TAP EQUATIONS ARE REPULSIVE.

STEPHAN GUFLER, JAN LUKAS IGELBRINK, AND NICOLA KISTLER

Abstract. We show that for low enough temperatures, but still above the AT line, the Jacobian of the TAP equations for the SK model has a macroscopic fraction of eigenvalues outside the unit interval. This provides a simple explanation for the numerical instability of the fixed points, which thus occurs already in high temperature. The insight leads to some algorithmic considerations on the low temperature regime, also briefly discussed.

1. Introduction

Let \( N \in \mathbb{N}, \beta > 0, h \in \mathbb{R}, \) and consider independent standard Gaussians \( g = (g_{ij})_{1 \leq i < j \leq N} \) issued on some probability space \((\Omega, \mathcal{F}, \mathbb{P})\). The TAP equations [18, after Thouless, Anderson and Palmer] for the spin magnetizations \( m = (m_i)_{i=1}^N \in [-1,1]^N \) in the SK-model [11, after Sherrington and Kirkpatrick] at inverse temperature \( \beta \) and external field \( h \) read

\[
m_i = \tanh \left( h + \frac{\beta}{\sqrt{N}} \sum_{j : j \neq i} g_{ij} m_j - \beta^2 (1 - q) m_i \right), \quad i = 1, \ldots, N. \tag{1.1}
\]

The \( \beta^2 \)-term is the (limiting) Onsager correction: it involves the high temperature order parameter \( q \) which is the (for \( \beta \leq 1 \) or \( h \neq 0 \) unique, see [12, Proposition 1.3.8]) solution of the fixed point equation

\[
q = \mathbb{E} \tanh^2 (h + \beta \sqrt{q} Z), \tag{1.2}
\]

\( Z \) being a standard Gaussian, and \( \mathbb{E} \) its expectation.

The concept of high temperature is related to the AT-line [2, after de Almeida and Thouless], i.e. the \((\beta, h)\)-region satisfying

\[
\beta^2 \mathbb{E} \frac{1}{\cosh^4 (h + \beta \sqrt{q} Z)} = 1. \tag{1.3}
\]

For \((\beta, h)\) where the l.h.s. is strictly less than unity, the system is allegedly in the replica symmetric phase (high temperature), see e.g. Adhikari et.al. [1] for a recent thorough discussion of this issue, and Chen [9] for evidence supporting the conjecture.

Due to the fixed point nature of the TAP equations (1.2), one is perhaps tempted to solve them numerically via classical Banach iterations, i.e. to approximate solutions via

\[
m_i^{(k+1)} = \tanh \left( h + \frac{\beta}{\sqrt{N}} \sum_{j : j \neq i} g_{ij} m_j^{(k)} - \beta^2 (1 - q) m_i^{(k)} \right), \quad i = 1, \ldots, N, \tag{1.4}
\]
As it turns out, these plain iterations are astonishingly \textit{in}-efficient in finding stable fixed points insofar the mean squared error between two iterates, to wit:

\[
\text{MSE} (m^{(k+1)}, m^{(k)}) \equiv \frac{1}{N} \sum_{i=1}^{N} (m_i^{(k+1)} - m_i^{(k)})^2 ,
\]

(1.5)

often remains large, even for very large \(k\)'s. Even more surprising, this issue is not restricted to the low temperature phase, cfr. Figure 1 below. Bolthausen \cite{6} bypasses this problem by means of a modification of the Banach algorithm (recalled below) which converges up to the AT-line. Notwithstanding, the origin of the phenomenon captured by Figure 1 has not yet been, to our knowledge, identified. It is the purpose of this work to fill this gap. Precisely, we show in Theorem 1 below that classical Banach iterates become unstable for the simplest reason: for large enough \(\beta\), but still below the AT-line, TAP equations become \textit{repulsive}. This should be contrasted with the classical counterpart of the SK-model: it is well known (and a simple fact) that \textit{relevant} solutions of the fixed point equations for the Curie-Weiss model are attractive at \textit{any} temperature, with the \textit{irrelevant} solution even becoming repulsive in low temperature.

2. Main result

2.1. Iterative procedure for the magnetizations. Bolthausen \cite{6} constructs magnetizations \(m^{(k)} = (m_i^{(k)})_{1 \leq i \leq N}\) for given disorder \((g_{ij})_{1 \leq i < j \leq N}\) through an iterative procedure in \(k = 1, 2, \ldots\). These magnetizations approximate fixed points of the TAP equations in the limit \(N \to \infty\) followed by \(k \to \infty\). The algorithm uses the initial values \(m^{(0)} = 0\),

