Ramanujan–type systems of nonlinear ODEs for $\Gamma_0(2)$ and $\Gamma_0(3)$

Younes Nikdelan

Abstract

This paper aims to introduce two systems of nonlinear ordinary differential equations whose solution components generate the graded algebra of quasi-modular forms on Hecke congruence subgroups $\Gamma_0(2)$ and $\Gamma_0(3)$. Using these systems, we provide the generated graded algebras with an $\mathfrak{sl}_2(\mathbb{C})$-module structure. As applications, we introduce Ramanujan-type tau functions for $\Gamma_0(2)$ and $\Gamma_0(3)$, and obtain some interesting and non-trivial recurrence and congruence relations.

1 Introduction

Besides the classical works of Darboux-Halphen \cite{Dar78, Hal81} and Ramanujan \cite{Ram16}, we can find other works in the literature which are dedicated to the study of systems of ordinary differential equations (ODEs) whose solution components can be written in terms of quasi-modular forms, see for instance \cite{Ohy96, Zud03, Mai11, DGMS13}. What makes the results we present here distinct from the other studies are the origin of the systems which are considered here, and the elaboration of the similarities in comparison with the classical case of Ramanujan system. Indeed, in a geometric framework, the considered systems can be seen as vector fields, known as modular vector fields, in certain enhanced moduli spaces arising from the Dwork family. In general, solution components of modular vector fields generate the space of Calabi-Yau modular forms, which are interesting objects to study, see \cite{Mov16, Nik19}. In lower dimensions 1 and 2, which are studied in this paper, these spaces of Calabi-Yau modular forms coincide with the spaces of classical quasi-modular forms on $\Gamma_0(3)$ and $\Gamma_0(2)$, respectively. Hence, looking at the modular vector fields from the viewpoint of this paper can reveal new ways of proceeding with the theory of Calabi-Yau modular forms.

Srinivasa Ramanujan in 1916, while working on arithmetic properties and the relationships between divisor, Gamma and Riemann zeta functions \cite{Ram16}, encountered the system of nonlinear ODEs:

\[
\begin{align*}
\text{Ra} : & \quad t'_1 = \frac{1}{12} (t_1^2 - t_2), \\
& \quad t'_2 = \frac{1}{12} (t_1 t_2 - t_3), \\
& \quad t'_3 = \frac{1}{12} (t_1 t_3 - t_2^2).
\end{align*}
\]

(1.1)

Here, and throughout the paper, "\(\ast\)" refers to the derivation:

\[
\ast := \frac{\partial}{\partial q} = \frac{1}{2\pi i} \frac{d}{d\tau}, \text{ with } q = e^{2\pi i \tau}, \tau \in \mathbb{C} \text{ and } \Im(\tau) > 0.
\]

Keywords: Quasi-modular forms, Ramanujan system, modular vector field, Ramanujan tau function.

1Max Planck Institute for Mathematics (MPIM), Vivatsgasse 7, 53111, Bonn, Germany. e-mail: nikdelan@mpim-bonn.mpg.de

2Departamento de Análise Matemática, Instituto de Matemática e Estatística (IME), Universidade do Estado do Rio de Janeiro (UERJ), Rua São Francisco Xavier, 524, Rio de Janeiro, Brazil / CEP: 20550-900. e-mail: younes.nikdelan@ime.uerj.br
He showed that the triple \((E_2, E_4, E_6)\) of the Eisenstein series forms a particular solution of the system \(Ra\), where for \(j = 1, 2, 3\):

\[
E_{2j}(q) = 1 + b_j \sum_{k=1}^{\infty} \sigma_{2j-1}(k)q^k \text{ with } (b_1, b_2, b_3) = (-24, 240, 504),
\]

\[
\sigma_j(k) = \sum_{d \mid k} d^j.
\]

The system of equations (1.1) are known as the Ramanujan relations between Eisenstein series, and from now on we call them the Ramanujan system. We recall the following known facts.

• \(E_4\) and \(E_6\) are modular forms and \(E_2\) is a quasi-modular form for \(SL_2(\mathbb{Z})\).

• If we denote the space of the full modular forms and full quasi-modular forms, respectively, by \(M(SL_2(\mathbb{Z}))\) and \(\tilde{M}(SL_2(\mathbb{Z}))\), then \(M(SL_2(\mathbb{Z})) = \mathbb{C}[E_4, E_6]\) and \(\tilde{M}(SL_2(\mathbb{Z})) = \mathbb{C}[E_2, E_4, E_6]\).

• If we consider the vector field representation of the Ramanujan system, i.e. \(Ra = \frac{1}{12}(t_1^2 - t_2)\frac{\partial}{\partial t_1} + \frac{1}{3}(t_1 t_2 - t_3)\frac{\partial}{\partial t_2} + \frac{1}{2}(t_1 t_3 - t_2^2)\frac{\partial}{\partial t_3}\), which is known as Ramanujan vector field as well, then \(Ra\) along with the vector fields \(H := 2t_1\frac{\partial}{\partial t_1} + 4t_2\frac{\partial}{\partial t_2} + 6t_3\frac{\partial}{\partial t_3}\) and \(F := -12\frac{\partial}{\partial t_1}\) forms a copy of the Lie algebra \(sl_2(\mathbb{C})\).

• The modular discriminant

\[
\Delta := \frac{1}{1728}(E_4^3 - E_6^2) = \eta^{24}(q),
\]

is a cusp form of weight 12 for \(SL_2(\mathbb{Z})\) that satisfies (one can check this directly or using (1.1)):

\[
\Delta' = E_2\Delta \quad \text{(which is equivalent to } \eta' = \frac{1}{24}E_2 \eta),
\]

where \(\eta\) is the classical eta function:

\[
\eta(q) = q^{\frac{1}{24}} \prod_{k=1}^{\infty} (1 - q^k).
\]

The main objective of this paper is to establish analogous results for the congruence subgroups \(\Gamma_0(2)\) and \(\Gamma_0(3)\) of \(SL_2(\mathbb{Z})\). They are stated in the following theorems. In what follows, for any non-negative integer \(k\), we denote by \(M_k(\Gamma)\) and \(\tilde{M}_k(\Gamma)\), respectively, the space of modular forms and the space of quasi-modular forms of weight \(k\) for a subgroup \(\Gamma \subset SL_2(\mathbb{Z})\). Moreover, \(M(\Gamma) := \bigoplus_{k=0}^{\infty} M_k(\Gamma)\) and \(\tilde{M}(\Gamma) := \bigoplus_{k=0}^{\infty} \tilde{M}_k(\Gamma)\) stand for the graded algebra of modular forms and quasi-modular forms, respectively.

**Theorem 1.1.** Consider the following system of ODEs:

\[
R_2: \begin{cases}
t'_1 = \frac{1}{2}(t_1^2 - t_2^2) \\
t'_2 = \frac{1}{3}(t_1 t_2 - t_3) \\
t'_3 = \frac{1}{2}(t_1 t_3 - t_2^2)
\end{cases}
\]
Theorem 1.2. Consider the following system of ODEs:

$$
\begin{align*}
R_1 : & \quad \begin{cases} 
t'_1 &= \frac{1}{6}(t^3_1 - t^2_2) \\
t'_2 &= \frac{1}{3}(t_1t_2 - t^2_2 + 54t_3) \\
t'_3 &= \frac{3}{3}t_1t_3 + \frac{2}{3}tt_3 + 9t_4 \\
t'_4 &= t_1t_4 + t_2t_4 
\end{cases}
\end{align*}
$$

in which the polynomial relation \( t^3_3 - t_2t_4 = 0 \) holds.

1. A particular solution of \( R_1 \) is given as follows:

$$
\begin{align*}
t_1 &= \mathcal{P}_3(q) := \frac{1}{4}(E_2(q) + 3E_2(q^3)), \\
t_2 &= \mathcal{Q}_3(q) := \frac{1}{2}(3E_2(q^3) - E_2(q)), \\
t_3 &= \mathcal{R}_3(q) := \eta^6(q^3) + 9\eta^2(q^3)\eta^4(q^3), \\
t_4 &= \mathcal{S}_3(q) := \left(\frac{\eta^4(q^3)}{\eta(q)}\right)^2,
\end{align*}
$$

with \( \mathcal{Q}_3 \in \mathcal{M}_2(\Gamma_0(3)), \ \mathcal{R}_3 \in \mathcal{M}_4(\Gamma_0(3)), \ \mathcal{S}_3 \in \mathcal{M}_6(\Gamma_0(3)) \) and \( \mathcal{P}_3 \in \tilde{\mathcal{M}}_2(\Gamma_0(3)) \).

Moreover, if we set

$$
\Delta_3 := \eta^6(q)\eta^6(q^3),
$$

then it is a cusp form of weigh 6 for \( \Gamma_0(3) \), \( \Delta_3 = \mathcal{Q}_3\mathcal{R}_3 - 27\mathcal{S}_3 \) and

$$
\Delta'_3 = \mathcal{P}_3\Delta_3.
$$

2. If we consider \( \mathcal{P}_3, \mathcal{Q}_3, \mathcal{R}_3, \mathcal{S}_3 \) as free parameters and let \( \mathcal{I} \) and \( \tilde{\mathcal{I}} \) to be the ideals generated by \( \mathcal{R}_3^2 - \mathcal{Q}_3\mathcal{S}_3 \) in \( \mathbb{C}[\mathcal{Q}_3, \mathcal{R}_3, \mathcal{S}_3] \) and \( \mathbb{C}[\mathcal{P}_3, \mathcal{Q}_3, \mathcal{R}_3, \mathcal{S}_3] \), respectively, then:

$$
\begin{align*}
\mathcal{M}(\Gamma_0(3)) &\simeq \frac{\mathbb{C}[\mathcal{Q}_3, \mathcal{R}_3, \mathcal{S}_3]}{\mathcal{I}}, \\
\tilde{\mathcal{M}}(\Gamma_0(3)) &\simeq \frac{\mathbb{C}[\mathcal{P}_3, \mathcal{Q}_3, \mathcal{R}_3, \mathcal{S}_3]}{\tilde{\mathcal{I}}}.
\end{align*}
$$
3. The vector field \( R_1 = \frac{1}{6} (t_1^2 - t_2^2) \frac{\partial}{\partial t_1} + \frac{1}{3} (t_1 t_2 - t_2 t_1 + 5 t_3) \frac{\partial}{\partial t_2} + (\frac{2}{3} t_1 t_3 + \frac{1}{3} t_2 t_3 + 9 t_4) \frac{\partial}{\partial t_3} + (t_1 t_4 + t_2^2) \frac{\partial}{\partial t_4} \) along with the vector fields \( H_1 := 2 t_1 \frac{\partial}{\partial t_1} + 2 t_2 \frac{\partial}{\partial t_2} + 4 t_3 \frac{\partial}{\partial t_3} + 6 t_4 \frac{\partial}{\partial t_4} \) and \( F_1 := -6 \frac{\partial}{\partial t_1} \) is isomorphic to the Lie algebra \( \mathfrak{s}_2(\mathbb{C}) \).

