Abstract

We study a class of generalized linear programs (GLP) in a large-scale setting, which includes possibly simple nonsmooth convex regularizer and simple convex set constraints. By reformulating GLP as an equivalent convex-concave min-max problem, we show that the linear structure in the problem can be used to design an efficient, scalable first-order algorithm, to which we give the name Coordinate Linear Variance Reduction (CLVR; pronounced “clever”). CLVR is an incremental coordinate method with implicit variance reduction that outputs an affine combination of the dual variable iterates. CLVR yields improved complexity results for (GLP) that depend on the max row norm of the linear constraint matrix in (GLP) rather than the spectral norm. When the regularization terms and constraints are separable, CLVR admits an efficient lazy update strategy that makes its complexity bounds scale with the number of nonzero elements of the linear constraint matrix in (GLP) rather than the matrix dimensions. We show that Distributionally Robust Optimization (DRO) problems with ambiguity sets based on both $f$-divergence and Wasserstein metrics can be reformulated as (GLPs) by introducing sparsely connected auxiliary variables. We complement our theoretical guarantees with numerical experiments that verify our algorithm’s practical effectiveness, both in terms of wall-clock time and number of data passes.

1 Introduction

We study the following generalized linear program (GLP):

$$\min_{x} \ c^T x + r(x)$$
$$\text{s.t. } Ax = b, \ x \in \mathcal{X},$$

(GLP)

where $x, c \in \mathbb{R}^d$, $A \in \mathbb{R}^{n \times d}$, $b \in \mathbb{R}^n$, $r : \mathbb{R}^d \to \mathbb{R}$ is a convex regularizer that admits an efficiently computable proximal operator, and $\mathcal{X} \subseteq \mathbb{R}^d$ is a closed convex set with efficiently computable projection operator. When $\mathcal{X}$ is the nonnegative orthant \{\(x : x_i \geq 0, i \in [d]\)\} and $r \equiv 0$, (GLP) reduces to the standard form of a linear program (LP). When $\mathcal{X}$ is a convex cone and $r \equiv 0$, (GLP) reduces to a conic linear program. (GLP) has had a significant impact in traditional engineering disciplines such as transportation, energy, telecommunication, and manufacturing. In modern data science, we observe the renaissance of (GLP) due to its modeling power in such areas as reinforcement learning [De Farias and Van Roy, 2003], optimal transport [Villani, 2009], and neural network verification [Liu et al., 2020]. For traditional engineering disciplines with moderate scale or exploitable sparsity, off-the-shelf interior point methods that form and factorize matrices in each iteration are often good

choices as practical solvers [Gurobi 2020]. In data science applications, however, where the data are often dense or of extreme scale, the amount of computation and/or memory required by matrix factorization is prohibitive. Thus, first-order methods that avoid matrix factorizations are potentially appealing options. In this context, because the presence of the linear equality constraint in (GLP) may complicate the operation projection onto the feasible set, we consider the following equivalent reformulation of (GLP) as a min-max problem involving the Lagrangian:

\[
\min_{x \in \mathcal{X} \subseteq \mathbb{R}^d} \max_{y \in \mathbb{R}^n} \left\{ \mathcal{L}(x, y) = c^T x + r(x) + y^T Ax - y^T b \right\}. \tag{PD-GLP}
\]

In data science applications, both \( n \) and \( d \) can be very large. (PD-GLP) can be viewed as a structured bilinearly coupled convex-concave min-max problem, where the linearity of \( \mathcal{L}(x, y) \) w.r.t. the dual vector \( y \) is vital to our algorithmic development.

While the literature addressing (PD-GLP) is sparse — some special cases have been considered in [Mangasarian and Meyer [1979], Mangasarian [1984, 2004] — there has been significant recent work on first-order methods for general bilinearly coupled convex-concave min-max problems. Deterministic first-order methods include the proximal point method (PPM) of [Rockafellar [1976], the extragradient/mirror-prox method (EGM) of [Korpelevich [1976] and Nemirovski [2004], the primal-dual hybrid gradient (PDHG) method of [Chambolle and Pock [2011], and the alternating direction method of multipliers (ADMM) of [Douglas and Rachford [1956]. All these methods have per-iteration cost \( \Theta \left( \text{nnz}(A) + n + d \right) \) and convergence rate \( 1/k \), where \( \text{nnz}(A) \) denotes the number of nonzero elements of \( A \) and \( k \) is the number of iterations.

For better scalability, stochastic counterparts of these methods have been proposed. [Juditsky et al. [2011, Ouyang et al. [2013, Bianchi [2016, Patrascu and Necoara [2017] have used “vanilla” stochastic gradients to replace the full gradients of their deterministic counterparts. [Carmon et al. [2019], Hamedani and Jalilzadeh [2020], Alacaoglu and Malitsky [2021] have exploited the finite-sum structure of the interaction term \( \langle y, Ax \rangle \) involving both primal and dual variables to perform variance reduction. With a separability assumption for the dual variables, [Alacaoglu et al. [2017] and [Chambolle et al. [2018] have combined incremental coordinate approaches on the dual variables with an implicit variance reduction strategy on the primal variables. Recently, under a separability assumption for dual variables, [Song et al. [2021] have proposed a new incremental coordinate method with an initialization step that requires a single access to the full data. This approach, known as variance reduction via primal-dual accelerated dual averaging (VRPDA\(^2\)), obtains the first theoretical bounds that are better than their deterministic counterparts in the class of incremental coordinate approaches. The VRPDA\(^2\) algorithm serves as the main motivation for the approach used in this paper.

It is of particular interest to design algorithms that scale with the number of nonzero elements in \( A \) for at least two reasons: (i) the data matrix can be sparse; and (ii) when we consider simplified reformulations of certain complicated models, we often need to introduce sparsely connected auxiliary variables. Nevertheless, the randomized coordinate algorithms of [Alacaoglu et al. [2017, Chambolle et al. [2018, Song et al. [2021] have \( O(d) \) per-iteration cost regardless of the sparsity of \( A \). To address this issue, [Fercoq and Bianchi [2019, Latafat et al. [2019] have proposed incremental primal-dual coordinate methods with per-iteration cost which scales with the number of nonzero elements in the row from \( A \) that is used in each iteration, at the price of smaller step size for dense \( A \). Moreover, [Alacaoglu et al. [2020] has proposed a random extrapolation approach that admits both low per-iteration cost and large step size. Despite these developments, all these algorithms produce less accurate iterates than the methods with \( O(d) \) per-iteration cost, thus degrading their worst-case complexity.

Finally, for the special case of LP, based on the positive Hoffman constant [Hoffman [2003], [Applegate et al. [2021b] proved that the primal-dual formulation of LP exhibits a sharpness property, which bounds below the growth of a normalized primal-dual gap introduced in the same work. Based on this sharpness property, [Applegate et al. [2021b] proposed a restart scheme for the deterministic first-order methods discussed above to obtain linear convergence. [Applegate et al. [2021a] extended this restart strategy further using various heuristics to improve practical performance.
1.1 Motivation

We sharpen the focus from general bilinearly coupled convex-concave min-max problems to (GLP) and its primal-dual formulation (PD-GLP), because many complicated models can be reformulated as (GLP) and, further, (GLP) possesses additional structure that can be exploited in algorithm design. Our motivation for focusing on (GLP) is to bridge the large gap between the well-studied stochastic variance reduced first-order methods [Johnson and Zhang, 2013; Allen-Zhu, 2017; Song et al., 2020, 2021] and the increasingly popular and complicated, yet highly structured large-scale problems arising in distributionally robust optimization (DRO) [Wiesemann et al., 2014; Shafieezadeh Abadeh et al., 2015; Namkoong and Duchi, 2016; Esfahani and Kuhn, 2018; Hu et al., 2018; Duchi and Namkoong, 2018; Li et al., 2019; Duchi et al., 2021; Yu et al., 2021]; see also a recent survey by Rahimian and Mehrotra [2019] and references therein.

For DRO problems with ambiguity sets defined by $\phi$-divergence [Namkoong and Duchi, 2016; Hu et al., 2018; Levy et al., 2020], the original formulation is a nonbilinearly coupled convex-concave min-max problem. Even the well constructed reformulation in Levy et al. [2020] does not admit unbiased stochastic gradients, leading to complicated algorithms and analysis. For DRO problems with ambiguity sets defined by Wasserstein metric [Shafieezadeh Abadeh et al., 2015; Esfahani and Kuhn, 2018; Li et al., 2019; Yu et al., 2021], the original formulation is infinite-dimensional in general. (There are finite-dimensional reformulations [Shafieezadeh Abadeh et al., 2015; Esfahani and Kuhn, 2018] for the special cases of logistic regression or smooth convex losses.) Solvers that have been proposed for DRO with Wasserstein metric are either multiple-loop deterministic ADMM [Li et al., 2019] or are designed for general convex-concave problems [Yu et al., 2021].

By introducing auxiliary variables with sparse connections, we show that DRO with the ambiguity sets based on both $\phi$-divergence and the Wasserstein metric can be reformulated as (GLP). Therefore, solving complicated DRO problems can be addressed by designing a simple, efficient, and scalable algorithm for (GLP). Our algorithm for solving (GLP) and the proposed reformulations of DRO are the main contributions of this paper.

1.2 Contributions

Our main contributions can be summarized as follows.

Algorithm. Motivated by VRPDA$^2$ [Song et al., 2021], we propose a simple, efficient, and scalable algorithm for (PD-GLP). Our algorithm combines an incremental coordinate method with exploitation of the linear structure for the dual variables of (PD-GLP) and the implicit variance reduction effect in the algorithm, so we name it coordinate linear variance reduction (CLVR, pronounced as “clever”). CLVR is a simplified variant of VRPDA$^2$. By exploiting the linear structure—the max problem is linear and unconstrained in the dual variable vector $\mathbf{y} \in \mathbb{R}^n$—we find that there is no need for the expensive initialization step used in VRPDA$^2$ and we can take simpler and longer steps. Meanwhile, in the structured case where $\mathbf{A}$ is sparse and the convex constraint set $\mathcal{X}$ and $r(x)$ are fully separable, we show that the dual averaging update in CLVR enables us to design an efficient lazy update strategy for the primal variables, which makes the per-iteration cost of CLVR scale with the number of nonzero elements of the selected row from $\mathbf{A}$ in each iteration. Further, CLVR uses extrapolation on dual variables rather than on primal variables considered in VRPDA$^2$, which significantly reduces implementation complexity of our lazy update strategy for structured variants of (PD-GLP).

To present our complexity results, we denote $L := \|\mathbf{A}\|$. Our complexity results make use of the following assumption about scaling of the matrix $\mathbf{A}$, which is also widely adopted by modern LP solvers [Gurobi, 2020].

**Assumption 1.** Each row of $\mathbf{A}$ in (GLP) is normalized with Euclidean norm $R$.\(^1\)

\(^1\)We state the results here for the fully separable setting for convenience of comparison; however, our results are also applicable to the block separable setting.
Although this is an extreme case, there exist ill-conditioned practical datasets where we can expect significant performance gains if the complexity can be reduced from $O(L)$ to $O(R)$. In Table 1, we give the overall complexity bounds (total number of arithmetic operations) and per-iteration cost of a representative set of existing algorithms and our CLVR algorithm for solving structured (PD-GLP), i.e., $\mathcal{X} = X_1 \times \ldots \times X_d$ with $X_i \subset \mathbb{R}$ ($i \in [d]$) and $r(x) := \sum_{i=1}^{d} r_i(x^i)$. We further assume that for the stochastic algorithms [Chambolle et al.
2018][Alacaoglu and Malitsky, 2021][Song et al., 2021] and our CLVR algorithm we draw one row of $A$ per iteration uniformly at random to make the complexity results comparable. The general convex setting corresponds to $r(x)$ being general convex ($\sigma = 0$), while the strongly convex setting corresponds to $r(x)$ being $\sigma$-strongly convex ($\sigma > 0$).

As shown in Table 1, all the algorithms have the optimal dependence on $\epsilon$ [Ouyang and Xu, 2019], while the dependence on the ambient dimension $n, d$, the number of nonzero elements of $A$, $\text{nnz}(A)$, and the constants $L$ and $R$ are quite different. For both the general convex and strongly convex settings, CLVR is the first algorithm that has no dependence on the ambient dimensions $d$ and $n$, depending instead on the number of nonzero elements $\text{nnz}(A)$. Moreover, the complexity of CLVR depends on the max row norm $R$ rather than the spectral norm $L$, and the per-iteration cost of CLVR only depends on the nonzero elements of the selected row from $A$ in each iteration, which can be far less than $d^2$.

By exploiting the linear structure again, we provide explicit guarantees for both the objective value and the constraint satisfaction of (GLP), respectively. Further, the analysis of CLVR applies to the more general block-coordinate update setting, which is better suited to modern parallel computing platforms.

Finally, following the restart strategy based on the normalized duality gap for LP introduced in [Applegate et al., 2021], we propose a more straightforward strategy to restart our CLVR algorithm (as well as other iterative algorithms for (PD-GLP)): Restart the algorithm every time the widely known LP metric [Andersen and Andersen, 2000] halves. Compared with the normalized duality gap, the LP metric can be computed more efficiently and in a more straightforward fashion.

**Reformulations of Distributionally Robust Optimization (DRO).** When the loss function is convex, the DRO problems with ambiguity sets based on $f$-divergence [Namkoong and Duchi, 2016] or Wasserstein metric [Esfahani and Kuhn, 2018] are convex. However both original formulations either have very complicated constraints or are infinite dimensional, so that first-order methods cannot be applied efficiently, in general.

