ADDITIVE PROBLEMS WITH ALMOST PRIME SQUARES

VALENTIN BLOMER, JUNXIAN LI, AND SIMON L. RYDIN MYERSON

Abstract. Assuming GRH, we show that every sufficiently large integer is a sum of a prime and two almost prime squares, and also a sum of a smooth number and two almost prime squares. The number of such representations is of the expected order of magnitude. The methods involve a combination of analytic, automorphic and algebraic arguments.

1. Introduction

1.1. Statement of results. In his first paper, Hooley \cite{Ho1} gave a proof, conditional upon the Generalized Riemann Hypothesis, of a conjecture made by Hardy and Littlewood some 30 years before \cite{HL}: the number of representations of an integer \( n \) in the form

\[
    n = p + x_1^2 + x_2^2
\]

in primes \( p \) and non-zero integers \( x_1, x_2 \) as \( n \to \infty \) is asymptotic to

\[
    \pi \mathcal{S}(n) \text{Li}(n), \quad \text{where } \mathcal{S}(n) = \prod_p \left( 1 + \frac{\chi_{-4}(p)}{p(p-1)} \right) \prod_{p|n} \frac{(p-1)(p-\chi_{-4}(p))}{p^2 - p + \chi_{-4}(p)}.
\]

In particular every sufficiently large number is representable in this form. The Generalized Riemann Hypothesis (GRH) was removed a few years later by Linnik \cite{Li} who used his dispersion method to obtain the first unconditional proof of the Hardy-Littlewood problem. The proof could be greatly streamlined and simplified once the Bombieri-Vinogradov theorem became available, cf. e.g. \cite{EH}. The best error term in the asymptotic formula was recently established by Assing and the first two authors \cite{ABL} by invoking in addition the theory of automorphic forms.

In his last paper, Hooley \cite{Ho2} returned to this topic and considered a refined version. He showed that every sufficiently large number is representable as a sum of a prime and two squares of squarefree numbers and gave a lower bound for the number of such representations of the expected order of magnitude. At first sight this appears to be easy – squarefree numbers can be detected by zero-dimensional sieve, so only a little bit of inclusion-exclusion is required. On second thought, a major issue emerges: to sieve out even a fixed number of squares of primes, one needs an asymptotic formula for (1.1) with \( d_1 \mid x_1, d_2 \mid x_2 \). However, the quadratic form \( d_1^2x_1^2 + d_2^2x_2^2 \) fails to have class number one, in fact very soon it even fails to have one class per genus, and hence there is no convolution formula for the number of ways it represents a given integer. Without such a formula, all approaches to the Hardy-Littlewood problem and its variations become very problematic. Hooley finds an ingenious (but rather ad hoc) way to circumvent this issue altogether for the particular problem at hand.

In this paper, we continue on this avenue and introduce a general sieve process into the problem with the goal of showing that every sufficiently large integer is a sum of a prime and two squares of almost primes. Obviously, the application of a sieve to make \( x_1, x_2 \) almost prime requires the coefficients \( d_1 \) and \( d_2 \) to be some power of \( n \), and so quite likely we need technology that can deal...
with (1.1) with a power-saving error term. This makes the use of GRH, at least at the present state of knowledge, unavoidable.

**Theorem 1.1.** Assume GRH. Then there exists a constant \( C > 0 \) such that every sufficiently large integer \( n \neq 2 \pmod{3} \) can be represented in the form (1.1) with a prime \( p \) and integers \( x_1, x_2 \) having at most \( C \) prime factors. The number of such representations is \( \gg \mathcal{S}(n)(\log n)^{-3} \) with \( \mathcal{S}(n) \) as in (1.2).

We have made no effort to compute and optimize the value of \( C \), although an upper bound of size \( C \leq 10^6 \), say, can easily be obtained by careful book-keeping.

From a multiplicative point of view, complementary to primes are smooth numbers (“entiers friables” in French) all of whose prime factors are small. The smallness is measured in terms of a parameter \( y \), and following the usual notation we let \( \Psi(x, y) = \#S(x, y) \) where \( S(x, y) \) denotes the set of positive integers \( m \leq x \) such that \( p \mid m \) implies \( m \leq y \) for all primes \( p \). Smooth numbers appear quite frequently (with positive density if \( \log x \asymp \log y \)), yet additive problems with smooth numbers are often surprisingly difficult, see e.g. [Ba, BBD, KMS]. The present case is no exception, and the proof of Theorem 1.2 below turns out to be rather intricate. As a variation of (1.1) we consider the equation

\[
(1.3) \quad n = m + x_1^2 + x_2^2
\]

where \( x_1, x_2 \) are almost primes and \( m \) is \( y \)-smooth with \( y \geq \exp((\log \log n)^2) \). We prove the following.

**Theorem 1.2.** Assume GRH. There exists a constant \( C > 0 \) such that for any function \( g \) with \( \exp((\log \log n)^2) \leq g(n) \leq n \), every sufficiently large integer \( n \) can be represented in the form (1.3) with \( m \in S(n, g(n)) \) and integers \( x_1, x_2 \) having at most \( C \) prime factors. The number of such representations is \( \gg \Psi(n, g(n))((\log n)^{-2}) \).

In fact, in the representations we construct, \( m \) will in addition be a squarefree number times a power of 2. For orientation we remark that

\[
\Psi(x, y) \asymp x \rho(u) \asymp x \exp \left( -u \log \frac{n}{\log y} + O(\log \log n) \right), \quad u = \frac{\log x}{\log y}
\]

with \( \rho(u) \) being the Dickman function for \( y \geq \exp((\log \log x)^2) \) (see e.g. [Hi, Theorem 1]).

Our method to prove Theorems 1.1 and 1.2 can be generalized to deal with general fixed quadratic forms \( F(x_1, x_2) \) (of fundamental discriminant) instead of \( x_1^2 + x_2^2 \), at the cost of slightly more work.

### 1.2. Methods and ideas.

While the statements of Theorems 1.1 and 1.2 are purely arithmetic, the proofs combine a variety of different methods. We need the algebraic structure theory of orders in quadratic number fields, the full machinery of automorphic forms including some higher rank \( L \)-functions, and of course the toolbox of analytic number theory. Starting with the latter, the obvious approach to almost primes is the application of a sieve. Thus, for the proof of both theorems we need to analyze quite accurately the quantity

\[
(1.4) \quad \sum_{\ell} r_{d_1, d_2}(n - \ell), \quad r_{d_1, d_2}(n) = \# \{(x, y) \in \mathbb{Z}^2 \mid d_1^2 x_1^2 + d_2^2 x_2^2 = n\}
\]

for squarefree integers \( d_1, d_2 \) where \( \ell \) runs either over primes or over smooth numbers. As mentioned above, in general there is no closed convolution formula for \( r_{d_1, d_2} \), since there is typically more than one class per genus. For fixed \( d_1, d_2 \) one can lift the necessary ingredients to analyze (1.4) from [Iw1] or [VI], but for almost primes we need strong uniformity where \( d_1, d_2 \) can be as large as some small power of \( n \).

A robust substitute that may also be useful in other situations is as follows. Let \( F \) be a primitive binary quadratic form of discriminant \( D = D_0 f^2 < 0 \) (with \( D_0 \) fundamental) and let \( \mathcal{O}_D \subseteq \mathbb{Q}(\sqrt{D}) \) be the (not necessarily maximal) order of discriminant \( D \). The set of equivalence classes of primitive forms of discriminant \( D \) is in bijection with the proper (i.e. invertible) ideal classes \( \mathcal{C}_D \) of \( \mathcal{O}_D \) (see...
[Co, Section 7]), and we denote by $C_F \in C_D$ the class corresponding to $F$. Then for $(n, f) = 1$ we have the exact formula

$$\# \{ (x_1, x_2) \in \mathbb{Z}^2 \mid F(x_1, x_2) = n \} = w \sum_{\chi \in \hat{C}_F} \chi(C_F) \sum_{\nmid a \leq \mathcal{O}_K} \chi(a)$$

where $w$ is the number of units in $\mathcal{O}_D$. The key point is now to split the outer sum into two parts: class group characters $\chi$ of order at most two are genus characters and can be computed explicitly by some kind of convolution identity. For a character of order three or more, the inner sum is the $n$-th Hecke eigenvalue of a cusp form of weight 1 and level $|D|$. In this way, the theory of automorphic forms enters, and (1.5) can be seen as a version of Siegel’s mass formula.

The upshot is that – at least morally – we need to understand a sum as in (1.4) in two cases: when the arithmetic function in question is a Fourier coefficients of some cusp form and when the arithmetic function is a Dirichlet convolution of two characters, in other words the Fourier coefficient of an Eisenstein series. In particular, this is yet another example where the originally purely arithmetic problem of representing $n$ in the form (1.1) or (1.3) is intimately linked to the theory of automorphic forms.

As an aside we remark that there is a different way to build a bridge to automorphic forms. Instead of applying the algebraic identity (1.5), one could model the left hand side by a suitably truncated expression coming from a formal application of the circle method. More rigorously, one could apply a $\delta$-symbol method à la Heath-Brown [HB] and Duke-Friedlander-Iwaniec [DFI], followed by Poisson summation. This leads to sum of Kloosterman sums which after an application of the Kuznetsov formula returns a similar expression of cuspidal and non-cuspidal Fourier coefficients. An application of (1.5), however, seems more direct.

To understand (1.4) when $r_{d_1, d_2}$ is replaced by a cuspidal Fourier coefficient, we refine methods and results established in [ABL, Theorem 1.3] to obtain a power saving unconditionally with the required degree of uniformity. The Eisenstein contribution does not allow an unconditional treatment, at the very least we would have to deal with Siegel zeros [Dr2].

Returning to the re-interpretation of quadratic forms in terms of ideal classes, we observe that in our case the underlying quadratic field is fixed: for all $d_1, d_2$ we obtain the Gaussian number field $\mathbb{Q}(i)$, but the discriminant of the order increases with $d_1, d_2$, in particular the order is highly non-maximal. This is technically challenging and leads to involved computations of the corresponding main terms.

We close the introduction with some comments on the proof of Theorem 1.2. The arithmetic of smooth numbers is rather subtle, and it turns out that leading term in a suitable asymptotic formula of (1.4) for $\ell \in S(n, g(n))$ is not multiplicative in $d_1, d_2$. Multiplicativity does not fail by a lot, but we obtain secondary terms involving derivatives of Euler products. This makes the application of a sieve perhaps not impossible, but at least seriously problematic. There are some ways to handle non-multiplicative main terms without developing the theory in full generality (see [FI, p. 37]). But the fact that we have two variables to sieve makes the monotonicity principle, in particular [FI, Corollary 5.4/5.5], not applicable. We therefore take a different route and incorporate the sieve weights directly into the analysis. A prototype of this idea can be found in the proof of [FT96, Theorem 4], but such a strategy in the context of additive problems seems to be new. There are a number of interesting more technical details that we will discuss at the appropriate places.

Roadmap for the rest of the paper: In Section 2, we give the explicit formula for $r_{d_1, d_2}$ (see Lemma 2.2), which consists of a cuspidal part and an Eisenstein part. To deal with the cuspidal part, in Section 3 we prove general bounds for linear forms in Hecke eigenvalues over prime numbers (Theorem 3.3) and smooth numbers (Theorem 3.4) assuming a bilinear estimate (Proposition 3.1) and a $\tau_3$-type estimate (Proposition 3.2) with Hecke eigenvalues, whose proofs are given in Section 4. The proofs of Theorems 1.1 and 1.2 are given in Sections 5 and 6 respectively. The most involved
part is the rather subtle analysis of the main term in the sieving process, which covers Subsections 5.2 – 5.3 in the prime number case and Subsections 6.4 – 6.7 in the smooth number case.

2. Algebraic considerations

We recall the classical theory on binary quadratic forms. For \( f \in \mathbb{N} \) let \( O_f = \mathbb{Z} + f\mathbb{Z}[i] \subseteq \mathbb{Z}[i] \) be the unique order of discriminant \(-4f^2\) (the notation is slightly different than in Section 1.2). We have \( O_f^* = \{ \pm 1 \} \) unless \( f = 1 \) in which case \( O_f^* = \{ \pm 1, \pm i \} \). We write \( w_f = \#O_f^* \). Its class group \( C_f \) is the set of proper (= invertible) fractional \( O_f \)-ideals \( I_f \) modulo principal ideals \( P_f \). This is a finite group of cardinality [Co, Theorem 7.24]

\[
(2.1) \quad h_f = f \prod_{p \mid f} \left( 1 - \frac{\chi_{-4}(p)}{p} \right) \begin{cases} 1/2, & f > 1, \\ 1, & f = 1. \end{cases}
\]

We have a sequence of isomorphisms. Let \( \tilde{C}_f \) be the set of primitive binary quadratic forms with discriminant \(-4f^2\) modulo the action of \( \text{SL}_2(\mathbb{Z}) \). Let \( I_f^* \) be the set of fractional \( O_f \)-ideals coprime to \( f \) (these are automatically proper [Co, Lemma 7.18(ii)]) and \( P_f^* \) the subgroup of its principal ideals. Let \( I^* \) be the set of fractional \( O_1 = \mathbb{Z}[i]-\)ideals coprime to \( f \) and \( P^* \) the set of principal \( \mathbb{Z}[i] \)-ideals with a generator \( \alpha \in O_f \) coprime to \( f \). Then we have ([Co, Theorem 7.7(ii), Exercise 7.17(a), Propositions 7.19, 7.20, 7.22])

\[
(2.2) \quad \begin{align*}
\frac{N(ax^2 + bxy + cy^2)}{N\alpha} & \cong C_f = I_f/P_f \cong I_f^*/P_f^* \cong I^*/P^* \\
& \left\{ a \in [\alpha, \bar{\alpha}] \right\} \left\{ \mathbb{Z} \right\} \cong a \to a\mathbb{Z}[i] \\
& a \cap O_f \cong a \\
& (x_1, x_2) \mid F(x_1, x_2) = m \} / O_f^* \leftrightarrow \{ a \text{ integral } O_f \text{-ideal in the class } C_F \mid N\alpha = m \}.
\end{align*}
\]

If \( (m, f) = 1 \), then the last isomorphism in (2.2) shows

\[
(2.3) \quad \sum_{\substack{a \equiv m \\ a \in \mathbb{Z}[i]}} \chi_{-4}(d) = r(m)
\]

where \( r(m) = 1 \ast \chi_{-4} \) is the usual sums-of-two-squares function.

The elements of order 2 in \( C_f \) are well-understood by genus theory. In particular, for squarefree \( f \) the real characters \( \chi \) of \( \tilde{C}_f \) are parametrized by odd divisors \( D \mid f \), and for an ideal \( a \in I_f^* \) (i.e. coprime to \( f \)) and a real character associated with the divisor \( D \) we have

\[
(2.5) \quad \chi(a) = \chi_{D^*}(N\alpha), \quad D^* := \chi_{-4}(D)D \in \{ \pm D \}.
\]

We write

\[
(2.6) \quad G_f = \tau(f/(f, 2))
\]

for the number of genera.

From now on we focus on the form \( F_{a, b} = a^2x_1^2 + b^2x_2^2 \). We write \( C_{a, b} \in C_{ab} \) to denote the class corresponding to the form \( F_{a, b} \). We will give an explicit formula for \( r_{d_1, d_2} \) defined in (1.4). We first notice that we can compute the real characters of \( \tilde{C}_{ab} \) explicitly for the class \( C_{a, b} \).

**Lemma 2.1.** Let \( a, b \in \mathbb{N} \) be coprime and squarefree. Let \( F_{a, b} \) be as above and let \( \chi \) be a real character of \( \tilde{C}_{ab} \). Then \( \chi(C_{a, b}) = 1 \).
Proof. Then \( F_{a,b} \) is equivalent to the form \((a^2 + b^2)x_1^2 + 2b^2x_1x_2 + b^2x_2^2\), which under the isomorphism (2.2) corresponds to an ideal of norm \(a^2 + b^2\) coprime to \(ab\), so if \(\chi\) belongs to the divisor \(D \mid ab\), then by (2.5) we have

\[
\chi(C_{a,b}) = \chi(D^*) (a^2 + b^2) = 1.
\]

Remark: Alternatively one can explicitly compute the class group structure from the exact sequence [Co, (7.25), (7.27), Exercise 7.30]

\[
1 \rightarrow \{ \pm 1 \} \rightarrow (\mathbb{Z}/f\mathbb{Z})^* \times \{ \pm 1, \pm i \} \rightarrow (\mathbb{Z}[i]/f\mathbb{Z}[i])^* \rightarrow \mathcal{C}_f \rightarrow 1.
\]

For instance, if \(f\) is even, one can conclude that \(\text{rk}_2(\mathcal{C}_f) = \text{rk}_4(\mathcal{C}_f)\), so that all real characters are trivial on elements of order 2 (and hence a fortiori on diagonal forms).

From Lemma 2.1 we can give the explicit formula for \(r_{d_1,d_2}\) in (1.4). We recall the notation (2.1) and (2.6).

Lemma 2.2. Let \(d_1, d_2\) be two squarefree numbers, and write \(\delta = (d_1, d_2), d_1' = d_1/\delta,\) and \(d_2' = d_2/\delta\). Let \(L \subseteq \mathbb{N}\) be a finite set and define

\[
S := \sum_{l \in L} r_{d_1,d_2}(l).
\]

Then \(S = S_{\leq 2} + S_{\geq 3}\) where we have

\[
S_{\leq 2} = \sum_{\delta_1 \delta_2 = d_1' \delta_2 d_2} \sum_{\delta_1 \delta_2 = d_2} \frac{ug_1 g_2}{\delta_1 \delta_2} G_{\delta_1 \delta_2} \sum_{l \equiv 0 (\text{mod} \ l \in L) \equiv 0 (\text{mod} \ l \in L)} r\left(\frac{l}{\delta_1 \delta_2}\right),
\]

with

\[
G_{\delta_1 \delta_2} = \{ w \in (\mathbb{Z}/\delta_1 \delta_2 \mathbb{Z})^*: \chi_p^*(n) = 1 \ for \ all \ 2 \nmid \ p \ \delta_1 \delta_2 \},
\]

and

\[
S_{\geq 3} = \sum_{\delta_1 \delta_2 = d_1' \delta_2 d_2} \sum_{\chi \in \mathcal{C}_{\delta_1 \delta_2}} \sum_{\text{ord} \chi \geq 3} \bar{\chi}(C_{\delta_1 \delta_2}) \sum_{l \equiv 0 (\text{mod} \ l \in L) \equiv 0 (\text{mod} \ l \in L)} \lambda\chi\left(\frac{l}{\delta_1 \delta_2}\right),
\]

with a Hecke eigenvalue \(\lambda\chi\) of some holomorphic cuspidal newform of weight 1, character \(\chi_{-4}\) and level dividing \(4d_1^2 d_2^2\).

