\gamma_j\}_{j \geq 0}$. Now we show such $x$ is unique. We may assume that $\gamma_j \neq \alpha_\infty$ for all $j \geq 0$. For otherwise, the uniqueness of $x$ follows immediately from the fact that $f$ is a bijection on each $\gamma \in A$. Suppose that $\tilde{x} \in J(f)$ also has the code sequence $\{\gamma_j\}_{j \geq 0}$. Then $f^n(\tilde{x})$ and $f^n(x)$ are in $\gamma$. Hence $|f^n(\tilde{x}) - f^n(x)|$ is bounded for all $n \geq 0$. However, there exists a sequence $\{n_i\}$ such that $f^{n_i}$ is scaling on $\gamma_0$ with scaling ratio no less than $2^i$. Hence

$$|f^{n_i}(x) - f^{n_i}(\tilde{x})| \geq 2^i|x - \tilde{x}|.$$

Thus $\tilde{x} = x$. \hfill \Box

Recall that $\sigma : \Sigma_A \to \Sigma_A$ is the (left-)shift. Considering the code sequences in Lemma \ref{4.12}, we obtain a conjugacy between $f$ and $\sigma$ via $h$.

**Corollary 4.13.** On $J(f)$,

$$h \circ f = \sigma \circ h.$$

**Proof.** For $x \in J(f)$, let $\{\gamma_j\}_{j \geq 0}$ be its code sequence. Then for any $\{y_j\} \subset J(f)$ with $y_j \in \gamma_j$, we have

$$h \circ f(x) = h \circ f\left(\lim_{j \to \infty} T_{\gamma_0, \gamma_1} \circ \cdots \circ T_{\gamma_{j-1}, \gamma_j}(y_j)\right).$$

Note that $f \circ T_{\gamma_0, \gamma_1} = id_{\gamma_1}$. It follows that

$$h \circ f(x) = h\left(\lim_{j \to \infty} T_{\gamma_1, \gamma_2} \circ \cdots \circ T_{\gamma_{j-1}, \gamma_j}(y_j)\right) = (\gamma_1, \gamma_2, \cdots) = \sigma \circ h(x).$$

The conclusion follows. \hfill \Box

Now we are ready to prove Theorem \ref{4.2}.

**Proof.** By Proposition \ref{4.12} and Corollary \ref{4.13}, it suffices to prove that the map $h$ is continuous and open from $I(f)$ to $\Sigma_A \setminus h(GO(1))$. We first show the continuity of $h$. Let $U$ be an open set in $h(I(f))$ and pick $x \in I(f)$ with $h(x) \in U$. Write $h(x) = (\gamma_i)_{i \geq 0}$. Then there exists $m \geq 1$ such that the cylinder set $C := [\gamma_0 \cdots \gamma_m] \subset \Sigma_A$ is contained in $U$. For the set $h^{-1}(C)$, we have $x \in h^{-1}(C)$ and $h^{-1}(C) = \bigcap_{j=0}^m f^{-j}(\gamma_j)$. Since $x \notin GO(1)$, we have $\gamma_j \notin \{\alpha_\infty, \beta_\infty\}$ and hence $\gamma_j$ is an open set in $J(f)$. Since $f$ is continuous, then $f^{-j}(\gamma_j)$ is open and hence $h^{-1}(C)$ is open. Therefore, $h$ is continuous.

Now we show the openness of $h$. Let $W$ be an open subset in $I(f)$. By Propositions \ref{4.5} and \ref{4.7}, there exists $\ell \geq 0$ such that $f^\ell(W) \supset (1 + 4Z_2) \cap I(f)$. Then $f^{\ell+1}(W) \supset 4Z_2 \cap I(f)$, and hence $f^{\ell+2}(W) \supset Z_2 \cap I(f) = I(f)$.