For DRO with $f$-divergence, we show that by using convex conjugates and introducing auxiliary variables, the problem can be reformulated in the form of (GLP). As a result, we do not have the issue of biased stochastic

---

In a private communication, A. Alacaoglu indicated that the PURE-CD algorithm of [Alacaoglu et al., 2020] has the bound $O(\text{nnz}(A)(L + d)/\epsilon)$ in the setting of $\sigma = 0$.

gradients encountered in [Levy et al., 2020] and our CLVR algorithm can be applied. Even though the resulting problem has larger dimensions, due to the sparseness of the introduced auxiliary variables and the lazy update strategy of CLVR, it can be solved with complexity scaling only with the number of nonzero elements of the data matrix. Due to being cast in the form of (GLP), the DRO problem can be solved with \( O(1/\epsilon) \) iteration complexity with our CLVR algorithm, while existing methods such as [Levy et al., 2020] have \( O(1/\epsilon^2) \) iteration complexity, with higher iteration cost because of the batch of samples needed to reduce bias. This improvement is enabled in part by considering the primal-dual gap (rather than the primal gap considered in [Levy et al., 2020]) and by allowing the constraints to be approximately satisfied (see Corollary 1).

For DRO with Wasserstein metric, following the reformulation of [Shaheezadeh Abadeh et al., 2015, Theorem 1], we show further that the problem can be cast in the form of (GLP). Compared with the existing reformulations [Shaheezadeh Abadeh et al., 2015, Esfahani and Kuhn, 2018, Li et al., 2019, Yu et al., 2021], our reformulation can handle both smooth and nonsmooth convex loss functions. In fact, our reformulation can provide a more compact form for nonsmooth piecewise-linear convex loss functions (such as hinge loss). Moreover, compared with algorithms customized to this problem [Li et al., 2019] and extragradient methods [Korpelevich, 1976, Nemirovski, 2004, Yu et al., 2021] for general convex-concave min-max problems, our CLVR method attains the best-known iteration complexity and per-iteration cost, as shown in Table 1.

1.3 Notation and Preliminaries

For any positive integer \( p \), we use \([p]\) to denote \{1, 2, ..., \( p \)\}. We assume that there is a given disjoint partition of the set \([n]\) into sets \( S^j \), \( j \in [m] \), where \(|S^j| = n^j > 0\) and \( \sum_{j=1}^{m} n^j = n \). For \( j \in [m] \), we use \( A^{S^j} \) to denote the submatrix of \( A \) with rows indexed by \( S^j \) and \( y^{S^j} \) to denote the subvector of \( y \) indexed by \( S^j \). We use \( 0_d \) and \( 1_d \) to denote the vectors with all ones and all zeros in \( d \) dimensions, respectively. Unless otherwise specified, we use \( \| \cdot \| \) to denote the Euclidean norm for vectors and the spectral norm for matrices. For a given proper convex lower semi-continuous function \( f : \mathbb{R} \rightarrow \mathbb{R} \cup \{+\infty\} \), we define the convex conjugate in the standard way as \( f^*(y) = \sup_{x \in \mathbb{R}} \{yx - f(x)\} \) (so that \( f^{**} = f \)). For a vector \( u \), the inequality \( u \geq 0 \) is applied element-wise. For a convex function \( r(x) \), we use \( r^r(x) \) to denote an element of the subdifferential set \( \partial r(x) \). The proximal operator of \( r(x) \) is defined by:

\[
\text{prox}_r(\hat{x}) = \arg\min_{x \in \mathcal{X}} \left\{ \frac{1}{2} \| x - \hat{x} \|^2 + r(x) \right\}. \tag{1}
\]

Furthermore, we make the following assumptions, which apply throughout the convergence analysis.

**Assumption 2.** There exists at least one Nash point \((x^*, y^*)\) for (PD-GLP).

**Assumption 3.** \( \hat{L} = \max_{j \in [m]} \| A^{S^j} \|, \) where \( \| A^{S^j} \| = \max_{\|x\| \leq 1} \| A^{S^j} x \| \).

By combining Assumption 3 and Assumption 1, we see that \( R \leq \hat{L} \leq \sqrt{\max_{j \in [m]} |S^j|R} \).

**Assumption 4.** \( r(x) \) is \( \sigma \)-strongly convex \( (\sigma \geq 0)\): that is, for all \( x_1 \) and \( x_2 \) in \( \mathcal{X} \) and all \( r'(x_2) \in \partial r(x_2) \), we have

\[
r(x_1) \geq r(x_2) + \langle r'(x_2), x_1 - x_2 \rangle + \frac{\sigma}{2} \| x_1 - x_2 \|^2.
\]

2 The Coordinate Linear Variance Reduction Method

In Section 2.1, we state the CLVR algorithm and provide iteration complexity guarantees. We propose an efficient implementation version for the case in which \( r \) and \( \mathcal{X} \) are component-separable in Section 2.2. In Section 2.3, we describe a restart strategy that allows the method to attain linear convergence.
2.1 Algorithm Description and Analysis for General Formulation

Algorithm 1 specifies CLVR for \([\text{PD-GLP}]\) in the general setting. The algorithm alternates the full update for \(x_k\) in Step 4 \((O(d)\) cost) with an incremental block coordinate update for \(y_k\) in Steps 5 and 6 \((O(|S^j|d)\) cost for dense \(A\). The cost of updating auxiliary vectors \(z_k\) and \(q_k\) is \(O(|S^j|d)\) and \(O(d)\), respectively. IN essence, CLVR is a primal-dual coordinate method that uses a dual averaging update for \(x_k\), then updates the state variables \(\{q_k\}\) by a linear recursion, and computes \(x_k\) from \(q_{k-1}\) via a proximal step without direct dependence on \(x_{k-1}\). The output \(\bar{x}_K\) is a convex combination of the iterates \(\{x_k\}_{k=1}^K\), as is standard for primal-dual methods. However, \(\bar{y}_K\) is only an affine (not convex) combination of \(\{y_k\}_{k=0}^K\), as it involves the term \(-(m-1)y_0\) whose coefficient is negative — and some of the coefficients \(ma_k-(m-1)a_{k+1}\) multiplying \(y_k\) for \(k \in \{1,\ldots,K-1\}\) may also be negative. An affine combination still provides valid bounds because the dual variable vector \(y\) appears linearly in \([\text{PD-GLP}]\). Moreover, in Step 9, the term \(ma_k(z_k-z_{k-1})\) serves to cancel certain errors from the randomization of the update w.r.t. \(y_k\), thus playing a key role in implicit variance reduction.

**Algorithm 1** Coordinate Linear Variance Reduction (CLVR)

1: **Input:** \(x_0 \in \mathcal{X}, y_0 \in \mathbb{R}^m, z_0 = A^T y_0, \gamma > 0, \hat{L} > 0, \sigma \geq 0, K, m, \{S^1, S^2, \ldots, S^m\}\).
2: \(a_1 = 1 = A_1 = 1/\sqrt{2Lm}, q_0 = a_1(z_0 + c)\).
3: for \(k = 1, 2, \ldots, K\) do
4: \(x_k = \text{prox}_{\frac{1}{A_k}a_k} \left(x_0 - \frac{1}{A_k} q_{k-1}\right)\).
5: Pick \(j_k\) uniformly at random in \([m]\).
6: \(y^S_{k+1} = \left\{\begin{array}{ll} y^S_{k+1} & i \neq j_k \\ y^S_{k+1} + \gamma ma_k (A^S x_k - b^S) & i = j_k \end{array}\right\}\).
7: \(a_{k+1} = (1 + \sigma A_k)/\sqrt{2Lm}, A_{k+1} = A_k + a_{k+1}\).
8: \(z_k = z_{k-1} + A^S j_k T (y^S_{k+1} - y^S_{k-1})\).
9: \(q_k = q_{k-1} + a_{k+1}(z_k + c) + ma_k(z_k - z_{k-1})\).
10: end for
11: return \(\bar{x}_K := \frac{1}{A_K} \sum_{k=1}^K a_k x_k, \bar{y}_K = \frac{1}{A_K} \sum_{k=1}^K a_k y_k + (m-1)a_k(y_k - y_{k-1})\).

Theorem 1 provides the convergence results for Algorithm 1. The proof is provided in Appendix A. Note that in the theorem (as in the algorithm), \(\gamma\) is a positive parameter which can be tuned.

**Theorem 1.** For any \((u, v) \in \mathcal{X} \times \mathbb{R}^m\), the vectors \(x_k, y_k, k = 1, \ldots, K\) and the averages \(\bar{x}_k, \bar{y}_k\) generated by Algorithm 1 satisfy the following bound:

\[
\mathcal{L}(\mathbb{E}[\bar{x}_k], v) - \mathcal{L}(u, \mathbb{E}[\bar{y}_k]) \leq \mathbb{E}[\mathcal{L}(\bar{x}_k, v) - \mathcal{L}(u, \bar{y}_k)] \leq \frac{\gamma \| u - x_0 \|^2 + \| v - y_0 \|^2}{2A_k},
\]

where \(\bar{x}_k = \frac{1}{A_K} \sum_{i=1}^k a_i x_i\) and \(\bar{y}_k = \frac{1}{A_K} \sum_{i=1}^k (a_i y_i + (m-1)a_i(y_i - y_{i-1}))\). Further, if \((x^*, y^*)\) is a primal-dual solution to \([\text{PD-GLP}]\), then we also have

\[
\mathbb{E}\left[\frac{\gamma + \sigma A_k}{4} \| x^* - x_k \|^2 + \frac{1}{2\gamma} \| y^* - y_k \|^2\right] \leq \frac{\gamma \| x^* - x_0 \|^2 + \| y^* - y_0 \|^2}{2\gamma}.
\]

Defining \(K_0 = \left\lceil \frac{\sigma}{9\hat{L}m\gamma} \right\rceil\), we have

\[
A_k \geq \max\left\{ \frac{k}{\sqrt{2Lm}}, \frac{\sigma}{(3\sqrt{2Lm})^2\gamma} \left( k - K_0 + \max\left\{ \sqrt{9\sqrt{2Lm}\gamma/\sigma}, 1 \right\} \right)^2 \right\}.
\]
The parameter $\gamma$ can be tuned to balance the relative weights of primal and dual initial quantities $\|x^* - x_0\|$ and $\|y^* - y_0\|$ (or estimates of these quantities), which can significantly influence practical performance of the method. In addition to the guarantee on the variational form, due to the linear structure, we can also provide explicit guarantees for both the objective and the constraints in (GLP), summarized in the following corollary.

**Corollary 1.** In Algorithm\(\text{[7]}\) for all $k \geq 1$, $\bar{x}_k$ satisfies

\[
\|A E[\bar{x}_k] - b\| \cdot \|y^*\| \leq \frac{\gamma \|u - x_0\|^2 + 4 \|v - y_0\|^2 / \gamma}{2A_k} \leq 2A_k \leq 2A_k,
\]

\[
(c^T E[\bar{x}_k] + r(E[\bar{x}_k])) - (c^T x^* + r(x^*)) \geq - \gamma \|u - x_0\|^2 + 4 \|v - y_0\|^2 / \gamma,
\]

\[
(c^T E[\bar{x}_k] + r(E[\bar{x}_k])) - (c^T x^* + r(x^*)) \leq \gamma \|u - x_0\|^2 + 4 \|v - y_0\|^2 / \gamma,
\]

where $u = x^*$ and $\|A E[\bar{x}_k] - b\| \cdot \|y^*\| (A E[\bar{x}_k] - b)$.

In CLVR, we allow for arbitrary $(x_0, y_0) \in X \times \mathbb{R}^n$. Nevertheless, by setting $y = 0_n$, we can obtain $x_0 = 0_d$ at no cost — a useful strategy for large-scale problems since it avoids the (potentially expensive) single matrix-vector multiplication w.r.t. $A$. On the other hand, direct computation of $y_k$ can be expensive. However, Dang and Lan\([2015]\) shows that we need only to update the averaged vector in the coordinate block chosen for that iteration. This strategy requires us to record the most recent update for each coordinate block and update it only when it is selected again. We show next that such a lazy update strategy for $y_k$ can be used even for the update of $x_k$ and $\bar{x}_k$, thus making the complexity of CLVR independent of the ambient dimension $n \cdot d$ for sparse and structured instances of (PD-GLP).

### 2.2 Lazy Update for Sparse and Structured Instances of (PD-GLP)

In Algorithm\(\text{[7]}\) for dense $A$, the $O(|S^{jk}|d)$ cost of Steps 6 and 8 dominates the $O(d)$ cost of Steps 4 and 9. However, when $A$ is sparse and $|S^{jk}|$ is small, the cost of Steps 6 and 8 will be $O(\text{nnz}(A S^{jk}))$, which may be less than the $O(d)$ cost of Steps 4 and 9. Using this observation, we show that the nature of the dual averaging update enables us to propose an efficient implementation whose complexity depends on $\text{nnz}(A)$ rather than $n \cdot d$.

Recall that we partition $[n]$ into subsets $\{S^1, S^2, \ldots, S^m\}$ and use $\text{A}^S(j \in [m])$ to denote the $j$th row block of $A$. For each block $\text{A}^{S^j}$, we use $C^j \subset [d]$ to denote the indices of those columns of $\text{A}^{S^j}$ that contain at least one nonzero element. (Of course, $\{C^1, \ldots, C^m\}$ is not in general a partition of $[d]$; different subsets $S^j$ may have nonzeros in the same columns.) We assume further that $X$ and $r$ are coordinate separable, that is, $X = X_1 \times \cdots \times X_d$ with $X_i \subset \mathbb{R}$ for all $i$ and $r(w) := \sum_{i=1}^d t(w^i)$ with $w^i \in X_i$.