We call the systems \( (1.7) \) and \( (1.11) \) the Ramanujan-type systems for \( \Gamma_0(2) \) and \( \Gamma_0(3) \), respectively.

Part 3 of Theorem 1.1 and Theorem 1.2 provides the spaces \( \tilde{M}(\Gamma_0(2)) \) and \( \tilde{M}(\Gamma_0(3)) \) with an \( \mathfrak{s}_2(\mathbb{C}) \)-module structure, respectively. This property, in general, is important on the one hand to assign correct weights to the Calabi-Yau modular forms, see \[Nik20, Nik19\], and on the other hand to study the dynamics of modular vector fields, see \[Gui07, GR12\].

Modular forms, in particular their Fourier coefficients, play an important role in number theory. As applications, in Section 7 we use the modular forms and the relations given in the above theorems to find some interesting and non-trivial recurrence formulas and congruence relations.

The author is aware that some of the proofs and details stated in this paper are maybe standard and known facts for specialists who work on modular forms. Nevertheless, since he wishes to reach a wider class of readers and researchers in the other areas such as Differential Equations and Holomorphic Dynamical Systems, he decided to include a section of preliminaries and basic facts, and also write the proofs in a more detailed form.

The structure of the present work is as follows. In Section 2 we state the preliminaries and basic facts for non-experts in modular form theory, so the experts in this subject can simply skip this section. In Section 3 we give the origin of Ramanujan type systems \( (1.7) \) and \( (1.11) \). Section 4 and Section 5, respectively, are devoted to the proofs of Theorem 1.1 and Theorem 1.2. In Section 6 we find some more analogies for \( \tilde{M}(\Gamma_0(2)) \) and \( \tilde{M}(\Gamma_0(3)) \) in comparison to \( \tilde{M}(\text{SL}_2(\mathbb{Z})) \). Section 7 comes up with some applications, where we introduce Ramanujan-type tau functions for \( \Gamma_0(2) \) and \( \Gamma_0(3) \) and give some congruence and recurrence relations.

Acknowledgment. Some parts of Section 7 are results of valuable discussions that the author had during his stay at Max Planck Institute for Mathematics (MPIM) in Bonn with Pieter Moree. So, he would like to express his sincere gratitude to him and he also wishes to thank MPIM and its staff for preparing such an excellent ambiance for doing mathematical work.

## 2 Preliminaries and basic facts

In order to make this paper self contained we start by recalling some basic and useful definitions, terminologies and known facts, which can be found in any standard reference on modular forms, such as \[BHGZ, CS17, DS05\].

Throughout \( \Gamma \) refers to a subgroup of \( \text{SL}_2(\mathbb{Z}) \) of the finite index which we denote by \([\text{SL}_2(\mathbb{Z}) : \Gamma]\). Any \( \Gamma \) acts from the left on \( \mathbb{H}^* := \mathbb{H} \cup \mathbb{P}^1_{\mathbb{Q}} \) as follows:

\[
\gamma \cdot \tau = \frac{a \tau + b}{c \tau + d} \quad \forall \tau \in \mathbb{H}^* \quad \text{and} \quad \forall \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma,
\]

where \( \mathbb{H} := \{ \tau \in \mathbb{C} : \text{Im}(\tau) > 0 \} \) is the upper half-plane and \( \mathbb{P}^1_{\mathbb{Q}} := \mathbb{Q} \cup \{ \infty \} \). Note that \( \gamma \cdot \infty = \frac{a}{c} \), and \( \gamma \cdot \tau = \infty \) if \( c \tau + d = 0 \). It is well known that \( X(\Gamma) := \Gamma \backslash \mathbb{H}^* \) is a compact Riemann surface. We denote by \( \mathcal{C}(\Gamma) := \Gamma \backslash \mathbb{P}^1_{\mathbb{Q}} \) the set of the cusps of \( \Gamma \), by \( \overline{\Gamma} \) the image
of $\Gamma$ in $\text{PSL}_2(\mathbb{Z}) := \text{SL}_2(\mathbb{Z})/\{\pm 1\}$, and by $d\Gamma := |\text{PSL}_2(\mathbb{Z}) : \Gamma|$ the index of $\Gamma$ in $\text{PSL}_2(\mathbb{Z})$. Evidently, if $\Gamma$ is an even subgroup, i.e. $-1 \in \Gamma$, then $d\Gamma = |\text{SL}_2(\mathbb{Z}) : \Gamma|' = \frac{d}{\eta}$, and $\eta = e^{2\pi i \tau}$, and if $\Gamma$ is an odd subgroup, i.e. $-1 \notin \Gamma$, then $d\Gamma = |\text{SL}_2(\mathbb{Z}) : \Gamma|/2$.

The width $h$ of $\Gamma$ at the cusp $[\infty]$ is the least $h \in \mathbb{N}$ for which at least one of $\left( \begin{smallmatrix} 1 & h \\ 0 & 1 \end{smallmatrix} \right)$ and $\left( \begin{smallmatrix} -1 & 0 \\ b & -1 \end{smallmatrix} \right)$ belongs to $\Gamma$. If $\Gamma$ contains a cusp $P \in \mathbb{C}(\Gamma)$ different from $[\infty]$, then there exists a $\gamma \in \left( \begin{smallmatrix} a & b \\ c & d \end{smallmatrix} \right) \in \text{SL}_2(\mathbb{Z})$ such that $[\gamma \cdot \infty] = P$, and the width $h$ of $\Gamma$ at $\Gamma$ is defined as the width of $\gamma^{-1}\Gamma\gamma$ at the cusp $[\infty]$ (which of course will be independent of the choice of $\gamma$).

For any integer $k$, by a weakly modular function of weight $k$ on $\Gamma$ we mean a meromorphic function $f : \mathbb{H} \to \mathbb{C}$ that satisfies the following modularity property:

\begin{equation}
(f|k\gamma)(\tau) = f(\tau), \quad \forall \gamma = \left( \begin{smallmatrix} a & b \\ c & d \end{smallmatrix} \right) \in \Gamma,
\end{equation}

in which $(f|k\gamma)(\tau) := (c\tau + d)^{-k}f(\gamma \cdot \tau)$. Let $f$ be a weakly modular function of weight $k$ on $\Gamma$ and set $q_h := e^{2\pi i \tau}/h$, where $h$ is the width of $\Gamma$ at $\infty$ and $\tau \in \mathbb{H}$. Then there exists a meromorphic function $\tilde{f}$ on the punctured disc $\mathbb{D}^* := \{z \in \mathbb{C} : 0 < |z| < 1\}$ such that either $f(\tau) = \tilde{f}(q_h)$ or $f(\tau) = q_h^{1/2}\tilde{f}(q_h)$, for all $\tau \in \mathbb{H}$. Hence, if we consider the Laurent expansion of $\tilde{f}$ in $0$, then we get $f(\tau) = \sum_{n=-\infty}^{+\infty} a_n(f)q_h^n$, or $f(\tau) = \sum_{n=-\infty}^{+\infty} a_n(f)q_h^{n+1/2}$, where $a_n(f) \in \mathbb{C}$ for all $n \in \mathbb{Z}$. This expansion is known as the $q$-expansion of $f$ at $\infty$, and sometimes, by abuse of notation, we write $f(q_h)$ instead $f(\tau)$. We say that $f$ is meromorphic at $\infty$ if there exists $N \in \mathbb{Z}$ such that $a_N(f) \neq 0$ and $a_n(f) = 0$ for all $n < N$. The integer $N$ is known as the order of $f$ at the cusp $[\infty]$ on $\Gamma$, and we write $\text{ord}_\infty(f; \Gamma) = N$. Indeed, $f$ is holomorphic at the cusp $[\infty]$ if $\text{ord}_\infty(f; \Gamma) \geq 0$ and $f$ vanishes at $[\infty]$ if $\text{ord}_\infty(f; \Gamma) > 0$. If $P \in \mathbb{C}(\Gamma)$ is any other cusp of $\Gamma$, then the order of $f$ at the cusp $P$ on $\Gamma$, denoted by $\text{ord}_P(f; \Gamma)$, is defined as $\text{ord}_P(f; \Gamma) := \text{ord}_\infty(f|k\gamma; \gamma^{-1}\Gamma\gamma)$, where $\gamma \in \text{SL}_2(\mathbb{Z})$ is the same as above such that $[\gamma \cdot \infty] = P$ (one can see that this definition is independent of the choice of $\gamma$). Thus, $f$ is meromorphic at $P$ if $\text{ord}_P(f; \Gamma) \geq 0$, and $f$ vanishes at $P$ if $\text{ord}_P(f; \Gamma) > 0$. Indeed, if $f$ is holomorphic at $P$, then one can define $f(P) := (f|k\gamma)(\infty)$ provided $k$ is even, but for odd $k$’s $f(P)$ can be defined up to sign.