Proof. Since \(\delta, d_1', d_2'\) are pairwise coprime and squarefree, we have

\[
S := \sum_{l \in L} r_{d_1,d_2}(l) = \sum_{\delta \mid l \in L} r_{d_1,d_2}(l) = \sum_{\delta_1 \delta_2 = d_1' \delta_2 d_2} \sum_{l \equiv 0 (\text{mod} \ l \in L) \equiv 0 (\text{mod} \ l \in L)} r_{\delta_1 \delta_2}(l).
\]

Note that \((\delta_1, \delta_2) = 1, so the form \((\delta_1')^2 x_1^2 + (\delta_2')^2 x_2^2\) is primitive and \(f = \delta_1' \delta_2'\) is squarefree. Moreover, the argument of \(r_{\delta_1 \delta_2}\) is coprime to \(\delta_1' \delta_2'\). We have by (2.3) and orthogonality of characters

\[
r_{a,b}(m) = \frac{u_{ab}}{h_{ab}} \sum_{\chi \in \mathcal{C}_{a,b}} \bar{\chi}(C_{a,b}) \sum_{m=1} \chi(a).
\]

If \(\chi\) is real and belongs to the odd divisor \(D \mid \delta_1' \delta_2'\), then by (2.5) and (2.4) for \((m, \delta_1' \delta_2') = 1\) we have

\[
\sigma(\chi, m) = \chi(D^*) (m) \sum_{N\mathfrak{a} = m} \chi(\mathfrak{a}).
\]

Combining this with Lemma 2.1, we obtain

\[
S_{\leq 2} = \sum_{\delta_1 \delta_2 = d_1' \delta_2 d_2} \sum_{\delta_1 \delta_2 = d_2} \frac{ug_1 g_2}{\delta_1 \delta_2} G_{\delta_1 \delta_2} \sum_{l \equiv 0 (\text{mod} \ l \in L) \equiv 0 (\text{mod} \ l \in L)} r\left(\frac{l}{\delta_1 \delta_2}\right).
\]
which yields (2.7) after summing over \( 2 \nmid D \mid \delta_1^2 \delta_2^2 \).

If \( \text{ord}(\chi) \geq 3 \), it remains to show that \( \sigma(\chi, m) \) is a normalized Hecke eigenvalue of a weight 1 newform of level dividing \( 4d_1^2d_2^2 \) and character \( \chi_{-4} \). To see this, we observe first that by splitting into ideal classes we have that

\[
    f_\chi(z) = \sum_{a \in \mathcal{O}_{d_1d_2}} \chi(a)e(Na \cdot z)
\]

is a linear combination of theta series corresponding to forms \( F \in \mathcal{G}_{d_1d_2} \) and hence by [Iw4, Theorem 10.9] a modular form of weight 1, character \( \chi_{-4} \) and level \( 4(d_1d_2)^2 \). Since \( \text{ord}(\chi) \geq 3 \), it is a cusp form. This is a classical fact that can be proved in several ways: by the parametrization of Eisenstein series, a modular form is non-cuspidal if and only if the associated Dirichlet series factorizes into two Dirichlet \( L \)-functions, and this happens if and only if its Rankin-Selberg square \( L \)-function has a double pole at \( s = 1 \). The Rankin-Selberg square of a class group character \( \chi \) is, up to finitely many Euler factors, \( \zeta(s)L(s, \chi^2) \) which has a double pole at \( s = 1 \) if and only if \( \text{ord}(\chi) \leq 2 \). Using (2.2), one can check from the definition of the Hecke operators \( T_m \) that

\[
    T_m f_\chi(z) = \sigma(\chi, m)f_\chi(z)
\]

for \( (m, d_1d_2) = 1 \). Hence by strong multiplicity one, \( f_\chi \) belongs to the space generated by some newform of level dividing \( 4d_1^2d_2^2 \), and for \( (m, d_1d_2) = 1 \) the numbers \( \sigma(\chi, m) \) coincide with the Hecke eigenvalues. This completes the proof of the lemma.

**Remark:** The formula (2.7) depends on Lemma 2.1. For general quadratic forms not covered by Lemma 2.1 the summation over \( D \) can be carried out in the same way. This yields an expression similar to (2.7) with a set \( \mathcal{G}_{\delta_1^2, \delta_2^2} \) which may be different from the one defined in (2.8) but which has the same cardinality, namely \( \phi(\delta_1^2 \delta_2^2) / \mathcal{G}_{\delta_1^2, \delta_2^2} \). This is a consequence of the fact that numbers coprime to the order can only be represented in one genus. More precisely, the Chinese Remainder Theorem induces a bijection \( \mathcal{G}_{\delta_1^2, \delta_2^2} \cong \prod_{p|\delta_1^2 \delta_2^2} \mathcal{G}_p \) where \( \mathcal{G}_p \subseteq (\mathbb{Z}/p\mathbb{Z})^\times \) has cardinality \( \phi(p)/2 \) for odd \( p \) and cardinality 1 for \( p = 2 \). This is all the information needed in the subsequent arguments. In this way, our main results generalize to other quadratic forms than sums of two squares, although some extra care may be necessary at the last step of (2.10).

### 3. Additive problems in cusp forms

In this section we deal with the innermost sum of (2.9) when the set \( \mathcal{L} \) consists of numbers \( n - \ell \) where \( \ell \) is either prime or smooth. We generally consider a holomorphic or Maaß cuspform Hecke newform \( \phi \) of level 4 \( |N| \), character \( \chi_{-4} \) and Hecke eigenvalues \( \lambda(n) \) whose archimedean parameter (weight or spectral parameter) we denote by \( \mu \). We start with two auxiliary results.

**Proposition 3.1.** Let \( M, X, Z \geq 1 \), \( \Delta \in \mathbb{N} \), and \( f, \sigma \in \mathbb{Z} \setminus \{0\} \). Let \( \alpha_n, \beta_n \) be sequences supported on \([M, 2M], [X, 2X]\) respectively. Suppose that \( |\alpha_n| \ll \epsilon \) for any \( \epsilon > 0 \) and \( \alpha_n \beta_n \) vanishes unless \( \sigma \alpha_n + f \) is in some dyadic interval \([\Xi, 2\Xi]\) with \( |\sigma|MX/Z \ll \Xi \ll |\sigma|MX + |f| \). Then

\[
    \sum_{\Delta|\sigma \alpha_n + f} \alpha_n \beta_n \lambda\left(\frac{\sigma \alpha_n + f}{\Delta}\right) \ll P^A\epsilon \left(\frac{M^{11/14}X^{1/2} + M^{5/4}X^{3/8}}{\Delta}\right)^{1+\epsilon}
\]

for some absolute constant \( A > 0 \) and any \( \epsilon > 0 \), where \( P = \Delta|\sigma|(1 + |\mu|)NZ(1 + |f|/MX) \).

**Proposition 3.2.** Let \( \Delta, q, d \in \mathbb{N}, r, f \in \mathbb{Z} \setminus \{0\}, Z, X_1, X_2, X_3 \geq 1/2 \). Suppose \( (\Delta, q) = 1 \) and that at least one of \( r, f \) is positive. Let \( G \) be a function with support on \( \times [X_1, 2X_1] \) and \( G^{(\nu_1, \nu_2, \nu_3)} \ll_{\nu} Z^{\nu_1 + \nu_2 + \nu_3}X_1^{-\nu_1}X_2^{-\nu_2}X_3^{-\nu_3} \) for all \( \nu \in \mathbb{N}^3 \). Write \( X = |r|X_1X_2X_3 \) and suppose that \( G(k, l, m) \)
vanishes unless \( rklm + f \) is in some dyadic interval \([\Xi, 2\Xi]\) with \( X/Z \ll \Xi \ll X + |f| \). Then

\[
\sum_{\substack{k,l,m \equiv -f \pmod{\Delta} \\ rklm \equiv d \pmod{q}}} G(k,l,m) \lambda\left(\frac{rklm + f}{\Delta}\right) \ll P^A X^{1 - 1/54 + \varepsilon}
\]

for some absolute constant \( A \) and any \( \varepsilon > 0 \), where \( P = q r \Delta (1 + |\mu|) N Z (1 + |f|/X) \).

Better bounds could be obtained with more work, but these bounds suffice for our purpose. We postpone the proofs to the next section and state the two main results of this section. As usual, \( \Lambda \) denotes the von Mangoldt function.

**Theorem 3.3.** There exist absolute constants \( A, \eta > 0 \) with the following property. Let \( \sigma, f \in \mathbb{Z} \setminus \{0\} \), \( X, Z \geq, \Delta, q, d \in \mathbb{N} \) with \( (\sigma, \Delta) = 1 \). Let \( G \) be a smooth function supported on \([X, 2X]\) with \( G^{(\nu)} \ll \nu (X/Z)^{-\nu} \) for \( \nu \in \mathbb{N}_0 \). Suppose that \( G(n) \) vanishes unless \( \sigma n + f \) is in some dyadic interval \([\Xi, 2\Xi]\) with \( |\sigma|X/Z \ll \Xi \ll |\sigma|X + |f| \). Then

\[
\sum_{\substack{\sigma n \equiv -f \pmod{\Delta} \\ n \equiv d \pmod{q}}} \lambda\left(\frac{\sigma n + f}{\Delta}\right) \Lambda(n) G(n) \ll P^A X^{1 - \eta}
\]

where \( P = q |\sigma| \Delta (1 + |\mu|) N Z (1 + |f|/|\sigma| X) \).

**Proof.** Based on Propositions 3.1 and 3.2, this could be proved similarly as in [ABL, Prop. 9.1] which in turn is the argument of [Pi, Section 9]. The proof in [Pi] uses Vaughan’s identity to decompose \( \Lambda \) iteratively three times. This is slightly cumbersome, but has the advantage that we only need \( \alpha_m \) to be supported on squarefree integers in the bilinear estimate in Proposition 3.1, which could yield better error terms numerically. Here we give a shorter independent proof at the cost of slightly weaker error terms. Instead of using Vaughan’s identity as in [Pi], we apply Heath-Brown’s identity in the form

\[
(3.1) \quad \Lambda(n) = \sum_{j=1}^{4} (-1)^{j-1} \binom{j}{4} \sum_{m_1, \ldots, m_j \leq X^{1/4}} \prod_{i=1}^{j} \mu(m_i) \sum_{m_1 \cdots m_j n_1 \cdots n_j = n} \log n_1
\]

for \( 1 \leq n \leq X \). Next we apply a smooth partition of unity to the variables \( m_i, n_i \). To be precise, let \( 0 < Z \leq 1 \) be a parameter to be chosen later and let \( \psi(x) \) be a smooth function supported on \([-1 - Z, 1 + Z]\) that equals 1 on \([-1, 1]\) and satisfies \( \psi^{(j)}(t) \ll Z^j \). Let \( D = \{(1 + Z)^m, m \geq 0\} \). Then we have the smooth partition of unity

\[
(3.2) \quad 1 = \sum_{N \in D} \psi_N(n)
\]

for any natural number \( n \), where \( \psi_N(n) = \psi(n/N) - \psi((1 + Z)n/N) \). Here we can choose \( Z = 1 \) (later parts of the paper we use the same argument with different choices of \( Z \)) so that

\[
\sum_{\substack{\sigma n \equiv -f \pmod{\Delta} \\ n \equiv d \pmod{q}}} \lambda\left(\frac{\sigma n + f}{\Delta}\right) \Lambda(n) G(n) \ll (\log X)^8 \max_{M_1, \ldots, M_j} \max_{N_1, \ldots, N_j} |S|
\]

where

\[
S = \sum_{\sigma \prod_{i=1}^{j} m_i, n_i \equiv -f \pmod{\Delta}, \prod_{i=1}^{j} m_i n_i \equiv d \pmod{q}} \prod_{i=1}^{j} \mu(m_i) \psi_{M_i}(m_i) \log(n_1) \psi_{N_1}(n_1) \prod_{i=2}^{j} \psi_{N_i}(n_i)
\]

\[
\times \lambda\left(\frac{\sigma \prod_{i=1}^{j} m_i n_i + f}{\Delta}\right) G\left(\prod_{i=1}^{j} m_i n_i\right).
\]
Therefore it is enough to show that there exist some absolute constants $A, \eta > 0$ such that

\begin{equation}
S \ll P^A X^{1-\eta}.
\end{equation}

We distinguish two cases. If there exists some $i$ such that $X^{\eta_0} \leq M_i$ (or $N_i \leq X^{1/4+\eta_0}$ for some $\eta_0 > 0$, then we can split $m_i$ or $n_i$ into residue classes modulo $q$, use Mellin inversion to separate variables $m_i, n_i$ (see e.g. [Pi, Section 7]) and then apply Proposition 3.1 to obtain

\[ S \ll P^A X^{(1-3\eta_0/14) + X^{31/32+3\eta_0/8}}. \]

Otherwise, we must have

\[ R := \prod_{i : M_i \leq X^{\eta_0}, N_i \leq X^{\eta_0}} M_i N_i \leq X^{8\eta_0} \]

and

\[ \#\{1 \leq i \leq j : N_i \geq X^{1/4+\eta_0}\} \leq 3, \quad 1 \leq j \leq 4, \]

in which case we can apply Proposition 3.2 to obtain

\[ S \ll P^A X^{1-1/54+8A\eta_0+\epsilon}. \]

Combining the bounds in these two cases and choosing $\eta_0$ suitably, we complete the proof of (3.3).

Our second main result treats the case of smooth numbers. As usual, $P^+(n)$ denotes the largest prime factor of $n$ with the convention $P^+(1) = 1$.

**Theorem 3.4.** There exist absolute constants $A, \eta > 0$ with the following property. Let $\sigma, f \in \mathbb{Z} \setminus \{0\}$, $X, Z, y \geq 1$, $\Delta, q, d \in \mathbb{N}$ with $(\sigma q, \Delta) = 1$. Let $G$ be a smooth function supported on $[X, 2X]$ with $G^{(\nu)} \ll_{\nu} (X/Z)^{-\nu}$. Suppose that $G(n)$ vanishes unless $\sigma n + f$ is in some dyadic interval $[\Xi, 2\Xi]$ with $|\sigma| X/Z \ll \Xi \ll |\sigma| X + |f|$. Then

\[ \sum_{\substack{\sigma n \equiv f \pmod{\Delta} \\ n \equiv d \pmod{q} \\ P^+(n) \leq y}} \lambda\left(\frac{\sigma n + f}{\Delta}\right) G(n) \ll P^A X^{1-\eta}. \]

where $P = q|\sigma| \Delta(1 + |\mu|)NZ(1 + |f|/|\sigma|X)$.

**Proof.** The proof follows along the lines in [FT90, Lemme 2.1] on averages of smooth numbers in arithmetic progressions to large moduli, which we also generalize (see Proposition 6.1). Throughout the proof, we use $A$ to denote some absolute positive constant, not necessarily the same at each occurrence. For $t \geq 1$ let $g_t(n)$ be the characteristic function on numbers $n$ with $P^+(n) \leq t$. The starting point is Buchstab’s identity that we iterate. For $y \geq 1$ we have

\begin{equation}
g_y(n) = 1 - \sum_{\substack{p \mid n \\text{and } p > y}} g_p\left(\frac{n}{p}\right) = 1 + \sum_{j=1}^{3} (-1)^j \sum_{p_1 \cdots p_j \mid n} 1 + \sum_{y < p_1 < \cdots < p_4} g_{p_4}\left(\frac{n}{p_1 \cdots p_4}\right).
\end{equation}

Thus

\[ \sum_{\substack{\sigma n \equiv f \pmod{\Delta} \\ n \equiv d \pmod{q} \\ P^+(n) \leq y}} \lambda\left(\frac{\sigma n + f}{\Delta}\right) G(n) = \sum_{\substack{\sigma n \equiv f \pmod{\Delta} \\ n \equiv d \pmod{q}}} \lambda\left(\frac{\sigma n + f}{\Delta}\right) g_y(n) G(n) = S_0 + \sum_{i=1}^{3} (-1)^i S_i + \overline{S}, \]

where $S_0 = \sum_{\substack{\sigma n \equiv f \pmod{\Delta} \\text{and } n \equiv d \pmod{q}}} \lambda\left(\frac{\sigma n + f}{\Delta}\right) G(n)$.
say, where

\[
\begin{align*}
S_0 &= \sum_{\sigma n \equiv -f (\mod \Delta), n \equiv d (\mod q)} \lambda \left( \frac{\sigma n + f}{\Delta} \right) G(n), \\
S_i &= \sum_{\sigma n \equiv -f (\mod \Delta), y < p_1 < \cdots < p_i, p_{i+1} \cdots p_m \equiv d (\mod q)} \lambda \left( \frac{\sigma p_1 \cdots p_i m + f}{\Delta} \right) G(p_1 \cdots p_i m), \\
\mathfrak{S} &= \sum_{\sigma n \equiv -f (\mod \Delta), y < p_1 < \cdots < p_i, p_{i+1} \cdots p_m \equiv d (\mod q)} \lambda \left( \frac{\sigma p_1 \cdots p_i m + f}{\Delta} \right) g_{p_i}(m) G(p_1 \cdots p_i m).
\end{align*}
\]

For \( S_0 \), we apply \cite[Corollary 7.6]{ABL} to obtain

\[
S_0 = \sum_{k \equiv \Delta (f + ad) (\mod q)} \lambda(k) G \left( \frac{\Delta k - f}{\sigma} \right) \ll P^A. \tag{3.5}
\]

For \( \mathfrak{S} \), we localize \( p_i \) in intervals \((P_i, P_{i+1})\) where \( P_j = y(1+Z)^j \) with some \( Z \leq 1 \) to be chosen later and \( 0 \leq j \leq J = 1 + \lceil \log(X/y) \rceil \). Then

\[
\mathfrak{S} = \sum_{0 \leq i_1 < i_2 < \cdots < i_4 < J, p_{i_k} \in (P_{i_k}, P_{i_k+1})} \lambda \left( \frac{\sigma p_1 \cdots p_i m + f}{\Delta} \right) g_{p_i}(m) G(p_1 \cdots p_i m) + O \left( P^A X^{1+\varepsilon} Z^{1/2} \right). \tag{3.6}
\]

To justify this, we see that \( \mathfrak{S} \) and the sum in (3.6) differ only by integers \( n \) that lie in \([X(1+Z)^{-4}, X(1+Z)^4] \) or have at least two prime factors \( p_i, p_j \) with \( p_i < p_j < (1+Z) p_i \). The contribution from these integers can be bounded by

\[
\ll \left( \sum_{X/(1+Z)^{-4} < n \leq X(1+Z)^4} \left| \lambda \left( \frac{\sigma n + f}{\Delta} \right) \right| \right)^{1/2} + \left( \sum_{n \in X} \left| \lambda \left( \frac{\sigma n + f}{\Delta} \right) \right| \right) \left( \sum_{\sigma n \equiv -f (\mod \Delta), p_i < p_j \leq (1+Z) p_i} \left| \lambda \left( \frac{\sigma n + f}{\Delta} \right) \right| \right)^{1/2} \ll P^A X^{1+\varepsilon} Z^{1/2}.
\]

Since \( y < P_{i_1} \ll X^{1/4} \), we can apply Proposition 3.1 with \( m = p_1 \) and \( n = |\sigma| p_2 \cdots p_i m \) to the main term in (3.6) by splitting \( m, n \) into residue classes modulo \( q \) to obtain

\[
\mathfrak{S} \ll Z^{-4} X^\varepsilon P^A \left( \frac{X}{y^{1/4^2}} + X^{31/32} \right) + P^A X^{1+\varepsilon} Z^{1/2} \ll P^A X^{1+\varepsilon} \max(y^{-1/42}, X^{-1/288}) \tag{3.7}
\]

upon choosing \( Z = \max(y^{-1/21}, X^{-1/144}) \).