In Step 4 of Algorithm\(\text{[7]}\) the separability of $X'$ and $r$ means that an update to one coordinate of $x_k$, which requires a projection and an application of the proximal operator, does not influence other coordinates of $x_k$. Meanwhile, since $q_{k-1}$ and $A_k$ uniquely determine the value of $x_k$, we can track the values of $q_{k-1}$ and $A_k$, and compute $x_k$ only when it is actually needed in the algorithm. Note that $\{A_k\}$ is a sequence of scalars, and $q_k$ admits a linear recursion relationship with $O(d)$ cost resulting from the weighted sum of dense vectors $q_{k-1}$ and $z_k$. However, as $z_k$ differs from $z_{k-1}$ only at coordinates $C^{jk}$, we can use this observation to design a more efficient update. Consider the $k$th iteration and let $\theta \in \mathbb{Z}^d$ be the vector whose $i$th coordinate records the most recent iteration $k'$ prior to $k$ such that $i \in C^{jk}$. By telescoping the recursion of Step 9 of Algorithm\(\text{[7]}\) from $\theta^i$ to $k$, $q^i_k$ can be computed using the following shortcut:

\[
\begin{align*}
q^i_k &= q^i_{\theta^i} + (A_{k+1} - A_{\theta^i + 1})(z^i_{\theta^i} + c^i) + (a_{k+1} + ma_k)(z^i_k - z^i_{k-1}), &\text{if } i \in C^{jk}, \\
q^i_k &= q^i_{\theta^i} + (A_{k+1} - A_{\theta^i + 1})(z^i_{\theta^i} + c^i), &\text{otherwise}.
\end{align*}
\]

The product $(A_{k+1} - A_{\theta^i + 1})(z^i_{\theta^i} + c^i)$ replaces the consecutive additions $\sum_{t=\theta^i+1}^{k} a_{t+1}(z^i_t + c^i)$, since $z^i_{\theta^i} = z^i_{\theta^i + 1} = \cdots = z^i_{k-1}$, and $z^i_k = z^i_{k-1} + (z^i_k - z^i_{k-1})$ if $i \in C^{jk}$ and $z^i_k = z^i_{k-1}$, otherwise. As the update of $y_k$
Algorithm 2 Coordinate Linear Variance Reduction (Lazy Update Version)

1: Input: $x_0 \in X, y_0 \in \mathbb{R}^n, z_0 = A^T y_0, \hat{x}_0 = \theta = 1_d, \hat{\theta} = 1_n, \gamma > 0, \hat{L} > 0, K, m, \{S^1, S^2, \ldots, S^m\}, \{C^1, C^2, \ldots, C^m\}.$
2: $a_0 = A_0 = 0, a_1 = A_1 = \frac{1}{\sqrt{2m}}, q_0 = \hat{q}_0 = a_1(z_0 + c).$
3: for $k = 1, 2, \ldots, K$ do
4: Pick $j_k$ uniformly at random in $[m].$
5: $\hat{q}_{k-1} = q_{k-1} + (A_k - A_{\theta+1})(\hat{z}_{k-1} + c), \forall i \in C^j_k.$
6: $\hat{x}_{k-1} = \text{prox}_{\frac{1}{2} A_k \gamma}(x_0^{C^j_k} - \frac{1}{2} \hat{q}_{C^j_{k-1}}^{C^j_k}).$
7: $\hat{y}_k^{S_i} = \begin{cases} y_{k-1}^{S_i}, i \in [m] \setminus \{j_k\} \\
\hat{y}_{k-1}^{S_i} + \gamma ma_k \left(A^{S_i,C^j_k} \hat{x}_{k-1} - b^{S_i}\right), i = j_k
\end{cases}.$
8: $a_{k+1} = \frac{1+\sigma A_k^2/\gamma}{\sqrt{2m}}, A_{k+1} = A_k + a_{k+1}.$
9: $z_{k}^{C^j_k} = z_{k-1}^{C^j_k} + (A^{S_k,C^j_k})^T(y_{k}^{S_k} - y_{k-1}^{S_k}).$
10: $q_{k}^{i} = q_{k-1}^{i} + (A_{k+1} - A_{\theta+1})(z_{k-1}^{i} + c) + (a_{k+1} + ma_k)(z_{k}^{i} - z_{k-1}^{i}), \forall i \in C^j_k.$
11: $\hat{x}_{k}^{i} = \hat{x}_{k-1}^{i} + (A_{k-1} - A_{\theta+1})x_{k-1}^{i}, \forall i \in C^j_k.$
12: $\hat{y}_{k}^{i} = \hat{y}_{k-1}^{i} + (A_{k-1} - A_{\theta+1})y_{k-1}^{i} + (m-1)a_k(y_{k}^{i} - y_{k-1}^{i}), \forall i \in S^j_k.$
13: $x_{k}^{C^j_k} = \text{prox}_{\frac{1}{2} A_k \gamma}(x_0^{C^j_k} - \frac{1}{2} q_{C^j_k}^{C^j_k}).$
14: $\theta^{i} \leftarrow k, \forall i \in C^j_k.$
15: $\hat{\theta}^{i} \leftarrow k, \forall i \in S^j_k.$
16: $q_{k}^{i} = q_{k-1}^{i} - z_{k-1}^{i}, x_{k}^{i} = x_{k-1}^{i} = x_{k}^{i}, \hat{x}_{k}^{i} = \hat{x}_{k-1}^{i}, \forall i \in [d]\setminus C^j_k.$
17: $\hat{y}_{k}^{i} \leftarrow \hat{y}_{k-1}^{i}, \forall i \in [d]\setminus C^j_k.$
18: end for
19: $\hat{x}_{K}^{i} \leftarrow \hat{x}_{K-1}^{i} + (A_{K} - A_{\theta+1})x_{K}^{i}, \forall i \in [d].$
20: $\hat{y}_{K}^{i} \leftarrow \hat{y}_{K-1}^{i} + (A_{K} - A_{\theta+1})y_{K}^{i}, \forall i \in [n].$
21: return $\hat{x}_K / A_K, \hat{y}_K / A_K.$

Remark 1. While we consider the case of $r$ and $x$ fully coordinate separable for simplicity, our lazy update approach is also applicable to the coordinate block partitioning case in which $X = X_1 \times \cdots X_m$ with $X_i \in \mathbb{R}^{d_i}$ ($i \in [m])$, $\sum_{i=1}^m d_i = d$ and $r(w) := \sum_{i=1}^m r(w^i)$ with $w^i \in X_i$. The difference is that for each coordinate block $A^{S^j}$ ($j \in [m]$), we overload $C^j \subset [m]$ to denote the set of blocks in $A^{S^j}$ where each coordinate block contains at least one nonzero element.

Remark 2. Except for the dual averaging variant from Song et al. [2021], all stochastic primal-dual methods [Zhang and Lin 2015] Chambolle et al. [2018] Fercq and Bianchi [2019] Latafat et al. [2019] Macaagolu et al. [2020] are based on mirror descent-style updates in which $x_k$ depends directly on $x_{k-1}$ in a nonlinear way when proximal terms exist. As a result, it is not obvious (and maybe not possible) to design lazy update strategies for these methods in full generality. Our lazy update strategy can be adapted to the VRPDA algorithm from Song et al. [2021], but the implementation becomes more complicated due to the extrapolation steps on the primal variables in VRPDA.
Remark 3. Dual averaging has been shown to have significant advantage in producing sparser iterates than mirror descent in the context of online learning [Xiao 2010; Lee and Wright 2012]. It has also been shown to lead to better bounds in well-conditioned finite-sum optimization [Song et al., 2020]. In this work, we show that dual averaging offers better flexibility with sparse matrices than does mirror descent.

2.3 Restart Scheme

The special case of standard LP, which corresponds to (GLP) with $y$ much easier to work with. A more natural strategy, which we adopt, is to restart whenever the LPMetric halves. Since LPMetric is easy from more common representation such as the representation in Applegate et al. [2021b].

Denoting by $W^*$ the optimal solution set of the LP, we define the distance to $W^*$ by $\text{dist}(w, W^*) = \min_{w^* \in W^*} \|w - w^*\|$ for some norm $\| \cdot \|$. When the norm $\| \cdot \|$ is Euclidean norm $\| \cdot \|_2$, it is well-known [Hoffman 2003] that there exists a Hoffman constant $H$ such that

$$\text{LPMetric}(w) \geq H \text{dist}(w, W^*).$$

In the following discussion of this section, we assume that $\| \cdot \|$ denotes the weighted norm $\|w\| = \sqrt{\gamma \|x - x^*\|_2^2 + \frac{1}{\gamma} \|y - y^*\|_2^2}$ ($\gamma > 0$). Using the equivalence of norms in finite dimensions, we can conclude that there exists another constant $H_\gamma$ (to which we refer as the generalized Hoffman’s constant) such that

$$\text{LPMetric}(w) \geq H_\gamma \text{dist}(w, W^*).$$

Using (5) and the result from Theorem 1, we can then obtain the following bound based on the LPMetric.

Proposition 1. With $R \geq \|\hat{w}_k\| + \|\hat{w}_k - w_0\|$, we have

$$\mathbb{E}[\text{LPMetric}(\hat{w}_k)] \leq \frac{6\sqrt{2} \sqrt{1 + R^2 Lm}}{H_\gamma k} \text{LPMetric}(w_0),$$

where we take expectation on all the randomness up to the $k^{th}$ iteration.

Proposition 1 is proved based on the concept of normalized duality gap [Applegate et al., 2021b] (see the analysis in Appendix A.2). By Proposition 1, after $k = \frac{H_\gamma}{12\sqrt{2} \sqrt{1 + R^2 Lm}}$ iterations of the CLVR algorithm, the expected value of LPMetric will decrease by a factor of 2. As a result, if the parameters $H_\gamma, R$ (as well as $\hat{L}, m$) are known, then we can run CLVR for $K = \frac{H_\gamma}{12\sqrt{2} \sqrt{1 + R^2 Lm}}$ iterations, then restart CLVR by using the output to initialize the next cycle. Because the generalized Hoffman constant $H_\gamma$ is nontrivial to obtain, however, we must tune the number of iterations per each restart epoch if we consider such a fixed frequency restart, which is time-consuming.

A more natural strategy, which we adopt, is to restart whenever the LPMetric halves. Since LPMetric is easy to monitor and update, implementation of this strategy is straightforward. Since CLVR is a randomized algorithm, bounding the number of iterations required to halve the LPMetric is a nontrivial task; we will discuss this issue further in a future version of this work. By contrast, in a deterministic algorithm like PDHG, we can bound the number of iterations for each restart cycle, as in [Applegate et al., 2021b]. The latter paper makes use of a "normalized duality gap" whose computation requires solution of an auxiliary optimization problem. LPMetric is much easier to work with.

[1] In our primal-dual reformulation (PD-GLP), we reformulate the constraint $Ax = b$ by $y^T(Ax - b)$ rather than $y^T(b - Ax)$, so in our LP metric, there exist a sign difference for $y$ from more common representation such as the representation in [Applegate et al., 2021b].
3 Application: Distributionally Robust Optimization

Here we study distributionally robust optimization (DRO) in the context of robust empirical risk minimization. Consider sample vectors \(\{a_1, a_2, \ldots, a_n\}\) with labels \(\{b_1, b_2, \ldots, b_n\}\), where \(b_i \in \{1, -1\}\). The DRO problem with \(f\)-divergence based ambiguity set is

\[
\min_{x \in X} \sup_{p \in P_{\rho,n}} \sum_{i=1}^{n} p_i g_i(b_i a_i^T x),
\]

where \(P_{\rho,n} = \{p \in \mathbb{R}^n : \sum_{i=1}^{n} p_i = 1, p_i \geq 0 (i \in [n]), D_f(p\|1/n) \leq \frac{\rho}{n}\}\) is the ambiguity set, \(g_i\) is a convex loss function and \(D_f\) is an \(f\)-divergence defined by \(D_f(p\|q) = \sum_{i=1}^{n} q_i f(p_i/q_i)\) with \(p, q \in \{p \in \mathbb{R}^n : \sum_{i=1}^{n} p_i = 1, p_i \geq 0\}\) and \(f\) being a convex function [Namkoong and Duchi, 2016]. The formulation (7) is a nonbilinearly coupled convex-concave min-max problem with constraint set \(P_{\rho,n}\) for which efficient projections are not available in general. When \(g_i\) is a nonsmooth loss (e.g., the hinge loss), many well-known methods such as the extragradient [Korpelevich, 1976, Nemirovski, 2004] cannot be used even if we could project onto \(P_{\rho,n}\) efficiently. However, by introducing auxiliary variables and additional linear constraints and simple convex constraints, we can make the interacting term between primal and dual variables bilinear, as shown next. (See Appendix B for a proof.)