A weakly modular form of weight $k$ on $\Gamma$ is a weakly modular function $f : \mathbb{H} \to \mathbb{C}$ of weight $k$ on $\Gamma$ that is holomorphic in $\mathbb{H}$. Moreover, if $f$ is holomorphic in the all cusps of $\Gamma$, then we call it a modular form of weight $k$ on $\Gamma$. A modular form $f$ of weight $k$ on $\Gamma$ is called a cusp form of weight $k$ on $\Gamma$ if it vanishes in all cusps of $\Gamma$. We denote the space of weakly modular functions, weakly modular forms, modular forms and cusp forms of weight $k$ on $\Gamma$, respectively, by $\mathcal{M}_k^*(\Gamma)$, $\mathcal{M}_k^0(\Gamma)$, $\mathcal{M}_k(\Gamma)$ and $\mathcal{S}_k(\Gamma)$, which are $\mathbb{C}$-vector spaces.

We state below the valence formula (for more details see [CS17, §5.6.2 and Theorem 5.6.11]). Here $e_\Gamma(\tau)$ refers to the order of the stabilizer of $\tau$ in $\Gamma$. If $e_\Gamma(\tau) > 1$, then $\tau$ is called an elliptic point of $\Gamma$ (or $X(\Gamma)$). In fact, $e_\Gamma(\tau) \in \{1, 2, 3\}$, and if $\tau$ does not belong to the $\text{SL}_2(\mathbb{Z})$-orbit of $i := \sqrt{-1}$ or $e^{2\pi i /3}$, then $e_\Gamma(\tau) = 1$.

**Theorem 2.1. (The valence formula)** Let $f \in \mathcal{M}_k^*(\Gamma)$ be a non-zero weakly modular function. Then the following holds:

\begin{equation}
\sum_{\tau \in \Gamma \setminus \mathbb{H}} \frac{\text{ord}_\Gamma(f)}{e_\Gamma(\tau)} + \sum_{P \in \mathbb{C}(\Gamma)} \text{ord}_P(f; \Gamma) = d\Gamma \frac{k}{12}.
\end{equation}
**Remark 2.1.** Note that if \( f \in \mathcal{M}_k(\Gamma) \) is a modular form of weight \( k \), then for any \( \tau \in \mathbb{H} \) and any \( P \in \mathcal{E}(\Gamma) \), \( \text{ord}_\tau(f) \geq 0 \) and \( \text{ord}_P(f; \Gamma) \geq 0 \). In particular, \( \text{ord}_\tau(f) = 0 \) or \( \text{ord}_P(f; \Gamma) = 0 \) if and only if \( f(\tau) \neq 0 \) or \( f(P) \neq 0 \), respectively. Hence, the valence formula implies that:

(i) if \( k < 0 \), then \( \mathcal{M}_k(\Gamma) = 0 \),

(ii) \( \mathcal{S}_0(\Gamma) = 0 \), since for non-zero cusp forms \( f \) we have, \( \sum_{P \in \mathcal{E}(\Gamma)} \text{ord}_P(f; \Gamma) > 0 \),

(iii) \( \mathcal{M}_0(\Gamma) = \mathbb{C} \), since for any non-constant modular forms \( f \in \mathcal{M}_0(\Gamma) \) we obtain that \( (f - f(\infty)) \in \mathcal{M}_0(\Gamma) \) is a non-zero modular form and \( \sum_{P \in \mathcal{E}(\Gamma)} \text{ord}_P(f - f(\infty); \Gamma) > 0 \).

Therefore, we can consider the graded algebras (or the spaces) of modular forms and cusp forms on \( \Gamma \), respectively, as \( \mathcal{M}(\Gamma) = \bigoplus_{k=0}^\infty \mathcal{M}_k(\Gamma) \) and \( \mathcal{S}(\Gamma) = \bigoplus_{k=0}^\infty \mathcal{S}_k(\Gamma) \).

Another immediate result of the valence formula is the following very useful fact.

**Corollary 2.1.** (The effectiveness of modular forms) Let \( f, g \in \mathcal{M}_k(\Gamma) \), for some non-negative integer \( k \), having \( q \)-expansions: \( f(q) = \sum_{j=0}^\infty a_f(j)q^j \) and \( g(q) = \sum_{j=0}^\infty a_g(j)q^j \). If \( a_f(j) = a_g(j) \) for all \( 0 \leq j \leq |d_{\Gamma} - k/12| \), then \( f = g \).

**Proof.** Let \( h := f - g \). Then \( h \in \mathcal{M}_k(\Gamma) \) and by hypothesis \( \text{ord}_\infty(f; \Gamma) \geq d_{\Gamma} - k/12 + 1 \), hence the valence formula implies that \( h \equiv 0 \). □

A quasi-modular form of weight \( k \) and depth \( p \) on \( \Gamma \) is a holomorphic function \( f \) of moderate growth such that for all \( \tau \in \mathbb{H} \) and \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma \) we get:

\[
(f|k\gamma)(\tau) = \sum_{j=0}^{p} f_j(\tau) \left( \frac{c}{c\tau + d} \right)^j,
\]

where \( f_1, f_2, \ldots, f_p \) are holomorphic functions of moderate growth, \( f_0 = f \) and \( f_p \neq 0 \). We denote the space of quasi-modular forms of weight \( k \) on \( \Gamma \) by \( \tilde{\mathcal{M}}_k(\Gamma) \), and the space (or graded algebra) of quasi-modular forms on \( \Gamma \) by \( \tilde{\mathcal{M}}(\Gamma) = \bigoplus_{k=0}^\infty \tilde{\mathcal{M}}_k(\Gamma) \). For example one can check that (see for instance [BHGZ]) for all \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}_2(\mathbb{Z}) \):

\[
(E_2|2\gamma)(\tau) = E_2(\tau) - \frac{6i}{\pi} \frac{c}{c\tau + d},
\]

hence \( E_2 \) is quasi-modular form of weight 2 and depth 1 on \( \text{SL}_2(\mathbb{Z}) \). Or, if \( f \in \mathcal{M}_k(\Gamma) \) for some integer \( k \geq 0 \), then one can easily observe that for all \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \Gamma \):

\[
(f'|k+2\gamma)(\tau) = f'(\tau) + \frac{k}{2\pi i} f(\tau) \frac{c}{c\tau + d},
\]

which implies that \( f' \) is a quasi-modular form of weight \( k + 2 \) and depth 1 on \( \Gamma \). In particular, if \( k > 0 \), then \( f' \) is not a modular form, and therefore the space of modular forms is not closed under the differentiation.

**Remark 2.2.** Let \( \Gamma \) be a non-compact subgroup of \( \text{SL}_2(\mathbb{Z}) \). Due to [BHGZ, Proposition 20], the space of quasi-modular forms \( \tilde{\mathcal{M}}(\Gamma) \) is closed under differentiation. Furthermore, there exists a \( \lambda \in \tilde{\mathcal{M}}_2(\Gamma) \setminus \mathcal{M}_2(\Gamma) \) such that any quasi-modular form on \( \Gamma \) is a polynomial in \( \lambda \) with modular coefficients, i.e., \( \tilde{\mathcal{M}}(\Gamma) = \mathcal{M}(\Gamma)[\lambda] \).
As we observed above the derivative of a modular form is not necessarily a modular form, but there are certain combinations of modular forms and their derivatives which are again modular forms. More precisely, for any non-negative integer \( n \) and any \( f \in \mathcal{M}_k(\Gamma) \), \( g \in \mathcal{M}_l(\Gamma) \), \( k, l \in \mathbb{Z}_{\geq 0} \), the \( n \)-th Rankin-Cohen bracket \([f, g]_n\) is defined as:

\[
[f, g]_n := \sum_{i+j=n} (-1)^j \binom{n+k-1}{i} \binom{n+l-1}{j} f^{(j)} g^{(i)},
\]

where \( f^{(j)} \) and \( g^{(j)} \) refer to the \( j \)-th derivative of \( f \) and \( g \) with respect to the derivation \( s' \) given in (1.1). Cohen \cite{Coh} proved that:

\[(2.6) \quad [f, g]_k \in \mathcal{M}_{k+l+2n}(\Gamma).\]

Zagier \cite{Zag} introduced Rankin-Cohen algebraic structures and studied them.

**Remark 2.3.** Since in this paper we are considering \( \Gamma = \Gamma_0(2) \) and \( \Gamma = \Gamma_0(3) \), we summarize some important properties and facts about \( \Gamma_0(N) \) valid for all \( N \in \mathbb{N} \). Recall that

\[\Gamma_0(N) := \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \SL_2(\mathbb{Z}) : \begin{pmatrix} a & b \\ c & d \end{pmatrix} \equiv \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \pmod{N} \right\},\]

is an even congruence subgroup of \( \SL_2(\mathbb{Z}) \) of finite index. We have the following facts, in which we suppose that \( N \in \mathbb{N} \) and \( p \) is a prime number.

(i) If \( k \) is odd, then \( \mathcal{M}_k(\Gamma_0(N)) = 0 \).

(ii) If \( f(\tau) \in \mathcal{M}_k(\SL_2(\mathbb{Z})) \) or \( f(\tau) \in \mathcal{S}_k(\SL_2(\mathbb{Z})) \), then \( f(N\tau) \in \mathcal{M}_k(\Gamma_0(N)) \) or \( f(N\tau) \in \mathcal{S}_k(\Gamma_0(N)) \), respectively.

(iii) \( d_{\Gamma_0(p)} = [\SL_2(\mathbb{Z}) : \Gamma_0(p)] = p + 1 \).

(iv) \( \mathcal{C}(\Gamma_0(p)) = \{[\infty], [0]\} \), and the width of \( \Gamma_0(p) \) at \([\infty]\) and \([0]\) respectively, is \( 1 \) and \( p \).

(v) If we denote the number of elliptic points of period 2 in \( X_0(p) := \Gamma_0(p) \backslash \mathbb{H}^* \) by \( \varepsilon_2 \), then \( \varepsilon_2 = 2 \) if \( p \equiv 1 \pmod{4} \), \( \varepsilon_2 = 0 \) if \( p \equiv 3 \pmod{4} \), and \( \varepsilon_2 = 1 \) if \( p = 2 \).