For \( S_k \), \( 1 \leq k \leq 3 \), we first replace the characteristic function on primes with the von Mangoldt function \( \Lambda \). As above, we see that the contribution of higher prime powers is at most

\[
\ll P^A X^{1+\varepsilon} y^{-1/2}
\]

which can be absorbed in the existing bounds. Now similar to the proof of Theorem 3.3, we use Heath-Brown’s identity (3.1) to decompose the prime variables. Again we split all variables into
short intervals using the smooth partition (3.2) for some parameter $Z$ to be chosen later. We first bound

$$\tilde{S} = \sum_{m} \sum_{m_i} \sum_{\sigma m n_1 \cdots m_n \equiv f (\text{mod } \Delta)} \psi_M(m) \prod_{i=1}^r \mu(m_i) \psi_M(m_i) \prod_{j=1}^s \psi_N(n_j)$$

$$\lambda \left( \frac{\sigma m n_1 \cdots m_n \equiv f (\text{mod } \Delta)}{\Delta} \right) G(m n_1 \cdots m_n)$$

where $1 \leq r, s \leq 12, M \prod_{i=1}^r M_i \prod_{j=1}^s N_j \sim X$ and $M_i \ll X^{1/4}$. Again we distinguish two cases.

If there exists a subset $\mathcal{I} \subset \{M, M_i, N_j\}$ such that $K := \prod_{I \in \mathcal{I}} f$ such that $X^{\eta_0} < K \leq X^{1/4 + \eta_0}$, then we can apply Proposition 3.1 to obtain

$$\tilde{S} \ll P^A X^{\varepsilon} (X^{1-3\eta_0/14} + X^{31/32 + 3\eta_0/8}).$$

If such $\mathcal{I}$ does not exist, then all the $M_i$'s and possibly some of the $M, N_j$'s can be combined into $R \ll X^{\eta_0}$ and the number of $M, N_j$'s of size $\gg X^{1/4 + \eta_0}$ is less than, or equal to three. So it is enough to bound

$$\sum_{r \ll R/|\sigma|} \left| \sum_{k,l,m} \alpha_r \lambda \left( \frac{r k l m + f (\text{mod } \Delta)}{\Delta} \right) \psi_k(k) \psi(l) \psi_M(m) G(r k l m) \right|$$

which by Proposition 3.2 is

$$\ll P^A X^{1-1/54 + A \eta_0 + \varepsilon}$$

for some absolute constant $A > 0$. Then by the same argument as above we see that

$$S_i \ll P^A X^{\varepsilon} (Z^{-24} X^{1-1/54 + A \eta_0 + \varepsilon} + X Z^{1/2}), \quad 1 \leq i \leq 3$$

and hence by choosing $Z = X^{\eta}$ for some suitable $\eta > 0$ we obtain

$$S_i \ll P^A X^{1-\eta}, \quad 1 \leq i \leq 3$$

for some $\eta_2 > 0$. Combining (3.5), (3.7) and (3.8), we have shown that there exist some absolute constants $A, \eta > 0$ such that

$$\sum_{\sigma n \equiv f (\text{mod } \Delta)} \lambda \left( \frac{\sigma n + f (\text{mod } \Delta)}{\Delta} \right) G(n) \ll P^A X^{\varepsilon} (X^{1-\eta} + X y^{-\eta}).$$

On the other hand, when $y$ is very small we can do better using the flexible factorization of smooth numbers to create some bilinear structure so that Proposition 3.1 can be applied directly. Recall [FT96, Lemme 3.1]: for any $M \geq 1$, every $n \geq M$ with $P^+(n) \ll y$ has a unique representation in the form

$$n = l m, \quad P^+(l) \leq P^-(m), \quad M \leq m \leq y M.$$

We can separate $l$ and $m$ in the condition $P^+(l) \leq P^-(m)$ using [Dr1, eq. (3.37)] with an acceptable error. Thus by the same argument as before, we can localize $m$ into short intervals and apply Proposition 3.1 to obtain

$$\sum_{\sigma n \equiv f (\text{mod } \Delta)} \lambda \left( \frac{\sigma n + f (\text{mod } \Delta)}{\Delta} \right) G(n) \ll P^A X^{\varepsilon} (Z^{-1} (X M^{-3/14} + (M y)^{3/8} X^{7/8}) + X Z^{1/2})$$

$$\ll P^A X^{1-1/66+\varepsilon} y^{1/22}$$
by choosing \( M = X^{7/33} y^{-7/11} \), \( Z = X^{1/33} y^{-1/11} \). Applying (3.9) when \( y \geq X^\eta \) and (3.1) when \( y \leq X^\eta \) for some suitable \( \eta > 0 \) we obtain the theorem.

**Remark** Similar to the proof of Theorem 3.3 and 3.4, we can replace \( \Lambda(n) \) or \( 1_{P^+(n) \leq y} \) by \( \tau_k(n) \) and obtain an unconditional power saving bound uniformly in all parameters.

## 4. Proofs of Propositions 3.1 and 3.2

We still owe the proofs of Propositions 3.1 and 3.2. Recall that \( P \) is the product of the “unimportant” parameters which has slightly different meanings in Proposition 3.1 and Proposition 3.2. For notational simplicity we write

\[
R \ll S :\iff R \ll X^\epsilon P^A S
\]

for some sufficiently small \( \epsilon > 0 \) and some sufficiently large \( A > 0 \), not necessarily the same at each occurrence.

### 4.1. Proof of Proposition 3.1

This is an extension of [ABL, Proposition 8.1] where we relax the condition \( \alpha_m \) supported on squarefree numbers at the cost of slightly weaker bounds. Let \( \mathcal{B}(\alpha, \beta) \) denote the \( m, n \)-sum we want to bound. We use the notation \( \Delta = \Delta_1 \Delta_2 \) and \( \Delta_2 = (\Delta, (m_3 m_4)\infty) \) to accommodate the new parameter \( \Delta \).

\[
\mathcal{B}(\alpha, \beta) \ll \|\beta\|(XM)^{1/2} + X^{1/4} M^{3/2} + X^{3/8} M^{5/4}.
\]

To deduce the result for general sequences, we write

\[
\mathcal{B}(\alpha, \beta) = \sum_{\Delta | \sigma^2 mn + f} \mu^2(m) \alpha_{\sigma m^2} \beta_n \lambda\left(\frac{\sigma m^2 n + f}{\Delta}\right)
\]

We choose a parameter \( L > 1 \). By Hölder’s inequality, we see that the contribution from \( l \geq L \) gives

\[
\ll \left( \sum_{L \leq \lambda \leq M^{1/2}} \sum_{m \leq M/\lambda} \sum_{n \leq X} |\alpha_{\sigma m^2} \beta_n|^2 \right)^{3/4} \left( \sum_{L \leq \lambda \leq M^{1/2}} \sum_{m \leq M/\lambda} \sum_{n \leq X} |\lambda (\sigma m^2 n + f)\lambda|^4 \right)^{1/4}
\]

\[
\ll \left( \sum_{L \leq \lambda \leq M^{1/2}} \sum_{m \leq M/\lambda} 1 \right)^{3/4} \left( \sum_{n \leq X} |\beta_n|^2 \right)^{1/2} \left( \sum_{n \leq X} 1 \right)^{1/4} (M X)^{1/4} \ll \|\beta\| \frac{MX^{1/2}}{L^{3/4}}
\]

using the well-known bound for the fourth moment of Hecke eigenvalues

\[
\sum_{n \leq Y} |\lambda(n)|^4 \ll Y.
\]

Indeed, the Dirichlet series \( \sum_n \lambda\phi(n)^4 n^{-s} \) equals \( L(s, \text{sym}^2 \phi \times \text{sym}^2 \phi) L(s, \text{sym}^2 \phi)^2 \zeta(s) \) up to an Euler product that is absolutely convergent in \( \Re s > 1/2 + 2\theta \) where \( \theta \leq 7/64 \) is an admissible exponent for the Ramanujan-Petersson conjecture. Hence if \( C_\phi \) denotes the conductor of \( \phi \), then we conclude from the convexity bound and standard bounds for \( L \) functions at \( s = 1 \) [XLi] the estimate

\[
\sum_{m \leq x} |\lambda\phi(m)|^4 \ll (x C_\phi)^{1/2 + 2\theta + \epsilon} C_\phi^{O(1)}.
\]
On the other hand, for \( l \leq L \) we combine \( n \) and \( l^2 \) to one variable and apply (4.2) with \( \tilde{\beta}(l) = \beta_n/|1|_n \) to obtain
\[
\sum_{l \leq L} \sum_{m|l^2} \sum_{n|X^2} \mu^2(m) \alpha_{nm} \beta(l) n \lambda\left(\frac{\sigma}{M} + f\right)
\]
\[
\ll \sum_{l \leq L} \|\tilde{\beta}(l)\| \left(\frac{M}{X}\right)^{1/2} + \left(\frac{X^3}{l^2}\right) \left(\frac{M}{(l^2)^{3/2}} + \left(\frac{M}{l^2}\right)^{5/4} \left(\frac{X}{l^2}\right)^{3/8}\right)
\]
\[
\ll \|\beta\| \left(\frac{L}{X}\right)^{1/2} + \left(\frac{X^3}{M}\right) \left(\frac{M}{X^3/2} + \left(\frac{M}{X^3/2}\right)^{5/4} \left(\frac{X}{M}\right)^{3/8}\right).
\]
With \( L = M^{2/7} \), we obtain
\[
\mathcal{A}(\alpha, \beta) \ll \|\beta\| \left(\frac{X^{1/2}}{M^{11/14}} + \frac{X^{1/4}}{M^{3/2}} + \frac{M^{5/4} X^{3/8}}{X}\right).
\]
Here we can drop the middle term, because if it dominates the last term, then \( M > X^{1/2} \) in which case the claim is trivially true. This completes the proof.

4.2. Proof of Proposition 3.2. This result has a precursor in [ABL, Theorem 2.5], but it turns out that here the extra congruence conditions modulo \( q \) and \( \Delta \) are somewhat subtle and not completely straightforward to implement due to well-known difficulties in the Voronoi summation formula for general moduli. We therefore modify the proof, the biggest difference being that we replace the delta-symol method ([ABL, Lemma 7.3]) of Duke-Friedlander-Iwaniec with Jutila’s circle method.¹

Let us denote by \( \mathcal{F} \) the \( k, l, m \)-sum that we want to bound and recall that \( P \) is the product of the “unimportant” parameters (keeping in mind that the definition of \( P \) differs slightly from the previous proof). Assume without loss of generality \( X_1 \geq X_2 \geq X_3 \).

By Voronoi summation (cf. [ABL, Corollary 7.7]) it is easy to see that
\[
\mathcal{F} \ll (X/X_1)^{3/2}.
\]
We can also write
\[
\mathcal{F} = \sum_{r, k, l, m \equiv d (\text{mod } q)} \sum_{n \in \mathcal{C}} G(k, l, m) g(n) \lambda(n) \int_0^1 e\left(\alpha (r k l m + f - \Delta n)\right) d\alpha.
\]
where the redundant function \( g(n) \) has support on \( \frac{1}{2} \Xi / \Delta \leq n \leq 3 \Xi / \Delta \) and satisfies \( g(n) = 1 \) for \( \Xi / \Delta \leq n \leq 2 \Xi / \Delta \) and \( g^{(\nu)}(n) \ll \left(\frac{\Xi}{\Delta}\right)^{-\nu} \) for all \( \nu \in \mathbb{N}_0 \). We now employ Jutila’s circle method as in the corollary to [Ju, Lemma 1], i.e. we insert the constant function into the \( \alpha \)-integral and approximate it by a step function of small rational intervals. This device will simplify the argument especially with respect to the extra congruence condition on \( q \). Let \( C \) be a large parameter and \( \mathcal{C} \subset [C, 2C] \) be the set of moduli which are coprime to \( \Delta N q \). Define
\[
L = \sum_{c \in \mathcal{C}} \phi(c) \gg C^2 (\Delta N q C)^{-\varepsilon}
\]
and let \( \delta \) be a real number such that \( C^{-2} \ll \delta \ll C^{-1} \). Then we have (bounding the error term with Cauchy-Schwarz and Rankin-Selberg)
\[
\mathcal{F} = \tilde{\mathcal{F}} + O\left(\frac{(X/\Xi)^{1/2}}{\delta^{1/2} C}(X C)^{\varepsilon}\right)
\]
where
\[
\tilde{\mathcal{F}} = \sum_{r, k, l, m \equiv (d \text{mod } q)} \sum_{n \in \mathcal{C}} G(k, l, m) g(n) \lambda(n) \frac{1}{L} \sum_{c \in \mathcal{C}} \sum_{a \equiv \alpha (\text{mod } c)} \frac{1}{2\delta} \int_{-\delta}^{\delta} e\left(\frac{a}{c} + \alpha\right) (r k l m + f - \Delta n) d\alpha.
\]
¹As an aside we remark that we could also follow Munshi’s strategy [Mu2], but note that his Lemma 6 needs to be corrected by a factor \( q_1 \) when \( q_1 = \tilde{q}_1 \).
We now apply Voronoi summation [KMV, Theorem A.4] to the $n$-sum and note that by construction $(\Delta N, c) = 1$ (this flexibility is the main advantage of the present set-up). We obtain
\[
\sum_n g(n)e(\alpha \Delta n)\lambda(n)e\left(\frac{a\Delta}{c}n\right) = \frac{\xi}{c\sqrt{N}}\sum_{\pm} \chi_{-4}(\pm c) \sum_n \lambda(n)e\left(\frac{a\Delta N}{c}n\right)G^\pm\left(\frac{n}{c^3N}\right)
\]
for $(a, c) = 1$, some constant $\xi \in S^1$ depending only on the cusp form $\phi$ and functions $G^\pm$ which by [ABL, Lemma 7.5] satisfy the bound
\[
y^{\nu}d^{\nu}G^\pm(y) \ll_{A,\nu} \frac{\xi}{\Delta} \left(1 + \frac{1}{(\Xi/\Delta)^{2\tau+\epsilon}}\right)\left((1+|\mu|)(1+\sqrt{\frac{y\Xi}{\Delta}})^\nu\left(1 + \frac{y\Xi/\Delta}{(\delta\Xi/\Delta + 1)^2} + \frac{y\Xi/\Delta}{(1 + |\mu|^2)}\right)^{-A}\right)
\]
where $\tau = 0$ if $\phi$ is holomorphic and $\tau = 3t_\phi$ if $\phi$ is Maas with spectral parameter $t_\phi$. We choose $\delta = 1/X$.

With this choice we can truncate the $n$-sum at $\ll C^2/X$ and obtain
\[
\mathcal{S} \ll \frac{X}{L} \sum_{c \in C} \sum_{n \ll C^2/X} \frac{\left|\lambda(n)\right|}{c} \left(1 + \frac{C^2}{nX}\right)^{2\tau}\sum_{k,l,m} G(k,l,m)c\left((\alpha + \frac{b}{q})rklm\right)S(rklm + f, \pm \Delta n, c) + \frac{X^{3/2}}{C}.
\]

The factor $e(arklm)$ can be incorporated into $G$ at essentially no cost, since $arklm \ll \delta X = 1$. When $X_1 < C$, we can bound the $k, l, m$-sum using [ABL, Lemma 7.2] to obtain
\[
\mathcal{S} \ll \frac{X(c,f,n)^{1/2}}{c^{1/2}} + \left((c,f)^{1/2}c^{7/4} + X_1^{1/2}c^{3/2} + (X_2 X_3)^{1/2}c^{5/4} + X_1^2 X_2 X_1^{1/2}c^{1/2}\right)^{1/4}
\]
where $c_{\square}$ is the squarefull part of $c$. We can now evaluate the sums over $n$ (cf. [ABL, (7.1)]) and $c$ (with Rankin’s trick, cf. two displays after [ABL, (8.3)]) getting
\[
\mathcal{S} \ll \frac{X}{C^{1/2}} + C^{7/4} + X_1^{1/2}C^{3/2} + X_1^{1/3}c^{5/4} + X_1^2 X_1^{1/2}C^{1/2} + X_1^{3/2}/C
\]
(recall that $X_1 \geq X_2 \geq X_3$). At this point we make the admissible choice $C = X^{1/2+1/54}$ getting
\begin{equation}
\mathcal{S} \ll X^{53/54} + X_1^{1/2}X_1^{7/9}.
\end{equation}

Then the claim follows from (4.5) when $X_1^{1/3} \leq X_1 \leq X_2^{2/5}$ and from (4.4) when $X_1 \geq X_2^{2/5}$.

5. Proof of Theorem 1.1

5.1. Primes in arithmetic progressions. Before we start with the analysis of the main term, we recall [ABL, Theorem 2.1] on equidistribution of primes in long arithmetic progressions under GRH.

Proposition 5.1. Assume GRH. There exists some absolute constant $\varpi > 0$ with the following property. Let $x \geq 2$, $c, d \in \mathbb{N}$, $d \mid c^\infty$, $c_0, d_0 \in \mathbb{Z}$, $(d_0, d) = (c_0, c) = 1$, $a_1, a_2 \in \mathbb{Z} \setminus \{0\}$ such that for
\[
Q \leq x^{1/2+\varpi}, \quad |a_1| \leq x^{1+\varpi}, \quad |a_2| \leq x^\varpi, \quad c, d \leq x^\varpi
\]
we have
\[
\sum_{q \leq Q, q \equiv a_1 \pmod{c}} \sum_{0 < n \leq x} \Lambda(n) \frac{1}{\varphi(qd)} \sum_{n \equiv a_2 \pmod{q}} \Lambda(n) \ll x^{1-\varpi}.
\]

It is easy to see that we can replace the von Mangoldt function by the characteristic function on primes.
5.2. Preparing for the sieve. In this section, we use $\kappa$ to denote a sufficiently small (depending on $\varpi$ in Proposition 5.1 and $A, \eta$ as in Theorem 3.3) positive constant. We use $\varepsilon$ to denote an arbitrarily small positive constant.