**Theorem 2.** The DRO problem in Eq. (7) is equivalent to the following problem:

\[
\begin{align*}
\min_{x, u, v, w, \mu, q, \gamma} \quad & \left\{ \gamma + \frac{\rho \mu_1}{n} + \frac{1}{n} \sum_{i=1}^{n} \mu_i f^*\left(\frac{q_i}{\mu_i}\right) \right\} \\
\text{s.t.} \quad & w + v - \frac{q}{n} - \gamma 1_n = 0_n, \\
& u_i = b_i a_i^T x, \quad i \in [n] \\
& \mu_1 = \mu_2 = \cdots = \mu_n, \\
& g(u_i) \leq w, \quad i \in [n] \\
& q_i \in \mu_i \text{ dom}(f^*), \quad i \in [n] \\
& v_i \geq 0, \quad \mu_i \geq 0, \quad i \in [n] \\
& x \in X.
\end{align*}
\]

In Theorem 2, the domain of the one-dimensional convex function \(f^*(\cdot)\) is an interval such as \([a, b]\), so that \(q_i \in \mu_i \text{ dom}(f^*)\) denotes the inequality \(\mu_i a \leq q_i \leq \mu_i b\). Since the perspective function \(\mu f^*(\frac{q}{\mu})\) is a simple convex function of two variables, we can assume that the proximal operator for this function on the domain \(\{(\mu, q) : q \in \mu \text{ dom}(f^*), \mu > 0\}\) can be computed efficiently [Boyd and Vandenbergh, 2004]. Similarly, we can assume that the constraint \(g(u) \leq w\) admits an efficiently computable projection operator. As a result, the formulation (8) can be solved by CLVR. When expressing (8) in the form (PD-GLP), the primal and dual variable vectors have dimensions \(d + 4n + 3n - 1\), respectively. However, according to Table 1 provided that \(X\) is coordinate separable, the overall complexity of CLVR will be only \(O\left(\frac{(\text{nnz}(A)+n)(R+1)}{\epsilon}\right)\), where \(R = \max_{i \in [n]} \|a_i\|\).

The original DRO problem with Wasserstein metric based ambiguity set is an infinite-dimensional nonbilinear-early coupled convex-concave min-max problem defined by

\[
\min_{w \in \mathbb{R}^d} \sup_{p \in P_{\rho,n}} P(p \cdot) [g(ba^T w)],
\]

where \(a \in \mathbb{R}^d, b \in \{1, -1\}\), \(P\) is a distribution on \(\mathbb{R}^d \times \{1, -1\}\), \(g\) is a convex loss function and \(P_{\rho,n}\) is the Wasserstein metric-based ambiguity defined below [Shafieezadeh Abadeh et al., 2015].
Definition 1. Let $\mu$ and $\nu$ be two probability distributions supported on $\Theta = \mathbb{R}^d \times \{1, -1\}$ and let $\Pi(\mu, \nu)$ denote the set of all joint distributions between $\mu$ and $\nu$. Then the Wasserstein metric between $\mu$ and $\nu$ is defined by

$$W(\mu, \nu) = \inf_{\pi \in \Pi(\mu, \nu)} \int_{\Theta \times \Theta} \zeta(\xi, \xi') \pi(d\xi, d\xi'),$$

where $\xi, \xi' \in \Theta$ and $\zeta(\cdot, \cdot) : \Theta \times \Theta \to \mathbb{R}_+$ is a convex cost function defined by

$$\zeta((a, b), (a', b')) = \|a - a'\| + \kappa |b - b'|,$$

where $\| \cdot \|$ denotes a general norm and $\kappa > 0$ is used to balance the feature mismatch and label uncertainty.

Let $Q = \frac{1}{n} \sum_{i=1}^{n} \delta_{(a_i, b_i)}$, where $\delta_{(a_i, b_i)}$ is the Dirac Delta function (or a point mass) at point $(a_i, b_i)$. Then, the Wasserstein metric based ambiguity set is defined as

$$\mathcal{P}_{\rho, \kappa} = \left\{ \mathcal{P} : W(\mathcal{P}, Q) \leq \rho \right\}.$$

Assumption 5. We define $M \in \mathbb{R}$ to be $M = \sup_{\theta \in \text{dom}(g^*)} |\theta|.$

Then following [Shafieezadeh Abadeh et al., 2015, Theorem 1], we provide reformulations of the problem from Eq. (9) that can be addressed by computationally efficient solvers in Theorem 3.

Theorem 3. The optimization problem from Eq. (9) is equivalent to:

$$\min_{\omega, \lambda, u, v, s, t} \rho \lambda + \frac{1}{n} \sum_{i=1}^{n} s_i$$

s. t. $u_i = b_i a_i^T \omega$, $i \in [n]$,

$v_i = -u_i$, $i \in [n]$,

$t_i = 2\kappa \lambda + s_i$, $i \in [n]$,

$g(u_i) \leq s_i$, $i \in [n]$,

$g(v_i) \leq t_i$, $i \in [n]$,

$\|\omega\|_\ast \leq \lambda / M.$

When we assume that the conic constraints $g(u) \leq s$ and $\|\omega\|_\ast \leq \lambda / M$ in (12) admit efficient proximal operators, we can formulate this problem as (PD-GLP) and apply CLVR. The resulting complexity bounds will be similar to those discussed above for the $f$-divergence formulation (8).

4 Numerical Experiments and Discussion

In this section, we provide the experimental evaluation of our algorithm for the reformulation of the DRO with Wasserstein metric of $\ell_1$-norm (with parameters $\kappa = 0.1$ and $\rho = 10$) and hinge loss. Since the dual norm of the $\ell_1$ norm is the $\ell_\infty$ norm, the resulting reformulation in Theorem 3 for this particular DRO problem can be further simplified to a standard LP. For this formulation, we compare our CLVR method with several well-known methods: PDHG [Chambolle and Pock, 2011], SPDHG [Chambolle et al., 2018] and PURE-CD [Alacaoglu et al., 2020]. For all the algorithms, we use the LPMetric in Eq. (3) as the performance measure and use the restart strategy of halving the LPMetric from Section 2.3 to obtain linear convergence. We conducted efficient implementation of CLVR and other algorithms in the Julia programming language for high-performance numerical computing, and optimized all implementations to the best of our ability. For SPDHG, as per-iteration cost is at least $O(d)$, we use block size 50 to balance the effect of the $O(d)$ cost, while PURE-CD is an algorithm for sparse datasets with block size 1. For CLVR, we do experiments for both block sizes 1 and 50. Our code

is available at [https://github.com/ericlincc/Efficient-GLP](https://github.com/ericlincc/Efficient-GLP). For fair comparison in terms of wall-clock time, we ran each algorithm using one CPU core, and all the experiments were run on a Linux machine with a second generation Intel Xeon Scalable Processor (Cascade Lake-SP) with 128 GB of RAM.

We conducted our experiments on LibSVM datasets a9a, gisette, and rcv1.binary with different sparsity levels. In Table 2, we list the information about the three datasets and the corresponding matrices in reformulations. As we see, due to the sparsely connected auxiliary variables, all the matrices in reformulations are quite sparse. As a commonly adopted preprocessing step for LP, we normalize each row of the matrix in the standard LP with Euclidean norm one.

As the weight parameter $\gamma$ (see Theorem 1) between primal and dual variables strongly influences the empirical performance, we tune it for all datasets in $\{10^{-i}\} (i \in \mathbb{Z})$. We set the Lipschitz constant of PDHG as the largest singular value of the constraint matrix in the LP formulation. For PURE-CD and CLVR with block size 1, because the rows of the matrix are normalized, we set the Lipschitz constant to 1. For CLVR and SPDHG with block size 50, we set the Lipschitz constant to 9 times the block size.

In Figure 1, we give the comparison in terms of number of data passes. Note that CLVR with block size 1 and PURE-CD perform best on all three datasets. CLVR and SPDHG with block size 50 have second-tier performance, while PDHG is worst. For CLVR algorithm, such a phenomenon is expected because smaller block size corresponds to smaller $\hat{L}$ in Assumption 3, which corresponds to better iteration complexity by Theorem 1. Nevertheless, the consistency between empirical performance and theoretical guarantee for SPDHG and PURE-CD deserves further research as they have only been proved to have the same iteration complexity as PDHG so far.
Empirically, on a9a, we find that CLVR with block size 1 has better performance than PURE-CD in terms of number of data passes. Note that all performance curves contain spikes which are caused by the restart strategy. At the beginning of each cycle, the value of LP metric will significantly increase, but decreases rapidly thereafter.

Figure 2 shows comparisons in terms of wall-clock time. Due to the per-iteration cost, the architecture of our computer, and the parallelism in the Julia programming language, the picture is significantly different from the comparisons based on data passes. Even with block size 50, SPDHG still has much higher per-iteration cost than CLVR with the same block size. As a result, SPDHG remains slowest for the sparse datasets a9a and rcv1, but is still faster than PDHG on the dense dataset gisette. Meanwhile, on a9a, CLVR with block size 50 is not fastest in terms of data passes, but due to the potential acceleration by parallelism, it remains fastest in terms of wall-clock time. On gisette, the effect of parallelism and the advantage of small block size cancel each other out, so CLVR block size 50 has the competitive performance with CLVR block size 1 and PURE-CD. On rcv1, the advantage of small block size dominates the effect of parallelism, while the per-iteration cost of PURE-CD is only about 60% of that of CLVR with block size 1 for this dataset. Hence, despite almost the same performance in terms of data passes, PURE-CD remains the fastest algorithm in terms of wall-clock time.

In summary, our CLVR algorithm is either fastest or competitive on all the tested datasets in terms of number of data passes and in terms of wall-clock time. Considering the fact that it also has the strongest theoretical guarantee among all the algorithms, we believe that CLVR is an appropriate “method of choice” due to its performance and stability.

References

A Omitted Proofs from Section 2

A.1 Omitted Proofs from Section 2.1

In Algorithm 3, we state a version of CLVR that is convenient for the analysis, and equivalent to Algorithm 1 in the main body of the paper. Before analyzing the convergence of CLVR, we justify our claim of equivalence in Proposition 2.

Proposition 2. The iterates of Algorithm 1 and 3 are equivalent.

Proof. To argue equivalence, we show that the iterates of Algorithm 1 and 3 solve the same optimization problem. To avoid ambiguity, here we will use \( \hat{x}_k, \hat{y}_k \) to denote the iterates \( x_k, y_k \) in Algorithm 3 while we retain the notation \( x_k, y_k \) for the iterates of Algorithm 1.

Let us first start by writing an equivalent definition of \( x_k \) in Algorithm 1. To do so, we first unroll the recursive definitions of \( z_k \) and \( q_k \). Observe that, since, by definition, \( y_k \) and \( y_{k-1} \) only differ over the coordinate block \( S_j \), we have

\[
z_k = z_0 + \sum_{i=1}^k A^T (y_i - y_{i-1}) = A^T y_k. \tag{13}
\]

On the other hand, using Eq. (13), the definition of \( q_k \) implies

\[
q_k = A_{k+1} c + a_1 y_0 + \sum_{i=1}^k A^T [a_{i+1} y_i + m a_i (y_i - y_{i-1})] \tag{14}
\]

Using the definition of the proximal operator (see Eq. (1)) and the definition of \( x_k \) in Step 4 of Algorithm 1, we have

\[
x_k = \arg \min_{x \in \mathcal{X}} \left\{ \frac{\gamma}{2} \| x - x_0 \|^2 + A_k r(x) + \frac{1}{2} \| x - x_0 + \frac{1}{\gamma} q_{k-1} \|^2 \right\}
\]

\[
= \arg \min_{x \in \mathcal{X}} \left\{ \frac{\gamma}{2} \| x - x_0 \|^2 + A_k r(x) + \left\langle x, A_k c + A^T \left( \sum_{i=1}^k [a_i y_{i-1} + m a_i (y_{i-1} - y_{i-2})] \right) \right\rangle \right\}
\]

\[
= \arg \min_{x \in \mathcal{X}} \left\{ \frac{\gamma}{2} \| x - x_0 \|^2 + A_k r(x) + \left\langle x, q_{k-1} \right\rangle \right\}
\]

\[
= \arg \min_{x \in \mathcal{X}} \left\{ A_k r(x) + \frac{\gamma}{2} \| x - x_0 + \frac{1}{\gamma} q_{k-1} \|^2 \right\}
\]

\[
= x_k.
\]

It remains to argue that the definitions of \( y_k \) and \( \hat{y}_k \) agree. First, observe that since the definitions of \( \psi_k \) and \( \psi_{k-1} \) differ only over block \( S_j \), we have \( \hat{y}_k^i = \hat{y}_{k-1}^i \) for \( i \neq j \). For \( i = j \), we have by unrolling the recursive
Algorithm 3 Coordinate Linear Variance Reduction (Analysis Version)

1: **Input:** \( x_0 = x_{-1} \in \mathcal{X}, y_0 = y_{-1} \in \mathbb{R}^n, m, \{S^1, S^2, \ldots, S^m\}, K, \gamma > 0, \tilde{L} > 0 \).
2: \( \phi_0(\cdot) = \frac{\gamma}{2} \| \cdot - x_0 \|^2, \psi_0(\cdot) = \frac{1}{2\gamma} \| \cdot - y_0 \|^2 \).
3: \( a_1 = A_1 = \frac{1}{\sqrt{2}Lm} \).
4: **for** \( k = 1, 2, 3, \ldots, K \) **do**
5: \( x_k = \arg \min_{x \in \mathcal{X}} \{ \phi_k(x) = \phi_{k-1}(x) + a_k(\langle x - u, A^T y_{k-1} + c \rangle + r(x) - r(u)) \} \).
6: Pick \( j_k \) uniformly at random in \([m]\).
7: \( y_k = \arg \min_{y \in \mathbb{R}^n} \{ \psi_k(y) = \psi_{k-1}(y) + ma_k(\langle y^{S_j} - v^{S_j}, A^{S_j} x_k - b^{S_j} \rangle) \} \).
8: \( a_{k+1} = \frac{\sqrt{1+\sigma A_k}}{\sqrt{2Lm}}, A_{k+1} = A_k + a_{k+1} \).
9: \( \bar{y}_k = y_k + \frac{ma_k}{a_{k+1}} (y_k - y_{k-1}) \).
10: **end for**
11: **return** \( \bar{x}_K = \frac{1}{K} \sum_{k=1}^K x_k, \bar{y}_K = \frac{1}{K} \sum_{k=1}^K (a_k y_k + (m-1)a_k(y_k - y_{k-1})) \).