(vi) If we denote the number of elliptic points of period 3 in \( X_0(p) \) by \( \varepsilon_3 \), then \( \varepsilon_3 = 2 \) if \( p \equiv 1 \pmod{3} \), \( \varepsilon_3 = 0 \) if \( p \equiv 2 \pmod{3} \), and \( \varepsilon_3 = 1 \) if \( p = 3 \).

(vii) If we denote by \( g \) the genus of \( X_0(p) \), then \( g = \lfloor \frac{p+1}{12} \rfloor - 1 \) if \( p+1 \equiv 2 \pmod{12} \), and \( g = \lfloor \frac{p+1}{12} \rfloor \) otherwise.

(viii) If \( k \geq 2 \) is an even integer, then \( \dim \mathcal{M}_k(\Gamma_0(p)) = (k-1)(g-1) + \lfloor \frac{k}{2} \rfloor \varepsilon_2 + \lfloor \frac{k}{3} \rfloor \varepsilon_3 + k \).

(ix) If \( k \geq 4 \) is an even integer, then \( \dim \mathcal{S}_k(\Gamma_0(p)) = (k-1)(g-1) + \lfloor \frac{k}{4} \rfloor \varepsilon_2 + \lfloor \frac{k}{3} \rfloor \varepsilon_3 + k-2 \), and \( \dim \mathcal{S}_2(\Gamma_0(p)) = g \).

For more details see, for example, \cite{DS}.

**Remark 2.4.** It is well known that \( \eta(q) \) is a modular form of weight 1/2 (and non-trivial character) on \( \SL_2(\mathbb{Z}) \) which does not vanish on \( \mathbb{H} \). Due to (1.5) we know that \( \eta'(q)/\eta(q) = \frac{1}{24}E_2(q) \), which is a quasi-modular form of weight 2 on \( \SL_2(\mathbb{Z}) \). If for \( g = \)
\[ r_1^{t_1}r_2^{t_2}\ldots r_s^{t_s}, r_j > 0, t_j \in \mathbb{Z}, \text{ we suppose that the } \eta\text{-quotient } \eta_q(q) := \prod_{j=1}^{s} \eta_j^{t_j}(q^{r_j}) \text{ is a modular form (modular function) on } \Gamma, \text{ then:} \]

\[ (2.7) \quad \frac{\eta'_q(q)}{\eta_q(q)} = (\log(\eta_q(q)))' = \sum_{j=1}^{s} \frac{r_j t_j}{24} E_2(q^{r_j}). \]

It is a quasi-modular form of weight 2 on \( \Gamma \) (note that \( \eta_q \) does not vanish on \( \mathbb{H} \), and, \( \eta_q \) and \( \eta'_q \) have the same vanishing order at \( \infty \)). Moreover, if \( \eta_q \) is a modular function (i.e., weakly modular function of weight 0), then using (2.4) we conclude that \( \eta'_q(q)/\eta_q(q) \) is a modular form of weight 2 on \( \Gamma \).

### 3 Origin of the systems \( R_1 \) and \( R_2 \)

The initial version of the systems (1.7) and (1.11) first appeared in [MN16], where by applying an algebraic method, called *Gauss-Manin connection in disguise* (GMCD), in a geometric context the author and Hossein Movasati found these systems as a unique vector field on a special moduli space that satisfies certain conditions. More precisely, for any positive integer \( n \) we obtained a one-parameter family \( X := X_z, z \in \mathbb{P}^1 \setminus \{0,1,\infty\} \), of Calabi-Yau \( n \)-folds arising from the Dwork family:

\[ W_z := \{ z x_0^{n+2} + x_1^{n+2} + x_2^{n+2} + \cdots + x_n^{n+2} - (n + 2)x_0 x_1 x_2 \cdots x_{n+1} = 0 \} \subset \mathbb{P}^{n+1}, \]

and we introduced the moduli space \( T \) of the pairs \((X, [\alpha_1, \alpha_2, \ldots, \alpha_{n+1}])\), in which \( \{\alpha_1, \alpha_2, \ldots, \alpha_{n+1}\} \) is a basis of the \( n \)-th algebraic de Rham cohomology \( H^n_{\text{dR}}(X) \) satisfying some specific properties. In the main theorem of the same work [MN16] we proved that there exist a unique vector field \( R := R_n \) and regular functions \( Y_j, j = 1, 2, \ldots, n - 2 \) in \( T \) such that the Gauss-Manin connection of the universal family of \( T \) composed with the vector field \( R \), namely \( \nabla_R \), satisfies:

\[
(3.1) \quad \nabla_R = \begin{pmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \\ \vdots \\ \alpha_n \\ \alpha_{n+1} \end{pmatrix} = \begin{pmatrix} 0 & 1 & 0 & 0 & \cdots & 0 & 0 \\ 0 & 0 & \gamma_1 & 0 & \cdots & 0 & 0 \\ 0 & 0 & 0 & \gamma_2 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & 0 & 0 & \cdots & \gamma_{n-2} & 0 \\ 0 & 0 & 0 & 0 & \cdots & 0 & -1 \\ 0 & 0 & 0 & 0 & \cdots & 0 & 0 \end{pmatrix} \begin{pmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \\ \vdots \\ \alpha_n \\ \alpha_{n+1} \end{pmatrix}.
\]

Indeed, we get \( T = \text{Spec}(\mathbb{C}[t_1, t_2, \ldots, t_d, \frac{1}{t_{n+1}(t_{n+2} - t_1^{n+1})}]) \), where:

\[
(3.2) \quad d = d_n = \dim T = \begin{cases} \frac{(n+1)(n+3)}{4} + 1, & \text{if } n \text{ is odd;} \\ \frac{n(n+2)}{4} + 1, & \text{if } n \text{ is even.} \end{cases}
\]

In particular, for \( n = 1 \) we computed the vector field \( R_1 \) explicitly as follows:

\[
R_1 = (-t_1 t_2 - 9(t_1^3 - t_3)) \frac{\partial}{\partial t_1} + (8t_1(t_1^3 - t_3) - t_2^2) \frac{\partial}{\partial t_2} + (-3t_2 t_3) \frac{\partial}{\partial t_3}.
\]
and for $n = 2$ we got:

$$R_2 = (t_3 - t_1 t_2) \frac{\partial}{\partial t_1} + \left(2 t_1^2 - \frac{1}{2} t_2^2 \right) \frac{\partial}{\partial t_2} + (-2 t_2 t_3 + 8 t_1^3) \frac{\partial}{\partial t_3} + (-4 t_2 t_4) \frac{\partial}{\partial t_4},$$

where for $R_2$ the following polynomial equation holds among the $t_i$'s

$$t_3^2 = 4(t_1^4 - t_4).$$

We explain below how to get the systems (1.7) and (1.11) from $R_2$ and $R_1$, respectively.

For $n = 2$ let us consider the following representation of $R_2$ as a system of ODEs:

$$(3.3) \quad t_3^2 = 4(t_1^4 - t_4).$$

$$R_2 : \begin{cases} 
\dot{t}_1 = t_3 - t_1 t_2 \\
\dot{t}_2 = 2 t_1^2 - \frac{1}{2} t_2^2 \\
\dot{t}_3 = -2 t_2 t_3 + 8 t_1^3, \\
\dot{t}_4 = -4 t_2 t_4
\end{cases}$$

where $\dot{} = a \cdot q \cdot \frac{\partial}{\partial q}$ refers to a logarithmic derivation with some constant $a \in \mathbb{C}$. In [MN16] we computed the $q$-expansion of a solution of (3.3) for $a = -\frac{1}{9}$ by computer and we observed that at least the first 100 coefficients of the $q$-expansions coincide with the coefficients of the following functions:

$$(3.4) \quad \begin{cases} 
\frac{104 t_1(\frac{t_1}{10})}{8} = \frac{1}{21} \left(\theta_3(q^2) + \theta_4(q^2)\right), \\
\frac{104 t_2(\frac{t_1}{10})}{4} = \frac{1}{21} \left(E_2(q^2) + 2E_2(q^2)\right), \\
104 t_3(\frac{t_1}{10}) = \eta^8(q) \eta^8(q^2),
\end{cases}$$

but we did not prove theoretically that these functions form a solution of the system (3.4). If we apply the change of variables $\tilde{t}_1 = 20 t_2$, $\tilde{t}_2 = 40 t_1$ and $\tilde{t}_3 = 800 t_3$, then the system (3.4) transforms to the system:

$$(3.5) \quad \begin{cases} 
\dot{t}_1 = \frac{1}{7}(t_1^2 - t_2^2) \\
\dot{t}_2 = \frac{1}{7}(t_1 t_2 - t_3) \\
\dot{t}_3 = \frac{1}{2}(t_1^3 - t_2^2)
\end{cases}$$

in which $\dot{} = q \frac{\partial}{\partial q} = -5 \dot{}$. Note that due to (3.3) $t_4$ depends to $t_1$ and $t_3$, hence we can omit it, indeed, in Theorem 1.1 we consider $\Delta_2 = t_4$. If, by abuse of notation, we use again $t_1, t_2, t_3$ instead of $\tilde{t}_1, \tilde{t}_2, \tilde{t}_3$, then we get the system (1.7) from (3.6).