Let $d = (d_1, d_2)$ denote a pair of two squarefree numbers with $d_1, d_2 \leq n^\kappa$. In preparation for a sieve we define

$$A_d(n) = \{(p, x_1, x_2) \mid p + d_1^2x_1^2 + d_2^2x_2^2 = n\}$$

(where of course $p$ denotes a prime). As usual, we denote by $c_p(n)$ the Ramanujan sum. The key input for the sieve is the following:

**Proposition 5.2.** Assume GRH. With the above notation, there exists some absolute constant $\kappa > 0$ such that uniformly for $d_1, d_2 \leq n^\kappa$ we have

$$\#A_d(n) = \text{Li}(n)\hat{S}_{d_1, d_2}(n) + O(n^{1-\kappa})$$

where the singular series $\hat{S}_{d_1, d_2}(n)$ is given by

$$\frac{\pi}{d_1 d_2} \prod_{p | (d_1, d_2)} \left(1 - \frac{c_p(n)}{p - 1}\right) \prod_{p | d_1 d_2} \left(1 - \frac{\chi_4(p)}{p - 1}\right) \prod_{p | n} \left(1 - \frac{\chi_4(p)}{p}\right). \tag{5.1}$$

**Remark:** One can check that this matches the main term coming from a formal application of the circle method. In particular, we see that $\hat{S}_{d_1, d_2}(n) = 0$ if $(d_1, d_2, n) > 1$ as it should.

**Proof.** Let $\delta = (d_1, d_2), d'_1 = d_1/\delta, d'_2 = d_2/\delta$ as in Lemma 2.2. By Lemma 2.2 and Theorem 3.3 (with $\kappa$ sufficiently small depending on the constants $A, \eta$) we have

$$\#A_d(n) = \sum_{\delta_1 \delta'_1 = d'_1} \sum_{\delta_2 \delta'_2 = d'_2} \frac{w_{\delta_1 \delta'_1}}{h_{\delta_1 \delta'_1}} G_{\delta_1 \delta'_1} \sum_{w \in G_{\delta_1 \delta'_1}} \sum_{p \equiv \epsilon (\delta_1 \delta'_1)^2} r\left(\frac{n - p}{\delta_1 \delta'_1}\right) + O(n^{1-\kappa}) \tag{5.2}$$

where $G_{\delta_1 \delta'_1} \subseteq (\mathbb{Z}/\delta_1 \delta'_1 \mathbb{Z})^*$ is as in (2.8) and $r = 1 * \chi_4$ as before. From (2.1) we obtain

$$\frac{w_{\delta_1 \delta'_1}}{h_{\delta_1 \delta'_1}} = \frac{4}{\delta_1 \delta'_1} \prod_{p | \delta_1 \delta'_1} \left(1 - \frac{\chi_4(p)}{p}\right)^{-1}$$

in all cases, including $\delta_1 \delta'_1 = 1$. We apply the Dirichlet’s hyperbola method to the $r$-function so that the innermost $p$-sum in (5.2) can for some parameter $Y > 0$ be written as

$$\sum_{Y \leq p \leq \sqrt{d_1^2d_2^2}} \sum_{\chi_4(b) + O(Y^{1+\varepsilon}) = S_1 + S_2 + O(Y^{1+\varepsilon}),}$$

say, where

$$S_1 = \sum_{\alpha \leq \sqrt{Y}} \left(\sum_{Y \leq p \leq n} \chi_4\left(\frac{n - p}{a \delta^2 \delta_1 \delta'_2}\right)\right),$$

$$S_2 = \sum_{b \leq \sqrt{Y}} \left(\sum_{Y \leq p \leq n - b \sqrt{\delta_1 \delta'_1}} \chi_4(b)\right).$$

We choose $Y = n^{1-2\kappa}$ so that the error term is acceptable. We will evaluate $S_1$ and $S_2$ by Proposition 5.1. This requires some preparation. It turns out that the contribution from $S_1$ will be negligible, but as there are some complications from the powers of two, we start with a detailed treatment for $S_1$. 
We use the notation
\[ r_2 = (\delta \delta_2, 2^{2\infty}), \quad d = \frac{\delta \delta_1 \delta_2}{r_2}, \quad d' = \frac{\delta' \delta_2}{(\delta'_1 \delta'_2, 2)}, \quad a_2 = (a, 2^{\infty}), \quad a_d = (a, d^{\infty}). \]

We see that \( S_1 \) equals
\[
\sum_{(a_2, \delta'_1 \delta'_2) = 1} \sum_{\substack{a \leq \sqrt{n/a_2} \leq n \atop (a, n) = 1}} \sum_{\substack{Y \leq p \leq n \atop p \equiv n / (mod \ a_2 r_2^2 d^2) \atop n - p \equiv w / (mod \ \delta_2)}} \chi_{-4}(a) \chi_{-4}(\frac{n-p}{a_2 r_2^2}) = \sum_{a_2 | 2^{\infty}} \sum_{(a_2, \delta'_1 \delta'_2) = 1} \chi_{-4}(a) \sum_{u \equiv 0 (mod \ 4)} \chi_{-4}(u) \sum_{v \equiv 0 (mod \ 4)} \chi_{-4}(v) \sum_{Y \leq p \leq n} \chi_{-4}(v) 1.
\]

Here we have used the fact that if \( 2 \mid \delta'_1 \delta'_2 \) then we must have \( a_2 r_2 = 1 \) and \( (w, 2) = 1 \). The contribution when one of \( a_2, a_d \) is at least \( n^{4\kappa} \) can be bounded by
\[
\sum_{a \geq n^{4\kappa}} \sum_{q \leq n / a} n \phi(a) \phi(q) \ll n^{-2\kappa + \varepsilon},
\]
so from now on we restrict to \( a_2, a_d \leq n^{4\kappa} \) (note that \( r_2, d', d \) are automatically at most \( n^{2\kappa} \)). Splitting into further residue classes, the \( a, p \)-sum equals
\[
\sum_{\lambda (mod \ d')} \sum_{a \equiv \sqrt{n / a_2 a_d} (mod \ (a, n) = 1)} Y \leq p \leq n \quad p \equiv n / (mod \ a) \quad p \equiv n / (mod \ d') \quad p \equiv n / (mod \ a d d') \quad 1 + O(n^{1/2 + \varepsilon})
\]
where the error term comes from the artificially added condition \( (a, n) = 1 \). For the same reason we can restrict to \( (n, d) = (n - w, d') = 1 \). We are now in a position to apply Proposition 5.1 (since \( \kappa \) is sufficiently small in terms of \( \varepsilon \)) together with the prime number theorem to the two innermost sums and recast the previous display as
\[
\mathbb{I}_{(n-d, d')=(n,d)} = 1 \sum_{a \leq \sqrt{n / a_2 a_d} \leq n} \frac{\mathbb{L}(n)}{\phi(a) \phi(d') \phi(4 a_2 a_d d^2 d'^2)} + O(n^{1 - \kappa}).
\]

Plugging back, we obtain
\[
S_1 = \mathbb{I}_{(n, d')=(n,d)} \sum_{a_2 | 2^{\infty}} \sum_{a_2 | d^{\infty}} \sum_{a_2 \leq n^{4\kappa} \atop a_2 \leq n^{\varepsilon} / (n - v a_2 r_2^2, 4) = 1} \chi_{-4}(v) \sum_{u \equiv 0 (mod \ 4)} \chi_{-4}(u) \sum_{Y \leq p \leq n} \chi_{-4}(v) \sum_{Y \leq p \leq n} \frac{\mathbb{L}(n)}{\phi(a) \phi(d') \phi(4 a_2 a d d^2 d'^2)} + O(n^{1 - \kappa}).
\]

But now the \( v \)-sum vanishes: with \( h = a_2 r_2^2 \mid 2^{\infty} \) we have
\[
\sum_{v \equiv 0 (mod \ 4)} \chi_{-4}(v) = \sum_{\ell \equiv 0 (mod \ 4)} \sum_{v \equiv 0 (mod \ \ell)} \chi_{-4}(v).
\]
Since $\chi_{-4}$ is primitive, by [IK, (3.9)] the inner sum vanishes, unless $4 \mid \ell (\ell, h)$ (which can only happen if $h = 1$), but then the Möbius function vanishes. We conclude $S_1 \ll n^{1-\kappa}$, as announced before.

We now turn to $S_2$ where the calculation is similar, and we obtain

$$
S_2 = \sum_{b_d | (\delta_1 \delta_2)} \chi_{-4}(b_d) \sum_{\substack{b \leq n^{1-\kappa} \mod 4 \\ (b, \delta_1 \delta_2) = 1 \mod 4}} \chi_{-4}(b) \sum_{\substack{Y \leq p \leq \sqrt{n b_d \delta_1^2 \delta_2^2} \\ p \equiv n \mod b \mod p \equiv w \mod \delta_1^2 \delta_2^2}} 1.
$$

As before we restrict to $b_d \leq n^{4\kappa}$ at the cost of an error of $O(n^{1-\kappa})$. The contribution from $(\delta_1 \delta_2, n) > 1$ is also negligible, so let us from now on assume $(\delta_1 \delta_2, n) = 1$. Before we can apply Proposition 5.1 to the $b, p$-sum, we must first separate variables in the summation condition. To this end, we split the $p$-sum into intervals of the form $((1 - \Delta)P, P)$ with $\Delta = n^{-2\kappa}$. There are $O(\Delta^{-1} \log n)$ such intervals. The condition $p \leq n - n b_d \sqrt{n \delta_1^2 \delta_2^2}$ interferes in at most one such interval, whose contribution we estimate by the Brun-Titchmarsh inequality at the cost of an admissible error $O(n^{1-\kappa})$. For all other intervals we can apply Proposition 5.1 on GRH in combination with the prime number theorem. Assembling the main term, we recast $S_2$, up to an error of $O(n^{1-\kappa})$, as

$$
\sum_{u \pmod{4}} \chi_{-4}(u) \sum_{b_d | (\delta_1 \delta_2)} \chi_{-4}(b_d) \sum_{\substack{b \leq n^{1-\kappa} \mod 4 \\ (b, \delta_1 \delta_2) = 1 \mod 4}} \chi_{-4}(b) \sum_{\substack{Y \leq p \leq \sqrt{n b_d \delta_1^2 \delta_2^2} \\ p \equiv n \mod b \mod p \equiv w \mod \delta_1^2 \delta_2^2}} 1 = \mathrm{Li}(n) \sum_{b_d | (\delta_1 \delta_2)} \chi_{-4}(b_d) \sum_{\substack{b \leq n^{1-\kappa} \mod 4 \\ (b, \delta_1 \delta_2) = 1 \mod 4}} \chi_{-4}(b) \sum_{\substack{Y \leq p \leq \sqrt{n b_d \delta_1^2 \delta_2^2} \\ p \equiv n \mod b \mod p \equiv w \mod \delta_1^2 \delta_2^2}} 1.
$$

As a last step, we compute the $b$-sum using [ABL, Lemma 5.2] and complete the sum over $b_d$, and recast the previous display up to an admissible error as

$$
\mathrm{Li}(n) L(1, \chi_{-4}) \prod_p \left( 1 + \frac{\chi_{-4}(p)}{p(p-1)} \right) \epsilon(d_1 d_2 n) \sum_{b_d | (\delta_1 \delta_2)} \chi_{-4}(b_d) \sum_{\substack{b \leq n^{1-\kappa} \mod 4 \\ (b, \delta_1 \delta_2) = 1 \mod 4}} \chi_{-4}(b) \sum_{\substack{Y \leq p \leq \sqrt{n b_d \delta_1^2 \delta_2^2} \\ p \equiv n \mod b \mod p \equiv w \mod \delta_1^2 \delta_2^2}} 1 = \mathrm{Li}(n) \sum_{b_d | (\delta_1 \delta_2)} \chi_{-4}(b_d) \sum_{\substack{b \leq n^{1-\kappa} \mod 4 \\ (b, \delta_1 \delta_2) = 1 \mod 4}} \chi_{-4}(b) \sum_{\substack{Y \leq p \leq \sqrt{n b_d \delta_1^2 \delta_2^2} \\ p \equiv n \mod b \mod p \equiv w \mod \delta_1^2 \delta_2^2}} 1.
$$

where

$$
\epsilon(f) = \prod_{p \mid f} \left( 1 + \frac{\chi_{-4}(p)}{p(p-1)} \right)^{-1} \left( 1 - \frac{\chi_{-4}(p)}{p} \right).
$$

This finishes the analysis of $S_2$.

We now return to (5.2) and summarize that there exists some absolute constant $\kappa > 0$ such that uniformly for $d_1, d_2 \leq n^{\kappa}$ we have

$$
\# \mathcal{A}_d = \mathrm{Li}(n) S_{d_1, d_2}(n) + O(n^{1-\kappa}),
$$
where the singular series $S_{d_1,d_2}(n)$ is given by

$$
S_{d_1,d_2}(n) = \sum_{\delta_1 \delta_2} \frac{A}{\phi(\delta_1 \delta_2)} \prod \left(1 - \frac{\chi_4(p)}{p}\right)^{-1} \sum_{w \equiv \delta_1 \delta_2 \mod n} 1
$$

$$
\times \sum_{b_d \mid \delta_1 \delta_2} \frac{\chi_4(b_d)}{\phi(b_d \delta_2^2 \delta_4^2)} L(1, \chi_4) \prod_p \left(1 + \frac{\chi_4(p)}{p(p-1)}\right) c(d_1 d_2 n).
$$

The sum over $w \equiv \delta_1 \delta_2 \mod n$ can be computed using (2.8) as

$$
\prod_{p \mid \delta_1 \delta_2} \left(\frac{p-1}{2} - \frac{\chi_4(n) + 1}{2}\right) \prod_{p \mid n} \left(\frac{p-1}{2}\right) \chi_4(n-1, \delta_1 \delta_2, z) = 1.
$$

It is now a straightforward exercise with Euler products, noting that $\chi_4(n) = (n/p)$ for odd $p$ and $L(1, \chi_4) = \pi/4$, to obtain the expression (5.1). This completes the proof.

5.3. Completion of the proof. With Proposition 5.2 available, Theorem 1.1 follows now easily from a sieve. Let $A = (a_k)$ be a finite sequence of non-negative real numbers. We introduce the notation

$$
S(A, z) = \sum_{(k,P_1(z)) = 1} a_k, \quad P_q(z) = \prod_{p \leq z, p | q} p, \quad A_c = \sum_{k \equiv 0 \mod c} a_k, \quad A = A_1.
$$

With these notation, we recall the following lemma from sieve theory (see e.g. [Iw2, Theorem 1]).

**Lemma 5.3.** Let $\gamma, L > 0$ be some fixed constants. Let $\Omega(c)$ be a multiplicative function satisfying $0 \leq \Omega(p) < p$ and

$$
\prod_{w \leq p \leq w'} \left(1 - \frac{\Omega(p)}{p}\right)^{-1} \leq \left(\frac{\log w'}{\log w}\right)^\gamma \left(1 + \frac{L}{\log w}\right)
$$

for all $2 \leq w \leq w'$. Then we have

$$
S(A, z) \geq A \prod_{p \leq z} \left(1 - \frac{\Omega(p)}{p}\right) \left(f_\gamma(s) - \frac{\sqrt{T} Q(s)}{(\log D)^{1/3}}\right) - \sum_{c \mid P_1(z)} \left|A_c - \frac{\Omega(c)}{c} A\right|,
$$

where $s = \log D/\log z$, $Q(s) < \exp(-s \log s + s \log \log 3s + O(s))$, and $f_\gamma(s)$ is some continuous function such that $0 < f_\gamma(s) < 1$ and $f(s) = 1 + O(e^{-s})$ as $s \to \infty$.

We are going to sieve the sequence $A = A(n) = (a_k)$ where $a_k = \#\{k = x_1 x_2 : p + x_1^2 + x_2^2 = n\}$. Then from Proposition 5.2, there exists some $\kappa > 0$ such that for $c \leq n^\kappa$ with $\mu^2(c) = 1$ we have

$$
A_c = \mu(c) \sum_{d_1 d_2 \mid c} \mu(d_1) \mu(d_2) \frac{\omega(d)}{d_1 d_2} S(n) \text{Li}(n) + O(c n^{1-\kappa + \epsilon})
$$

(5.6)
where
\[ \mathcal{G}(n) = \pi \prod_{p \mid n} \left( 1 + \frac{\chi^{-1}(p)}{p(p-1)} \right) \prod_{p \mid n} \left( 1 - \frac{\chi^{-1}(p)}{p} \right), \]
\[ \omega(d) = \prod_{p \mid (d_1, d_2)} \left( 1 - \frac{c_p(n)}{p-1} \right) \prod_{p \mid (d_1, d_2)} \left( 1 - \frac{\nu}{p} \right) \prod_{p \mid n} \left( 1 + \frac{\chi^{-1}(p)}{p(p-1)} \right)^{-1} \prod_{p \mid n} \left( 1 - \frac{\chi^{-1}(p)}{p} \right)^{-1} \]
\[ := \prod_{p^r \mid d_1 d_2} \omega_p(p). \]

For odd \( p \) we compute explicitly
\[ \omega_1(p) = \begin{cases} \left( 1 - \frac{(n/p)}{p-1} \right) \left( 1 + \frac{\chi^{-1}(p)}{p(p-1)} \right)^{-1}, & p \mid n, \\ \left( 1 - \frac{\chi^{-1}(p)}{p} \right)^{-1}, & p \mid n, \end{cases} \]
and
\[ \omega_2(p) = \begin{cases} \left( 1 - \frac{c_p(n)}{p-1} \right) \left( 1 + \frac{\chi^{-1}(p)}{p(p-1)} \right)^{-1}, & p \mid n, \\ \left( 1 - \frac{\chi^{-1}(p)}{p} \right)^{-1}, & p \mid n, \end{cases} \]
and for \( p = 2 \) we have
\[ \omega_1(2) = 1, \quad \omega_2(2) = 1 - \frac{c_2(n)}{p-1}. \]

Let \( \Omega(n) \) be the multiplicative function defined by
\[ \Omega(p) = 2\omega_1(p) - \omega_2(p)p^{-1} \]
so that we have from (5.6) that
\[ \sum_{c \leq D} \mu^2(c) \left| A_c - \frac{\Omega(c)}{c} A \right| \leq D^2 n^{1+\varepsilon} \]
where \( A = \mathcal{G}(n) \text{Li}(n) \). For \( n \not\equiv 2 \pmod{3} \), we also have
\[ 0 \leq \Omega(p) < 3, \quad \Omega(p) = 2 + O(1/p). \]

Thus there exists some absolute constant \( L \) such that (5.5) holds for \( \gamma = 2 \). We choose \( D = n^{\kappa_0} \) for some absolute small constant \( \kappa_0 \) (e.g. \( \kappa_0 = \kappa/3 \)) and choose \( C = C(\kappa_0) \) sufficiently large such that \( f_2(C\kappa_0) > 0 \). Then it follows from Lemma 5.3 that for \( n \not\equiv 2 \pmod{3} \) we have
\[ S(A, n^{1/C}) \geq \mathcal{G}(n) \text{Li}(n) \prod_{p \leq x} \left( 1 - \frac{\Omega(p)}{p} \right) \left( f_2(C\kappa_0) - \frac{e^{\sqrt{Q}(C\kappa_0)}}{(\log D)^{1/3}} \right) - O(n^{1-\kappa_0/2}) \]
\[ \gg \mathcal{G}(n) \text{Li}(n)(\log n)^{-2}. \]

This completes the proof of Theorem 1.1.