In the following two lemmas, we bound \( \phi_k(x_k) \) and \( \psi_k(y_k) \) below and above, which is then subsequently used to bound the primal-dual gap in Theorem 3.

**Lemma 1.** For all steps of Algorithm 3 with \( k \geq 1 \), we have, \( \forall (u, v) \in \mathcal{X} \times \mathbb{R}^n \),

\[
\phi_k(x_k) \leq \frac{\gamma}{2} \| u - x_0 \|^2 - \frac{\gamma + \sigma A_k}{2} \| u - x_k \|^2,
\]

\[
\psi_k(y_k) \leq \frac{1}{2\gamma} \| v - y_0 \|^2 - \frac{1}{2\gamma} \| v - y_k \|^2.
\]

**Proof.** By the definitions of \( \psi_k(y) \) and \( \phi_k(x) \) in Algorithm 3 it follows that, \( \forall k \geq 1 \),

\[
\phi_k(x) = \sum_{i=1}^k a_i(\langle x - u, A^T y_{i-1} + c \rangle + r(x) - r(u)) + \frac{\gamma}{2} \| x - x_0 \|^2.
\]  

(16)

and

\[
\psi_k(y) = \sum_{i=1}^k ma_i\left( - \langle y^{S_{i}} - v^{S_{i}}, A^{S_{i}} x_i - b^{S_{i}} \rangle \right) + \frac{1}{2\gamma} \| y - y_0 \|^2.
\]  

(17)

Observe that, as function of \( x \), \( \phi_k(x) \) is \((\gamma + \sigma A_k)\)-strongly convex. As, by definition, \( x_k = \arg \min_{x \in \mathcal{X}} \phi_k(x) \), it follows that

\[
\phi_k(u) \geq \phi_k(x_k) + \frac{\gamma}{2} \| x_k - u \|^2.
\]  

(18)
Now, writing $\phi_k(u)$ explicitly and rearranging the last inequality, the stated bound on $\phi_k(x_k)$ follows.

As function of $y$, $\psi_k(y)$ is $1/\gamma$-strongly convex. The proof for the bound on $\psi_k$ uses the same argument and is omitted. 

In the following proof, for $k \geq 1$, let $\mathcal{F}_{k-1}$ denote the natural filtration, containing all the randomness in the algorithm up to and including iteration $k$. Recall that $A = \begin{pmatrix} A_{S^1} \\ \vdots \\ A_{S^m} \end{pmatrix}$, and let $A_{S^j}$ ($j \in [m]$) denote the matrix $A$ with its $S^j$ block of rows replaced by a zero vector.

**Lemma 2.** For all steps of Algorithm 3 with $k \geq 1$, we have for all $(u,v) \in \mathcal{X} \times \mathbb{R}^n$ that

$$
\phi_k(x_k) \geq \phi_{k-1}(x_{k-1}) + \frac{\gamma + \sigma A_{k-1}}{2} \|x_k - x_{k-1}\|^2 + a_k(r(x_k) - r(u))
- a_k \langle x_k - u, A^T (y_k - y_{k-1}) \rangle + a_k \langle x_k - u, A^T y_k + c \rangle
+ m a_k \left( \langle x_{k-1} - u, A^T (y_{k-1} - y_{k-2}) \rangle + \langle x_k - x_{k-1}, A^T (y_{k-1} - y_{k-2}) \rangle \right),
$$

$$
\mathbb{E}[\psi_k(y_k) | \mathcal{F}_{k-1}] \geq \psi_{k-1}(y_{k-1}) + \frac{1}{2\gamma} \mathbb{E}[[\|y_k - y_{k-1}\|^2 | \mathcal{F}_{k-1}]] + m a_k \mathbb{E}\left[ \langle y_{S^j_k} - v_{S^j_k}, b_{S^j_k} \rangle \bigg| \mathcal{F}_{k-1} \right]
+ \mathbb{E}\left[ a_k \langle Ax_k, y_k - v \rangle \bigg| \mathcal{F}_{k-1} \right] - (m - 1) a_k \mathbb{E}\left[ \langle Ax_k, y_k - y_{k-1} \rangle \bigg| \mathcal{F}_{k-1} \right],
$$

where the expectations are w.r.t. all the randomness in the algorithm.

**Proof.** For bounding $\phi_k(x_k)$, from the definition of $\phi_k(x_k)$, and using that $\phi_{k-1}(x_{k-1})$ is $(\gamma + \sigma A_{k-1})$-strongly convex and minimized at $x_{k-1}$, we have

$$
\phi_k(x_k) \geq \phi_{k-1}(x_{k-1}) + \frac{\gamma + \sigma A_{k-1}}{2} \|x_k - x_{k-1}\|^2 + a_k \langle x_k - u, A^T y_k - y_{k-1} + c \rangle + r(x_k) - r(u).
$$

Meanwhile, by the definition of $\{\bar{y}_k\}$, we also have

$$
a_k \langle x_k - u, A^T y_{k-1} \rangle
= a_k \langle x_k - u, A^T (y_{k-1} + \frac{m a_{k-1}}{a_k} (y_{k-1} - y_{k-2})) \rangle
= - a_k \langle x_k - u, A^T (y_k - y_{k-1}) \rangle + a_k \langle x_k - u, A^T y_k \rangle
+ m a_k \left( \langle x_{k-1} - u, A^T (y_{k-1} - y_{k-2}) \rangle + \langle x_k - x_{k-1}, A^T (y_{k-1} - y_{k-2}) \rangle \right).
$$

The bound on $\phi_k(x_k)$ from the statement of the lemma follows by combining Eqs. (19) and (20).

On the other hand, by the definition of $\psi_k$, we have

$$
\psi_k(y_k) - \psi_{k-1}(y_{k-1}) = \psi_{k-1}(y_k) - \psi_{k-1}(y_{k-1})
- m a_k \langle y_{S^j_k} - v_{S^j_k}, A_{S^j_k} x_k - b_{S^j_k} \rangle.
$$

To obtain the claimed bound on $\psi_k$, we now proceed to bound the terms from the first and second line in Eq. (21), respectively. To keep the notation simple, we define

$$
E_k := - m a_k \langle y_{S^j_k} - v_{S^j_k}, A_{S^j_k} x_k - b_{S^j_k} \rangle
$$

for the terms from the second line.
As $\psi_{k-1}$ is $(1/\gamma)$-strongly convex and minimized at $y_{k-1}$, we have
\[
\psi_{k-1}(y_k) - \psi_{k-1}(y_{k-1}) \geq \frac{1}{2\gamma} \|y_k - y_{k-1}\|^2.
\]
(23)

To bound $E[E_k]$, observe that $y_k$ and $y_{k-1}$ only differ over the coordinate block $S^j$, which is chosen uniformly at random, independent of the history. Then, we have
\[
E\left[-\langle y_k^{S_j} - v^{S_j}, A^{S_j} x_k \rangle \mid F_{k-1}\right] = E\left[-\langle Ax_k, y_k - v \rangle + \langle A^{S_j} x_k, y_k - v \rangle \mid F_{k-1}\right]
\]
\[
= E\left[-\langle Ax_k, y_k - v \rangle \mid F_{k-1}\right] + \frac{m-1}{m} E\left[\langle Ax_k, y_k - y_{k-1} - v \rangle \mid F_{k-1}\right],
\]
where the second equality follows from $y_k$ being equal to $y_{k-1}$ over all the coordinate blocks apart from $S_j$, and from $y_k$ being chosen uniformly at random in $[m]$. Taking expectations on both sides of the last equality and using $\langle Ax_k, y_k - v \rangle = \langle Ax_k, y_k - y_{k-1} \rangle + \langle Ax_k, y_{k-1} - v \rangle$, we have
\[
E\left[\langle y_k^{S_j} - v^{S_j}, A^{S_j} x_k \rangle \mid F_{k-1}\right] = \frac{1}{m} E\left[-\langle Ax_k, y_k - v \rangle \mid F_{k-1}\right] - \frac{m-1}{m} E\left[\langle Ax_k, y_k - y_{k-1} \rangle \mid F_{k-1}\right].
\]

Thus, we have
\[
E[E_k \mid F_{k-1}] = a_k E\left[-\langle Ax_k, y_k - v \rangle \mid F_{k-1}\right] - (m-1) a_k E\left[\langle Ax_k, y_k - y_{k-1} \rangle \mid F_{k-1}\right].
\]
(24)
The bound on $\psi_k(y_k)$ from the statement of the lemma now follows by combining Eqs. (21)–(24) $\square$

Then using Lemma 2, we have Lemma 3

**Lemma 3.** The sum of $\psi_k(y_k) + \phi_k(x_k)$ can be bounded in expectation as follows:
\[
E[\phi_k(x_k) + \psi_k(y_k) \mid F_{k-1}] 
\geq \phi_{k-1}(x_{k-1}) + \psi_{k-1}(y_{k-1}) 
- m a_k E\left[\langle x_k - u, A^T(y_k - y_{k-1}) \rangle \mid F_{k-1}\right] + m a_k \langle x_{k-1} - u, A^T(y_{k-1} - y_{k-2}) \rangle 
+ \frac{1}{2\gamma} E[\|y_k - y_{k-1}\|^2 \mid F_{k-1}] - \frac{1}{2\gamma} \|y_{k-1} - y_{k-2}\|^2 + E[Q_k \mid F_{k-1}],
\]
(25)

where $Q_k := a_k (m \langle b^{S_j}, y_k^{S_j} - v^{S_j} \rangle + r(x_k) - r(u) - \langle Au, y_k \rangle + \langle x_k, A^T v \rangle - (m-1) \langle Au, y_k - y_{k-1} \rangle)$. 

**Proof.** Fix any $(u, v) \in \mathcal{X} \times \mathbb{R}^n$. By combining the bounds on $\phi_k(x_k)$ and $\psi_k(y_k)$ from Lemma 2, we have $\forall k \geq 1$ that
\[
E[\phi_k(x_k) + \psi_k(y_k) \mid F_{k-1}] 
\geq \phi_{k-1}(x_{k-1}) + \psi_{k-1}(y_{k-1}) 
- m a_k E\left[\langle x_k - u, A^T(y_k - y_{k-1}) \rangle \mid F_{k-1}\right] + m a_k \langle x_{k-1} - u, A^T(y_{k-1} - y_{k-2}) \rangle 
+ E[P_k \mid F_{k-1}] + E[Q_k \mid F_{k-1}],
\]
(26)

where
\[
P_k = \frac{\gamma + \sigma A_{k-1}}{2} \|x_k - x_{k-1}\|^2 + \frac{1}{2\gamma} \|y_k - y_{k-1}\|^2 + m a_k \langle x_k - x_{k-1}, A^T(y_{k-1} - y_{k-2}) \rangle
\]
(27)

and
\[
Q_k = a_k (m \langle b^{S_j}, y_k^{S_j} - v^{S_j} \rangle + r(x_k) - r(u) - \langle Au, y_k \rangle + \langle x_k, A^T v \rangle - (m-1) \langle Au, y_k - y_{k-1} \rangle).
\]
(28)
Observe that the first line in Eq. (26) gives the desired recursive relationship for the sum of estimate sequences, while the second line telescopes. Thus, we only need to focus on bounding $P_k$ and $Q_k$.

To bound $P_k$, we start by bounding the inner product terms that appear in it. Recall that $y_k$ and $y_{k-1}$ only differ on coordinate $j_k$. We thus have:

$$|ma_{k-1}(x_k - x_{k-1}, A^T(y_{k-1} - y_{k-2}))|$$

$$= |ma_{k-1} \langle A^{S/k-1}(x_k - x_{k-1}), y_{k-1}^{S/k-1} - y_{k-2}^{S/k-1} \rangle|$$

$$\leq ma_{k-1} \| A^{S/k-1}(x_k - x_{k-1}) \| \| y_{k-1}^{S/k-1} - y_{k-2}^{S/k-1} \|$$

$$\leq (ma_{k-1})^2 \gamma \| A^{S/k-1}(x_k - x_{k-1}) \|^2 + \frac{1}{4\gamma} \| y_{k-1}^{S/k-1} - y_{k-2}^{S/k-1} \|^2$$

$$\leq (m \hat{L}a_{k-1})^2 \gamma \| x_k - x_{k-1} \|^2 + \frac{1}{4\gamma} \| y_{k-1} - y_{k-2} \|^2$$

where the second inequality is by Young’s inequality, and the third inequality is by Assumption 3 where $\| A^{S/k-1}(x_k - x_{k-1}) \| \leq \hat{L} \| x_k - x_{k-1} \|.$

Then with our setting $a_{k-1} = \sqrt{\frac{T+\sigma}{4L/k-1}}$, $\forall k \geq 1$, we can further simplify the bound on $P_k$ to

$$P_k \geq \frac{1}{2\gamma} \| y_k - y_{k-1} \|^2 - \frac{1}{2\gamma} \| y_{k-1} - y_{k-2} \|^2$$

$$\geq \frac{1}{2\gamma} \| y_k - y_{k-1} \|^2 - \frac{1}{2\gamma} \| y_{k-1} - y_{k-2} \|^2,$$  

(30)

which telescopes.