Pick $(\gamma_i)_{i \geq 0} \in h(W)$. Since $f$ is a bijection from $\gamma$ to $f(\gamma)$ for any $\gamma \in A$, the set $h(W)$ contains the cylinder $[\gamma_0 \cdots \gamma_{\ell+1}] \subset \Sigma_A$. Therefore, $h$ is open. \hfill \Box
4.4. Gurevich entropy. Consider the natural directed graph $\Gamma_A$ induced by the matrix $A$ in Section 4.3, that is, $\Gamma_A$ has vertices in $A$, and possesses an edge from $\gamma_i \in A$ to $\gamma_j \in A$ if and only if $A_{b_i b_j} = 1$. From Section 4.2, the graph $\Gamma_A$ is not strongly connected. Hence the matrix $A$ is reducible. Now we consider its irreducible component that corresponds to a maximal strongly connected subgraph of $\Gamma_A$. In fact, the matrix $A$ has a unique such irreducible component $A'$, which corresponds to the symbol set

$$A' := \{\alpha_1, \alpha_2, \beta_2', \ldots, \alpha_n, \beta_n, \beta_n', \ldots\}.$$  

Denote by $\Sigma_A'$ the corresponding subspace and let $(\Sigma_A', \sigma')$ be the corresponding subsystem of $(\Sigma_A, \sigma)$. We now compute the Gurevich entropy $h_G(\Sigma_A', \sigma')$ of the system $(\Sigma_A', \sigma')$.

Note that the matrix $A'$ has the form

$$A' = \begin{pmatrix}
\alpha_1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & \ldots \\
\alpha_2 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & \ldots \\
\beta_2' & 1 & 1 & 1 & 1 & 1 & 1 & 1 & \ldots \\
\beta_3 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & \ldots \\
\beta_4 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & \ldots \\
\beta_5' & 1 & 1 & 1 & 1 & 1 & 1 & 1 & \ldots \\
\vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \ddots
\end{pmatrix}.$$  

Then the number of first return loops at $\alpha_1$ of length $n \geq 1$ is

$$\delta_{\alpha_1}(n) = \begin{cases}
0 & \text{if } n \leq 2, \\
2 & \text{if } n \geq 3.
\end{cases}$$  

Recall Section 2.6 and consider

$$G_{\alpha_1}(z) = \sum_{n \geq 1} \delta_{\alpha_1}(n) z^n = \sum_{n \geq 3} 2 z^n.$$  

If $|z| < 1$, then

$$G_{\alpha_1}(z) = \frac{2 z^3}{1-z}.$$  

In this case, $1 - G_{\alpha_1}(z)$ has a root $R \approx 0.58975$ that is a root of $2 z^3 + z - 1$ and hence is algebraic. Note that $0 < R < 1$. Then $G_{\alpha_1}(z)$ converges on $|z| < R$. Thus,

$$h_G(\Sigma_A', \sigma') = \log R \approx 0.52806.$$  

5. Geometrically finite rational maps

The goal of this section is to prove Theorem 1.3. We first investigate the case that the Julia critical points are iteratedly prefixed in Section 5.1. Then we prove the general case in Section 5.2.
5.1. Reduced version of Theorem 1.3. Recall that a point $x \in \mathbb{P}^1_K$ is iterated prefixed under a rational map $\phi \in K(z)$ if there exists $n \geq 0$ such that $\phi^n(x)$ is a fixed point of $\phi$.

**Theorem 5.1.** Let $\phi \in K(z)$ be a rational map of degree at least 2. Suppose all the critical points in $\text{Crit}^*_K(\phi)$ are iterated prefixed under $\phi$. Then the conclusion of Theorem 1.3 holds.

**Remark 5.2.** Since all the fixed points in Julia set are repelling, any point in $\text{Crit}^*_K(\phi)$ in Theorem 5.1 is mapped to some repelling fixed point.

The remainder of this section is devoted to proving Theorem 5.1. To unify the proof, we consider a suitable finite extension $\tilde{K}$ of $K$ such that $\phi$, regarded as a map acting on $\mathbb{P}^1_{\tilde{K}}$, has a nonempty Fatou set. The existence of such extension follows form the fact that $\phi$ has a nonrepelling fixed point in $F_{\text{Crit}^*_K(\phi)}$, see [9] Proposition 4.2. Since the conjugacy via an automorphism of $\mathbb{P}^1_{\tilde{K}}$ preserves the corresponding dynamics, we may assume that $J_{\tilde{K}}(\phi)$ is contained in the ring $\mathcal{O}_{\tilde{K}}$ of integers of $\tilde{K}$. It follows that $J_K(\phi) \subset J_{\tilde{K}}(\phi) \subset \mathcal{O}_{\tilde{K}}$.