\footnote{this observation has been made, at times anecdotally, ever since: it is already present in Mézard, Parisi and Virasoro \cite{13} Section II.4].}
\[ \mathbf{m}^{(1)} = \sqrt{q} \mathbf{1}. \] The iteration step reads
\[ m_i^{(k+1)} = \tanh \left( h + \frac{\beta}{\sqrt{N}} \sum_{j: j \neq i} g_{ij} m_j^{(k)} - \beta^2 (1 - q) m_i^{(k-1)} \right), \tag{2.1} \]
for \( i \leq N \), and \( k \in \mathbb{N} \). Remark in particular that contrary to the classical Banach algorithm, the above scheme invokes a time delay in the Onsager correction: we will thus refer to (2.1) as \textit{Two Steps Banach algorithm}, 2STEB for short. By [6, Proposition 2.5], the quantity
\[ q_N := N^{-1} \sum_{i=1}^{N} \left( m_i^{(k)} - m_i^{(k-1)} \right)^2, \]
for \( i \leq N \), and \( k \in \mathbb{N} \). Moreover, by [6, Theorem 2.1],
\[ \lim_{k, k' \to \infty} \limsup_{N \to \infty} \mathbb{E} \left[ \frac{1}{N} \sum_{i=1}^{N} \left( m_i^{(k)} - m_i^{(k')} \right)^2 \right] = 0, \tag{2.2} \]
provided \((\beta, h)\) is below the AT-line, i.e. if the left-hand side of (1.3) is less than unity.

2.2. Spectrum of the Jacobian. Denote by \( F_i(\mathbf{m}^{(k)}) \) the right-hand side of (1.4), and consider the Jacobian \( J^{(k)} \) with entries
\[ J_{ij}^{(k)} := \frac{\partial F_i}{\partial m_j}(\mathbf{m}^{(k)}) = \begin{cases} \frac{\beta}{\sqrt{N}} g_{ij} \left( 1 - F_i(\mathbf{m}^{(k)})^2 \right) : i \neq j \\ -\beta^2 (1 - q) \left( 1 - F_i(\mathbf{m}^{(k)})^2 \right) : i = j, \end{cases} \tag{2.3} \]
omitting the obvious \( N \)-dependence to lighten notations.

The Jacobian \( J^{(k)} \) is not symmetric, but we claim that it is nonetheless diagonalizable, and that all eigenvalues are real. To see this we write the Jacobian as a product
\[ J^{(k)} = \hat{J} \text{diag} \left( 1 - F_i(\mathbf{m}^{(k)})^2 \right), \tag{2.4} \]
where
\[ \hat{J}_{ij} := \begin{cases} \frac{\beta}{\sqrt{N}} g_{ij} & i < j, \\ \frac{\beta}{\sqrt{N}} g_{ji} & j < i, \\ -\beta^2 (1 - q) & i = j. \end{cases} \tag{2.5} \]
The first matrix on the r.h.s. of (2.4) is symmetric, whereas the second is negative definite: it thus readily follows from [10, Theorem 2] that \( J^{(k)} \) itself is diagonalizable, and that all its eigenvalues are real, settling our claim.

Denoting the ordered sequence of the real eigenvalues of a matrix \( M \) by \( \lambda_1(\mathcal{M}) \geq \ldots \geq \lambda_N(\mathcal{M}) \), we then consider the empirical spectral measure of the Jacobian
\[ \mu^{(k)} := \frac{1}{N} \sum_{i=1}^{N} \delta_{\lambda_i(\hat{J}^{(k)})}. \tag{2.6} \]
Our main result states that in a region below the AT-line, \( \mu^{(k)} \) has mass outside the unit interval.

\[ \text{See also [6] for a treatment similar in spirit to our considerations, albeit with radically different tools, for } \mathbb{Z}_2 \text{-synchronization}. \]
Theorem 1. For all $\beta \in (\sqrt{2} - 1, 1)$ and $\epsilon > 0$, there exists $h_0 > 0$ such that the following holds true: for all $h \in [0, h_0]$, there exists $k_0 \in \mathbb{N}$, and for all $k \geq k_0$, there exists $N_0 \in \mathbb{N}$, such that $P(\mu^{(k)}(-\infty, -1) > 0) \geq 1 - \epsilon$, for all $N \geq N_0$.

TAP equations thus become repulsive due a macroscopic fraction of low-lying ($<-1$) eigenvalues. Before giving a proof of this statement, we remark that the measures $\mu^{(k)}$ converge to a limiting measure $\mu$ which can be stated as a free multiplicative convolution

$$\mu = \lambda_{\beta, q} \boxtimes \nu,$$

where $\lambda_{\beta, q}$ is the law of $\beta X - \beta^2(1-q)$ for $X$ distributed according to the standard semicircular law with density $x \in [-2, 2] \mapsto (2\pi)^{-1/2} \sqrt{4-x^2}$, and $\nu$ is the law of $1 - \text{tanh}^2(h + \beta \sqrt{q} Z)$ for $Z$ standard Gaussian. To sketch a proof of this claim, we use the decomposition (2.4) and make the following observations: i) The empirical spectral distribution of the first factor $\hat{J}$ weakly-converges almost surely to the scaled/shifted semicircular law $\lambda_{\beta, q}$; ii) The empirical spectral distribution of the second factor $1 - F(m^{(k)})^2$ can similarly be shown to converge to $\nu$. These observations, together with the (asymptotic) independence of the two factors which follows from [17], finally [4, Theorem 5.4.2] then yield the representation (2.7).