6. Proof of Theorem 1.2

The rest of the paper is devoted to the proof of Theorem 1.2. The basic idea is similar to the preceding proof, but it is technically and structurally substantially much more involved. Again we start with the distribution of smooth numbers in arithmetic progressions to large moduli.
6.1 Smooth numbers in arithmetic progressions. Denote
\[ \Psi(x, y) = \sum_{m \in S(x, y)} 1, \quad \Psi_q(x, y) = \sum_{m \in S(x, y)} 1. \]

We have the following analogue of Proposition 5.1 for smooth numbers under GRH.

**Proposition 6.1.** Assume GRH. There exists some absolute constant \( \varpi > 0 \) with the following property. Let \( x, y \geq 2, c, d \in \mathbb{N}, d \mid c^\infty, c_0, d_0 \in \mathbb{Z}, (d_0, d) = (c_0, c) = 1, a_1, a_2 \in \mathbb{Z} \setminus \{0\} \) such that for
\[ Q \leq x^{1/2+\varpi}, \quad |a_1| \leq x^{1+\varpi}, \quad c, d, |a_2| \leq x^\varpi, \quad y \gg (\log \log x)^2 \]
we have
\[ \sum_{q \leq Q} \left( \sum_{m \in S(x, y)} \frac{1 - 1}{\phi(qd)} \Psi_q(x, y) \right) \ll x^{1-\varpi}. \]

As a preparation for the proof we need the following lemma.

**Lemma 6.2.** Let \( A > 0 \). Assume GRH, \( \log y \gg (\log \log x)^2 \) and \( 1 < q \leq x^A \). Then for any non-principal Dirichlet character \( \chi \) (mod \( q \)) and any \( \varepsilon > 0 \), we have
\[ \sum_{m \in S(x, y)} \chi(m) \ll x^{1/2+\varepsilon}. \]

Remark: Any bound of the shape \( x^{1-\eta} \) would suffice, and this can be obtained by applying a result of Harper [Ha, Proposition 1] with \( H = x^{\delta}, \varepsilon = \alpha/2 \) in the proof of [Ha, (3.1)], as we assume GRH, and the condition \( \varepsilon \geq 40 \log \log(qyH)/\log y \) is satisfied if \( \log y \gg (\log \log x)^2 \). Since the situation is much simpler under GRH, we give an independent proof along the lines of [FT91, Théorème 4].

Proof. Let \( s = \sigma + it \) with \( \sigma > 0 \) and let \( L(s, \chi, y) = \prod_{p \leq y} (1 - \chi(p) p^{-s})^{-1} \) be the Dirichlet series for \( y \)-smooth numbers weighted by \( \chi \). Then for any \( \alpha > 0 \) we have from Perron’s formula
\[ \sum_{m \in S(x, y)} \chi(m) = \frac{1}{2\pi i} \int_{\alpha - iT}^{\alpha + iT} L(s, \chi, y) \frac{x^s}{s} ds + O \left( x^\alpha \sum_{p^s (m) \leq y} \frac{1}{m^\alpha} \min \left( 1, \frac{1}{T \log(x/m)} \right) \right). \]

We take \( \alpha = 1 + 1/\log x \) so that \( O \)-term is bounded by
\[ \frac{x^\alpha}{T} + \sum_{|m-x| \leq x/T} 1 \ll \frac{x \log x}{T}. \]

For the first term, we would like to approximate \( L(s, \chi, y) \) by \( L(s, \chi) \) and shift the contour to the left. Similarly as in [FT91, Lemme 6.3], we can show that under GRH for any \( \sigma > 1/2 \) and \( |t| \leq T \) we have
\[ L(s, \chi, y) = L(s, \chi) \exp \left( O(y^{1/2-\sigma} \log(qyT)^3) \right). \]

To prove (6.3), we first note that for any \( \sigma > 1/2 \) (cf. [FT91, (6.19)])
\[ - \frac{L'(s, \chi, y)}{L(s, \chi, y)} = \sum_{m \leq y} \frac{\Lambda(m) \chi(m)}{m^s} + O(y^{1/2-\sigma}). \]

The \( m \)-sum can be estimated again using Perron’s formula (see [FT91, (6.20)])
\[ \sum_{m \leq y} \frac{\Lambda(m) \chi(m)}{m^s} = \frac{1}{2\pi i} \int_{1-\sigma+1/\log y-iY}^{1-\sigma+1/\log y+iY} \frac{L'(s+w, \chi)}{L(s+w, \chi)} \frac{y^w}{w} dw + O(y^{1-\sigma} Y^{-1} \log^2 y) \]
for a parameter \( Y > 1 \). Shifting the line to \( 1/2 - \sigma + 1/\log y \), we only encounter the pole at \( w = 0 \) (assuming GRH). The contribution from the horizontal lines of the contour can be bounded by
$y^{1-\sigma} Y^{-1} (\log q T Y)^2$ and the contribution from the vertical line of the contour can be bounded by $y^{1/2-\sigma} (\log q T Y)^3$. Therefore choosing $Y = y^{1/2}$, we obtain

$$-\frac{L'(s, \chi, y)}{L(s, \chi, y)} = -\frac{L'(s, \chi)}{L(s, \chi)} + O(y^{1/2-\sigma} (\log q T y)^3),$$

and hence (6.3) by integrating along the line $\{s + t, t \geq 0\}$.

Now we can shift the line of integration in (6.1) to $T = x^{1/2}$, we see that $y^{1/2-\sigma_0} (\log q T y)^3 \ll 1$ since $\log y \gg (\log \log x)^2$ and $q \leq x^A$. On GRH, it follows that

$$\int_{\alpha-iT}^{\alpha+iT} L(s, \chi, y) \frac{x^s}{s} ds = \int_{\sigma_0+iT}^{\sigma_0+iT} L(s, \chi, y) \frac{x^s}{s} ds + O \left( \frac{x(qT)^\epsilon}{T} \right) \ll x^{1/2+\epsilon}.$$

Combining (6.2) and (6.4), we complete the proof of the lemma.

**Proof of Proposition 6.1:** The proof follows by combining the proofs of [FT90, Lemme 2.1] and [ABL, Theorem 2.1]. We use $\epsilon$ as an arbitrary positive constant, not necessarily the same at each occurrence. For a parameter $R > 1$ (which eventually will be chosen as a small power of $x$) denote

$$u_R(m; q) = 1_{m \equiv 1 \pmod{q}} - \frac{1}{\phi(q)} \sum_{\chi \pmod{q}} \chi(m) = \frac{1}{\phi(q)} \sum_{\chi \pmod{q} \text{cond } \chi \leq R} \chi(m),$$

so that we can write (note the assumptions imply $(q, d) = 1$)

$$\sum_{q \leq Q} \sum_{(q, a_1 a_2) = 1} \sum_{m \equiv S(x, y) \pmod{m} \equiv d_0 (\pmod{d})} \frac{1}{\phi(q)} \sum_{\chi \pmod{q} \text{cond } \chi \leq R} \chi(m a_1 a_2) \psi(md_0),$$

where

$$S_1 = \sum_{q \leq Q} \frac{1}{\phi(d)} \sum_{(q, a_1 a_2) = 1} \sum_{m \equiv S(x, y) \pmod{q} \equiv 0 (\pmod{c})} \frac{1}{\phi(q)} \sum_{\chi \pmod{q} \text{cond } \chi \leq R} \chi(m a_1 a_2) \psi(md_0),$$

$$S_2 = \sum_{q \leq Q} \frac{1}{\phi(d)} \sum_{(q, a_1 a_2) = 1} \sum_{m \equiv S(x, y) \pmod{q} \equiv 0 (\pmod{c})} u_R(m a_1 a_2; q) \psi(md_0).$$

For the contribution from non-principal characters in $S_1$, we use Lemma 6.2 to conclude that

$$\sum_{q \leq Q} \frac{1}{\phi(d)} \sum_{q \equiv 0 (\pmod{c})} \frac{1}{\phi(q)} \sum_{\chi \pmod{q} \text{cond } \chi \leq R} \chi(m a_1 a_2) \psi(md_0) \ll R x^{1/2+\epsilon}$$

and thus

$$S_1 = \sum_{q \equiv 0 (\pmod{c})} \frac{1}{\phi(q)} \Psi_{q d}(x) + O(R x^{1/2+\epsilon}).$$

Similar to the proof of Theorem 3.4, we now complete the argument by showing that there exists some absolute $\omega > 0$ such that

$$S_2 \ll x^{1-\omega}.$$

To prove (6.5), we consider separately the cases $y \geq x^\eta$ and $y < x^\eta$ for some sufficiently small $\eta > 0$. 

When $y \geq x^\eta$, we use the Buchstab’s identity (3.4) to write

$$S_2 = S_0 + \sum_{i=1}^{3} (-1)^i S_i + \mathcal{S},$$

where

$$S_0 = \sum_{q \leq Q \atop (q,a_1,a_2) = 1} \frac{1}{\phi(d)} \frac{1}{\phi(q)} \left( \sum_{\psi(\mod d) \atop m \equiv m_1,2 \atop m \leq x} 1 - \sum_{\psi(\mod q \atop \cond(\chi) \leq R}} \chi(m \bar{a}_2) \right) \psi(m \bar{d}_0),$$

$$S_j = \sum_{q \leq Q \atop (q,a_1,a_2) = 1} \frac{1}{\phi(d)} \sum_{\psi(\mod d \atop y < p_1 < \cdots < p_j} \sum_{\psi(\mod p_1 \cdot \cdots \cdot p_j \atop x}} u_R(m \bar{a}_1 \bar{a}_2; q) \psi(m \bar{d}_0),$$

$$\mathcal{S} = \sum_{q \leq Q \atop (q,a_1,a_2) = 1} \frac{1}{\phi(d)} \sum_{\psi(\mod d \atop y < p_1 < \cdots < p_j} \sum_{\psi(\mod p_1 \cdot \cdots \cdot p_j \atop x}} u_R(m \bar{a}_1 \bar{a}_2; q) g_{p_4}(m) \psi(m \bar{d}_0).$$

Consider $\mathcal{S}$ first. Note that we can assume $y < p_1 \ll x^{1/4}$ since otherwise the sum is empty. Similar to the proof of Theorem 3.4, we localize $m$ and $p_i$ into intervals $m \in (M, M(1+\mathcal{Z}))$ and $p_i \in (P_j, P_{j+1}]$ with $P_j = y(1+\mathcal{Z})^j$ and with $\mathcal{Z} = x^{-\eta_0}$ for some $\eta_0 > 0$ so that

$$\mathcal{S} \ll \mathcal{Z}^{-4}(\log x)^{O(1)} \sup_{M,P_j} |S| + x(\log x)^{O(1)} \mathcal{Z}$$

where

$$\mathcal{S} = \sum_{q \leq Q \atop (q,a_1,a_2) = 1} \frac{1}{\phi(d)} \sum_{\psi(\mod d \atop p_i \in (P_j, (1+\mathcal{Z})P_j)_{1 \leq i \leq 4}} \sum_{\psi(\mod (M,M(1+\mathcal{Z})) \atop 1 \leq i \leq 4)} g_{p_4}(m) u_R(m \bar{a}_1 \bar{a}_2 \bar{d}_0) \psi(m \bar{d}_0).$$

If $M \prod_{i=1}^{4} P_{j_i} \leq x^{1-\eta/2}$, we can bound $\mathcal{S} \ll x^{1-\eta/2+\epsilon}$ trivially. Otherwise, we can apply the bilinear estimate [ABL, Proposition 4.1] with $m = p_1$ to $\mathcal{S}$ since $x^\eta \leq y \leq P_{j_i} \ll x^{1/4} \ll (M \prod_{i=1}^{4} P_{j_i})^{1/4+\eta}$. We obtain

$$\mathcal{S} \ll \mathcal{Z}^{-4} c x (\log x)^{O(1)} R^{-1} + x(\log x)^{O(1)} \mathcal{Z}$$

as long as

$$Q \leq x^{1/2+\varpi_0}, \quad c, R, |a_2| \leq x^{\varpi_0}, \quad a_1 \leq x^{1+\varpi_0}$$

for some absolute constant $\varpi_0 > 0$. Since $R$ is a small power of $x$, this suffices for the bound $\mathcal{S} \ll x^{-1-\eta}$ by choosing a suitable $\eta_0$.

For $S_k$, $1 \leq k \leq 3$, we can replace the characteristic function of the primes by the von Mangoldt function, apply Heath-Brown’s identity (3.1) to each prime variable $p_i$ and then localize the new variables so that we have

$$S_k \ll \mathcal{Z}^{-24}(\log x)^{O(1)} \sup_{M,M',N_j \atop 1 \leq r \leq 12} \sup_{1 \leq s \leq 12} |\hat{S}| + x(\log x)^{(1)} \mathcal{Z},$$

where

$$\hat{S} = \sum_{q \leq Q \atop (q,a_1,a_2) = 1} \frac{1}{\phi(d)} \sum_{\psi(\mod d \atop p_i \in (P_j, (1+\mathcal{Z})P_j)_{1 \leq i \leq 4}} \sum_{\psi(\mod (M,M(1+\mathcal{Z})) \atop 1 \leq i \leq 4)} g_{p_4}(m) u_R(m \bar{a}_1 \bar{a}_2 \bar{d}_0) \psi(m \bar{d}_0).$$
where

\[
\hat{S} = \sum_{q \leq Q} \frac{1}{\phi(d)} \sum_{(q,a_1a_2) = 1 \atop q \equiv c_0 \pmod{c}} \sum_{m \in (M,(1+Z)M]} \sum_{m_i \in (M_i,(1+Z)M_i]} \sum_{n_j \in (N_j,(1+Z)N_j]}
\]

\[
\prod_{i=1}^{r} \mu(m_i) u_R \left( \prod_{i=1}^{r} m_i \prod_{j=1}^{s} n_j \bar{a}_1 \bar{a}_2; q \right) \psi \left( \sum_{i=1}^{r} m_i \prod_{j=1}^{s} n_j \bar{d}_0 \right)
\]

with

\[
M \prod_{i=1}^{r} M_i \prod_{j=1}^{s} N_j \ll x, \quad M_i \leq x^{1/4}.
\]

As before, we can assume \(M \prod_{i=1}^{r} M_i \prod_{j=1}^{s} N_j \geq x^{1-\eta/2} \) since otherwise we can bound \(\hat{S} \ll x^{1-\eta/2+\varepsilon} \) trivially. Now we argue similarly as in the proof of Theorem 3.4. If there is a subset \(I \subseteq \{M, M_i, N_j\} \) such that \(K := \prod_{i \in I} I \) such that \(x^{\eta} \leq K \leq x^{1/4+\eta} \), then we can apply [ABL, Proposition 4.1] with \(m = k \) to obtain

\[
\hat{S} \ll c x (\log x)^{O(1)} R^{-1}
\]

as long as (6.6) is satisfied. Otherwise, it is enough to show that there exists some absolute constant \(\varepsilon > 0 \) such that

\[
\sum_{q \leq Q} \sum_{m \leq M} \sum_{k \leq K} \sum_{l \leq L} \alpha_r u_R (r m k l a_1 a_2; q) \ll x^{1-\varepsilon}
\]

for \(r \leq x^\eta, x^{1-\eta/2} \ll r M K L \ll x \) and \(\alpha_r \ll r^\varepsilon \). This can be rewritten and then estimated in the same way as in [ABL, eq. (4.5)], where ultimately Deligne’s estimates for exponential sums over algebraic varieties over finite fields are used. By choosing \(Z \) suitably, we see that there exists some \(\varepsilon > 0 \) such that \(S_k \ll x^{1-\varepsilon} \) for \(1 \leq k \leq 3 \).

We can also treat \(S_0 \) by (6.7) when \(y \geq x^\eta \).

When \(y \leq x^\eta \), we can apply [FT96, Lemme 3.1] in the form of (3.10) so that it is enough to show that there exists some absolute constant \(\varepsilon > 0 \) such that

\[
\sum_{q \leq Q} \sum_{l \leq x} \sum_{m \leq M} \frac{g_y(l) g_y(m) u_R (l m a_1 a_2; q) \psi(l m a_0)}{l m d_0} \ll x^{1-\varepsilon}.
\]

After splitting \(l, m \) into residue classes modulo \(d \), separating variables \(l \) and \(m \) as in [Dr1, eq. (3.37)] and localizing \(l, m \) into short intervals \(l \asymp L \) and \(m \asymp M \), we can apply [ABL, Proposition 4.1] to obtain (6.8), as long as \(x^{\eta_2} \leq M \) and \(M y \leq (LM)^{1/4+\eta_2} \), which can be satisfied by choosing \(M = x^{\eta_2} \) for some suitable \(\eta_2 > 0 \) when \(LM \geq x^{1-\eta_3} \). If \(LM \leq x^{1-\eta_3} \), we can obtain (6.8) trivially, and this complete the proof of (6.5) when \(y \leq x^\eta \).

### 6.2. Implementing sieve weights

The most straightforward approach to Theorem 1.2 would be to use Proposition 6.1 to evaluate

\[
\sum_{m \leq S(x,y)} r_{d_1, d_2} (n - m)
\]

for squarefree numbers \(d_1, d_2 \), and then apply a sieve. Unfortunately the main term in the asymptotic formula is not a multiplicative function of \(d_1 d_2 \). As mentioned in the introduction, this makes it problematic to implement a sieve, so instead we will work with the sieve weights directly. We recall [Iw3, Lemma 3].
Lemma 6.3. Let $\gamma, L > 0$ be some fixed constants. Then there exists a sequence $\lambda_c^-$ supported on squarefree integers less than $D$ such that

$$\lambda_1^- = 1, \quad |\lambda_c^-| \leq 1, \quad \mu * 1 \geq \lambda^- * 1$$

and that for all multiplicative functions $w$ satisfying $0 \leq w(p) < 1$ and

$$\prod_{w \leq p \leq w'} (1 - w(p))^{-1} \leq \left( \frac{\log w'}{\log w} \right)^{\gamma} \left( 1 + \frac{L}{\log w} \right)$$

for all $2 \leq w \leq w'$ we have

$$\sum_{c \mid \prod(z)} \lambda_c^- w(c) \geq \prod_{p \leq z} (1 - w(p)) \left( f_\gamma(s) + O\left( e^{sL-s} (\log D)^{1/3} \right) \right), \quad s = \frac{\log D}{\log z} \geq 2,$$

where $f_\gamma(s)$ is some continuous function such that $0 < f_\gamma(s) < 1$ and $f_\gamma(s) = 1 + O(e^{-s})$ as $s \to \infty$.

The idea is to estimate the sieve weights $\lambda_c^-$ with multiplicative factors $w(c)$ first to get a lower bound using Lemma 6.3, and then sum over the smooth numbers $m$. In order to avoid major technical difficulties, we need to prepare the set-up very carefully.