By Corollary 2.6, we can construct a scaling covering $P_0$ of $J_K(\phi)$ in $\mathbb{P}^1_{\tilde{K}}$, that is, $P_0$ is a set of disks in $\mathbb{P}^1_{\tilde{K}}$ such that

1. each $U \in P_0$ is either the restriction of a scaling disk of $\phi$ to $\mathbb{P}^1_{\tilde{K}}$, or a singleton,
2. $U \cap J_K(\phi) \neq \emptyset$, and
3. $J_K(\phi) \subset \bigcup_{U \in P_0} U$.

Indeed, there is only finitely many maximal scaling disks intersecting $J_K(\phi)$ outside a small neighborhood $W$ of $\text{Crit}^*_K(\phi)$, and in $W$ there are countably many maximal scaling disks intersecting $J_K(\phi)$ together with the singletons of points in $\text{Crit}^*_K(\phi)$.

By Remark 5.2, for any $c \in \text{Crit}^*_K(\phi)$, considering the forward orbit $\mathcal{O}_c(c)$ and the corresponding forward orbit of the elements in $P_0$ near $c$, we can decompose a small neighborhood of each point $x \in \mathcal{O}_c(c)$ into countably many scaling disks together with the singleton $\{x\}$. Then we obtain a new scaling covering from $P_0$, and to abuse notation, we also denote it by $P_0$. Note that $P_0$ contains countably many elements, in particular, it contains all the singletons with one element in $\bigcup_{n \geq 0} \phi^n(\text{Crit}^*_K(\phi))$. Moreover, since by Theorem 2.13 and the fact that $F_{\text{Crit}^*_K(\phi)} \cap \mathbb{P}^1_{\tilde{K}} \subset F_K(\phi)$, there are finitely many nonrepelling cycles in $\mathbb{P}^1_{\tilde{K}}$, we can assume that each element in $P_0$ is uniformly away from the nonrepelling cycles. Furthermore, we can also assume that each element in $P_0$ is uniformly away from $\text{Crit}_{\text{Crit}^*_K(\phi)} \setminus \text{Crit}^*_K(\phi)$.

The next result claims that any nonsingleton element in $P_0$ has an iterated image containing at least two distinct elements in $P_0$.

**Lemma 5.3.** For any $U \in P_0$, suppose $U$ is not a singleton. Then there exists $m \geq 1$ such that $\phi^m(U)$ contains at least two distinct elements in $P_0$.

**Proof.** Let $U_{\text{Crit}^*_K(\phi)} \subset \mathbb{P}^1_{\text{Crit}^*_K(\phi)}$ be the set such that $U_{\text{Crit}^*_K(\phi)} \cap \mathbb{P}^1_K = U$. If there exists $n_0 \geq 1$ such that $\phi^{n_0}(U) \cap \text{Crit}^*_K(\phi) \neq \emptyset$, consider the smallest such $n_0$ and pick a point $c_0$ in this intersection. It follows that $\{c_0\}$ is a singleton in $P_0$. Moreover, there exists $x \in \phi^{n_0}(U) \setminus \{c_0\}$ since $U$ is not a singleton and $\phi^{n_0}$ is scaling on $U_{\text{Crit}^*_K(\phi)}$. Then letting $U_x$ be the element in $P_0$ such that $x \in U_x$, we have $U_x \subset \phi^{n_0}(U)$. Hence $U_x \cup \{c_0\} \subset \phi^{n_0}(U)$, which, in this case, implies the conclusion by taking $m = n_0$.

Now we assume that $\phi^n(U) \cap \text{Crit}^*_K(\phi) = \emptyset$ for any $n \geq 1$. Suppose, on contrary that there is no such $m$. Then from the construction of $P_0$, the map $\phi^n$ is scaling on $U_{\text{Crit}^*_K(\phi)}$ for all $n \geq 1$. If $\text{Crit}^*_K(\phi) = \emptyset$, then by Corollary 2.6, $P_0$ contains finitely many elements and hence the union $\bigcup_{n \geq 1} \phi^n(U_{\text{Crit}^*_K(\phi)})$ disjoints $\text{Crit}^*_K(\phi)$. If $\text{Crit}^*_K(\phi) \neq \emptyset$, picking $c \in \text{Crit}^*_K(\phi)$, we have the union $\bigcup_{n \geq 1} \phi^n(U_{\text{Crit}^*_K(\phi)})$ does not contain $c$. Noting that $\text{Crit}_{\text{Crit}^*_K(\phi)}$ contains at least two distinct points and $c \in J_K(\phi) \subset J_{\text{Crit}^*_K(\phi)}$, by [9] Theorem 5.19, in both cases, we conclude...
that \( U_{C_p} \subset F_{C_p}(\phi) \). This is a contradiction, since \( U \cap J_K(\phi) \neq \emptyset \) and hence \( U_{C_p} \) intersects \( J_{C_p}(\phi) \). \( \square \)