The free convolution can also be evaluated more explicitly using Voiculescu’s S-transform via inversion of moment generating functions, see e.g. [4, Chapter 5.3]. We believe this approach allows to remove the small-$h$ condition in Theorem 1. The ensuing analysis is however both long and (tediously) technical. As the outcome arguably adds little to the main observation of this work, we refrain from pursuing this route here.

Proof of Theorem 1. In a first step we consider a simplified version of the Jacobian, namely the matrix $\hat{J}$ from (2.5) in place of $J^{(k)}$. We write $\hat{J} = W - \beta^2(1-q) I$, where $W$ is a Wigner matrix. As a consequence of Wigner’s theorem, see e.g. [17, Theorem 2.4.2], the empirical spectral measure $\hat{\mu}$ associated with $\hat{J}$ converges a.s. with respect to the vague topology to the law of $\beta X - \beta^2(1-q)$, where $X$ has the standard semicircular density. We note that this limit law has mass in any right vicinity of $-2\beta - \beta^2(1-q)$.

Next we show that $\mu^{(k)}$ and $\hat{\mu}$ converge to the same limit as $N \to \infty$ followed by $k \to \infty$, and finally $h \to 0$. To this aim, let $R^{(k)}(z) = (J^{(k)} - z I)^{-1}$ and $\hat{R}(z) = (\hat{J} - z I)^{-1}$ denote the resolvents of $J^{(k)}$ and $\hat{J}$, respectively. It suffices to show that the Stieltjes transforms $N^{-1} \text{tr} \hat{R}(z)$ and $N^{-1} \text{tr} R^{(k)}(z)$ of $\hat{\mu}$ and $\mu^{(k)}$, respectively, converge to the same limit in probability as $N \to \infty$ followed by $k \to \infty$ and $h \to 0$, pointwise for all $z \in \mathbb{C}$ with $\Im z > 0$ (see e.g. [17, Section 2.4.3] for properties of the Stieltjes transform). By the resolvent identity,

$$N^{-1} \text{tr} R^{(k)}(z) - N^{-1} \text{tr} \hat{R}(z) = N^{-1} \text{tr} R^{(k)}(z) \left( \hat{J} - J^{(k)} \right) \hat{R}(z).$$

(2.8)

The $p$-Schatten norm of an $N \times N$ matrix $M$ whose eigenvalues are all real is defined by

$$\|M\|_p := \left( \sum_{i=1}^{N} |\lambda_i(M)|^p \right)^{1/p} \quad \text{for } p \in [1, \infty), \quad \|M\|_\infty := \max \{|\lambda_i(M)| : i = 1, \ldots, N\}$$

(2.9)
TAP EQUATIONS ARE REPULSIVE.

which satisfies \( \|M\|_1 \geq |\text{tr } M| \) and the Hölder inequality. Hence, the expression in (2.8) is bounded in absolute value by

\[
\| R^{(k)}(z) \|_\infty \| \hat{R}(z) \|_\infty \| \hat{J} \|_\infty N^{-1} \| \text{diag} F(m^{(k)}) \|^2_1, \tag{2.10}
\]

where we evaluated \( \hat{J} - J^{(k)} \) using (2.4). Each of the first two terms in (2.10) is bounded by \( 1/|3z| \), which follows from the definition of the resolvent. The third term \( \| \hat{J} \|_\infty \) converges in probability to \( 2\beta + \beta^2(1 - q) \) as \( N \to \infty \) by Wigner’s theorem in conjunction with edge scaling for Wigner matrices, see e.g. [4, Chapter 3], and [3] for a recent reference. From the definitions of \( F_i(m^{(k)}) \) and \( m_i^{(k+1)} \), and as the function \( x \mapsto \tanh^2(x) \) is 2-Lipschitz continuous, we obtain

\[
\left| F_i(m^{(k)})^2 - m_i^{(k+1)^2} \right| = \left| \tanh^2 \left( h + \frac{\beta}{\sqrt{N}} \sum_{j \neq i} g_{ij} m_j^{(k)} - \beta^2(1 - q)m_i^{(k)} \right) \right.
\]

\[
- \left. \tanh^2 \left( h + \frac{\beta}{\sqrt{N}} \sum_{j \neq i} g_{ij} m_j^{(k)} - \beta^2(1 - q)m_i^{(k-1)} \right) \right| \leq 2\beta^2(1 - q) \left| m_i^{(k)} - m_i^{(k-1)} \right|. \tag{2.11}
\]