Then combining Eqs. (26), (27), (28) and the bound Eq. (30) for $P_k$, we obtain Lemma 3.

Based on Lemma 3, we are now ready to prove our main result.

**Theorem 1.** For any $(u, v) \in X \times \mathbb{R}^n$, the vectors $x_k, y_k, k = 1, \ldots, K$ and the averages $\{\bar{x}_k\}$ and $\{\bar{y}_k\}$ generated by Algorithm 7 satisfy the following bound:

$$\mathcal{L}(E[\bar{x}_k], v) - \mathcal{L}(u, E[\bar{y}_k]) \leq E[\mathcal{L}(\bar{x}_k, v) - \mathcal{L}(u, \bar{y}_k)] \leq \frac{\gamma}{2} \left( \| u - x_0 \|^2 + \| v - y_0 \|^2 \right) / \gamma,$$

where $\bar{x}_k = \frac{1}{A_k} \sum_{i=1}^{k} a_i x_i$ and $\bar{y}_k = \frac{1}{A_k} \sum_{i=1}^{k} (a_i y_i + (m - 1)a_i (y_i - y_{i-1})).$ Further, if $(x^*, y^*)$ is a primal-dual solution to (PD-GLP), then we also have

$$E\left[ \gamma + \frac{\sigma A_k}{4} \| x^* - x_k \|^2 + \frac{1}{2\gamma} \| y^* - y_k \|^2 \right] \leq \frac{\gamma}{2} \left( \| x^* - x_0 \|^2 + \| y^* - y_0 \|^2 \right) / \gamma.$$

Defining $K_0 = \left[ \frac{\sigma}{9Lm\gamma} \right],$ we have

$$A_k \geq \max \left\{ \frac{k}{\sqrt{2Lm}}, \frac{\sigma}{(3\sqrt{2Lm})^2 \gamma} \left( k - K_0 + \max \left\{ \sqrt{9\sqrt{2Lm}\gamma / \sigma}, 1 \right\} \right)^2 \right\}.$$

**Proof.** For the inequality in Lemma 3, with the tower property of conditional expectation $E[.] = E[E[.|F_{k-1}]],$
taking expectation on all the randomness and telescoping, we have

\[ E[\phi_k(x_k) + \psi_k(y_k)] \geq E[\phi_0(x_0) + \psi_0(y_0)] - m a_k \langle x_k - u, A^T(y_k - y_{k-1}) \rangle + m a_0 \langle x_0 - u, A^T(y_0 - y_{-1}) \rangle + \frac{1}{2\gamma} \|y_k - y_{k-1}\|^2 - \frac{1}{2\gamma} \|y_0 - y_{-1}\|^2 + \sum_{i=1}^{k} Q_i \]

\[ = E[-m a_k \langle x_k - u, A^T(y_k - y_{k-1}) \rangle + \frac{1}{2\gamma} \|y_k - y_{k-1}\|^2 + \sum_{i=1}^{k} Q_i], \]

where the least equality is by the fact that \( \psi_0(y_0) = \phi_0(x_0) = 0, a_0 = 0, \) and \( y_{-1} := y_0. \)

We now proceed to bound \( E[\sum_{i=1}^{k} Q_i]. \) Observe that

\[ E[\langle b^{S_i}, y_i^{S_i} - v^{S_i} \rangle] = E=E[\langle b, y_i - v \rangle - \langle b^{S_i}, y_i^{S_i} - v^{S_i} \rangle | F_{i-1}] \]

\[ = E[b^T(y_i - v) - \frac{m-1}{m} b^T(y_{i-1} - v)], \]

where \( F_{i-1} \) is the natural filtration, containing all randomness up to and including iteration \( i - 1. \) Therefore, we can bound \( E[\sum_{i=1}^{k} Q_i] \) as follows:

\[ E[\sum_{i=1}^{k} Q_i] = E\left[ \sum_{i=1}^{k} a_i (m b^T(y_i - v) - (m-1) b^T(y_{i-1} - v)) \right] + E\left[ \sum_{i=1}^{k} a_i (r(x_i) - r(u)) \right] + E\left[ \sum_{i=1}^{k} a_i (-m \langle Au, y_i \rangle + (m-1) \langle Au, y_{i-1} \rangle + \langle x_i, A^T v \rangle) \right] \]

\[ = E[ma_k b^T(y_k - v) + \sum_{i=1}^{k-1} (ma_i - (m-1)a_{i+1}) b^T(y_i - v) - (m-1)a_1 b^T(y_0 - v)] \]

\[ + E[-ma_k \langle Au, y_k \rangle + \sum_{i=1}^{k-1} (-ma_i + (m-1)a_{i+1}) \langle Au, y_i \rangle + (m-1)a_1 \langle Au, y_0 \rangle] \]

\[ + E\left[ \sum_{i=1}^{k} a_i (r(x_i) - r(u)) + \sum_{i=1}^{k} a_i \langle x_i, A^T v \rangle \right] \]

\[ \geq A_k E\left[ b^T(y_k - v) - \langle Au, y_k \rangle + \langle \bar{x}_k, A^T v \rangle + r(\bar{x}_k) - r(u) \right] \]

\( = A_k E[\text{Gap}^u,v(\bar{x}_k, \bar{y}_k)]. \) (31)

(32)

where Eq. (31) is the definition of \( \bar{y}_k = \frac{1}{A_k} (ma_k y_k + \sum_{i=1}^{k-1} (ma_i - (m-1)a_{i+1}) y_i - (m-1)a_1 y_0) = \frac{1}{A_k} \sum_{i=1}^{k} (a_i y_i + (m-1)a_i (y_i - y_{i-1})), \bar{x}_k = \frac{1}{A_k} \sum_{i=1}^{k} \gamma_i x_i, \) and by the convexity of \( r(x). \) Eq. (32) is by the definition of \( \text{Gap}^u,v(x, y). \) Rearranging Eq. (31) and using Lemma[1] we have

\[ A_k E[\text{Gap}^u,v(\bar{x}_k, \bar{y}_k)] \]

\[ \leq E[\psi_k(y_k) + \phi_k(x_k) + ma_k \langle x_k - u, A^T(y_k - y_{k-1}) \rangle - \frac{1}{2\gamma} \|y_k - y_{k-1}\|^2] \]

\[ \leq E\left[ \frac{1}{2\gamma} \|v - y_0\|^2 - \frac{1}{2\gamma} \|v - y_k\|^2 + \frac{\gamma}{2} \|u - x_0\|^2 - \frac{\gamma + \sigma A_k}{2} \|u - x_k\|^2 \right. \]

\[ + ma_k \langle x_k - u, A^T(y_k - y_{k-1}) \rangle - \frac{1}{2\gamma} \|y_k - y_{k-1}\|^2 \].

22
Finally, we have from Young’s inequality and the definition of $a_k$ that

$$
\begin{align*}
|ma_k(x_k - u, A^T (y_k - y_{k-1})| & = ma_k(A^{S_{jk}}(x_k - u), y_k^{S_{jk}} - y_{k-1}^{S_{jk}}) \\
& \leq ma_k \|A^{S_{jk}}(x_k - u)\| y_k^{S_{jk}} - y_{k-1}^{S_{jk}} \|
\end{align*}
$$

leading to

$$
A_k \mathbb{E}[\text{Gap}^{u,v}(\bar{x}_k, \bar{y}_k)] \leq \mathbb{E}\left[\frac{\gamma}{2} \|u - x_0\|^2 + \frac{1}{2\gamma} \|v - y_0\|^2 - \frac{1}{2\gamma} \|v - y_k\|^2 - \frac{\gamma + \sigma A_k}{4} \|u - x_k\|^2\right].
$$

Since $\text{Gap}^{u,v}(\cdot, \cdot)$ is convex in both its arguments, by Jensen’s inequality, $\mathbb{E}[\text{Gap}^{u,v}(\bar{x}_k, \bar{y}_k)] \leq \mathbb{E}[\text{Gap}^{u,v}(\tilde{x}_k, \tilde{y}_k)]$, and we have that $\forall (u, v) \in \mathcal{X} \times \mathbb{R}^n$,

$$
\text{Gap}^{u,v}(\mathbb{E}[\bar{x}_k], \mathbb{E}[\bar{y}_k]) \leq \mathbb{E}[\text{Gap}^{u,v}(\bar{x}_k, \bar{y}_k)] \leq \frac{\gamma \|u - x_0\|^2 + \|v - y_0\|^2}{2A_k}.
$$

and, as $\text{Gap}^{x^*,y^*}(\bar{x}_k, \bar{y}_k) \geq 0$, we also have

$$
\mathbb{E}\left[\frac{\gamma + \sigma A_k}{4} \|x^* - x_k\|^2 + \frac{1}{2\gamma} \|y^* - y_k\|^2\right] \leq \frac{\gamma \|x^* - x_0\|^2 + \|y^* - y_0\|^2}{2}/\gamma.
$$

Finally, by Lemma 4 and the definitions of $\{a_k\}, \{A_k\}$, we obtain the claimed bound of $A_k$. $\square$

**Corollary 1.** In Algorithm 7 for all $k \geq 1$, $\bar{x}_k$ satisfies

$$
\|A \mathbb{E} [\bar{x}_k] - b\| \cdot \|y^*\| \leq \frac{\gamma \|u - x_0\|^2 + 4 \|v - y_0\|^2}{2A_k}/\gamma,
$$

$$(c^T \mathbb{E}[\bar{x}_k] + r(\mathbb{E}[\bar{x}_k])) - (c^T x^* + r(x^*)) \geq - \frac{\gamma \|u - x_0\|^2 + 4 \|v - y_0\|^2}{2A_k}/\gamma,$$

$$(c^T \mathbb{E}[\bar{x}_k] + r(\mathbb{E}[\bar{x}_k])) - (c^T x^* + r(x^*)) \leq \frac{\gamma \|u - x_0\|^2 + 4 \|v - y_0\|^2}{A_k}/\gamma,$$

where $u = x^*$ and $\|A \mathbb{E} [\bar{x}_k] - b\| \cdot v = \|y^*\|(A \mathbb{E} [\bar{x}_k] - b)$.

**Proof.** Let $(x^*, y^*)$ be an optimal solution of (PD-GLP). Assume that $\|A \mathbb{E} [\bar{x}_k] - b\| \neq 0$, as otherwise the first bound follows trivially. Let $u = x^*$ and $v = \|y^*\|(A \mathbb{E} [\bar{x}_k] - b)$. Then by Theorem 1 and the fact that $Ax^* = b$, we have

$$
\gamma \|u - x_0\|^2 + 4 \|v - y_0\|^2/\gamma
$$

$$
\geq \mathcal{L}(\mathbb{E} [\bar{x}_k], v) - \mathcal{L}(u, \mathbb{E} [\bar{y}_k])
$$

$$
= (c^T \mathbb{E}[\bar{x}_k] + r(\mathbb{E}[\bar{x}_k]) + 2 \|y^*\| \|A \mathbb{E} [\bar{x}_k] - b\|) - (c^T x^* + r(x^*) + \mathbb{E}[\bar{y}_k]^T (Ax^* - b))
$$

$$
= (c^T (\mathbb{E}[\bar{x}_k] - x^*) + r(\mathbb{E}[\bar{x}_k]) - r(x^*)) + 2 \|y^*\| \|A \mathbb{E} [\bar{x}_k] - b\|.
$$
By the KKT condition of (PD-GLP) and the optimality of \((x^*, y^*)\), we have: \(\forall x \in \mathcal{X},\)
\[
(c^T x + r(x)) - (c^T x^* + r(x^*)) - \langle y^*, Ax - b \rangle \geq 0,
\]
so we have
\[
(c^T x + r(x)) - (c^T x^* + r(x^*)) \geq -\|y^*\| \|Ax - b\|.
\] (34)

Then combining Theorem 1, Eq. (33) and Eq. (34) with
\[
\text{Lemma 4.} \quad \text{[Song et al., 2021]} \quad \text{Let} \quad x \in \mathbb{R} \text{ and } y_0 = 0, \text{ we have}
\]
\[
\|A\mathbb{E}[\tilde{x}_k] - b\| \cdot \|y^*\| \leq \frac{\gamma\|u - x_0\|^2 + 4\|v - y_0\|^2}{2A_k},
\]
and
\[
(c^T \mathbb{E}[\tilde{x}_k] + r(\mathbb{E}[\tilde{x}_k])) - (c^T x^* + r(x^*)) \geq \frac{-\gamma\|u - x_0\|^2 + 4\|v - y_0\|^2}{A_k},
\]
\[
(c^T \mathbb{E}[\tilde{x}_k] + r(\mathbb{E}[\tilde{x}_k])) - (c^T x^* + r(x^*)) \leq \frac{\gamma\|u - x_0\|^2 + 4\|v - y_0\|^2}{A_k},
\]
as claimed.

**Lemma 4.** [[Song et al., 2021]] Let \(\{A_k\}_{k \geq 0}\) be a sequence of nonnegative real numbers such that \(A_0 = 0\) and \(A_k\) is defined recursively via \(A_k = A_{k-1} + \sqrt{c_1^2 + c_2A_{k-1}}\), where \(c_1 > 0\) and \(c_2 \geq 0\). Define \(K_0 = \lceil \frac{c_2}{9c_1} \rceil\). Then
\[
A_k \geq \begin{cases} \frac{c_2}{9} (k - K_0 + \max \left\{ 3, \frac{c_2}{c_1}, 1 \right\})^2, & \text{if } c_2 > 0 \text{ and } k > K_0, \\ \frac{c_2}{9} k, & \text{otherwise}. \end{cases}
\]

**A.2 Omitted Proof from Section 2.3**

To derive the restart scheme based on (5), in the following, we introduce the concept of normalized duality gap from [[Applegate et al., 2021b]]: given \((x, y)\), the normalized duality gap is defined by
\[
\rho_r(w) := \max_{\tilde{w} \in \mathcal{W}_r(w)} \left\{ \frac{L(x, \tilde{y}) - L(\tilde{x}, y)}{r} \right\},
\] (35)
where \(\mathcal{W}_r(w) = \{ \tilde{w} \in \mathcal{W} : \|w - \tilde{w}\| \leq r \}\). Then for CLVR, we have Lemma 5.