We say that a scaling covering \( \mathcal{P} \) of \( J_K(\phi) \) is compatible if for each \( V \in \mathcal{P} \), the image \( \phi(V) \) is a union of elements in \( \mathcal{P} \). In the following result, decomposing the elements in \( \mathcal{P}_0 \), we obtain a compatible scaling covering \( \mathcal{P} \) of \( J_K(\phi) \) in \( \mathbb{P}^1_K \), which will turn out that the intersections of elements in \( \mathcal{P} \) and \( J_K(\phi) \) give us the states of the desired Markov shift.

**Lemma 5.4.** There is a compatible scaling covering \( \mathcal{P} \) of \( J_K(\phi) \) in \( \mathbb{P}^1_K \) such that \( \mathcal{P} \) has countably many elements and each singleton in \( \mathcal{P} \) contains only one element in the union \( \bigcup_{n \geq 0} \phi^n(\text{Crit}_K(\phi)) \).

**Proof.** Let \( c \in \text{Crit}_K^*(\phi) \). By Remark 5.2 in the forward orbit of \( c \), there is a repelling fixed point \( z_c \). Consider a small neighborhood \( V_{z_c} \) of \( z_c \) and let \( X_c \) be the set of corresponding iterated preimages of \( V_{z_c} \) along the orbit \( O_\phi(c) = \{ c, \phi(c), \cdots, z_c \} \). Define \( X_c \) to be the union of all elements in \( X_c \), and denote \( Y := \bigcup_{c \in \text{Crit}_K^*(\phi)} X_c \). By Proposition 2.5, the map \( \phi \) has a constant scaling ratio on \( V_{z_c} \). Moreover, there is a finite subset \( D_{z_c} \subset \mathcal{P}_0 \), each of whose elements is a subset of \( V_{z_c} \), such that for any element \( V \in \mathcal{P}_0 \) with \( V \subset V_{z_c} \), there exists a smallest \( m \geq 0 \) such that \( \phi^m(V) \subset D_{z_c} \). Then for any points in \( O_\phi(c) \), we denote by \( Y_c \) the set of the finitely many elements in \( \mathcal{P}_0 \) that are the corresponding iterated preimages of elements in \( D_{z_c} \) along \( O_\phi(c) \), and write \( Y = \bigcup_{c \in \text{Crit}_K^*(\phi)} Y_c \).

For a nonsingleton element \( U \in \mathcal{P}_0 \), let us consider the orbit of \( U \) and decompose the elements in \( \mathcal{P}_0 \) intersecting this orbit as follows. In the case that \( U \) is either in \( \mathcal{V} \) or not a subset of \( Y \), if there exist \( i \geq 1 \) and \( U_i \in \mathcal{P}_0 \) such that \( \phi^i(U) \subset U_i \), then let \( r_i := \text{diam}(\phi^i(U)) \) and decompose \( U_i \) into small disks in \( U_i \) with diameter \( r_i \). Note that \( U_i \neq U \); for otherwise, since \( U_i \cap J_K(\phi) \neq \emptyset \), it follows that there exists \( 1 \leq j \leq i-1 \) such that \( \phi^j(U) \) contains a critical point in \( \text{Crit}_K^*(\phi) \) and, in turn, \( \phi^j(U) = \phi^{j-1}(\phi^j(U)) \) and hence \( U \) contains an iterated image \( x \) of \( c_0 \), so \( U = \{ x \} \) since \( U \) and \( \{ x \} \) are contained in \( \mathcal{P}_0 \), which contradicts the assumption that \( U \) is not a singleton. By Lemma 5.3, and the finiteness of such \( U \) in this case, the decomposition procedure stops in finitely many steps. Now for each \( U \in \mathcal{P}_0 \) that is not in \( \mathcal{V} \) but a subset of \( Y \), there exists \( \ell \geq 1 \) such that \( \phi^\ell(U) \) is in \( \mathcal{V} \), and then we can decompose \( U \) according the decomposition on \( \phi^\ell(U) \).