- Many estimates are sensitive to the prime factorization of $m$, and it simplifies our life to restrict $m$ to be squarefree. On the other hand, if $n \equiv 2 \pmod{4}$, we will need $4 \mid m$ in order to represent $n$ by $m$ and two odd integer squares. Thus we only restrict $m$ to have an odd squarefree part. This restriction will not change the order of the number of solutions, but the fact that squarefree numbers are not equidistributed among all residue classes will leads to different constants for different $n$.
- It turns out that a factor $\chi_{-4}(h)$ with $h \mid (n, m)$ appears in the main term. It is convenient to force $\chi_{-4}(h) > 0$ (so that a lower bound suffices), and thus we also restrict $m$ to be coprime to all primes $p \equiv 3 \pmod{4}$ dividing $n$. Since $n - m$ is a sum of two squares, this is a harmless maneuver and affects only square factors, but it makes an important difference for the computation if we implement this. Note that we could simplify the computations by restricting $m$ to be coprime to $n$, but this could lose some order of magnitude for certain cases of $n$, e.g. when $n$ is the product of the first few primes that are $1 \pmod{4}$.
- Finally, the sieve weights behave a bit erratically for small primes, so we sieve them out directly by M"obius inversion.

With these general remarks in mind, we fix the following notation. We write

$$\mathfrak{N} = \prod_{p \mid n} p, \quad m_o = \prod_{p \mid m} p' = \frac{m}{(m, 2\infty)},$$

Recall the notation (5.4). Let

$$\mathcal{A} = \mathcal{A}(n) = (a_k), \quad a_k = \# \left\{ k = x_1x_2 : \frac{m}{\mathcal{P}^+(m)} \leq y, \quad x_1^2 + x_2^2 = n, \quad \mu^2(m_o) = 1, \quad (m, \mathfrak{N}) = 1 \right\}.$$

Then for $c$ squarefree, we have

$$A_c = \mu(c) \sum_{p \mid d_1, d_2 \equiv p \mid c} \mu(d_1)\mu(d_2) \sum_{m \leq x} \sum_{\mathcal{P}^+(m) \leq y} r_{d_1, d_2}(n - m).$$

Let $Q$ be some fixed absolute constant (we will later choose $Q = 30$). Let $\lambda^-_c$ be some lower bound sieve weights as in Lemma 6.3 of dimension $\gamma$, level $D = n^{\kappa_0}$ for some sufficiently small $\kappa_0$ and
\[ z = n^{1/d} \] for some sufficiently large \( C \) so that \( f_N(Cr_0) > 0 \). Then we have the following lower bound for \( S(A, z) \):

\[
(6.9) \quad S(A,z) = \sum_{\substack{m \leq n \\mu^2(m_\sigma) = (m, \mathfrak{N}) = 1}} \sum_{\substack{d \leq n \\mu^2(m_\sigma) = (m, \mathfrak{N}) = 1}} \sum_{\substack{\eta \leq y \\mu^2(m_\sigma) = (m, \mathfrak{N}) = 1}} \mu(c) \sum_{\substack{x_1^2 + x_2^2 = n - m \\mu^2(m_\sigma) = (m, \mathfrak{N}) = 1}} \mu(c) \sum_{\substack{x_1^2 + x_2^2 = n - m \\mu^2(m_\sigma) = (m, \mathfrak{N}) = 1}} \mu(c)
\]

\[
\sum_{u|Q} \sum_{c|P_Q(z)} \sum_{\substack{d_1, d_2 \\mu^2(m_\sigma) = (m, \mathfrak{N}) = 1}} \lambda(c) \mu(d_1) \mu(d_2) \sum_{\substack{m \leq n \\mu^2(m_\sigma) = (m, \mathfrak{N}) = 1}} r_{d_1, d_2} (n - m).
\]

Our next goal is to evaluate the innermost sum using Lemma 2.2.

### 6.3. The cuspidal contribution.

We first treat the contribution to the \( m \)-sum in (6.9) that corresponds to (2.9). To this end we need to show that there exists some absolute constant \( \eta > 0 \) (which eventually will depend on the constants in Theorem 3.4) such that

\[
(6.10) \quad \sum_{\substack{m \leq n \\mu^2(m_\sigma) = (m, \mathfrak{N}) = 1}} \lambda \left( \frac{n - m^2}{\Delta} \right) < n^{1-\eta}
\]

uniformly for \( \Delta, q \leq n^{\eta} \) with \((\Delta w, q) = 1\) (specifically, in the notation of (2.9) we have \( \Delta = (\delta_1 \delta_2)^2 \), \( q = \delta_1^2 \delta_2 \)) and Hecke eigenvalues of a cusp form \( \phi \) whose conductor is less than \( n^{\eta} \). By M"obius inversion, the previous display equals

\[
\sum_{d \leq n^{\eta}} \sum_{\substack{m | n/d^2 \\mu^2(m_\sigma) = (m, \mathfrak{N}) = 1}} \mu(d) \sum_{\substack{m \leq n/d^2 \\mu^2(m_\sigma) = (m, \mathfrak{N}) = 1}} \lambda \left( \frac{n - d^2 m}{\Delta} \right).
\]

The contribution from \( d \geq n^{\eta} \) can be bounded by

\[
\sum_{d \geq n^{\eta}} \left( \sum_{\substack{m \leq n/d^2 \\mu^2(m_\sigma) = (m, \mathfrak{N}) = 1}} 1^{3/4} \lambda \left( \frac{n - d^2 m}{\Delta} \right) \right)^{1/4} \ll n^{\varepsilon} \sum_{d \geq n^{\eta}} n^{1+\varepsilon-2\eta},
\]

using the bound (4.3) for the fourth moment of Hecke eigenvalues and recalling that presently the conductor \( C_\phi \leq n^{\eta} \).

For \( d \leq n^{\eta} \), we detect the condition \((m, \mathfrak{N}) = 1\) using M"obius inversion to write

\[
\sum_{\substack{m \leq n/d^2 \\mu^2(m_\sigma) = (m, \mathfrak{N}) = 1}} \lambda \left( \frac{n - d^2 m}{\Delta} \right) = \sum_{\substack{\tau | \mathfrak{N} \\mu^2(m_\sigma) = (m, \mathfrak{N}) = 1}} \mu(\tau) \sum_{\substack{m \leq n/d^2 \\mu^2(m_\sigma) = (m, \mathfrak{N}) = 1}} \lambda \left( \frac{n - d^2 \tau m}{\Delta} \right).
\]
The contribution from $\tau \geq n^{4\eta}$ can be bounded by
\[ n^{1+\varepsilon} \sum_{\tau \geq n^{4\eta}} \frac{1}{\tau} \ll \frac{n^{1+\varepsilon} \tau(n)}{n^{4\eta}} \ll n^{1+2\varepsilon-4\eta}. \]

Both error terms are acceptable. Thus, for $d, \tau \leq n^{4\eta}$ and automatically $(d\tau, q) = 1$ and $d_0 := (d^2\tau, \Delta) \mid n$, we are left with bounding
\[ \sum_{m \leq n/d^2\tau} \lambda(\frac{n - d^2\tau m}{\Delta}), \]
and the desired power saving as in (6.10) follows (after obvious smoothing) from Theorem 3.4.

6.4. Computing the main term I – summing over arithmetic progressions. We now return to (6.9) and insert the contribution corresponding to (2.7). In view of the bounds in the previous subsection, we have for $D = n^{\kappa_0}$ for sufficiently small $\kappa_0$ (depending on the constants $\varpi$ in Proposition 6.1 and $\eta$ is as in (6.10))
\[ S(A, z) \geq \sum_{u \mid Q} \sum_{c \mid P_Q(z)} \lambda(c) \mu(c) \sum_{d_1, d_2} \mu(d_1)\mu(d_2)S_{d_1, d_2} + O(n^{1-\kappa_0}) \]
where
\[ S_{d_1, d_2} = \sum_{\delta = (d_1, d_2)} \sum_{\delta' = d_1/\delta} \frac{4}{p|\delta_1', \delta_2'} \prod_{p|\delta_1', \delta_2'} (1 - \frac{\chi_4(p)}{p})^{-1} G_{\delta_1', \delta_2'} \sum_{\lambda \in S_{\delta_1', \delta_2'}} \sum_{\delta_1 = (\delta_1, \delta_2)} \sum_{\delta_2 = (\delta_1, \delta_2)} \lambda(\frac{n - m}{\delta_1' \delta_2')}. \]

As in the proof of Proposition 5.2, we apply Dirichlet’s hyperbola method to the $r$-function. Let $\eta_0$ be some small positive constant that will be chosen appropriately later. Let
\[ x = n(1 - 1/Z), \quad Z = n^{\eta_0} \]
for some $\eta_0 > 0$ be chosen later. In particular, in terms of orders of magnitude, $n$ and $x$ can (and will) be used interchangeably. Note that the contribution from $m \geq x$ or $m \leq n - x$ can be bounded by $Z^{-1}n^{1+\varepsilon} \ll n^{1-\eta_0/2}$. Thus we can write
\[ S_{d_1, d_2} =: S_1 + S_2 + O(n^{1-\eta_0/2}), \]
where
\[ S_1 = \sum_{\delta = (d_1, d_2)} \sum_{\delta' = d_1/\delta} \frac{4}{p|\delta_1, \delta_2} \prod_{p|\delta_1, \delta_2} (1 - \frac{\chi_4(p)}{p})^{-1} G_{\delta_1, \delta_2} \sum_{\lambda \in S_{\delta_1, \delta_2}} \sum_{\delta_1 = (\delta_1, \delta_2)} \sum_{\delta_2 = (\delta_1, \delta_2)} \chi_4(\frac{n - m}{a\delta_1^2 \delta_2^2}), \]
\[ S_2 = \sum_{\delta = (d_1, d_2)} \sum_{\delta' = d_1/\delta} \frac{4}{p|\delta_1, \delta_2} \prod_{p|\delta_1, \delta_2} (1 - \frac{\chi_4(p)}{p})^{-1} G_{\delta_1, \delta_2} \sum_{\lambda \in S_{\delta_1, \delta_2}} \sum_{\delta_1 = (\delta_1, \delta_2)} \sum_{\delta_2 = (\delta_1, \delta_2)} \chi_4(b), \]
for $1 \leq a \leq \sqrt{\frac{1}{\mu}(\delta_1, \delta_2)}, 1 \leq b \leq \sqrt{\frac{1}{\mu}(\delta_1, \delta_2)}$. 

ADDITIVE PROBLEMS WITH ALMOST PRIME SQUARES 25
Again we expect that $S_1$ gives a negligible contribution, as in the proof of Proposition 5.2, due to a particular behaviour at the prime $2$ which makes the main term disappear, but this is not so easy to see in the present situation. We will carry out the computation for both $S_1$ and $S_2$ and combine them to a joint main term for which we obtain the desired lower bound. As before, the computation of $S_1$ is slightly harder, so we focus on this part in detail, while the computation of $S_2$ is similar, but technically slightly easier. Our first step is to establish the asymptotic evaluations (6.16) and (6.19) below.

We would like to choose $\eta_0$ sufficiently small so that we can evaluate the inner two sums by Proposition 6.1, but this requires some preparation. We consider $S_1$ first. As before we write

$$r_2 = (\delta_1 \delta_2, 2^\infty), \quad d = \delta_1 \delta_2 / r_2, \quad a_2 = (a, 2^\infty), \quad a d = (a, d^\infty), \quad d' = \delta_1' \delta_2' / (\delta_1' \delta_2, 2),$$

so that $a, m$-sum in $S_1$ becomes

$$\sum_{a \leq \sqrt{m/a_2 a_d} \mod 4} \sum_{n-x \leq m \leq x \mod 2} \mu^2(m) \chi_2(m) \sum_{n-m \equiv w \mod d'} \chi_2(v)$$

so that $a, m$-sum in $S_1$ becomes

$$\begin{align*}
\sum_{a \leq \sqrt{m/a_2 a_d} \mod 4} & \sum_{n-x \leq m \leq x \mod 2} \mu^2(m) \chi_2(m) \sum_{n-m \equiv w \mod d'} \chi_2(v) \\
& \sum_{a \equiv u \mod (d')} \sum_{w \mod (d')} \chi_2(v)
\end{align*}$$

Here we have used the fact that if $2 \mid \delta_1' \delta_2'$, then we must have $r_2 a_2 = 1$ and $(w, 2) = 1$ so that the condition $n - m \equiv w \mod (2)$ is incorporated in the $v$-sum. As before, we can restrict $a, a_d \leq n^{\eta_0}$ at the cost of an error of size $O(n^{1+\varepsilon-\eta_0/2})$. The $a, m$-sum in (6.12) can be written as

$$\begin{align*}
\sum_{a \leq \sqrt{m/a_2 a_d} \mod 4} & \sum_{n-x \leq m \leq x \mod 2} \mu^2(m) \chi_2(m) \sum_{n-m \equiv w \mod d'} \chi_2(v) \\
& \sum_{a \equiv u \mod (d')} \sum_{w \mod (d')} \chi_2(v)
\end{align*}$$

By the Chinese remainder theorem, the congruence conditions modulo $a_d d^2, 4 a_2 r_2^2$, $d'$ can be written as a single congruence condition $\frac{m}{g_1} \equiv c_1 \mod (F_1)$ with $(c_1, F_1) = 1$, where

$$F_1 = \frac{4 a_2 r_2^2 a_d d^2}{g_1}, \quad g_1 = (n - v a_2 r_2^2, 4 a_2 r_2^2) (n - w, d')(n, a_d d^2).$$

In order for the $m$-sum to be nonempty, we must have

$$P^+(g_1) \leq y, \quad \mu((g_1)_0)^2 = (g_1, \mathfrak{N}) = 1,$$

as well as

$$P^+(a, n) \leq y, \quad \mu((a, n))^2 = (a, n, \mathfrak{N}) = 1,$$

in which case we can re-write the $a, m$-sum in (6.13) as

$$\begin{align*}
\sum_{a \leq \sqrt{m/a_2 a_d} \mod 4} & \sum_{n-x \leq m \leq x \mod 2} \mu^2(m) \chi_2(m) \sum_{n-m \equiv w \mod d'} \chi_2(v) \\
& \sum_{a \equiv u \mod (d')} \sum_{w \mod (d')} \chi_2(v)
\end{align*}$$

Note that from the construction of the sieve weights we have $d_1, d_2 \leq QD \ll n^\eta$ and thus we automatically have $g_1 \ll n^{2\eta_0 + 4\eta_0}$, a small power of $n$. Also note that $g_1 \mid (2d_1 d_2)^\infty$, so that automatically $(g_1, h) = 1$.

We can again restrict $h \leq n^{\eta_0}$ with a total error of size $O(n^{1+\varepsilon-\eta_0/2})$. Finally we detect the conditions $\mu^2(m) = 1$ and $(m, g_1 h \mathfrak{N}) = 1$ by Möbius inversion. We summarize that the $a, m$-sum
in (6.12) can, up to an admissible error of size $O(n^{1+\varepsilon-m/2})$, be replaced with

\[
\sum_{h \mid n} \frac{\mu(k)}{k^2} \sum_{\lambda \mid g, h} \mu(\lambda) \sum_{\mu \leq x} \frac{1}{\phi(F)} \sum_{\lambda \mid g, h} \mu(\lambda) \sum_{\mu \leq x} \frac{1}{\phi(F)} \sum_{\lambda \mid g, h} \mu(\lambda)
\]

where $a_2, a_d \ll n^{\varepsilon_0}, g_1 \ll n^{2\varepsilon_0+4\kappa_0}$ are sufficiently small powers of $n$. As before, we may also restrict $\lambda$ and $k$ up to $n^{\varepsilon_0}$, up to an admissible error of size $O(n^{1+\varepsilon-m_0}/2)$. We can now complete the $\lambda, k$-sums in the same way as we truncated them, and incorporate them back into the $a, m$-sum. Substituting back into (6.12) and evaluating the $u$-sum, we obtain (writing the condition (6.15) on $g_1$ in terms of the remaining variables and noting that $\mu^2(d') = 1, a_d \mid d^\infty$) the expression

\[
S_1 = \sum_{\chi \neq 1, \mu \leq x} \left(1 - \frac{\chi(4p)}{p}\right)^{-1} G_{\lambda, \mu, k} M_1 + O(n^{1+\varepsilon-m/2}),
\]

where

\[
M_1 = \sum_{w \equiv 0 \pmod{2}} \sum_{(w, d') = 1} \sum_{\mu \leq x} \chi(4h) \sum_{v \equiv 0 \pmod{4}} \chi(4(v)) \sum_{a_2 a_d \leq n^{\varepsilon_0}} \sum_{\mu \leq x} \chi(4h) \sum_{v \equiv 0 \pmod{4}} \chi(4(v))
\]

Next we change the summation order of $m$ and $a$, evaluate the $a$-sum by [ABL, Lemma 5.2] and then complete the $a_2, a_d, h$-sums with an admissible error to finally obtain (with e.g. $\eta_0 = 10\kappa_0$), uniformly for $d_1, d_2 \ll n^{\kappa_0}$ (with $\kappa_0$ sufficiently small), that

\[
M_1 = \prod_p \left(1 + \frac{\chi(4p)}{p(p-1)}\right) \sum_{(a_2, d_1, d_2) = 1} \sum_{\mu \leq x} \chi(4h) \sum_{v \equiv 0 \pmod{4}} \chi(4(v)) \sum_{m \equiv x \pmod{2}} \sum_{(m, 2d_1 d_2 a_2) = 1} \sum_{\mu \leq x} \chi(4h) \sum_{v \equiv 0 \pmod{4}} \chi(4(v))
\]
with \( \epsilon(f) \) as in (5.3). (The error term ensures that even after summing over \( d_1, d_2 \) it is still acceptable.)