For $n = 1$ we have:

$$(3.6) \quad \begin{cases} 
\dot{t}_1 = -t_1 t_2 - 9(t_1^2 - t_3) \\
\dot{t}_2 = 81 t_1 (t_1^2 - t_3) - t_2^2 \\
\dot{t}_3 = -3 t_2 t_3
\end{cases}$$

where $\dot{} = 3 \cdot q \cdot \frac{\partial}{\partial q}$. We verified that at least the first 100 coefficients of the $q$-expansions of the following quasi-modular forms satisfy the system (3.7):

$$(3.7) \quad \begin{cases} 
t_1(q) = \frac{1}{3}(2 \theta_3(q^2) \theta_3(q^6) - \theta_3(-q^2) \theta_3(-q^6)), \\
t_2(q) = \frac{1}{3}(E_2(q^2) - 9 E_2(q^6)), \\
t_3(q) = \frac{\eta^9(q)}{\eta(q)}.
\end{cases}$$

Here $t_1, t_3$ are modular forms of weight 1, 3, respectively, and character $\chi_{-3}$ for $\Gamma_0(3)$, where $\chi_{-3}(d) := (\frac{d}{3})$, $d \in \mathbb{Z}$ (here $(\frac{d}{3})$ refers to the Jacobi (Legendre) symbol). Note
that neither of the eta quotients $t_3(q) = \frac{\eta^3(q^3)}{\eta(q^3)}$ and $27(t_1(q)^3 - t_3(q)) = \frac{\eta^9(q)}{\eta(q^3)}$ are cusp forms for $\Gamma_0(3)$, while $27t_3(q)(t_1(q)^3 - t_3(q)) = \eta^6(q)\eta^6(q^3) = \Delta_3$ is a cusp form of weight 6 for $\Gamma_0(6)$ (see Section 5). By applying the change of variables $t_1 = -2t_2 - 9t_3^2$, $t_2 = 9t_1^2$, $t_3 = 3t_4$ and $t_4 = t_2^2$ to the system (3.7), we get the system (1.11), where again by abuse of notation we use $t_1, t_2, t_3, t_4$ instead of $\bar{t}_1, \bar{t}_2, \bar{t}_3, \bar{t}_4$, and $\ast' = \frac{\partial x}{\partial q} = \frac{1}{3} \ast$.

It is worth to point out that the Ramanujan system also can be reenountered through GMCD. Indeed, Hossein Movasati [Mov12] showed that the vector fields $Ra$ satisfies $\nabla_{Ra}\alpha = \left( \begin{array}{c} 0 \\ 1 \\ 0 \end{array} \right) \alpha$, where $\alpha$ is the transpose of the vector $\left( \begin{array}{c} \frac{dx}{y} \\ \frac{dy}{y} \end{array} \right)$ and $\nabla$ is the Gauss-Manin connection of the universal family of the elliptic curves:

$$(3.9) \quad y^2 = 4(x - t_1)^3 - t_2(x - t_1) - t_3,$$

where $(t_1, t_2, t_3) \in \mathbb{C}^3$ such that $27t_3^2 - t_2^3 \neq 0$.

In the same work one can find that the modular discriminant $\Delta$ can be written in terms of the parameters of the family (3.9) which is actually a constant multiple of the discriminant of this family, i.e., $27t_3^2 - t_2^3$. Analogously, we find out that the modular forms $\Delta_2$ and $\Delta_3$ are a factor of the discriminant of a modified version of the Dwork family. More precisely, if for any integer $n$ we let $z = \frac{t_n^{n+2}}{t_1^2}$, then the Dwork family is equivalent to the family:

$$t_{n+2}x_0^{n+2} + x_1^{n+2} + x_2^{n+2} + \cdots + x_{n+1}^{n+2} - (n + 2)t_1x_0x_1x_2 \cdots x_{n+1} = 0,$$

whose discriminant is $t_{n+2}(t_1^{n+2} - t_{n+2})$ (see [MN16] for more details). As we saw above, for $n = 1$ we get $\Delta_3 = 27t_3(t_1^3 - t_3)$, and for $n = 2$ we have $\Delta_2 = t_4$.

### 4 Proof of Theorem 1.1

First note that, due to Remark 2.3, $\Gamma_0(2)$ has two cusps $[0], [\infty]$ and one elliptic point of period 2, and the genus of $X_0(2)$ is zero. Hence:

$$(4.1) \quad \dim \mathcal{M}_k(\Gamma_0(2)) = \left\lfloor \frac{k}{4} \right\rfloor + 1, \quad \text{provided } k \geq 2 \text{ is even},$$

$$(4.2) \quad \dim \mathcal{S}_k(\Gamma_0(2)) = \left\lfloor \frac{k}{4} \right\rfloor - 1, \quad \text{provided } k \geq 4 \text{ is even},$$

otherwise $\mathcal{M}_k(\Gamma_0(2)) = 0$ and $\mathcal{S}_k(\Gamma_0(2)) = 0$. On account of Remark 2.3(ii) one gets that $\mathcal{P}_2, \mathcal{Q}_2, \mathcal{R}_2$ (given in (1.8)) are (quasi-)modular forms for $\Gamma_0(2)$. Their $q$-expansions are as follows:

$$(4.3) \quad \mathcal{P}_2 = 1 - 8q - 40q^2 - 32q^3 - 104q^4 - 48q^5 - 160q^6 - 64q^7 - \ldots,$$

$$(4.4) \quad \mathcal{Q}_2 = 1 + 24q + 24q^2 + 96q^3 + 24q^4 + 144q^5 + 96q^6 + 192q^7 + \ldots,$$

$$(4.5) \quad \mathcal{R}_2 = 1 - 80q - 400q^2 - 2240q^3 - 2960q^4 - 10080q^5 - 11200q^6 - 27520q^7 - \ldots.$$

If we denote the vector space generated by functions $f_1, f_2, \ldots, f_n$ over $\mathbb{C}$ by $\langle f_1, f_2, \ldots, f_n \rangle$, then we claim that:

$$(4.6) \quad \mathcal{M}_2(\Gamma_0(2)) = \langle \mathcal{Q}_2 \rangle,$$

$$(4.7) \quad \mathcal{M}_4(\Gamma_0(2)) = \langle \mathcal{Q}_2^2, \mathcal{R}_2 \rangle,$$

$$(4.8) \quad \mathcal{M}_6(\Gamma_0(2)) = \langle \mathcal{Q}_2^3, \mathcal{Q}_2^2 \mathcal{R}_2 \rangle,$$

$$(4.9) \quad \mathcal{M}_8(\Gamma_0(2)) = \langle \mathcal{Q}_2^4, \mathcal{Q}_2^2 \mathcal{R}_2, \mathcal{R}_2^2 \rangle.$$
Indeed, due to Remark 2.14 we obtain:

\[
(4.10) \quad \frac{(\eta_{24}(q^2)/\eta_{24}(q))'}{(\eta_{24}(q^2)/\eta_{24}(q))} = 2E_2(q^2) - E_2(q) = \Omega_2,
\]

where \( \eta_{24}(q^2)/\eta_{24}(q) \) is a modular function (of weight 0) for \( \Gamma_0(2) \). Hence, \( \Omega_2 \in \mathcal{M}_2(\Gamma_0(2)) \), and since \( \dim \mathcal{M}_2(\Gamma_0(2)) = 1 \), (4.10) is proved. It is evident that \( R_2 \in \mathcal{M}_4(\Gamma_0(2)) \), and since \( \dim \mathcal{M}_4(\Gamma_0(2)) = 2 \), in order to prove (4.7) it is enough to show that \( \Omega_2^2 \) and \( R_2 \) are linearly independent on \( \mathbb{C} \). To this end, due to the effectiveness of modular forms given in Corollary 2.1 it suffices to observe that the vectors \((a_{\Omega_2^2}(0), a_{\Omega_2^2}(1)) = (1, 48) \) and \((a_{R_2}(0), a_{R_2}(1)) = (1, -80) \) are linearly independent (note that \( d_{\Gamma_0(2)} = 3 \)). Analogously, (4.8) follows from the fact that \((a_{\Omega_2^2}(0), a_{\Omega_2^2}(1)) = (1, 72) \) and \((a_{R_2\Omega_2}(0), a_{R_2\Omega_2}(1)) = (1, -56) \) are linearly independent, and the linear independence of \((a_{\Omega_2^2}(0), a_{\Omega_2^4}(1), a_{\Omega_2^4}(2)) = (1, 96, 3552), (a_{R_2\Omega_2}(0), a_{R_2\Omega_2}(1), a_{R_2\Omega_2}(2)) = (1, -32, -3616) \) and \((a_{R_2}(0), a_{R_2}(1), a_{R_2}(2)) = (1, -160, 5600) \) imply (4.9).

1. By Remark 2.14 we know that \( \Delta_2(q) = \eta^8(q)\eta^8(q^2) \in \mathcal{M}_8(\Gamma_0(2)) \), which does not vanish in \( \mathbb{H} \), hence on account of the valence formula given in Theorem 2.1 \( \text{ord}_0(\Delta_2; \Gamma_0(2)) + \text{ord}_\infty(\Delta_2; \Gamma_0(2)) = 2 \). Note that the \( q \)-expansion of \( \Delta_2 \) at \( \infty \) is as follows:

\[
\Delta_2(q) = q \prod_{k=1}^{\infty} (1 - q^k)^8(1 - q^{2k})^8 = q - 8q^2 + 12q^3 + 64q^4 - 210q^5 - 96q^6 + \ldots,
\]

thus \( \text{ord}_\infty(\Delta_2; \Gamma_0(2)) = 1 \), which implies

\[
(4.11) \quad \text{ord}_0(\Delta_2; \Gamma_0(2)) = 1.
\]

Therefore \( \Delta_2 \in \mathcal{S}_8(\Gamma_0(2)) \) and (2.7) gives:

\[
\frac{\Delta_2'(q)}{\Delta_2(q)} = \frac{1}{3} (E_2(q) + 2E_2(q^2)) = P_2.
\]