After decomposing, we consider the disks intersecting \( J_K(\phi) \), and obtain a scaling covering \( \mathcal{P} \) of \( J_K(\phi) \), each of whose countably many elements is either a disk or a singleton having element in \( \bigcup_{n \geq 0} \phi^n(\text{Crit}_K^*(\phi)) \).

Let us check that \( \mathcal{P} \) is compatible. It suffices to show that if \( \phi(U') \subset U'' \) for some \( U', U'' \in \mathcal{P} \), then \( \phi(U') = U'' \). Considering iterated image if necessary, we can assume that \( U' \) is either in \( \mathcal{V} \) or not a subset of \( Y \). Let \( \tilde{U}' \) and \( \tilde{U}'' \) be the elements in \( \mathcal{P}_0 \) such that \( U' \subset \tilde{U}' \) and \( U'' \subset \tilde{U}'' \), respectively. If \( U' = \tilde{U}' \), from the construction of \( \mathcal{P} \), we immediately have \( \phi(U') = U'' \). If \( U' \subset \tilde{U}' \), again from the construction of \( \mathcal{P} \), there exists \( U' \subset \tilde{U}' \) such that \( \text{diam}(U') = \text{diam}(U') \) and \( \text{diam}(\phi(U')) = \text{diam}(U'') \). Letting \( \tilde{U}_{C_p} \subset \mathbb{P}^1_{C_p} \) be the set such that \( \tilde{U}_{C_p} \cap \mathbb{P}^1_{C_p} = U' \), since \( \phi \) is scaling on \( \tilde{U}_{C_p} \), we conclude that \( \text{diam}(\phi(U')) = \text{diam}(\phi(U')) \) and hence \( \text{diam}(\phi(U')) = \text{diam}(U'') \), which implies that \( \phi(U') = U'' \).

Thus \( \mathcal{P} \) is a desired scaling covering of \( J_K(\phi) \). \( \square \)

Let \( \mathcal{P} \) be the compatible scaling covering in Lemma 5.4. Similar argument as in the proof of Lemma 5.3 implies the following result. We omit the proof here.

**Lemma 5.5.** If \( U \in \mathcal{P} \) is not a singleton, then there exists \( m \geq 1 \) such that \( \phi^m(U) \) is the union of at least two elements in \( \mathcal{P} \).
Now define \( A := \{ U \cap J_K(\phi) : U \in \mathcal{P} \} \) and let \( A = (A_{n_i, j})_{n_i, j \in A} \) be the matrix with
\[
A_{n_i, j} = \begin{cases} 
1 & \text{if } j \in \phi(\gamma_i), \\
0 & \text{otherwise.}
\end{cases}
\]
Denote by \((\Sigma_A, \sigma)\) the countable state Markov shift defined by \( A \). We have the following code sequence for each point in \( J_K(\phi) \):

Lemma 5.6. For each \( x \in J_K(\phi) \), there is a unique sequence \((\gamma_j)_{j \geq 0} \in \Sigma_A\) such that \( \phi^j(x) \in \gamma_j \).

By Lemma 5.6 we obtain a coding map
\[
h : J_K(\phi) \to \Sigma_A,
\]
sending \( x \in J_K(\phi) \) to its code sequence. Now we prove that \( h \) is in fact a bijection.

Proposition 5.7. The map \( h \) is a bijection from \( J_K(\phi) \) onto \( \Sigma_A \).

Proof. We will show that for any \((\gamma_j)_{j \geq 0} \in \Sigma_A\), there is a unique point \( x \in J_K(\phi) \) such that the code sequence of \( x \) is \((\gamma_j)_{j \geq 0} \). If there is \( \gamma_0 \in \Sigma_A \), then \( \gamma_0 \) is a singleton of point in \( J_K(\phi) \), then we can find such a unique \( x \in J_K(\phi) \) such that \( \phi^{-\gamma_0}(\gamma_0) \cap \gamma_0 \subset \text{GO}_K(\Sigma_A) \).

Since \( \text{Crit}_K(\phi) \subset J_{\Sigma_A}(\phi) \), it follows that \( x \in J_{\Sigma_A}(\phi) \). By Theorem 1.2 we conclude that \( x \in J_K(\phi) \).