The same strategy can be applied to \( S_2 \). We give a sketch of the manipulations highlighting the differences from those for \( S_1 \). To begin with, we do not need to separate \( r_2 \) from \( \delta \delta_1 \delta_2 \), so that the \( b, m \)-sum in \( S_2 \) becomes

\[
\sum_{b \mid (\delta \delta_1 \delta_2)^\infty} \chi_{-4}(b_d) \sum_{u \equiv (mod 4)}^* \chi_{-4}(u) \sum_{b \leq \frac{y}{(b, d_1 d_2)^2} \sqrt{\eta}} \sum_{m \leq n - b d_1 d_2 (\delta \delta_1 \delta_2)^2 \sqrt{\eta}} \sum_{m \equiv n (mod (\delta_1 \delta_2)^2)} 1.
\]

We can restrict \( b_d \leq n^{r_0} \) with an error of size \( O(n^{1+\epsilon - r_0}/2) \). After splitting \( m \) into residue classes modulo \( d_1 d_2 \), using the Chinese remainder theorem to rewrite the congruence condition modulo \( b_d (\delta \delta_1 \delta_2)^2 \delta_1' \delta_2' \) as \( m \equiv c_2 \) (mod \( F_2 \)) with

\[
F_2 = \frac{b_d (\delta \delta_1 \delta_2)^2 \delta_1' \delta_2'}{g_2}, \quad g_2 = (n - w, \delta_1' \delta_2')(n, b_d^2 \delta_1^2 \delta_2'^2)
\]

and then extracting \((b, n)\), we can write the \( b, m \)-sum in (6.17) as

\[
\sum_{b \leq \frac{y}{(b, d_1 d_2)^2} \sqrt{\eta}} \sum_{m \leq n - b d_1 d_2 (\delta \delta_1 \delta_2)^2 \sqrt{\eta}} \sum_{m \equiv n \delta_1' \delta_2' \delta_1'^2 \delta_2'^2 (mod 4)} 1.
\]

We can again restrict \( b \leq n^{r_0} \) with a total error of size \( O(n^{1+\epsilon - r_0}/2) \). Additionally, we need to separate \( b, m \) in the summation condition in order to apply Proposition 6.1. As usual, this can be achieved by splitting \( m \) into intervals of the form \([M, (1 + \Delta)M]\) with \( \Delta = n^{-r_0} \) so that at most one interval interferes with the condition \( m g_2 h \leq n - b d_1 d_2 (\delta \delta_1 \delta_2)^2 \), in which case the contribution can be bounded by \( O(n^{1+\epsilon - r_0}) \) trivially. After Möbius inversion and splitting \( b \) into residue classes modulo \( d_1 d_2 \), we can finally apply Proposition 6.1 so that the \( b, m \)-sum in the last display can be evaluated, up to an admissible error, as

\[
\sum_{b \leq \frac{y}{(b, d_1 d_2)^2} \sqrt{\eta}} \sum_{m \leq n - b d_1 d_2 (\delta \delta_1 \delta_2)^2 \sqrt{\eta}} \frac{1}{\phi(b) \phi(F_2)}.
\]

After changing the order of summation, evaluating the \( b \)-sum by [ABL, Lemma 5.2] (note that the upper limit for \( b_d \) is always \( \gg n^{1/2 - r_0} \) unless \( |n - m g_2 h| \leq n^{1 - r_0} \) whose contribution can be bounded by \( O(n^{1- r_0}/2) \)) and completing the \( b, h \)-sums, we obtain, uniformly for \( d_1, d_2 \leq n^{\kappa_0} \), that

\[
S_2 = \sum_{\delta_1' \delta_2' = \delta_1' \delta_2'} \sum_{p | \delta_1' \delta_2'} \prod_{p | \delta_1' \delta_2'} \left( 1 - \frac{\chi_{-4}(p)}{p} \right) G_{\delta_1' \delta_2'} M_2 + O(n^{1 - 3 \kappa_0}),
\]
where
\[ M_2 = \frac{\pi}{4} \prod_{p} \left( 1 + \frac{\chi_4(p)}{p(p-1)} \right) \sum_{\substack{b \in [\delta_1, \delta_2]^2 \cap \mathbb{Z} \times \mathbb{Z} \setminus \{0\} \\ \Phi((n, m_1, m_2)) \leq y}} \chi_4(b) \times \sum_{\substack{h \mid n \\ \Phi((h, m_1, m_2)) \leq y}} \chi_4(h) \sum_{\substack{m \leq x/gz \\ \Phi((m, m_1, m_2)) \leq y}} \phi(F_2) + O(n^{1-3\sigma}). \]

6.5. Computing the main term II – Euler products. We substitute (6.16) and (6.19) back into (6.11). By choosing \( D = n^{\kappa_0} \) sufficiently small, it follows from (6.9) together with (6.10) that
\[ S(A, z) \geq \pi \prod_{p} \left( 1 + \frac{\chi_4(p)}{p(p-1)} \right) (S_1^- + S_2^-) + O(n^{1-\kappa_0}), \]
where
\[ S_1^- = \sum_{u \mid Q} \sum_{c \mid P_2(z)} \chi(c) \mu(u) \sum_{d_1, d_2} \mu(d_1) \mu(d_2) \sum_{\substack{d_1, d_2 \mid n \\ \Phi((d_1, d_2)) \leq y}} \chi_4(d_1 d_2) \sum_{\substack{r_{2d} = d_1 \delta_1 \delta_2 \equiv d_1 \mod{d_2} \\ \Phi((r_{2d}, m_1, m_2)) \leq y}} \phi(F_1) \]
\[ \times G_{d'} \sum_{w \mid (n, m_1, m_2)} \chi_4(w) \sum_{\substack{m \leq x/g_1 h \\ \Phi((m, m_1, m_2)) \leq y}} \phi(F_2) \]
with \( F_1, g_1 \) as in (6.14), and
\[ S_2^- = \sum_{u \mid Q} \sum_{c \mid P_2(z)} \chi(c) \mu(u) \sum_{d_1, d_2} \mu(d_1) \mu(d_2) \sum_{\substack{d_1, d_2 \mid n \\ \Phi((d_1, d_2)) \leq y}} \chi_4(d_1 d_2) \sum_{\substack{r_{2d} = d_1 \delta_1 \delta_2 \equiv d_1 \mod{d_2} \\ \Phi((r_{2d}, m_1, m_2)) \leq y}} \phi(F_2) \]
\[ \times G_{d'} \sum_{w \mid (n, m_1, m_2)} \chi_4(w) \sum_{\substack{m \leq x/g_2 h \\ \Phi((m, m_1, m_2)) \leq y}} \phi(F_2) \]
with \( F_2, g_2 \) as in (6.18). Now we rename \( mg_i \) as \( m \), change the order of summation and evaluate \( S_1^-, S_2^- \) in roughly the form
\[ \sum_{h \mid n} \sum_{m \leq x/h} \sum_{u \mid Q} \chi(c) w_{m, n, h}(c) \]
for some multiplicative function \( w_{m,n,h}(c) \). In particular, we postpone the summation over \( m \) to the last moment. Precisely, we write

\[
S_1^- = \sum_{\substack{h \mid n \\ P^+(h) \leq y \\ \mu^2(h) = 1 \\ (h,n) = 1}} \chi_4(h) \sum_{\substack{m \leq x/h \\ (m,91) = 1 \\ P^+(m) \leq y \\ \mu^2(m,n,h) = 1}} \lambda^- \mu(c) \sum_{\substack{d_1, d_2 \\ d_{1,2} \in \mathbb{Z}^+}} \mu(d_1) \mu(d_2) \epsilon \left( 2d_1d_2n/h \right)
\]

(6.21)

\[
\sum_{\substack{\delta = (d_1, d_2), \delta' = d_1, / \delta \\ \delta d - (d_1, d_2, 2, (d, 2) = 1}} \frac{G_{d'}}{|d'_1d'_2|} \prod_{p | d'd} \left( 1 - \frac{\chi_4(p)}{p} \right)^{-1} \sum_{\substack{\delta_1, \delta_2}} \sum_{\substack{\delta_1, \delta_2}} \chi_4(d') \phi(F_1)
\]

where \( c(f) \) is as in (5.3), \( F_1 \) is as in (6.14), and

\[
R_1 = \left\{ a_2 \mid 2^\infty, a_2 | d^\infty \\ v \mod 4, w \mod d' : \begin{cases} (m, 4a_2r_2^2) = (n - a_2r_2^2, 4a_2r_2^2) \\ (m, a_2d^2) = (n, a_2d^2) \end{cases} \right\}
\]

To see this, we recall the conditions (6.15) and observe that after replacing \( mg_1 \) with \( m \), the new conditions \( P^+(m) \leq y, \mu^2(m,n,h) = 1 \) take care of the old conditions \( P^+(m,91) = 1 \leq y, P^+(m,n,d') \leq y, \mu^2((m,n,d'), (n,91) = 1 \). Moreover, the old condition \( (m, F_1) = 1, mg_1 \leq x/h \) is equivalent to the new condition \( (m, 4a_2r_2^2a_2d^2d') = g_1, m \leq x/h \) after replacing \( mg_1 \) with \( m \). Note also that \( G_{d'} \gamma_2 \simeq G_{d'} \). Similarly, we write

\[
S_2^- = \sum_{\substack{h \mid n \\ P^+(h) \leq y \\ \mu^2(h) = 1 \\ (h,n) = 1}} \chi_4(h) \sum_{\substack{m \leq x/h \\ \mu^2(m,n,h) = 1}} \lambda^- \mu(c) \sum_{\substack{d_1, d_2 \\ d_{1,2} \in \mathbb{Z}^+}} \mu(d_1) \mu(d_2) \epsilon \left( d_1d_2n/h \right)
\]

(6.22)

\[
\sum_{\substack{\delta = (d_1, d_2), \delta' = d_1, / \delta \\ \delta d - (d_1, d_2, 2, (d, 2) = 1}} \frac{G_{d'}}{|d'_1d'_2|} \prod_{p | d'd} \left( 1 - \frac{\chi_4(p)}{p} \right)^{-1} \sum_{\substack{b_{d, w} \in \mathcal{R}_2}} \chi_4(b_{d, w}) \phi(F_2)
\]

where \( F_2 \) is as in (6.18) and

\[
R_2 = \left\{ b_{d} \mid d^\infty \\ w \mod d' : \begin{cases} (m, b_{d}d^2) = (n, a_2d^2) \\ (m, d') = (n - w, d') \end{cases} \right\}
\]

Our next aim is to write the second line in (6.21) as an Euler product which will be given in (6.27) below. The \( v \)-sum modulo 4 in (6.21) contributes

\[
\sum_{v \mod 4} \frac{\chi_4(v)}{(n - v_a2r_2^2, 4a_2r_2^2) = (m, 4a_2r_2^2) \phi(4a_2r_2^2)} = \mathbb{I}_{2a_2r_2^2} | m | \mathbb{I}_{a_2r_2^2} | n | \chi_4 \left( \frac{n}{a_2r_2^2} \right) \left\{ \begin{array}{ll} -1 & 4a_2r_2^2 \mid m, \\ 1 & 4a_2r_2^2 \mid m. \end{array} \right.
\]

(6.23)

In particular, we see that for each \( r_{a_2} \), only one \( a_2 \) with \( (a_2, \delta_1') = 1 \) gives a non-zero contribution. The \( v \)-sum together with \( G_{d'} \) can be evaluated as (treat each prime \( p \mid d' \) at a time)

\[
G_{d'} = \frac{1}{\phi(d'/(n - w, d'))} = \mathbb{I}_{(d', m, n) = 1} \prod_{p | d'} \left( 1 + \chi_{d'}(n) \right) \prod_{p | d'} \left( 1 - \frac{1 + \chi_{d'}(n)}{p - 1} \right).
\]

(6.24)
Finally, the sum over \( a_d \mid d^\infty \) gives

\[
\sum_{a_d \mid d^\infty} \frac{\chi_4(a_d)}{\phi(a_d d^2/(n, a_d d^2))} = \prod_{p \mid d} \mathfrak{d}(p; m, n)
\]

where

\[
\mathfrak{d}(p; m, n) = \begin{cases} 
\frac{1}{(p-1)(p-\chi_4(p))}, & p \nmid mn, \\
\frac{p}{(p-1)(p-\chi_4(p))}, & \nu_p(m) = \nu_p(n) = 1, \\
0, & \text{else}.
\end{cases}
\]

Here we use crucially that (the odd part of) \( m \) is squarefree. For more general \( m \), the formula would look much more complicated, in particular the contribution could be much larger which would create considerable technical problems in apply Lemma 6.3.

We summarize: the second line in (6.21) can be written as an Euler product

\[
\sum_{\delta_1 \delta_2 = \delta_1'} \mathfrak{f}_1(p, \nu; m, n) = \prod_{p \mid d_1 d_2} \mathfrak{f}_1(p, \nu; m, n)
\]

where the Euler factor is composed of (6.23), (6.24) and (6.25).

We compute \( \mathfrak{f}_1(2, \nu; m, n) \) explicitly using (6.23). If \( 2 \nmid d_1 d_2 \), then \( r_2 = 1 \) and only \( a_2 = 2^{\nu_2(n)} \) contributes. If \( 2 \parallel d_1 d_2 \), then we have two cases: when \( 2 \parallel \delta_1' \delta_2' \), we have \( r_2 = 1 \) and only \( a_2 = 1 \) contributes (since we require \( (a_2, \delta_1' \delta_2') = 1 \)); and when \( 2 \parallel \delta_1 \delta_2 \), we have \( r_2 = 2 \) and only \( a_2 = 2^{\nu_2(n)-2} \) contributes. If \( 2 \mid (d_1, d_2) \), then \( r_2 = 2 \) and only \( a_2 = 2^{\nu_2(n)-2} \) contributes. Precisely, we have

\[
\mathfrak{f}_1(2, \nu; m, n) = \begin{cases} 
1, & \nu = 0, \\
\frac{1}{(p-1)(p-\chi_4(p))}, & p \nmid mn, \nu = 1, \\
\frac{1}{(p-1)(p-\chi_4(p))} \cdot \frac{1}{p} (1 - \chi_4(p))^{-1} (1 + \chi_4(n)), & p \mid mn, p \nmid (m, n) \mid \nu = 1, \\
\frac{1}{(p-1)(p-\chi_4(p))} \cdot \frac{1}{p} (1 - \chi_4(p))^{-1} (1 + \chi_4(n)), & p \parallel (m, n), \nu = 1, \\
\phi(d; m, n), & \nu = 2.
\end{cases}
\]

For \( \mathfrak{S}_2 \), we have analogous results with \( \mathfrak{f}_1 \) replaced by \( \mathfrak{f}_2 \) where

\[
\mathfrak{f}_2(2, \nu; m, n) = \begin{cases} 
1, & \nu = 0, \\
\frac{1}{(p-1)(p-\chi_4(p))} \cdot \frac{1}{p} (1 - \chi_4(p))^{-1} (1 + \chi_4(n)), & p \nmid mn, \nu = 1, \\
\frac{1}{(p-1)(p-\chi_4(p))} \cdot \frac{1}{p} (1 - \chi_4(p))^{-1} (1 + \chi_4(n)), & p \parallel (m, n), \nu = 1, \\
\phi(d; m, n), & \nu = 2.
\end{cases}
\]

(noting that if \( 2 \mid \delta_1' \delta_2' \) then the \( w \)-sum is zero unless \( 2 \parallel mn, 2 \nmid (m, n) \); and if \( 2 \parallel \delta_1 \delta_2 \) then the 2-part in the \( b_d \)-sum becomes \( \frac{1}{\phi(n)} \cdot \chi_4(n) \cdot \phi(d; m, n) \), and for \( 2 \parallel p \) we have

\[
\mathfrak{f}_2(p, \nu; m, n) = \mathfrak{f}_1(p, \nu; m, n).
\]
6.6. Computation of the main term III—the sieve weights. We are now prepared to further evaluate $S_1^-$ and $S_2^-$. We will bound $S_1^-$ and $S_2^-$ from below by (6.35) using properties of the lower bound sieve weights in Lemma 6.3.

To begin with, we substitute (6.27) into (6.21). We still keep $h$ and $m$ fixed and consider the $u, c, d_1, d_2$-sum in (6.21) which now equals

$$\sum_{u \mid Q} \sum_{c \mid P(z)} \lambda_c \cdot \mu(c) \sum_{d_1, d_2} \mu(d_1) \mu(d_2) \left(2d_1 d_2 \frac{n}{h} m \right) \prod_{p \mid d_1 d_2} f_1(p, \nu; m, n).$$

We recast this as (noting $\epsilon(2) = 1$)

$$\epsilon \left(\frac{n}{h} m \right) \sum_{u \mid Q} \sum_{c \mid P(z)} \lambda_c \cdot \mu(c) \sum_{d_1, d_2} \mu(d_1) \mu(d_2) \prod_{p \mid d_1 d_2} \epsilon \left(\frac{2d_1 d_2 n}{h} m \right) \prod_{2^v \mid d_1 d_2} f_1(2, \nu; m, n).$$

(OF course each of the product over primes has only one factor, since $\nu$ is unique) where

$$\tag{6.32} \epsilon(p, \nu; m, n, h) = \begin{cases} \epsilon(p) f_1(p, \nu; m, n), & p \nmid \frac{n}{h} m, \\ f_1(p, \nu; m, n), & 2 \nmid p \mid \frac{n}{h} m. \end{cases}$$

We observe that the sum over $d_1, d_2$ gives

$$\tilde{f}_1(2; m, n; u) \prod_{p \mid \nu c u} \left(-2 \epsilon(p, 1; m, n, h) + \epsilon(p, 2; m, n, h)\right)$$

where

$$\tag{6.33} \tilde{f}_1(2; m, n; u) = \begin{cases} -2f_1(2; 1; m, n) + f_1(2; 2; m, n), & 2 \mid u, \\ f_1(2; 0; m, n), & 2 \nmid u. \end{cases}$$

Using the formulas (6.30) and (6.31) instead of (6.28) and (6.29), the same computation evaluates the corresponding $u, c, d_1, d_2$-sums of $S_2^-$ in (6.22) as

$$\sum_{u \mid Q} \sum_{c \mid P(z)} \lambda_c \cdot \mu(c) \sum_{d_1, d_2} \mu(d_1) \mu(d_2) \left(2d_1 d_2 \frac{n}{h} m \right) \prod_{p \mid d_1 d_2} f_2(p, \nu; m, n)$$

$$= \epsilon \left(\frac{n}{h} m \right) \sum_{u \mid Q} \sum_{c \mid P(z)} \lambda_c \cdot \mu(c) \tilde{f}_2(2; m, n; u) \prod_{2^p \mid \nu c u} \left(-2 \epsilon(p, 1; m, n, h) + \epsilon(p, 2; m, n, h)\right)$$

where $\tilde{f}_2(2; m, n; u)$ is defined in the same way as (6.33), replacing the index 1 with the index 2. Combining the above calculations, we have shown

$$S_1^- + S_2^- = \sum_{j=1}^2 \sum_{\substack{h \mid n \leq \lambda \leq x \mu^2(h) = (h, \Omega) = 1 \mu^2(h) \mid \nu c u}} \chi_{-4}(h) \sum_{\substack{hm \leq x \mu^2(m) \mid \nu c u \mu^2(mh) = 1}} \epsilon \left(\frac{n}{h} m \right) \sum_{u \mid Q} \sum_{\substack{c \mid P(z) \mu^2(c) \mid \nu c u \mu^2(ch) = (c, \Omega) = 1}} \lambda_c \cdot \mu(c) \times \tilde{f}_j(2; m, n; u) \prod_{2^p \mid \nu c u} \left(-2 \epsilon(p, 1; m, n, h) + \epsilon(p, 2; m, n, h)\right).$$
We are now finally in a position to apply Lemma 6.3 to bound from below the sum over the sieve weights. We make the following important observations. From (6.32), (6.29), (6.26), (5.3) we have

\[
0 \leq 2\omega(p; 1; m, n, h) - \omega(p; 2; m, n, h)
\]

\[
(6.34) = \begin{cases} 
\frac{1}{2} \left( 2 - \frac{2 \chi_p(n) + 1}{p - 1} \right) \frac{1}{1 + \frac{\chi_p(n)}{p(p-1)}}^{-1}, & p \nmid nm \\
\frac{1}{p} \left( 1 - \frac{2 \chi_p(n)}{p} \right) \frac{1}{1 + \frac{\chi_p(n)}{p}}^{-1}(1 + \chi_p(n)), & p \mid \frac{m}{p}m, p \nmid (m, n) \\
\frac{1}{p - 1} (1 - \frac{2 \chi_p(n)}{p}) \frac{1}{1 + \frac{\chi_p(n)}{p}}^{-1} \mathbb{1}_{\nu_p(n) = 1}, & p \mid (m, n)
\end{cases} \leq \frac{5}{p},
\]

for \( p \mid 2h \). So we can choose \( Q = 30 \) and use a sieve of dimension \( \gamma = 5 \). Secondly, since \( h \mid n, (h, 2\Omega) = 1 \), we have \( \chi_{-4}(h) = 1 \), so that a lower bound for the sum of sieve weights with multiplicative coefficients suffices. This is an important device in the argument. Now applying Lemma 6.3 and (6.20), we obtain

\[
(6.35) S(A, n^{1/C}) \geq S(n) \left( f_5(C\kappa_0) + O\left( \frac{e^{-C\kappa_0}}{(\log D)^{1/3}} \right) \right) + O(x^{1-\kappa_0}),
\]

where \( f_5 \) has the same meaning as in Lemma 6.3, \( D = n^{\kappa_0} \) for some small \( \kappa_0 > 0 \) and \( C \) a large constant such that \( f_5(C\kappa_0) > 0 \),

\[
S(n) = \sum_{h \mid n} \sum_{\mu^2(h) = (h, 2\Omega) = 1} \sum_{\mu^2(h) \leq \gamma} \sum_{\mu^2(h) \leq \gamma} \mathbb{1}_{\nu_p(n) = 1} \frac{n}{h} \mathfrak{F}(m, n, h) \prod_{p \leq z} \prod_{p \mid h} \left( 1 - 2\omega(p; 1; m, n, h) + \omega(p; 2; m, n, h) \right).
\]

where \( \mathfrak{F}(m, n, h) = \prod_{p \mid \mathfrak{Q}} \mathfrak{F}_p(m, n, h) \) with

\[
(6.36) \mathfrak{F}_2(m, n, h) = \sum_{j=1}^{2} (f_j(2, 0; m, n) - 2f_j(2, 1; m, n) + f_j(2, 2; m, n))
\]