Hence, by definition of the 1-Schatten norm,

\[
N^{-1} \| \text{diag} F(m^{(k)})^2 \|_1 \leq N^{-1} \sum_{i=1}^N \left( m_i^{(k)} \right)^2 + 2N^{-1} \sum_{i=1}^N \left| 1 \cdot \left( m_i^{(k)} - m_i^{(k-1)} \right) \right|. \tag{2.12}
\]

The second term on the r.h.s. is bounded by

\[
2N^{-1/2} \left[ \sum_{i=1}^N \left( m_i^{(k)} - m_i^{(k-1)} \right)^2 \right]^{1/2} \tag{2.13}
\]

by the Cauchy-Schwarz inequality and thus converges to 0 in probability as \( N \to \infty \) followed by \( k \to \infty \) by (2.2). The first term on the r.h.s. of (2.12) equals \( q_N \) and thus converges to \( q \) in probability as \( N \to \infty \) followed by \( k \to \infty \). From (1.2), we obtain

\[
q = E \tanh^2 (h + \beta \sqrt{qZ}) \leq h^2 + \beta^2 q, \tag{2.14}
\]

and

\[
0 \leq q \leq \frac{\hbar^2}{1 - \beta^2}, \tag{2.15}
\]

for \( \beta \in (0, 1) \), hence \( h \to 0 \) implies \( q \to 0 \).

From the above, it follows that \( \mu^{(k)} \) and \( \hat{\mu} \) converge in probability to the same vague limit \( \mu \) as \( N \to \infty \) followed by \( k \to \infty \) and \( h \to 0 \). For \( h = 0 \) and \( \beta \in (\sqrt{2} - 1, 1) \), we have \( \mu(-\infty, -1) > 0 \) a.s. as a consequence of the first part of the proof. The assertion now follows from the vague convergence in probability of \( \mu^{(k)} \) to \( \mu \). \( \square \)

3. Yet another algorithm, and simulations

The above considerations pertain to high temperature, but naturally lead to insights into the low temperature regime, where finding solutions of the TAP equations is notoriously hard. Indeed, Theorem\[H\] suggests that the numerical instability of classical iteration
schemes is “nothing structural”, but heavily depends on the way TAP equations are written. Under this light, the following iteration scheme, which we refer to as $\varepsilon$-BANACH, is quite natural: for $\varepsilon \in \mathbb{R}$ an additional free parameter, it reads

$$m_i^{(k+1)} = \varepsilon m_i^{(k)} + (1 - \varepsilon) \tanh \left( h + \frac{\beta}{\sqrt{N}} \sum_{j \neq i} g_{ij} m_j^{(k)} - \beta^2 (1 - q_N) m_i^{(k)} \right), \quad (3.1)$$

for $i = 1 \ldots N, k \in \mathbb{N}$. The idea behind the “$\varepsilon$-splitting” is of course to mitigate the impact of large negative Jacobian-eigenvalues. We emphasize that:

- Here and henceforth we consider the finite-$N$ Onsager reaction term $q_N := \frac{1}{N} \sum_{i=1}^{N} m_i^{(k)2}$.

- Iterations are classical: unlike (2.1), no time-delay appears in Onsager’s correction.

In this section we present a summary of numerical simulations run on the High Performance Computer Elwetritsch; additional material may be found in the supplementary material.

Anticipating, 2SteB is largely outperformed, in low temperature, by $\varepsilon$-BANACH: this is due to the fact that the former is extremely sensitive to the initialization, to the point of becoming eventually hopeless at finding stable fixed points; this limitation is not shared by the latter, in virtue (also) of the additional “degree of freedom” $\varepsilon$ which may be tweaked at our discretion.

### 3.1. Calibrating $\varepsilon$-Banach: high temperature.

Given our limited theoretical understanding, effective choices of the $\varepsilon$ parameter can only be found empirically. Here we show that a proper calibration does lead to an algorithmic performance of $\varepsilon$-BANACH which is, in high temperature, fully comparable to 2SteB. To do so, we appeal to the TAP free energy, TAP FE for short, which we recall is given by

$$N f_{\text{TAP}}(m) \equiv \frac{\beta}{\sqrt{N}} \sum_{i<j} \sum_{i \leq N} g_{ij} m_i m_j + h \sum_{i \leq N} m_i + \frac{\beta^2}{2N} \sum_{i<j} (1 - m_i^2) (1 - m_j^2) - \sum_{i \leq N} I(m_i), \quad (3.2)$$

where $m \in [-1, 1]^N$, and $I(x) \equiv \frac{1+x}{2} \log(1+x) + \frac{1-x}{2} \log(1-x)$.