Now assume that \( \gamma_j \) is a singleton of point in \( \bigcup_{n \geq 0} \phi^n(\text{Crit}_K(\phi)) \) for all \( j \geq 0 \). Then by Lemma 5.5, there is a smallest \( n_0 \geq 1 \) such that \( \phi^{-n_0}(\gamma_0) \) is a union of at least two elements in \( A \) and \( \gamma_0 \) is properly contained in \( \phi^{-n_0}(\gamma_0) \). Thus \( \phi^{-n_0}(\gamma_0) \) has a component \( \tilde{\gamma}_{m_0} \) properly contained in \( \gamma_0 \). Inductively, for \( i \geq 1 \), let \( n_i \geq 1 \) be the smallest integer such that \( \phi^{-n_i}(\gamma_{m_i-1}) \) is a union of at least two elements in \( A \). Then \( \phi^{-n_i}(\gamma_{m_i}) \) has a component \( \tilde{\gamma}_{m_i} \) properly contained in \( \gamma_{m_i-1} \). Set \( m_i := \sum_{j=0}^{i} n_i \). We conclude that for \( i \geq 1 \), \( \phi^{-m_i}(\gamma_{m_i}) \) has a component \( \tilde{\gamma}_{m_i} \) such that \( \tilde{\gamma}_{m_i} \subset \tilde{\gamma}_{m_{i-1}} \subset \gamma_0 \). Since the value group \(|\tilde{K}^\times|\) is discrete, \( \text{diam}(\tilde{\gamma}_{m_i}) \to 0 \), as \( i \to \infty \). Then \( \bigcap_{i \geq 0} \tilde{\gamma}_{m_i} \) is a singleton. Denote the unique point in this intersection by \( x \).

Now assume that \( \gamma_j \) is not a singleton of point in \( \bigcup_{n \geq 0} \phi^n(\text{Crit}_K(\phi)) \) for all \( j \geq 0 \). Then by Lemma 5.5, there is a smallest \( n_0 \geq 1 \) such that \( \phi^{-n_0}(\gamma_0) \) is a union of at least two elements in \( A \) and \( \gamma_0 \) is properly contained in \( \phi^{-n_0}(\gamma_0) \). Thus \( \phi^{-n_0}(\gamma_0) \) has a component \( \tilde{\gamma}_{m_0} \) properly contained in \( \gamma_0 \). Inductively, for \( i \geq 1 \), let \( n_i \geq 1 \) be the smallest integer such that \( \phi^{-n_i}(\gamma_{m_i-1}) \) is a union of at least two elements in \( A \). Then \( \phi^{-n_i}(\gamma_{m_i}) \) has a component \( \tilde{\gamma}_{m_i} \) properly contained in \( \gamma_{m_i-1} \). Set \( m_i := \sum_{j=0}^{i} n_i \). We conclude that for \( i \geq 1 \), \( \phi^{-m_i}(\gamma_{m_i}) \) has a component \( \tilde{\gamma}_{m_i} \) such that \( \tilde{\gamma}_{m_i} \subset \tilde{\gamma}_{m_{i-1}} \subset \gamma_0 \). Since the value group \(|\tilde{K}^\times|\) is discrete, \( \text{diam}(\tilde{\gamma}_{m_i}) \to 0 \), as \( i \to \infty \). Then \( \bigcap_{i \geq 0} \tilde{\gamma}_{m_i} \) is a singleton. Denote the unique point in this intersection by \( x \).

Now we are ready to prove Theorem 5.1

Proof of Theorem 5.1. By Proposition 5.7 and Corollary 5.8, it suffices to prove that the map \( h \) is continuous and open on \( I_K(\phi) \). Let \( U \) be an open set in \( h(I_K(\phi)) \) and consider \( x \in I_K(\phi) \) with \( h(x) \in U \). Write \( h(x) = (\gamma_i)_{i \geq 0} \). Then there exists \( m \geq 1 \) such that the cylinder set \( C := [\gamma_0 \cdots \gamma_m] \subset \Sigma_A \) is contained in \( U \). We conclude that \( x \in h^{-1}(C) \) and \( h^{-1}(C) = \bigcap_{j=0}^{m} \phi^{-j}(\gamma_j) \). Since each \( \gamma_j \) is not a subset of \( \text{GO}_K(\Sigma_A) \), it follows that \( \gamma_j \) is an open set in \( J_K(\phi) \). Note that \( \phi \) is continuous. Then \( \phi^{-j}(\gamma_j) \) is open in \( J_K(\phi) \). Moreover, \( \phi^{-j}(\gamma_j) \cap J_K(\phi) \neq \emptyset \). Then \( h^{-1}(C) \cap J_K(\phi) \) is open. Therefore, \( h \) is continuous.
Now let $W$ be an open subset in $I_K(\phi)$. We claim that there exists $\ell \geq 1$ such that $\phi^\ell(W)$ contains an element in $A$. Indeed, for otherwise, there exists $\gamma_j \in A$ such that $\phi^j(W) \subset \gamma_j$ for all $j \geq 0$, then $W$ is a subset of $\bigcap_{j=0}^\infty \phi^{-j}(\gamma_j)$, and hence by Lemma 5.5 and the local compactness of $K$, the set $W$ is a singleton, which is a contradiction since $W$ is open. Now pick $\gamma(\gamma_j) \in h(W)$. Note that $\phi$ is a bijection from $\gamma$ onto $\phi(\gamma)$ for any $\gamma \in A$. Then the cylinder set $\gamma_0 \cdots \gamma_\ell \in \Sigma_A$ is contained in $h(W)$. Therefore, $h$ is open. \hfill \Box