(the right hand side is independent of \( h \)) and

\[
(6.37) \mathfrak{F}_p(m, n, h) = \begin{cases} 
(1 - 2\omega(p; 1; m, n, h) + \omega(p; 2; m, n, h)), & p \nmid 2h \\
1, & p \mid h.
\end{cases}
\]

Recalling (6.34), we define multiplicative functions \( g_i(\bullet) \) supported on squarefree integers with \( g_i(p) = 1 \) except for \( p \mid P_{\mathfrak{Q}}(z) \) where

\[
g_0(p) = 1 - \left( 2 \left( 1 + \frac{\chi_p(n)}{p(p-1)} \right) \frac{1}{1 + \frac{\chi_p(n)}{p(p-1)}}^{-1},
\]

\[
g_1(p) = 1 - \frac{2}{p} \left( 1 + \frac{\chi_p(n)}{p} \right) \frac{1}{1 + \frac{\chi_p(n)}{p}}^{-1},
\]

\[
g_2(p) = 1 - \frac{1}{p - 1} \left( 1 - \frac{\chi_p(n)}{p} \right) \frac{1}{1 - \frac{\chi_p(n)}{p}}^{-1} \mathbb{1}_{\nu_p(n) = 1},
\]

so that

\[
S(n) = \sum_{h \mid n} \sum_{\mu^2(h) = (h, 2\Omega) = 1} \sum_{\mu^2(h) \leq \gamma} \sum_{\mu^2(h) \leq \gamma} \mathbb{1}_{\nu_p(n) = 1} \frac{n}{h} \mathfrak{F}(m, n, h) \prod_{p \mid nm} g_0(p) \prod_{p \mid h} g_1(p) \prod_{p \mid (m, n)} g_2(p).
\]
We rename $mh$ by $m, h$ by $hg$ where $h \mid (m, n), h \not\mid Q$, and $2 \not\mid g \mid (m, n, Q)$. In this way we can re-write $S(n)$ as

$$
\prod_{p \mid Q} g_0(p) \sum_{p \mid P^+(m) \leq g \mid (m, n, Q)} \sum_{(n, m, Q) = 1} \mathfrak{S}_Q \left( \frac{m}{g}, n, g \right) \prod_{p \mid Q} \epsilon(p) \sum_{(h, m, n, Q) = 1} \frac{1}{g_0(h)} \prod_{p \mid (m, n)} g_2(p) \prod_{p \mid (m, n)} g_1(p) \prod_{p \mid Q} \epsilon(p)
$$

$$=
\prod_{p \mid P^+(z)} g_0(p) \sum_{r \mid \infty} \mathfrak{S}_Q \left( \frac{r}{g}, n, g \right) \prod_{p \mid Q} \epsilon(p)
\times \sum_{n \leq r/C} \sum_{p \mid 
\prod_{p \mid (m, n)} \epsilon(p) \prod_{p \mid Q} \epsilon(p).
$$

We first see that the sum over $g$ can be written as (note that $\mathfrak{S}_p(\bullet, \bullet, p) = 1$)

$$
\prod_{p \mid Q} \left( \mathfrak{S}_p(r, n) = 1 \prod_{p \mid Q} \epsilon(p) \prod_{p \mid \not\mid Q} \epsilon(p) \right) =: \mathfrak{S}_Q(r, n) = \prod_{p \mid Q} \mathfrak{S}_p(r, n).
$$

With $Q = 30, \mu^2(r_5) = 1$, this becomes

$$
\mathfrak{S}_2(r, n) = \mathfrak{S}_3(r, n) = \prod_{3 \not\mid r} \mathfrak{S}_2(r, n) = \prod_{5 \not\mid r} \mathfrak{S}_2(r, n) = \sum_{n \equiv 1 (\text{mod } 2), 2 (\text{mod } 5), 0 (\text{mod } 4)}\epsilon(3) \mathfrak{S}_3(r, n) = \sum_{n \equiv 1 (\text{mod } 2), 3 (\text{mod } 5), 4 (\text{mod } 5)}\epsilon(3) \mathfrak{S}_3(r, n).
$$

Using (6.36), (6.28), (6.30) and (6.37), (6.34), we compute explicitly

$$
\mathfrak{S}_2(r, n) = \begin{cases}
\frac{1}{2} \mathbb{1}_{2|\nu}, & n \equiv 1 (\text{mod } 2), \\
\frac{1}{4} \mathbb{1}_{4|\nu}, & n \equiv 2 (\text{mod } 8), \\
\frac{1}{2} \mathbb{1}_{2|\nu}, & n \equiv 6 (\text{mod } 8), \\
\frac{1}{2} \mathbb{1}_{2|\nu}, & n \equiv 0 (\text{mod } 4).
\end{cases}
$$

(note that if $3 \mid n$ then $(r, 3) = 1$ since $(r, 3) = 1$) and (with $\epsilon(5) = \frac{1 + \nu}{2}$)

$$
\mathfrak{S}_3(r, n) = \begin{cases}
\epsilon(5) \mathbb{1}_{5|\nu}, & n \equiv 1, 4 (\text{mod } 5), \\
2\epsilon(5) \mathbb{1}_{5|\nu}, & n \equiv 2, 3, 0 (\text{mod } 5).
\end{cases}
$$

In particular, we can always find some residue class $r_0 (\text{mod } 120)$ such that $\mathfrak{S}_Q(r, n) > 0$ for $r \equiv r_0 (\text{mod } 120)$. 

Noting that \((m, \mathcal{Q}) = \mu^2(m) = 1\) and \(g_1(p) = 1\) if \(p \mid \mathcal{Q}\), we next evaluate the inner sum over \(h\) as

\[
\sum_{h \mid (m, n)} \frac{1}{g_0(h)} \prod_{p \mid (m, n)} g_2(p) \prod_{p \mid m, p \mid n} g_1(p) \prod_{p \mid Q} c(p)
\]

\[
= \sum_{h \mid (m, n)} \frac{1}{g_0(h)} \prod_{p \mid h} g_2(p) \prod_{p \mid n, \nu_p(n) > 1} \frac{1}{c(p)} \prod_{p \mid m, p \mid n} g_2(p) \prod_{p \mid m} g_1(p) \prod_{p \mid (m, n)} c(p) \prod_{p \mid Q} c(p) \prod_{p \mid n} c(p)
\]

\[
= \prod_{\nu_p(n) = 1} \left(1 + \frac{1}{g_2(p)} \sum_{p \mid (m, n)} g_2(p) \prod_{p \mid m} g_1(p) \prod_{p \mid (m, n)} c(p) \prod_{p \mid Q} c(p) \prod_{p \mid n} c(p)\right)
\]

where \(\mathcal{G}(m; n)\) is a multiplicative function of \(m\) with \(\mathcal{G}(p^r; n) = 0\) for \(\nu > 2\) and \(\mathcal{G}(p; n) = 0\) for \(p \mid Q\). We summarize

\[
S(n) = \prod_{p \mid Q} g_0(p) \sum_{r \mid 2^\infty Q} \mathcal{G}(r, n) \prod_{p \mid Q} \frac{g_1(p)}{g_0(p)} c(p) \sum_{m \leq x/r} \mathcal{G}(m; n).
\]

6.7. Computation of the main term \(IV\) – summing over smooth squarefree numbers.

Our last goal is a lower bound for \(S(n)\) based on the formula (6.42). This will be achieved in (6.53) below. In order to carry out the sum over \(m\) in (6.42), it is useful to define \(h(\bullet; n) = \mathcal{G}(\bullet; n) + \mu\).

Recall that the definition of \(\mathcal{G}(m; n)\) is implicit in (6.41), so that \(h(p^r; n) = 0\) if \(\nu > 2\), and for \(\nu \leq 2\) we have

\[
h(p; n) = \begin{cases} 
(1 + \frac{1}{g_0(h)g_2(p)} g_2(p)) - 1, & p \mid n, p \nmid Q, \nu_p(n) = 1, \\
(1 + \frac{1}{g_2(p)g_0(p)} g_0(p)) - 1, & p \mid n, p \nmid Q, \nu_p(n) > 1, \\
-1, & p \mid Q, \\
\frac{g_1(p)}{g_0(p)} c(p) - 1, & p \nmid Q.
\end{cases}
\]

and

\[
h(p^2; n) = -h(p, n) - 1.
\]

In particular, from (6.38) and (5.3) we have

\[
h(p; n) = \begin{cases} 
1 + \frac{4}{p-3}, & p \mid n, p \nmid Q, \\
-1, & p \mid Q, \\
O(\frac{1}{p}), & p \nmid Q\n\end{cases}
\]

where we can take 5 as implied constants. In order to evaluate

\[
\sum_{m \leq x/r} \mathcal{G}(m; n) = \sum_{t \leq x/r} h(t; n) \psi\left(\frac{x}{tr}, y\right).
\]

ADDITIVE PROBLEMS WITH ALMOST PRIME SQUARES 35
we first truncate the $t$-sum. To this end we recall [FT96, Lemma 4.2]: we have uniformly in
\[ \exp((\log \log x)^2) \leq y \leq x \text{ and } d \leq t \text{ the estimate} \]
\[
(6.45) \quad \Psi(x/d, y) \ll \frac{\Psi(x, y)}{d^{1-\beta}}
\]
where
\[
\beta = \beta(x, y) = \frac{\xi(u) + O(1)}{\log y} \text{ and } e^{\xi(t)} = 1 + t\xi(t)
\]
is an implicit definition for $\xi(t)$ and as usual $u = \log x/\log y$. It is easy to see that $\xi(u) = \log(u \log u) + O(1)$. Note that for $\log y \geq (\log \log x)^2$ we have $\beta = o(1)$.

Let $K = n^{1/100}$. The contribution from $t \geq K$ or $r \geq K$ to (6.44) can be bounded by
\[
(6.46) \quad \Psi(x, y) \sum_{t_1 t_2 \geq K} \frac{(t_1, n)}{t_1(t_1 t_2)^{1-\beta}} \ll \Psi(x, y) \frac{1}{K^{1-\beta}} \sum_{t_1, t_2} \frac{(t_1, n)}{t_1(t_1 t_2)^{1-\beta}} \ll K^{-1/3} \Psi(x, y).
\]
For $t, r \leq K$ we evaluate the sum by [FT91, Theorem 2 with $q = 1$] getting
\[
(6.47) \quad \sum_{p^* \mid y} \beta(t; n) \frac{x}{tr} \sum_{m \leq y} \frac{1}{m^{s-1}} \geq \Psi(x, y) \exp(-((\log y)^{0.55})) (1 + O(\exp(-(\log y)^{0.55}))).
\]
where $R(x) = [x]/x$. Strictly speaking, the application of [FT91, Theorem 2] requires $y \leq x/K^2 \leq x/(tr)$, which we can assume without loss of generality since $\Psi(x, y) \asymp \Psi(x, x)$ for $y > x^{1/2}$, say.

To estimate the error term, we use (6.45) again, and obtain the bound
\[
(6.48) \quad \sum_{t \leq K} |\beta(t; n)| \Psi \left( \frac{x}{tr} ; y \right) \exp(-((\log y)^{0.55})) \ll \prod_{p \mid n} \left(1 + \frac{O(1)}{p^{1-\beta}}\right) \Psi(x, y) \exp(-((\log y)^{0.55}))
\]
for $\log y \geq (\log \log x)^2$.

We now focus on the main term in (6.47) which we substitute back as the $m$-sum in (6.42). By partial summation, the main term equals
\[
(6.49) \quad \prod_{p \mid P \varphi(z)} g_0(p) \cdot x \int_{0}^{\infty} \rho(u - v) dW(y^v)
\]
where
\[
W(U) = \frac{1}{U} \prod_{p \mid Q} \frac{g_1(p)}{g_0(p)} \chi(p) \sum_{r \leq K} \mathfrak{S}(r, n) \sum_{m \leq y} \frac{1}{m^{s-1}} \sum_{r \leq K} \mathfrak{S}(r, n) \sum_{m \leq y} \frac{1}{m^{s-1}}
\]
It is clear that $W(U) = 0$ for $U < 1$ and $W(U) = c + O(1/U)$ for some constant $c$ (depending on $n$ and $z$). In preparation for an application of [FT90, Lemme 4.1] we define
\[
M(s) = \int e^{-sv} dW(e^v).
\]
We compute $M(s)$ as
\[
M(s) = \mathfrak{S}_K(n, s) \frac{s}{s+1} \zeta(s+1)
\]
where
\[
\mathfrak{S}_K(n, s) = \prod_{p \mid Q} \frac{g_1(p)}{g_0(p)} \chi(p) \sum_{r \leq K} \mathfrak{S}(r, n) \sum_{m \leq y} \frac{1}{m^{s-1}} \sum_{r \leq K} \mathfrak{S}(r, n) \sum_{m \leq y} \frac{1}{m^{s-1}}.
\]
Recalling (6.38) and (5.3) we have

\[ \frac{60}{67} \leq \frac{g_1(p)}{g_0(p)} c(p) = 1 - \frac{\chi_4(p)}{p} + O(p^{-2}), \quad p \mid n, \quad p \nmid \mathcal{Q} = 30. \]

We can extend \( r, t \) to infinity getting

\[ \mathcal{S}(n, s) = \prod_{p \mid \mathcal{Q}} \frac{g_1(p)}{g_0(p)} c(p) \sum_{k=0}^{\infty} \frac{\mathcal{S}_2(2^k, n)}{2^{k+1}} \prod_{p \nmid \mathcal{Q}} \left( \mathcal{S}_p(1, n) + \frac{\mathcal{S}_p(p, n)}{p^{s+1}} \right) \prod_{p \leq y} \left( 1 + \frac{\mathcal{h}(p; n)}{p^{s+1}} + \frac{\mathcal{h}(p^2; n)}{p^{s+2}} \right) \]

where uniformly in \( |s| \leq 1/2 \) we have (once again by Rankin’s trick)

\[ \mathcal{S}(n, s) - \mathcal{S}_K(n, s) \ll \frac{1}{K^{1/2}} \prod_{p \mid n} \left( 1 + \frac{1}{p^{s+1/2}} \right) \ll \frac{1}{K^{1/4}} = n^{-1/400}, \]

and by Cauchy’s formula this bound remains true for all fixed derivatives with respect to \( s \). Note that by (6.43) we have

\[ \frac{6}{7} \leq 1 + \frac{\mathcal{h}(p; n)}{p} + \frac{\mathcal{h}(p^2; n)}{p^2} = 1 + \frac{\chi_4(p)}{p} + O(p^{-2}), \quad p \mid n. \]

Combining (6.39), (6.40), (6.43), (6.50) and (6.52), we obtain for all \( j \geq 0 \) that

\[ \frac{d^j}{ds^j} \mathcal{S}(n, s)_{s=0} = \prod_{p \mid n \atop p < \min(y, z)} \left( 1 + O\left( \frac{(\log p)^j}{p^2} \right) \right) \prod_{p \mid n \atop p \geq \min(y, z)} \left( 1 + O\left( \frac{(\log p)^j}{p} \right) \right) \ll 1 \]

for \( \log y \gg (\log \log x)^2 \) and \( \log z \gg \log n \), and we also see \( \mathcal{S}(n, 0) \gg 1 \).

We are now prepared to apply [FT90, Lemme 4.1] to evaluate (6.49), which we complement with [FT91, Lemme 4.1] for bounds of \( \rho^{(j)}(u) \). Using again \( \log y \gg (\log \log n)^2 \) and \( \log z \gg \log n \) and recalling the error terms (6.48), (6.46) and (6.51), we conclude

\[ \mathcal{S}(n) \asymp \left( \prod_{p \mid \mathcal{Q}(z)} g_0(p) \right) \mathcal{S}(n, 0) x \rho(u) \left( 1 + O\left( \frac{(\log \log n)}{(\log z)} \right) \right) + O\left( \frac{\Psi(x, y)}{(\log x)^{100}} \right) \]

\[ > \frac{x \rho(u)}{(\log z)^{1/2}} + O\left( \frac{\Psi(x, y)}{(\log x)^{100}} \right) \asymp \frac{\Psi(x, y)}{(\log z)^{1/2}}, \]

We plug this lower bound back into (6.35) and choose \( C = C(\kappa_0) \) a sufficiently large constant so that \( f_5(C\kappa_0) > 0 \) getting

\[ S(A, n^{1/C}) \gg (\log z)^{-2} \Psi(x, y) \]

provided that \( \log y \gg (\log \log n)^2 \) and \( D = n^{\kappa_0} \) for some sufficiently small \( \kappa_0 > 0 \). This concludes the proof of Theorem 1.2.

**Remark.** We close the paper by a short comment on the “singular series” \( \mathcal{S}(n, 0) \) encountered in the final lower bound, which might look a bit unexpected. This is due to our restrictions on \( m \), in particular the fact that we impose a squarefree condition on \( m \). As squarefree numbers are not equidistributed among all residue classes, the singular series \( \mathcal{S}(n, 0) \) will genuinely depend on the factorization of \( n \) in our set-up. For example, we can see from (6.39) that there are fewer solutions to \( n = m + x^2 + y^2 \) with \( (xy, 3) = 1 \) when \( n \equiv 2 \pmod{3} \) than in the other cases, whilst the number of solutions to \( n = m + x^2 + y^2 \) with \( (xy, 3) = 1 \) and no extra conditions on \( m \) would be approximately equal for all residue classes of \( n \pmod{3} \).