Critical points of the TAP FE are solutions of the TAP equations: in our simulations we have thus computed the TAP FE of the fixed points found by both 2SteB and $\varepsilon$-BANACH. This is no simple task, for multiple reasons. First, the choice of the system’s size is a priori not clear: we have chosen this to be $N = 25$ throughout. This might look at first sight unreasonably small, but numerical evidence rejects the objection. As a matter of fact, we show below that the (way) more delicate issue pertains to the number of initial values where iterations must be started for algorithms to find anything reasonable at all.

---

3 This scheme is well-known in the numerical literature: it has been implemented e.g. by Aspelmeier et. al [5] to probe marginal stability of TAP solutions “at the edge of chaos”.

4 Analogously for 2SteB: the approximation (1.2) is of course wrong in low temperature.
TAP EQUATIONS ARE REPULSIVE.

C1. Even more challenging is the number of iterations, i.e. to decide whether these have stabilized. In this regard, our simulations (see also the supplementary material) suggest that the MSE (1.5) is way too inaccurate a tool: we have thus discarded it in favor of the maximum absolute error between iterates, i.e.

$$\text{MAE} (\bm{m}^{(k+1)}, \bm{m}^{(k)}) \equiv \max_{i=1}^{N} \left| m_i^{(k+1)} - m_i^{(k)} \right|, \quad (3.3)$$

thereby stopping iterations as soon as MAE $\leq 10^{-7}$.

C2. Criteria for the validity of the TAP-Plefka expansions (which lead to the TAP FE) are vastly unknown. The only criterion which seems to be unanimously accepted is the one by Plefka [16]. We thus require that (approximate) fixed points also satisfy Plefka’s condition, i.e.

$$\text{Plefka} (\bm{m}^{(k)}) \equiv \frac{\beta^2}{N} \sum_{i=1}^{N} \left( 1 - m_i^{(k)^2} \right)^2 \leq 1. \quad (3.4)$$

Yet another key test for an approximate solution to be physically relevant is the associated TAP FE, which in turn should coincide with the Parisi FE [14]. Figure 2 summarizes our findings concerning the calibration of $\varepsilon$-BANACH to yield TAP solutions which fulfill all above criteria.

**Figure 2.** TAP FE (y-axis) vs. $\varepsilon$ (x-axis) for $\beta = 1$ and $h = 0.5$ (way below AT-line). The red line is the FE computed from Parisi replica symmetric formula. We have run $\varepsilon$-BANACH for 1000 uniformly distributed start values: blue dots correspond to solutions which lie in the hypercube after $k = 1000$ iterations. The rightmost dot corresponds to the TAP FE of the (approximate) fixed point found by 2SteB. For $\varepsilon \approx 0.5$, say, the performance of $\varepsilon$-BANACH is thus fully equivalent to the 2SteB.

3.2. 2SteB vs. $\varepsilon$-Banach: low temperature. Henceforth the physical parameters are $h = 0.5$ and $\beta = 3$ (well above the AT-line). The size of the system is again $N = 25$.

In low temperature, the issue of initialization becomes salient. Since Plefka criterion must be satisfied, this amounts to starting the algorithm close to the facets of the hypercube: by this we mean that we will consider $\bm{m}^{(0)}$ drawn uniformly in the subset of the hypercube where coordinates satisfy $m_i^{(0)} \in [0.98, 1] \cup [-1, -0.98]$.

\[5\text{The low temperature SK-model allegedly requires } \infty \text{-many replica symmetry breakings (RSB). We use the Parisi FE obtained from a 2RSB approximation as the numerical error is mostly irrelevant [13].}\]
TAP EQUATIONS ARE REPULSIVE.

Figure 3. Eigenvalues of the Jacobian evaluated in one solution fulfilling C1-2). The Plefka value is 0.073206039645813 ≪ 1.

Figure 4. ε-BANACH: 500 start values close to the facets of the hypercube, 1000 disorder realizations. 1000 iterations for each start value and ε. Since the Parisi FE is an upper-bound [15], fixed points to the right of the red line in (C) must be rejected.

A second issue is the ε-calibration: the somewhat counterintuitive upshot is summarized in Figure 4 below. Anticipating, one evinces that calibrating ε-BANACH with positive ε leads to a wealth of approximate fixed points with unphysical TAP FE. We do not have any compelling explanation to this riddle, but it is tempting to believe that it finds its origin in the following: Plefka’s criterion [34], which is known to be a necessary condition for convergence of the TAP-Plefka expansion, is possibly one of (many?) still unknown criteria. Finally, ε-BANACH to negative ε possibly yields iterates that temporarily exit the hypercube: curiously, this appears to be an efficient way to overcome the repulsive nature of the fixed points which, as manifested by Figure 3 below, becomes even more dramatic in low temperature.