**Lemma 5.** For all \(k \geq 1\), we have
\[
\mathbb{E}[\rho]\mathbb{E}[\tilde{w}_k - w_0] \leq \frac{2\sqrt{2}Lm}{k}\mathbb{E}[\|\tilde{w}_k - w_0\|],
\] (36)
\[
\mathbb{E}[\|\tilde{w}_k - w_0\|] \leq 3\|w^* - w_0\|.
\] (37)

**Proof.** When applying Theorem 1 into LP, with the definition of the norm \(\|w\| = \sqrt{\gamma\|x - x^*\|^2 + \frac{1}{\gamma}\|y - y^*\|^2}\), we have: \(\forall k \geq 1, w = (x, y)\)
\[
\mathbb{E}[L(\tilde{x}_k, y) - L(x, \tilde{y}_k)] \leq \frac{2\sqrt{2}Lm}{k}\mathbb{E}[\|w_k - w_0\|^2],
\] (38)
\[
\mathbb{E}[\|w_k - w^*\|^2] \leq 2\|w_0 - w^*\|^2.
\] (39)
Then for $r = ||\tilde{w}_k - w_0|| \in (0, \infty)$, by the definition of $\rho_r$, the fact that $\mathcal{W}_r(\tilde{w}_k) \subset \mathcal{W}_{2r}(w_0)$ and Eq. (38),

$$
\mathbb{E}[\rho_{||\tilde{w}_k - w_0||}(\tilde{w}_k)] = \mathbb{E}[\rho_r(\tilde{w}_k)] = \mathbb{E}\left[\frac{1}{r} \max_{w \in \mathcal{W}_r(\tilde{w}_k)} \{L(\tilde{x}_k, \tilde{y}) - L(\tilde{x}, \tilde{y})\}\right]
\leq \mathbb{E}\left[\frac{1}{r} \max_{w \in \mathcal{W}_{2r}(w_0)} \{L(\tilde{x}_k, \tilde{y}) - L(\tilde{x}, \tilde{y})\}\right]
\leq \mathbb{E}\left[\frac{\sqrt{2} \hat{L}m(2r)^2}{2kr}\right] = \mathbb{E}\left[\frac{2\sqrt{2}\hat{L}m}{k}\right] = 2\sqrt{2}\hat{L}m\mathbb{E}[||\tilde{w}_k - w_0||]
$$

(40)

By Eq. (39) and the concavity of $\sqrt{\cdot}$, we have

$$
\mathbb{E}[||w_k - w^*||] \leq \sqrt{\mathbb{E}[||w_k - w^*||^2]} \leq \sqrt{2}||w_0 - w^*||.
$$

(41)

Then it follows that

$$
\mathbb{E}[||\tilde{w}_k - w_0||] \leq \mathbb{E}[||\tilde{w}_k - w^*|| + ||w^* - w_0||]
= \mathbb{E}\left[\left|\left|\frac{1}{k} \sum_{i=1}^{k} w_i - w^*\right|\right| + ||w^* - w_0||\right]
\leq \mathbb{E}\left[\frac{1}{k} \sum_{i=1}^{k} ||w_i - w^*|| + ||w^* - w_0||\right]
\leq \left(\frac{1}{k} \sum_{i=1}^{k} 2||w^* - w_0||\right) + ||w^* - w_0||
= 3||w^* - w_0||.
$$

(42)

Meanwhile, by [Applegate et al., 2021b, Lemma 4], we have Lemma 6.

**Lemma 6** ([Applegate et al., 2021b]). For all $R \in (0, +\infty)$, $r \in (0, R]$, and $z \in \mathcal{W}_R(0)$, we have

$$
\text{LPMetric}(w) \leq \rho_r(w) \sqrt{1 + R^2}.
$$

(43)

**Proposition 1.** With $R \geq ||\tilde{w}_k|| + ||\tilde{w}_k - w_0||$, we have

$$
\mathbb{E}[\text{LPMetric}(\tilde{w}_k)] \leq \frac{6\sqrt{2}\sqrt{1 + R^2} \hat{L}m}{H_s k} \text{LPMetric}(w_0),
$$

(6)

where we take expectation on all the randomness up to the $k^{th}$ iteration.

**Proof.** By the setting of $R$, we have $\tilde{w}_k \in \mathcal{W}_R(0)$ and $||\tilde{w}_k - w_0|| \in (0, R]$. Applying Lemma 6, we have

$$
\text{LPMetric}(\tilde{w}_k) \leq \rho_{||\tilde{w}_k - w_0||}(\tilde{w}_k) \sqrt{1 + R^2}.
$$

(44)

Then, combining Lemma 5 and Eq. (5), we have

$$
\mathbb{E}[\text{LPMetric}(\tilde{w}_k)] \leq \mathbb{E}[\rho_{||\tilde{w}_k - w_0||}(\tilde{w}_k) \sqrt{1 + R^2}]
\leq \frac{2\sqrt{2}\sqrt{1 + R^2} \hat{L}m}{k} \mathbb{E}[||\tilde{w}_k - w_0||]
\leq \frac{6\sqrt{2}\sqrt{1 + R^2} \hat{L}m}{H_s k} ||w^* - w_0||
\leq \frac{6\sqrt{2}\sqrt{1 + R^2} \hat{L}m}{H_s k} \text{LPMetric}(w_0).
$$

(45)

□
The DRO problem in Eq. (7) is equivalent to the following problem:

\[
\min_{x,u,v,w,\mu,q,\gamma} \left\{ \gamma + \frac{\rho \mu_1}{n} + \frac{1}{n} \sum_{i=1}^{n} \mu_i f^*(q_i) \right\} \\
\text{s.t. } w + v - \frac{q}{n} - \gamma 1_n = 0_n, \\
\quad u_i = b_i a_i^T x, \quad i \in [n] \\
\quad \mu_1 = \mu_2 = \cdots = \mu_n, \\
\quad g(u_i) \leq w_i, \quad i \in [n] \\
\quad q_i \in \mu_i \text{dom}(f^*), \quad i \in [n] \\
\quad v_i \geq 0, \mu_i \geq 0, \quad i \in [n] \\
\quad x \in X.
\]

**Proof.** Since the context is clear, to simplify the notation, in the following we use \( P \) to denote \( P_{\rho,n} \). First, using Sion's minimax theorem, we have that

\[
\min_{x \in X} \sup_{p \in P} \sum_{i=1}^{n} p_i g_i(b_i a_i^T x) = \sup_{p \in P} \min_{x \in X} \sum_{i=1}^{n} p_i g_i(b_i a_i^T x).
\]

Introducing auxiliary variables \( w \) and \( u \), the problem is further equivalent to

\[
\sup_{p \in P} \min_{x \in X,w,u: u_i=b_i a_i^T x,i \in [n], g(u_i) \leq w_i,i \in [n]} p^T w \equiv \min_{x \in X,w,u: u_i=b_i a_i^T x,i \in [n], g(u_i) \leq w_i,i \in [n]} \sup_{p \in P} p^T w,
\]

where the last equivalence is by applying Sion’s minimax theorem again. Hence, we can conclude that

\[
\min_{x \in X} \sup_{p \in P} \sum_{i=1}^{n} p_i g_i(b_i a_i^T x) = \min_{x \in X,w,u: u_i=b_i a_i^T x,i \in [n], g(u_i) \leq w_i,i \in [n]} \sup_{p \in P} p^T w. \tag{46}
\]

For a fixed tuple \((x, w, u)\), using Lagrange multipliers to enforce the constraints from \( P \), we can further write

\[
\sup_{p \in P} p^T w = - \inf_{p \in P} -p^T w \\
= - \inf_{p \in \mathbb{R}^n} \left( -p^T w + \sup_{v \geq 0, \gamma \in \mathbb{R}, \mu \geq 0} \left( -p^T v + \gamma \left( \sum_{i=1}^{n} p_i - 1 \right) + \mu \left( D_f(p \| 1/n) - \frac{\rho}{n} \right) \right) \right) \\
= \sup_{p \in \mathbb{R}^n} \inf_{v \geq 0, \gamma \in \mathbb{R}, \mu \geq 0} \left( p^T w + p^T v - \gamma \left( \sum_{i=1}^{n} p_i - 1 \right) - \mu \left( D_f(p \| 1/n) - \frac{\rho}{n} \right) \right).
\]

Now, using the definitions of \( D_f \) and the convex conjugate of \( f \), we have

\[
D_f(p \| 1/n) = \sum_{i=1}^{n} \frac{1}{n} f(np_i) = \sum_{i=1}^{n} \frac{1}{n} \sup_{q_i \in \text{dom}(f^*)} (np_i q_i - f^*(q_i)). \tag{47}
\]
where the last line is by strong duality. Thus, combining with Eq. (46), we conclude that the original DRO problem with $f$-divergence based ambiguity set is equivalent to the following problem:

$$
\min_{x,u,v,w,\mu,q} \max_{p \in \mathbb{R}^n} \left\{ \gamma + \frac{\mu_1}{n} + \frac{1}{n} \sum_{i=1}^{n} \mu_if^*(\frac{q_i}{\mu_i}) + p^T(w + v - \frac{q}{n} - \gamma 1_n) \right\}
$$

s.t. $u_i = b_i^T a_i^T x$, $i \in [n]$
$\mu_1 = \mu_2 = \cdots = \mu_n$, $g(u_i) \leq w_i$, $i \in [n]$,
$q_i \in \mu_i \text{ dom}(f^*)$, $i \in [n]$,
$v_i \geq 0$, $\mu_i \geq 0$, $i \in [n]$,
$x \in \mathcal{X}$.

Finally, noticing that the maximization problem over $p \in \mathbb{R}^n$ enforces the equality constraint $w + v - \frac{q}{n} - \gamma 1_n = 0$.
0_n, we obtain
\[
\begin{align*}
\min_{x,u,v,q,\gamma} & \quad \left\{ \gamma + \frac{\rho \mu_1}{n} + \frac{1}{n} \sum_{i=1}^{n} \mu_i f^\star \left( \frac{q_i}{\mu_i} \right) \right\} \\
\text{s.t.} & \quad w + v - \frac{q}{n} - \gamma 1_n = 0_n, \\
& \quad u_i = b_i a_i^T x, \quad i \in [n] \\
& \quad \mu_1 = \mu_2 = \cdots = \mu_n, \\
& \quad g(u_i) \leq w_i, \quad i \in [n] \\
& \quad q_i \in \mu_i \text{ dom}(f^\star), \quad i \in [n] \\
& \quad v_i \geq 0, \mu_i \geq 0, \quad i \in [n] \\
& \quad x \in \mathcal{X},
\end{align*}
\]

as claimed.

Example: Conditional Value at Risk (CVaR) with Hinge Loss. As a specific example of an application of Theorem 2, we consider CVaR at level \( \alpha \in (0, 1) \), which leads to the optimization problem:
\[
\begin{align*}
\min_{x \in \mathbb{R}^d} & \quad \sup_{p \geq 0, \frac{1}{\alpha n} \geq \frac{1}{p_i} \leq (i \in [d])} \sum_{i=1}^{n} p_i g_i(x), \\
\end{align*}
\]
where \( g_i(x) = \max\{0, 1 - b_i a_i^T x\} \) is the hinge loss. Here the ambiguity set constraint reduces to simple linear constraints \( p_i \leq \frac{1}{\alpha n} \), so the reformulation based on the convex perspective function can be avoided altogether and replaced by simple Lagrange multipliers for this linear constraint. In particular, in the proof of Theorem 2 we can write
\[
\begin{align*}
\sup_{p \in \mathcal{P}} p^T w &= \sup_{p \in \mathbb{R}^n} \inf_{v \geq 0, \gamma \in \mathbb{R}, \mu \geq 0} \left( p^T w + p^T v - \gamma \left( \sum_{i=1}^{n} p_i - 1 \right) - \sum_{i=1}^{n} \mu_i \left( p_i - \frac{1}{\alpha n} \right) \right) \\
&= \sup_{p \in \mathbb{R}^n} \inf_{v \geq 0, \gamma \in \mathbb{R}, \mu \geq 0} \left( \gamma + p^T (w + v - \gamma 1_n - \mu) + \frac{1}{\alpha n} \mu^T 1_n \right) \\
&= \inf_{v \geq 0, \gamma \in \mathbb{R}, \mu \geq 0} \sup_{p \in \mathbb{R}^n} \left( \gamma + p^T (w + v - \gamma 1_n - \mu) + \frac{1}{\alpha n} \mu^T 1_n \right).
\end{align*}
\]
Following the argument from the proof of Theorem 2, the problem reduces to
\[
\begin{align*}
\min_{x,u,v,w,\gamma} & \quad \left\{ \gamma + \frac{1}{\alpha n} \mu^T 1_n \right\} \\
\text{s.t.} & \quad w + v - \gamma 1_n - \mu = 0_n, \\
& \quad u_i = b_i a_i^T x, \quad i \in [n], \\
& \quad w_i \geq 0, \quad w_i \geq 1 - u_i, \quad i \in [n], \\
& \quad v_i \geq 0, \quad \mu_i \geq 0, \quad i \in [n],
\end{align*}
\]
which is a linear program. To write it in the standard form, we further introduce slack variables \( s \in \mathbb{R}^n, s \geq 0 \), to replace inequality constraints \( w_i \geq 1 - u_i \) by \( s_i - u_i - w_i = -1 \). For implementation purposes, we define \( \mathcal{X} \) to be the set of simple non-negativity constraints \( (w_i \geq 0, s_i \geq 0, v_i \geq 0, \mu_i \geq 0, \forall i \in [n]) \) from Eq. (49). The
Theorem 3. A similar result for the special case of a logistic loss function can be found in Shafieezadeh Abadeh et al. [2015].