To prove \( P_2' = \frac{1}{8}(P_2^2 - \Omega_2^2) \) and \( \Omega_2' = \frac{1}{4}(P_2\Omega_2 - R_2) \) we first point out that:

\[
(4.12) \quad P_2' - \frac{1}{8}P_2^2 = \left(\frac{\Delta_2'}{\Delta_2}\right)' - \frac{1}{8} \frac{\Delta_2'^2}{\Delta_2} = \frac{8\Delta_2''\Delta_2 - 9\Delta_2'^2}{8\Delta_2^2} = \frac{[\Delta_2, \Delta_2^2]}{72\Delta_2^2},
\]

\[
(4.13) \quad \Omega_2' - \frac{1}{4}P_2\Omega_2 = t_2' - \frac{2\Omega_2\Delta_2'}{8\Delta_2} = \frac{8\Omega_2\Delta_2 - 2\Omega_2\Delta_2'}{8\Delta_2} = \frac{[\Delta_2, \Omega_2]}{8\Delta_2},
\]

where \([\cdot, \cdot]_1\) and \([\cdot, \cdot]_2\) are the first and second Rankin-Cohen brackets. Hence, due to (2.6), both \( P_2' = -\frac{1}{8}P_2^2 \) and \( \Omega_2' = -\frac{1}{4}P_2\Omega_2 \) belong to \( \mathcal{M}_4(\Gamma_0(2)) \). Therefore, after comparing the coefficients of the \( q \)-expansion of \( P_2' \) and \( \Omega_2' = \frac{1}{4}P_2\Omega_2 \) with \( \Omega_2^2 \) and \( R_2 \), from (4.7) and the effectiveness of modular forms we get \( P_2' = -\frac{1}{8}P_2^2 = -\frac{1}{8}\Omega_2^2 \) and \( \Omega_2' = -\frac{1}{4}P_2\Omega_2 = -\frac{1}{4}R_2 \). Analogously, we observe that:

\[
R_2' - \frac{1}{2}P_2R_2 = \frac{[\Delta_2, R_2]}{8\Delta_2} \in \mathcal{M}_6(\Gamma_0(2)),
\]
and (4.8) implies that $\mathcal{R}_2' = \frac{1}{2} \mathcal{P}_2 \mathcal{R}_2 - \frac{1}{2} \mathcal{Q}_2^3$, and this finishes the proof of $\mathcal{R}_2' = \frac{1}{2} (\mathcal{P}_2 \mathcal{R}_2 - \mathcal{Q}_2^3)$. Finally, using (4.9) and the effectiveness of modular forms we get that:

\begin{equation}
\Delta_2 = \frac{1}{256} (\mathcal{Q}_2^4 - \mathcal{R}_2^2), \tag{4.14}
\end{equation}

and this completes the proof of part 1.

2. To prove $M(\Gamma_0(2)) = \mathbb{C}[\mathcal{Q}_2, \mathcal{R}_2]$ it is enough to show that for any non-negative integer $k$, the set:

$$
\mathcal{B}_k := \{ \mathcal{Q}_2^r \mathcal{R}_2^s : r, s \in \mathbb{Z}_{\geq 0} \text{ and } 2r + 4s = 2k \},
$$

forms a basis for $M_{2k}(\Gamma_0(2))$ (note that $M_{2k+1}(\Gamma_0(2)) = 0$). To this end, first note that:

$$
\mathcal{Q}_2^r \mathcal{R}_2^s \in \mathcal{B}_k \iff r, s \in \mathbb{Z}_{\geq 0} \text{ and } 2r + 4s = 2k,
$$

$$
\iff r = k - 2s \text{ and } 0 \leq s \leq \frac{k}{2}, \ s \in \mathbb{Z}_{\geq 0},
$$

which implies:

$$
\# \mathcal{B}_k = \left\lfloor \frac{k}{2} \right\rfloor + 1 = \dim M_{2k}(\Gamma_0(2)).
$$

Hence, it remains to show that the elements of $\mathcal{B}_k$ are linearly independent. We claim that:

\begin{equation}
\exists P_1, P_2 \in \mathbb{H} \cup \{0\} \text{ with } P_1 \neq P_2 \text{ such that } \mathcal{Q}_2(P_1) = \mathcal{R}_2(P_2) = 0,
\end{equation}

which implies for any two pairs $(r_1, s_1), (r_2, s_2) \in \mathbb{Z}_{\geq 0} \times \mathbb{Z}_{\geq 0}$ with $(r_1, s_1) \neq (r_2, s_2)$, the modular forms $\mathcal{Q}_2^r \mathcal{R}_2^s$ and $\mathcal{Q}_2^{r_2} \mathcal{R}_2^{s_2}$ have zeros of different order in $\mathbb{H} \cup \{0\}$, and hence they are linearly independent over $\mathbb{C}$. Then, $\mathcal{B}_k$ is a set of linearly independent elements, and in particular, we proved that $\mathcal{Q}_2$ and $\mathcal{R}_2$ are algebraically independent over $\mathbb{C}$. Thus we have proved that $M(\Gamma_0(2)) = \mathbb{C}[\mathcal{Q}_2, \mathcal{R}_2]$. Now, since $\mathcal{P}_2$ is a quasi-modular form (which is not a modular form), Remark 2.2 implies that $M(\Gamma_0(2)) = M(\Gamma_0(2))[\mathcal{P}_2] = \mathbb{C}[\mathcal{P}_2, \mathcal{Q}_2, \mathcal{R}_2]$, and this finishes the proof of part 2.

To prove (4.15), first note that on account of (4.4) and (4.5) we have $\text{ord}_{[\infty]}(\mathcal{Q}_2; \Gamma_0(2)) = \text{ord}_{[\infty]}(\mathcal{R}_2; \Gamma_0(2)) = 0$, and hence the valence formula gives:

\begin{align*}
\sum_{\tau \in \Gamma_0(2) \setminus \mathbb{H}} & \frac{\text{ord}_r(\mathcal{Q}_2)}{e_{\Gamma_0(2)}(\tau)} + \text{ord}_{[0]}(\mathcal{Q}_2; \Gamma_0(2)) = \frac{1}{2}, \\
\sum_{\tau \in \Gamma_0(2) \setminus \mathbb{H}} & \frac{\text{ord}_r(\mathcal{R}_2)}{e_{\Gamma_0(2)}(\tau)} + \text{ord}_{[0]}(\mathcal{R}_2; \Gamma_0(2)) = 1, \tag{4.17}
\end{align*}

which imply that there are $P_1, P_2 \in \mathbb{H} \cup \{0\}$ such that $\mathcal{Q}_2(P_1) = \mathcal{R}_2(P_2) = 0$. If $P_1, P_2 \in \mathbb{H}$, then due to (4.14) and the fact that $\Delta_2$ is non-zero in $\mathbb{H}$ we get that $P_1$ and $P_2$ must be distinct. If, by contradiction, we suppose that $\mathcal{Q}_2$ and $\mathcal{R}_2$ do not have distinct zeros, then the only possibility for $P_1$ and $P_2$ is $P_1 = P_2 = 0$. Thus, (4.16) and (4.17) imply that $\text{ord}_{[0]}(\mathcal{Q}_2; \Gamma_0(2)) = \frac{1}{2}$ and $\text{ord}_{[0]}(\mathcal{R}_2; \Gamma_0(2)) = 1$, hence $\text{ord}_{[0]}(\mathcal{Q}_2; \Gamma_0(2)) = \text{ord}_{[0]}(\mathcal{R}_2^3; \Gamma_0(2)) = 2$, and therefore $\text{ord}_{[0]}(\Delta_2; \Gamma_0(2)) = \frac{1}{256} (\mathcal{Q}_2^4 - \mathcal{R}_2^2) \geq 2$, which contradicts (4.14).
3. Recall that the special linear Lie algebra \( \mathfrak{sl}_2(\mathbb{C}) \) is the Lie algebra of \( 2 \times 2 \) matrices with trace zero. Three matrices

\[
(4.18) \quad e := \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad f := \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad h := \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},
\]

form the standard basis of \( \mathfrak{sl}_2(\mathbb{C}) \) with the commutators:

\[
(4.19) \quad [e, f] = h, \quad [h, e] = 2e, \quad [h, f] = -2f.
\]

We also recall that if we have two vector fields \( V = \sum_{j=1}^{d} V^j \frac{\partial}{\partial t_j} \) and \( W = \sum_{j=1}^{d} W^j \frac{\partial}{\partial t_j} \), then

\[
(5.1) \quad [V, W] = VW - WV = \sum_{j=1}^{d} \left( V(W^j) - W(V^j) \right) \frac{\partial}{\partial t_j}.
\]

Using (4.20) one can easily check that:

\[
[R_2, F] = H, \quad [H, R_2] = 2R_2, \quad [H, F] = -2F.
\]

Hence, the correspondences \( R_2 \mapsto e, H \mapsto h \) and \( F \mapsto f \) show that the Lie algebra generated by \( R_2, H \) and \( F \) is isomorphic to \( \mathfrak{sl}_2(\mathbb{C}) \), and this completes the proof of part 3.

5 Proof of Theorem 1.2

The proof is analogous to the proof of Theorem 1.1. Using Remark 2.3 we get:

\[
(5.1) \quad \dim M_k(\Gamma_0(3)) = \left\lfloor \frac{k}{3} \right\rfloor + 1, \quad \text{provided } k \geq 2 \text{ is even},
\]

\[
(5.2) \quad \dim S_k(\Gamma_0(3)) = \left\lfloor \frac{k}{3} \right\rfloor - 1, \quad \text{provided } k \geq 4 \text{ is even},
\]

otherwise \( M_k(\Gamma_0(3)) = 0 \) and \( S_k(\Gamma_0(3)) = 0 \). The \( q \)-expansions of \( \mathcal{P}_3, \mathcal{Q}_3, \mathcal{R}_3 \) and \( \mathcal{S}_3 \) are as follows:

\[
(5.3) \quad \mathcal{P}_3 = 1 - 6q - 18q^2 - 42q^3 - 42q^4 - 36q^5 - 126q^6 - 48q^7 - 90q^8 - 150q^9 - \ldots,
\]

\[
(5.4) \quad \mathcal{Q}_3 = 1 + 12q + 36q^2 + 12q^3 + 84q^4 + 72q^5 + 36q^6 + 96q^7 + 180q^8 + 12q^9 + \ldots,
\]

\[
(5.5) \quad \mathcal{R}_3 = q + 9q^2 + 27q^3 + 73q^4 + 126q^5 + 243q^6 + 588q^7 + 729q^8 + 1512q^9 + \ldots,
\]

\[
(5.6) \quad \mathcal{S}_3 = q^2 + 6q^3 + 27q^4 + 80q^5 + 207q^6 + 432q^7 + 863q^8 + 1512q^9 + \ldots,
\]

and \( \mathcal{P}_3 \in \tilde{M}_2(\Gamma_0(3)) \setminus M_2(\Gamma_0(3)), \mathcal{Q}_3 \in M_2(\Gamma_0(3)), \mathcal{R}_3 \in M_4(\Gamma_0(3)) \) and \( \mathcal{S}_3 \in M_6(\Gamma_0(3)) \).