3.3. One, or more solutions? The Parisi theory predicts, in low temperature, a large number of TAP solutions per realization. As can be evinced from Figure 7 below, numerical evidence for this is hard to come by: all solutions differ only after the 7th digit. The
crux of the matter seems to lie in the following: upon closer inspection, one finds that even after 1000 iterations, solutions (barely, but) still move. We have thus performed a more accurate numerical study, thereby recursively validating a fixed point as new whenever its $\ell_\infty$-distance to all previously validated is greater than $10^{-7}$. In order to facilitate the search for viable solutions we have also increased the accuracy of the $\varepsilon$-mesh. The outcome is summarized in Figure 8 below. All fixed points appearing in Figure 9 satisfy $C1-2$.) one evinces that $\varepsilon$-BANACH has indeed found multiple solutions. However, many of these

Figure 5. $\varepsilon$-BANACH vs. 2STE B: 1000 uniformly chosen initializations, 1000 iterations each. One clearly evinces that 2STE B comes, in low temperature, to a stall: the algorithm doesn’t even come close to a reasonable TAP FE (Figure A). In case of $\varepsilon$-BANACH, two choices lead to reasonable TAP free energies, but caution is needed: positive $\varepsilon = 0.5$ yields solutions violating Plefka’s criterion (Figure B). Only negative $\varepsilon \approx -0.7$ lead to viable solutions: a numerical analysis of these is presented in Figure 6.

Figure 6. $\varepsilon$-BANACH: TAP FE of all solutions satisfying $C1-2$), 500 initializations close to the facets of the hypercube, 1000 disorder realizations, $\varepsilon = -0.705 - 0.001 \cdot j$ for $j = 0, \ldots, 20$. Red is the 2RSB Parisi FE.
TAP EQUATIONS ARE REPULSIVE.

Figure 7. $\ell_\infty$-Distance (MAE) to a reference solution, C1-2) being satisfied, found by $\varepsilon$-BANACH in 1000 realizations, each with 500 start values close to the facets of the hypercube, and $\varepsilon = -0.705 - 0.001 \cdot j$, $j = 0, \ldots, 20$.

Figure 8. Iterations satisfying C1-2), and $\varepsilon = -0.505 + 0.001 \cdot j$, $j \leq 250$.

Figure 9. TAP FE as in Fig. 6 but with $\varepsilon = -0.505 + 0.001 \cdot j$, $j \leq 250$.

still yield TAP FE larger than the Parisi FE and must therefore be discarded. We believe this to be yet another instance of the aforementioned issue of unknown convergence criteria for the TAP-Plefka expansion.
TAP EQUATIONS ARE REPULSIVE.

In a sloppy language we call

\[
\text{MSE}_N \left( \mathbf{m}^{(k+1)}, \mathbf{m}^{(k)} \right) \equiv \frac{1}{N} \sum_{i=1}^{N} \left( m_i^{(k+1)} - m_i^{(k)} \right)^2
\]

the mean squared error between the two iterates $\mathbf{m}^{(k+1)}$ and $\mathbf{m}^{(k)}$. We call

\[
\text{MAE}_N \left( \mathbf{m}^{(k+1)}, \mathbf{m}^{(k)} \right) \equiv \max_{i=1}^{N} \left| m_i^{(k+1)} - m_i^{(k)} \right|
\]

the maximum absolute error between the two iterates $\mathbf{m}^{(k+1)}$ and $\mathbf{m}^{(k)}$.

3. How we chose the start values

We chose the start values uniformly out of the hypercube or uniformly out of all points inside the hypercube whose coordinates are in $[0.98, 1] \cup [-1, -0.98]$. The second method will be called as *chosen uniformly out of the corners of the hypercube*. 

4. Standard Banach algorithm

4.1. Using the maximum absolute error.

Figure 2. 1000 iterations of the standard Banach algorithm for $N = 10$ and $h = 0$. For $\beta \in [0, 1.5]$ we analyze the stability of this algorithm and see how quickly it takes off. To measure if the iterations stabilized we use the maximum absolute error between the last two iterates. The vertical line marks the AT line.

Figure 3. 1000 iterations of the standard Banach algorithm for $N = 10$ and $h = 0.5$. For $\beta \in [0, 1.5]$ we analyze the stability of this algorithm and see how quickly it takes off. To measure if the iterations stabilized we use the maximum absolute error between the last two iterates. The vertical line marks the AT line.

4.1.1. Uniform on the hypercube distributed start values.
Figure 4. 1000 iterations of the standard Banach algorithm for $N = 10$ and $h = 1$. For $\beta \in [0, 1.5]$ we analyze the stability of this algorithm and see how quickly it takes off. To measure if the iterations stabilized we use the maximum absolute error between the last two iterates. The vertical line marks the AT line.

Figure 5. 1000 iterations of the standard Banach algorithm for $N = 25$ and $h = 0$. For $\beta \in [0, 1.5]$ we analyze the stability of this algorithm and see how quickly it takes off. To measure if the iterations stabilized we use the maximum absolute error between the last two iterates. The vertical line marks the AT line.
Figure 6. 1000 iterations of the standard Banach algorithm for \( N = 25 \) and \( h = 0.5 \). For \( \beta \in [0, 1.5] \) we analyze the stability of this algorithm and see how quickly it takes off. To measure if the iterations stabilized we use the maximum absolute error between the last two iterates. The vertical line marks the AT line.