5.2. Proof of Theorem 1.3. In this subsection, we prove Theorem 1.3. We first show the following result concerning the rational maps whose iteration has iteratedly prefixed Julia critical points.

Proposition 5.9. Let $\phi \in K(x)$ be a rational map of degree at least 2. Suppose there exists $n \geq 1$ such that the critical points of $\phi^n$ in $J_{\Sigma_p}(\phi) \cap \mathbb{P}^1_K$ are iteratedly prefixed. Then the conclusion of Theorem 1.3 holds.

Proof. From the proof of Theorem 5.1, there exist a partition $A$ of $J_K(\phi^n)$ and an $|A| \times |A|$ matrix $A$ such that the dynamical system $(J_K(\phi^n), \phi^n)$ is conjugate to a countable state Markov shift $(\Sigma_A, \sigma)$, where $\Sigma_A \subset \Sigma_p^n$ is the subshift space defined by $A$. Note that by Theorem 1.2, we have $J_K(\phi) = J_K(\phi^n)$. Then $A$ is, in fact, a partition of $J_K(\phi)$. It follows that the map $H : J_K(\phi) \to A^N$, sending $x \in J_K(\phi)$ to $(\gamma_0 \gamma_1 \cdots) \in A^N$ with $\phi^n(x) \in \gamma_i$, is well-defined. Now we show that $H$ is injective. Indeed, considering the map $F : \Sigma_A \to A^N$, sending $(\gamma_0 \gamma_1 \gamma_2 \cdots)$ to $(\gamma_0 \gamma_1 \gamma_2 \cdots)$, and letting $h$ be as in Theorem 5.1, we have $H = F \circ h$; moreover, if $x_1, x_2 \in J_K(\phi^n)$ satisfy $H(x_1) = H(x_2)$, then $h(x_1) = h(x_2)$ and hence $x_1 = x_2$.

It is obvious that $h \circ \phi = \sigma \circ H$. Now we show that $H$ is a homeomorphism on $I_K(\phi)$. By Theorem 1.2, we obtain $I_K(\phi) = I_K(\phi^n)$. Hence $h$ is a homeomorphism on $I_K(\phi)$. Then the openness of $H$ follows from the continuity of $F$ and the fact that away from $H(G_{\Sigma_p}(\text{Crit}^*_K(\phi)))$ the map $F$ is locally one-to-one. The continuity of $H$ follows from the openness of $F$ since $F(U) = h(h^{-1}(U))$ for any set $U \subset H(J_K(\phi))$. \hfill \Box

Now we can finally prove Theorem 1.3.

Proof of Theorem 1.3. Since $\phi \in K(z)$ is a geometrically finite rational map, the points in $\text{Crit}^*_K(\phi)$ are mapped to repelling cycles. Since $\text{Crit}^*_K(\phi)$ is a finite set, let $n$ be the least common multiple of the periods of these repelling cycles. Then $\phi^n$ maps each point in $\text{Crit}^*_K(\phi)$ to a repelling fixed point of $\phi^n$. By Theorem 1.2 in $\mathbb{P}^1_K$, the Julia critical points of $\phi^n$ are the Julia critical points of $\phi$ and their $\ell$-th preimages for $1 \leq \ell < n$. Hence the Julia critical points of $\phi^n$ are iteratedly prefixed. Then Theorem 1.3 immediately follows from Theorem 5.1 and Proposition 5.9. \hfill \Box