Note that:

\[
(5.7) \quad \frac{(\eta^{24}(q^3)/\eta^{24}(q))^2}{(\eta^{24}(q^3)/\eta^{24}(q))} = 3E_2(q^3) - E_2(q) = 2\mathcal{Q}_3,
\]

where \( \eta^{24}(q^3)/\eta^{24}(q) \) is a modular function (of weight 0) for \( \Gamma_0(3) \). Similarly to (4.6)-(4.9) we observe that:

\[
(5.8) \quad M_2(\Gamma_0(2)) = \langle \mathcal{Q}_3 \rangle,
\]

\[
(5.9) \quad M_4(\Gamma_0(2)) = \langle \mathcal{Q}_3^2, \mathcal{R}_3 \rangle,
\]

\[
(5.10) \quad M_6(\Gamma_0(2)) = \langle \mathcal{Q}_3^3, \mathcal{Q}_3 \mathcal{R}_3, \mathcal{S}_3 \rangle,
\]

\[
(5.11) \quad M_8(\Gamma_0(2)) = \langle \mathcal{Q}_3^4, \mathcal{Q}_3^2 \mathcal{R}_3, \mathcal{R}_3^2 \rangle.
\]
1. We first verify that $\Delta_3(q) = q^6(q_3^6(q_3^3)^6 \in M_6(\Gamma_0(3))$ does not vanish in $H$, furthermore that $\text{ord}_{[0]}(\Delta_3; \Gamma_0(3)) + \text{ord}_{[\infty]}(\Delta_3; \Gamma_0(3)) = 2$ and the $q$-expansion of $\Delta_3$ at $\infty$ is as follows:

$$\Delta_3(q) = q \prod_{k=1}^{\infty} (1 - q^k)(1 - q^{3k})^6 = q - 6q^2 + 9q^3 + 4q^4 + 6q^5 - 54q^6 - 40q^7 + \ldots.$$ 

Using these facts, we can complete the proof in the same way as the proof part 1 of Theorem 1.1.

2. By (5.4), (5.5) and (5.6) we have $\text{ord}\ q(q_3^3)^2 = 3$. The proof of this part is also analogous to the proof of part 3 of Theorem 1.1.

3. The proof of this part is also analogous to the proof of part 3 of Theorem 1.1.

6 More analogies

The $j$-function (j-invariant) is an important tool in the classification of elliptic curves, and is defined as the following (weight 0) modular function for $SL_2(\mathbb{Z})$:

$$j(q) := \frac{E_4^3(q)}{\Delta} = \frac{1}{q} + 744 + 196884q + 21493760q^2 + 864299970q^3 + 20245856256q^4 + \ldots.$$
In this way, we find similarly the following modular functions for \( \Gamma_0(2) \) and \( \Gamma_0(3) \), respectively:

\[
\begin{align*}
\Delta_2 &= \frac{\Omega_1^2}{\Delta_2} = \frac{1}{q} + 104 + 4372q + 96256q^2 + 1240002q^3 + 10698752q^4 + 74428120q^5 + \ldots, \\
\Delta_3 &= \frac{\Omega_2^2}{\Delta_3} = \frac{1}{q} + 42 + 783q + 8672q^2 + 65367q^3 + 371520q^4 + 1741655q^5 + \ldots.
\end{align*}
\]

If we eliminate the variables \( t_2 \) and \( t_3 \) in the Ramanujan system \([1.1]\), then we get the Chazy equation:

\[
2y''' - 2yy'' + 3(y')^2 = 0,
\]

which is satisfied by \( E_2 \). Analogously, by eliminating the variables \( t_2 \) and \( t_3 \) from the system \([1.7]\) we obtain the differential equation:

\[
y'''(16y' - 2y^2) - y''(8y'' + 12yy' - 2y^3) + (y')^2(20y' - 3y^2) = 0,
\]

which is satisfied by the quasi-modular form \( \mathcal{P}_2 \). We will call \([6.1]\) a Chazy-type differential equation for \( \mathcal{P}_2 \). The author didn’t do the computations for the system \([1.11]\), but he believes that with a little more effort one can get the Cahazy-type equation in this case as well. Note that in the above differential equations we are substituting \( t_1 \) by the free parameter \( y \).

In Section 2 we observed that the derivative of a modular form is not necessarily a modular form. However, in the case of full modular forms we have the Ramanujan-Serre derivation which preserves the modularity. More precisely, if \( f \in \mathcal{M}_k(\text{SL}_2(\mathbb{Z})) \subset \mathbb{C}[E_4, E_6] \), then its Ramanujan-Serre derivative is defined as follows which is a modular form of weight \( k + 2 \):

\[
(6.2) \quad \partial f := f' - \frac{k}{12} E_2 f = -\frac{1}{3} E_6 \frac{\partial f}{\partial E_4} - \frac{1}{2} E_4 \frac{\partial f}{\partial E_6} \in \mathcal{M}_{k+2}(\text{SL}_2(\mathbb{Z})).
\]

Similarly we get the Ramanujan-Serre-type derivations \( \partial_2 \) and \( \partial_3 \) for \( \Gamma_0(2) \) and \( \Gamma_0(3) \), respectively, which preserve the modularity. In fact, if \( f \in \mathcal{M}_k(\Gamma_0(2)) \subset \mathbb{C}[\mathcal{Q}_2, \mathcal{R}_2] \) or \( f \in \mathcal{M}_k(\Gamma_0(3)) \subset \mathbb{C}[\mathcal{Q}_3, \mathcal{R}_3, \mathcal{S}_3]/\mathcal{J} \), then we define \( \partial_2 f \) or \( \partial_3 f \), respectively, as follows:

\[
(6.3) \quad \partial_2 f := f' - \frac{k}{8} \mathcal{P}_2 f = -\frac{1}{4} \mathcal{R}_2 \frac{\partial f}{\partial \mathcal{Q}_2} - \frac{1}{2} \mathcal{Q}_2 \frac{\partial f}{\partial \mathcal{R}_2} \in \mathcal{M}_{k+2}(\Gamma_0(2)),
\]

\[
(6.4) \quad \partial_3 f := f' - \frac{k}{6} \mathcal{P}_3 f = \frac{1}{3} (-\mathcal{Q}_3^2 + 54\mathcal{R}_3) \frac{\partial f}{\partial \mathcal{Q}_3} + (\frac{1}{3} \mathcal{Q}_3 \mathcal{R}_3 + 9\mathcal{S}_3) \frac{\partial f}{\partial \mathcal{R}_3} + \mathcal{Q}_3 \mathcal{S}_3 \frac{\partial f}{\partial \mathcal{S}_3} \in \mathcal{M}_{k+2}(\Gamma_0(3)).
\]

All quasi-modular forms introduced in this paper have integer Fourier coefficients, and some of them are listed in the On-line Encyclopedia of Integer Sequences [OEIS]. In the first and the second row of the following table we give, respectively, the modular forms and the corresponding reference number in [OEIS]. One can find more information about these modular forms in the referred webpage and references therein.

7 Applications

In this section using the Fourier coefficients of $P_2, P_3, Q_2, Q_3, R_2, R_3, \Delta_2, \Delta_3$ and the relations between them we find some interesting and non-trivial formulas and congruences. For any non-negative integers $k$ and $n$ we define:

$$\delta^k_n := \begin{cases} 
1, & \text{if } n \equiv 0 \pmod{k}; \\
0, & \text{if } n \not\equiv 0 \pmod{k}.
\end{cases}$$

In the rest of this article we denote the divisor (sigma) function by $\sigma(k) := \sigma_1(k) = \sum_{d|k} d, \ k \in \mathbb{Z}_{>0}$. We also define $\sigma(0) := -\frac{1}{24}$, hence we can write:

$$(7.1) \quad E_2(q) = -24 \sum_{n=0}^{\infty} \sigma(n)q^n,$$

from which we get:

$$(7.2) \quad P_2 = \sum_{n=0}^{\infty} -8\left(\sigma(n) + 2\delta^2_n \sigma\left(\frac{n}{2}\right)\right)q^n,$$

$$(7.3) \quad P_3 = \sum_{n=0}^{\infty} -6\left(\sigma(n) + 3\delta^3_n \sigma\left(\frac{n}{3}\right)\right)q^n.$$

7.1 A recurrence relation for $\sigma$

Using the first equation of (1.7) we get the following non-trivial recurrence formula for $\sigma$ function. Similarly one can obtain other relations from other equations of the systems (1.7) and (1.11).

**Proposition 7.1.** For any integer $k \geq 1$ we have:

$$(7.4) \quad \sigma(2k) = \frac{8}{2k-1} \sum_{j=1}^{k-1} \sigma(j)\left(2\sigma(2k-j) + 4\sigma(k-j) - 5\sigma(2k-2j)\right)$$

$$- \frac{4k+1}{2k-1}\sigma(k) + \frac{8}{2k-1}(\sigma(k))^2,$$

$$(7.5) \quad \sigma(2k+1) = \frac{1}{k} \sum_{j=1}^{k} \sigma(j)\left(8\sigma(2k+1-j) - 20\sigma(2k+1-2j)\right).$$

**Proof.** On account of the first equation of the system (1.7) we have:

$$P_2' = \frac{1}{8}(P_2^2 - Q_2^2).$$

After comparing the Fourier coefficients in both sides of this equality we obtain the desired recurrences. \[\Box\]

Using (7.4) and (7.5), for any integer $k \geq 1$, we find the following congruences:

$$(7.6) \quad (2k-1)\sigma(2k) \equiv (4k+7)\sigma(k) \pmod{8}, \quad \sigma(2k) \equiv \sigma(k) \pmod{2},$$

$$(7.7) \quad k\sigma(2k+1) \equiv 0 \pmod{4}.$$
7.2 Ramanujan tau function

The Ramanujan tau function, namely \( \tau(n) \), \( n \in \mathbb{N} \), is defined as the Fourier coefficients of the modular discriminant \( \Delta \), i.e.:

\[
\Delta = \frac{E_4^3 - E_6^2}{1728} = \eta^{24}(q) = \sum_{n=1}^{\infty} \tau(n)q^n.
\]

A vast number of works have been dedicated to this function, see for instance [BeOn, BCOT] and references therein. Here we also give some properties for \( \tau(n) \) and then find analogous properties for Fourier coefficients of \( \Delta_2 \) and \( \Delta_3 \), namely \( \tau_2 \) and \( \tau_3 \).