Figure 7. 1000 iterations of the standard Banach algorithm for \( N = 25 \) and \( h = 1 \). For \( \beta \in [0, 1.5] \) we analyze the stability of this algorithm and see how quickly it takes off. To measure if the iterations stabilized we use the maximum absolute error between the last two iterates. The vertical line marks the AT line.
Figure 8. 1000 iterations of the standard Banach algorithm for $N = 100$ and $h = 0$. For $\beta \in [0, 1.5]$ we analyze the stability of this algorithm and see how quickly it takes off. To measure if the iterations stabilized we use the maximum absolute error between the last two iterates. The vertical line marks the AT line.

Figure 9. 1000 iterations of the standard Banach algorithm for $N = 100$ and $h = 0.5$. For $\beta \in [0, 1.5]$ we analyze the stability of this algorithm and see how quickly it takes off. To measure if the iterations stabilized we use the maximum absolute error between the last two iterates. The vertical line marks the AT line.
Figure 10. 1000 iterations of the standard Banach algorithm for $N = 100$ and $h = 1$. For $\beta \in [0, 1.5]$ we analyze the stability of this algorithm and see how quickly it takes off. To measure if the iterations stabilized we use the maximum absolute error between the last two iterates. The vertical line marks the AT line.

Figure 11. 1000 iterations of the standard Banach algorithm for $N = 500$ and $h = 0$. For $\beta \in [0, 1.5]$ we analyze the stability of this algorithm and see how quickly it takes off. To measure if the iterations stabilized we use the maximum absolute error between the last two iterates. The vertical line marks the AT line.
Figure 12. 1000 iterations of the standard Banach algorithm for $N = 500$ and $h = 0.5$. For $\beta \in [0, 1.5]$ we analyze the stability of this algorithm and see how quickly it takes off. To measure if the iterations stabilized we use the maximum absolute error between the last two iterates. The vertical line marks the AT line.

Figure 13. 1000 iterations of the standard Banach algorithm for $N = 500$ and $h = 1$. For $\beta \in [0, 1.5]$ we analyze the stability of this algorithm and see how quickly it takes off. 4.3. **Short summary.** We see that no matter how we choose the start values the standard Banach-algorithm does not converge (no matter which of the two measures for the stability we use!) for $\beta$ large enough where *large enough* is way before thee AT-line. We see that for $h = 0, h = 0.5, h = 1$ and $N = 25, 100, 500, 1000$.

5. **$\varepsilon$-Banach and Two-Step-Banach in high temperature for $\beta = 1$ and $h = 0.5$**

![Figure 62](image.png)

**Figure 62.** 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta = 1$ and $h = 0.5$. To measure if the iterations stabilized we use the *mean squared error* between the last two iterates. We simulated 1000 uniform in the corners of the hypercube distributed start values for $\varepsilon = -0.9, -0.85, \ldots, 0.0$. The *mean squared error* seems to depend highly on the choice of $\varepsilon$. It’s obvious that the diverginess will be smaller for $\varepsilon \to 1$ and this does not mean that solutions found with those $\varepsilon$ are better ones.

5.0.1. **Uniform in the corners of the hypercube distributed start values.**
To measure if the iterations stabilized we use the maximum absolute error between the last two iterates. We simulated 1000 uniform in the corners of the hypercube distributed start values for $\varepsilon = -0.9, -0.85, \ldots, 0.0$. The maximum absolute error seems to depend highly on the choice of $\varepsilon$. It’s obvious that the diverginess will be smaller for $\varepsilon \to 1$ and this does not mean that solutions found with those $\varepsilon$ are better ones.

Figure 64. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta = 1$ and $h = 0.5$. To measure if the iterations stabilized we use the mean squared error between the last two iterates. We simulated 1000 uniform in the corners of the hypercube distributed start values for $\varepsilon = -0.9, -0.85, \ldots, 0.0$. We say that a found fix point is a good one if the found TAP free energy is between $0.35383069483591 \pm 0.05$ ($0.35383069483591$ is the value found with RS formulae), the mean squared error is smaller than 0.0001 and the plefka condition is fulfilled.
Figure 65. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta = 1$ and $h = 0.5$. We simulated 1000 uniform in the corners of the hypercube distributed start values for $\varepsilon = -0.9, -0.85, \ldots, 0.0$. We say that a found fix point is a good one if the found TAP free energy is between $0.35383069483591 \pm 0.05$ ($0.35383069483591$ is the value found with RS formulae), the mean squared error is smaller than 0.0001 and the Plefka condition is fulfilled. We plotted all found values of the tap free energy values of good iterations and excluded all iterations which landed outside the hypercube. The vertical line marks the TAP free energy value found with the RS formulae.