Proof. For completeness, we first prove the following auxiliary lemma that is subsequently used in the proof of B.2 DRO with Wasserstein Metric-based Ambiguity Set.

Lemma 7. Let \((a', b') \in \mathbb{R}^d \times \{1, -1\}\) be a given pair of data sample and label. Then, for every \(\lambda > 0\), we have

\[
\sup_{a \in \mathbb{R}^d} g(b' a^T w) - \lambda\|a - a'\| = \begin{cases} g(b' a^T w), & \text{if } \|w\|_* \leq \lambda/M, \\ +\infty, & \text{otherwise} \end{cases}
\]

(50)

Proof. Since \(g\) is assumed to be proper, convex, and lower semicontinuous, by the Fenchel-Moreau theorem, it is equal to its biconjugate. Applying this property, we have

\[
\sup_{a \in \mathbb{R}^d} \{g(b' a^T w) - \lambda\|a - a'\|\} = \sup_{a \in \mathbb{R}^d} \{\theta b' a^T w - g^*(\theta) - \lambda\|a - a'\|\}
\]

\[
= \sup_{a \in \mathbb{R}^d, \theta \in \text{dom}(g^*)} \{\theta b' (a - a')^T w + \theta b'(a')^T w - g^*(\theta) - \lambda\|a - a'\|\}
\]

\[
= \sup_{a \in \mathbb{R}^d, \theta \in \text{dom}(g^*)} \{g(b' a^T w) - \lambda\|a - a'\|\}.
\]
Applying the change of variable \( v := a - a' \), we further have

\[
\sup_{a \in \mathbb{R}^d} \{ g(b' a^T w) - \lambda \|a - a'\| \} \\
= \sup_{w \in \mathbb{R}^d, \theta \in \text{dom}(g^*)} \{ \theta b' v^T w + \theta b'(a')^T w - g^*(\theta) - \lambda \|v\| \} \\
= \sup_{\theta \in \text{dom}(g^*)} \{ 1_{\{\|\theta b' w\|_* \leq \lambda\}} + \theta b'(a')^T w - g^*(\theta) \} \\
= \begin{cases} 
  g(b'(a')^T w), & \text{if } \sup_{\theta \in \text{dom}(g^*)} \|\theta b' w\|_* \leq \lambda \\
  +\infty, & \text{otherwise}
\end{cases}
\]

where the second equality is by the convex conjugate of a norm \( \| \cdot \| \) being equal to the convex indicator of the unit ball w.r.t. the dual norm \( \| \cdot \|_* \). Finally, it remains to use that, by assumption, \( \sup_{\theta \in \text{dom}(g^*)} |\theta| = M \).

**Theorem 3.** The optimization problem from Eq. (9) is equivalent to:

\[
\min_{w, \lambda, u, v, s, t} \rho \lambda + \frac{1}{n} \sum_{i=1}^n s_i \\
\text{s.t. } u_i = b_i a_i^T w, \quad i \in [n] \\
v_i = -u_i, \quad i \in [n] \\
t_i = 2\kappa \lambda + s_i, \quad i \in [n] \\
g(u_i) \leq s_i, \quad i \in [n] \\
g(v_i) \leq t_i, \quad i \in [n] \\
\|w\|_* \leq \lambda/M.
\]

**Proof.** Let \( z = (a, b) \in \Theta := \mathbb{R}^d \times \{1, -1\} \) and let \( h_w(z) := g(ba^T w) \). Then by the definition of the Wasserstein metric,

\[
\sup_{P \in \mathcal{P}_{\rho, \kappa}} \mathbb{E}_P[g(ba^T w)] = \begin{cases} 
\sup_{\pi \in \Pi(P, \mathcal{P}_n)} \int_{\Theta} h_w(z) \pi(dz, \Theta) \\
\text{s.t. } \int_{\Theta \times \Theta} \zeta(z, z') \pi(dz, dz') \leq \rho.
\end{cases}
\]

Assume that the conditional distribution of \( z \) given \( z' = (a_i, b_i) \) is \( \mathcal{P}^i \), for all \( i \in [n] \). Then, based on the definition of \( \mathcal{P}_n = \frac{1}{n} \sum_{i=1}^n \delta_{(a_i, b_i)} \), we have

\[
\pi(dz, dz') = \frac{1}{n} \sum_{i=1}^n \delta_{(a_i, b_i)} \mathcal{P}^i(dz).
\]

As a result, the problem from Eq. (51) is equivalent to

\[
\sup_{P \in \mathcal{P}_{\rho, \kappa}} \mathbb{E}_P[g(ba^T w)] = \begin{cases} 
\sup_{\mathcal{P}_n} \frac{1}{n} \sum_{i=1}^n \int_{\Theta} h_w(z) \mathcal{P}^i(dz) \\
\text{s.t. } \frac{1}{n} \sum_{i=1}^n \int_{\Theta} \zeta(z, z') \mathcal{P}^i(dz) \leq \rho \\
\int_{\Theta} \mathcal{P}^i(dz) = 1.
\end{cases}
\]

Then substituting in \( z = (a, b) \), using that the domain of \( g \) is \( \{1, -1\} \), and decomposing \( \mathcal{P}^i \) into unnormalized
measures $\mathbb{P}_\pm(\mathbf{da}) = \mathbb{P}^\pm(\mathbf{da}, \{b = \pm 1\})$ supported on $\mathbb{R}^d$, the RHS of Eq. (53) can be simplified to

$$\sup_{\mathbb{P}_\pm} \frac{1}{n} \sum_{i=1}^{n} \int_{\mathbb{R}^d} (h_w(\mathbf{a}, 1)\mathbb{P}_1^i(\mathbf{da}) + h_w(\mathbf{a}, -1)\mathbb{P}_-^i(\mathbf{da}))$$

s.t. $\frac{1}{n} \sum_{i=1}^{n} \int_{\mathbb{R}^d} (\zeta((\mathbf{a}, 1), (\mathbf{a}_i, \mathbf{b}_i))\mathbb{P}_1^i(\mathbf{da}) + \zeta((\mathbf{a}, -1), (\mathbf{a}_i, \mathbf{b}_i))\mathbb{P}_-^i(\mathbf{da})) \leq \rho$

$$\int_{\mathbb{R}^d} (\mathbb{P}_1^i(\mathbf{da}) + \mathbb{P}_-^i(\mathbf{da})) = 1.$$
Finally, the resulting reformulation is
\[
\min_{\mathbf{w}, \lambda, \mathbf{s}} \rho \lambda + \frac{1}{n} \sum_{i=1}^{n} s_i \\
\text{s.t. } g(b_i \mathbf{a}_i^T \mathbf{w}) \leq s_i, \quad i \in [n], \\
g(-b_i \mathbf{a}_i^T \mathbf{w}) - 2\lambda \kappa \leq s_i, \quad i \in [n], \\
\sup_{\theta \in \text{dom}(g^*)} \|\theta \mathbf{w}\|_* \leq \lambda.
\]

Finally, recalling that, by assumption, \(\sup_{\theta \in \text{dom}(g^*)} |\theta| = M\), it follows that the constraint \(\sup_{\theta \in \text{dom}(g^*)} \|\theta \mathbf{w}\|_* \leq \lambda\) is equivalent to \(\|\mathbf{w}\|_* \leq \lambda/M\). Meanwhile, by introducing \(u_i = b_i \mathbf{a}_i^T \mathbf{w}, v_i = -u_i(i \in [n])\) and \(s_i, t_i(i \in [n])\), we obtain Theorem 3.

\[C\] Experiment Details

In the experiments, we consider solving the DRO problem with Wasserstein metric-based ambiguity set and we define \(\|\cdot\| = \|\cdot\|_1\), so \(\|\cdot\|_* = \|\cdot\|_\infty\). We further introduce standard auxiliary variables and reformulate the optimization problem in Theorem 3 into a standard form LP where the feasible region is simply the non-negative orthant. The following lemma fully describes the equivalent standard form LP problem.

Lemma 8. The optimization problem from Eq. (9) is equivalent to the following standard form LP:

\[
\min_{\mathbf{s}, \mathbf{u}, \mathbf{v}, \mathbf{t}, \mathbf{w}^+, \mathbf{w}^-, \lambda^+, \lambda^-, \mathbf{s}^{(1)}, \mathbf{s}^{(2)}} \rho (\lambda^+ - \lambda^-) + \frac{1}{n} \sum_{i=1}^{n} s_i \\
\text{s.t. } -s_i + u_i - 2\kappa \lambda^+ + 2\kappa \lambda^- = 0, \quad i \in [n], \\
s_i - v_i + b_i \mathbf{a}_i^T (\mathbf{w}^+ - \mathbf{w}^-) = 1, \quad i \in [n], \\
s_i + u_i - v_i - t_i = 2, \quad i \in [n], \\
w_j^+ - w_j^- + \lambda^+ - \lambda^- - s_j^{(1)} = 0, \quad j \in [d], \\
w_j^+ - w_j^- - \lambda^+ + \lambda^- + s_j^{(2)} = 0, \quad j \in [d], \\
\mathbf{s}, \mathbf{u}, \mathbf{v}, \mathbf{t}, \mathbf{w}^+, \mathbf{w}^-, \lambda^+, \lambda^-, \mathbf{s}^{(1)}, \mathbf{s}^{(2)} \geq 0, \\
\mathbf{s}, \mathbf{u}, \mathbf{v}, \mathbf{t} \in \mathbb{R}^n; \mathbf{w}^+, \mathbf{w}^-, \mathbf{s}^{(1)}, \mathbf{s}^{(2)} \in \mathbb{R}^d; \text{and } \lambda^+, \lambda^- \in \mathbb{R}.
\]

For completeness, we include the standard matrix-vector form used in our experiments. Based on the above lemma, we further rewrite the formulation in the form of \(\min \mathbf{c}^T \mathbf{x}\) subject to \(\mathbf{A} \mathbf{x} = \mathbf{d}\) and \(\mathbf{x} \geq 0\) where \(\mathbf{A}\) is the constraint matrix. Note that this corresponds to (GLP) where \(r(\mathbf{x}) = 0\) and \(\lambda\) is the non-negative orthant. In particular, we have

\[
\mathbf{A} = \begin{bmatrix}
-I_{n \times n} & I_{n \times n} & O_{n \times n} & O_{n \times d} & O_{n \times d} & O_{n \times d} & O_{n \times d} & -2\kappa \mathbf{1}_n & +2\kappa \mathbf{1}_n \\
I_{n \times n} & O_{n \times n} & -I_{n \times n} & O_{n \times n} & b \odot \mathbf{X} & -b \odot \mathbf{X} & O_{n \times d} & O_{n \times d} & \mathbf{0}_n & \mathbf{0}_n \\
I_{n \times n} & I_{n \times n} & -I_{n \times n} & I_{n \times n} & -O_{n \times d} & -I_{d \times d} & O_{n \times d} & O_{n \times d} & \mathbf{0}_n & \mathbf{0}_n \\
O_{d \times n} & O_{d \times n} & O_{d \times n} & O_{d \times n} & I_{d \times d} & -I_{d \times d} & -I_{d \times d} & O_{d \times d} & +\mathbf{1}_d & -\mathbf{1}_d \\
O_{d \times n} & O_{d \times n} & O_{d \times n} & O_{d \times n} & I_{d \times d} & -I_{d \times d} & O_{d \times d} & I_{d \times d} & -\mathbf{1}_d & +\mathbf{1}_d \\
\end{bmatrix},
\]

\[
\mathbf{d}^T = \begin{bmatrix}

\end{bmatrix},
\]

and
\[
\mathbf{c}^T = \begin{bmatrix}
\frac{1}{n} 1_n^T & \mathbf{0}_n^T & \mathbf{0}_n^T & \mathbf{0}_n^T & \mathbf{0}_n^T & \mathbf{0}_n^T & \mathbf{0}_d^T & \mathbf{0}_d^T & \mathbf{0}_d^T & +\rho & -\rho
\end{bmatrix}.
\]
where $I_{k\times k}$ denotes a $k$-dimensional identity matrix, $O_{k\times k}$ denotes a $k$-dimensional zero matrix, $1_k$ denotes a $k$-dimensional one-vector, and $0_k$ denotes a $k$-dimensional zero-vector. We use $X$ to denote the feature matrix and $b$ to denote the label vector, where $X = [a_1, a_2, ..., a_n]^T$ and $a_i$ for $i \in [n]$ are the feature vectors. We overload $\odot$ to denote the element-wise multiplication between a vector and each row of a matrix (i.e. $b \odot X = [b_1 a_1, b_2 a_2, ..., b_n a_n]^T$). Note that the constraint matrix $A$ has size $O(n + d)$ by $O(n + d)$, and has $O(n + d + \text{nnz}(X))$ nonzero elements.