The equation \( \Delta' = \Delta E_2 \) yields the relation:

\[
\tau(n) = -\frac{24}{n-1} \sum_{j=1}^{n-1} \tau(j)\sigma(n-j), \quad n \geq 2,
\]

which implies:

\[
(n-1)\tau(n) \equiv 0 \pmod{24}, \quad n \geq 2,
\]

and in particular:

\[
\tau(n) \equiv 0 \pmod{24}, \quad \text{if } \gcd(n-1,6) = 1.
\]

Using the Ramanujan system one can check that the following differential equation holds:

\[
4E_2^{(5)} - 10E_2E_2^{(4)} + 100E_2'E_2'' - 100(E_2'')^2 = 144\Delta.
\]

Alternately, one can obtain the above equation from the fact that \([E_2, E_2]_4 - 4E_2^{(5)} \in S_{12}(\text{SL}_2(\mathbb{Z}))\) (see [CS17, Proposition 5.3.27]), and that \(S_{12}(\text{SL}_2(\mathbb{Z}))\) is 1-dimensional and generated by \( \Delta \). Then, by comparing the Fourier coefficients of the equation (7.12) we obtain:

\[
\tau(n) = 40 \sum_{j=1}^{n-1} \left( \left( -10n^2j^2 + 30nj^3 - 21j^4 \right)\sigma(j)\sigma(n-j) \right) - \frac{1}{3}n^4(2n-5)\sigma(n).
\]

This relation implies:

\[
\tau(n) \equiv n^4\sigma(n) \equiv n\sigma(n) \pmod{2}\),
\]

and in particular implies the following known congruence relations of Ramanujan:

\[
\tau(2k) \equiv 0 \pmod{2} \quad \& \quad \tau(3k) \equiv 0 \pmod{3} \quad \& \quad \tau(5k) \equiv 0 \pmod{5}.
\]
7.3 Ramanujan-type tau function \( \tau_2 \)

We define the Ramanujan-type tau function \( \tau_2 \) to be the Fourier coefficients of \( \Delta_2 \), i.e.:

\[
\Delta_2(q) = \sum_{n=0}^{\infty} \tau_2(n) q^n = \eta^8(q) \eta^8(q^2) \in S_8(\Gamma_0(2)) .
\]

Using the equations \( \Delta'_2 = \Delta_2 \mathcal{P}_2 \) and (7.14), we obtain the following recursion formula:

\[
\tau_2(1) = 1 ,
\]

\[
\tau_2(n) = -\frac{8}{n-1} \sum_{j=1}^{n-1} \tau_2(j) \left( \sigma(n-j) + 2\delta_2^{n-j} \sigma \left( \frac{n-j}{2} \right) \right) , \quad n \geq 2 ,
\]

which implies:

\[
(n - 1) \tau_2(n) \equiv 0 \pmod{8} , \quad n \geq 2 .
\]

In particular, since g.c.d\((2k - 1, 8) = 1\), for any integer \( k \geq 1 \), we get:

\[
\tau_2(2k) \equiv 0 \pmod{8} .
\]

Using the system (1.7) we obtain that \( \mathcal{P}_2 \) and \( \Delta_2 \) satisfy the following differential equation:

\[
-6\mathcal{P}_2 \mathcal{P}_2'' + 9(\mathcal{P}_2')^2 + 4\mathcal{P}_2''' = 16\Delta_2 ,
\]

which also can be deduced from \( 4[\frac{1}{8}\mathcal{P}_2, \frac{1}{8}\mathcal{P}_2] - 2\left( \frac{1}{8}\mathcal{P}_2 \right)''' \in S_8(\Gamma_0(2)) \) (see [Nik21, Theorem 2.1]), and that \( S_8(\Gamma_0(2)) \) is 1-dimensional and is generated by \( \Delta_2 \). Using this equation we find \( \tau_2(n) \), \( n \geq 2 \), as follows:

\[
\tau_2(n) = 12 \sum_{j=1}^{n-1} \left\{ \left( 3nj - 5j^2 \right) \left( \sigma(j) + 2\delta_2^{j} \sigma \left( \frac{j}{2} \right) \right) \left( \sigma(n-j) + 2\delta_2^{n-j} \sigma \left( \frac{n-j}{2} \right) \right) \right\}
\]

\[
+ \left( 3n^2 - 2n^3 \right) \left( \sigma(n) + 2\delta_2^{n} \sigma \left( \frac{n}{2} \right) \right) .
\]

In particular we obtain:

\[
\tau_2(n) \equiv n^2 \sigma(n) \equiv n \sigma(n) \pmod{2} ,
\]

\[
\tau_2(n) \equiv n^3 \left( \sigma(n) + 2\delta_2^{n} \sigma \left( \frac{n}{2} \right) \right) \equiv n \left( \sigma(n) + 2\delta_2^{n} \sigma \left( \frac{n}{2} \right) \right) \pmod{3} .
\]

which imply:

\[
\tau_2(2k) \equiv 0 \pmod{2} , \quad k \geq 1 ,
\]

\[
\tau_2(3k) \equiv 0 \pmod{3} , \quad k \geq 1 .
\]

Equations (7.19) and (7.25) yield:

\[
\tau_2(6k) \equiv 0 \pmod{24} , \quad k \geq 1 .
\]
7.4 Ramanujan-type tau function \( \tau_3 \)

We consider the Ramanujan-type tau function \( \tau_3 \) as Fourier coefficients of \( \Delta_3 \), i.e.:

\[
\Delta_3(q) = \sum_{n=0}^{\infty} \tau_3(n)q^n = \eta^6(q)\eta^6(q^3) \in \mathcal{S}_6(\Gamma_0(3)).
\]

Using the equation \( \Delta_3' = \Delta_3 P_3 \) and (7.3), we get the following recursion formula:

\[
\tau_3(1) = 1,
\]

\[
\tau_3(n) = -\frac{6}{n-1} \sum_{j=1}^{n-1} \tau_3(j) \left( \sigma(n-j) + 3\delta_3^{n-j} \sigma \left( \frac{n-j}{3} \right) \right), \quad n \geq 2,
\]

which implies:

\[
(n-1)\tau_3(n) \equiv 0 \pmod{6}, \quad n \geq 2.
\]

In particular, if \( \gcd(n-1, 6) = 1 \), then:

\[
\tau_3(n) \equiv 0 \pmod{6}, \quad n \geq 2.
\]

Using the system (1.11) we can verify that \( P_3 \), \( Q_3 \) and \( \Delta_3 \) satisfy the following differential equation:

\[
P_3''' - 2P_3P_3'' + 3(P_3')^2 = 6\Omega_3\Delta_3,
\]

Note that similarly to \( \tau_2 \), this equation can also be checked from 4\left[ \frac{1}{6}P_3, \frac{1}{6}P_3 \right] - 2 \left[ \frac{1}{6}P_3 \right]''' \in \mathcal{S}_8(\Gamma_0(3)) \) (see [Nik21 Theorem 2.1]), and that \( \mathcal{S}_8(\Gamma_0(3)) \) is 1-dimensional and is generated by \( \Omega_3\Delta_3 \). After computing the \( q \)-expansion of \( \Omega_3 \) as follows:

\[
\Omega_3 = \sum_{n=0}^{\infty} 12 \left( \sigma(n) - 3\delta_3^n \sigma \left( \frac{n}{3} \right) \right) q^n.
\]

and using (7.31) we find \( \tau_3(n) \), \( n \geq 2 \), recursively as follows:

\[
\tau_3(n) = \sum_{j=1}^{n-1} \left\{ 6(3nj - 5j^2) \left( \sigma(j) + 3\delta_3^j \sigma \left( \frac{j}{3} \right) \right) \left( \sigma(n-j) + 3\delta_3^{n-j} \sigma \left( \frac{n-j}{3} \right) \right) \\
- 12\tau_3(j) \left( \sigma(n-j) - 3\delta_3^{n-j} \sigma \left( \frac{n-j}{3} \right) \right) \right\} \\
- n^2(n-2) \left( \sigma(n) + 3\delta_3^n \sigma \left( \frac{n}{3} \right) \right).
\]

Hence we obtain:

\[
\tau_3(n) \equiv 5n^2(n-2) \left( \sigma(n) + 3\delta_3^n \sigma \left( \frac{n}{3} \right) \right) \pmod{6},
\]

\[
\tau_3(n) \equiv n^3 \left( \sigma(n) + \delta_3^n \sigma \left( \frac{n}{3} \right) \right) \equiv n \left( \sigma(n) + \delta_3^n \sigma \left( \frac{n}{3} \right) \right) \pmod{2},
\]

\[
\tau_3(n) \equiv 2n^2(n-2) \sigma(n) \equiv 2n(n+1)\sigma(n) \pmod{3}.
\]

In particular we obtain:

\[
\tau_3(6k) \equiv 0 \pmod{6}, \quad k \geq 1,
\]

\[
\tau_3(2k) \equiv 0 \pmod{2}, \quad k \geq 1,
\]

\[
\tau_3(3k) \equiv 0 \pmod{3}, \quad k \geq 1.
\]