Figure 66. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta = 1$ and $h = 0.5$. We simulated 1000 uniform in the corners of the hypercube distributed start values for $\varepsilon = -0.9, -0.85, \ldots, 0.0$. We plotted all found $L_2$-norms of found fix points.
Figure 67. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta = 1$ and $h = 0.5$. We simulated 1000 uniform in the corners of the hypercube distributed start values for $\varepsilon = -0.9, -0.85, \ldots, 0.0$. We plotted all found plefka values of found fix points.

Figure 68. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta = 1$ and $h = 0.5$. It’s obvious that the diverginess will be smaller for \( \varepsilon \to 1 \) and this does not mean that solutions found with those \( \varepsilon \) are better ones.
To measure if the iterations stabilized we use the maximum absolute error between the last two iterates. We simulated 1000 uniform in the hypercube distributed start values for $\epsilon = -0.9, -0.85, \ldots, 0.0$. The maximum absolute error seems to depend highly on the choice of $\epsilon$. It’s obvious that the maximum absolute error will be smaller for $\epsilon \to 1$ and this does not mean that solutions found with those $\epsilon$ are better ones.

To measure if the iterations stabilized we use the mean squared error between the last two iterates. We simulated 1000 uniform in the hypercube distributed start values for $\epsilon = -0.9, -0.85, \ldots, 0.0$. We say that a found fix point is a good one if the found TAP free energy is between $0.35383069483591 \pm 0.05$ ($0.35383069483591$ is the value found with RS formulae), the mean squared error is smaller than 0.0001 and the plefka condition is fulfilled.
Figure 79. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta = 1$ and $h = 0.5$. We simulated 1000 uniform in the hypercube distributed start values for $\varepsilon = -0.9, -0.85, \ldots, 0.0$. We say that a found fix point is a good one if the found TAP free energy is between $0.35383069483591 \pm 0.05$ ($0.35383069483591$ is the value found with RS formulae), the mean squared error is smaller than 0.0001 and the plefka condition is fulfilled. We plotted all found values of the tap free energy values of good iterations and excluded all iterations which landed outside the hypercube. The vertical line marks the TAP free energy value found with the RS formulae.

Figure 80. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta = 1$ and $h = 0.5$. We simulated 1000 uniform in the hypercube distributed start values for $\varepsilon = -0.9, -0.85, \ldots, 0.0$. We plotted all found $L_2$-norms of found fix points.
Figure 81. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta = 1$ and $h = 0.5$. We simulated 1000 uniform in the hypercube distributed start values for $\varepsilon = -0.9, -0.85, \ldots, 0.0$. We plotted all found Plefka values of found fix points.

Figure 82. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta = 1$ and $h = 0.5$. We simulated 1000 uniform in the hypercube distributed start values for $\varepsilon = -0.9, -0.85, \ldots, 0.0$. We plotted all found values of the TAP free energy and excluded all iterations which landed outside the hypercube. The vertical line marks the TAP free energy value found with the RS formulae.
Figure 83. 1000 iterations of the ε-Banach algorithm for $N = 25, \beta = 1$ and $h = 0.5$. To measure if the iterations stabilized we use the mean squared error between the last two iterates. We simulated 1000 uniform in the hypercube distributed start values for $\varepsilon = -0.9, -0.85, \ldots, 0.0$. The $L_2$-diverginess seems to depend highly on the choice of $\varepsilon$. It's obvious that the mean squared error will be smaller for $\varepsilon \to 1$ and this does not mean that solutions found with those $\varepsilon$ are better ones.

5.1. **Short summary.** In the high temperature regime we see that Two-Step-Banach is not sensitive with respect to the start values. \( \varepsilon \)-Banach is very sensitive with respect to the start values for \( \varepsilon \) negative enough. In the high temperature regime there seems to be a positive lower bound on \( \varepsilon \) such that we find good solutions. It is very interesting that we always find a TAP free energy different from the one suggested by RS formulæ.

6. **Low temperature regime: \( \varepsilon \)-Banach and Two-Step**

6.1. **Uniform in the hypercube distributed start values for \( \varepsilon \)-Banach.**

![Figure 90. 1000 iterations of the \( \varepsilon \)-Banach algorithm for \( N = 10, \beta \in [0,5] \) and \( h = 0 \). We simulated one uniform in the hypercube distributed start value for \( \varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9 \). We plotted the \( L_2 \)-diverginess for the given parameters and used the same start value for all \( \beta \).**

6.1.1. **\( L_2 \)-diverginess.**
Figure 91. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta \in [0,5]$ and $h = 0.5$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L^2$-divergeness for the given parameters and used the same start value for all $\beta$.

Figure 92. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta \in [0,5]$ and $h = 1$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L^2$-divergeness for the given parameters and used the same start value for all $\beta$. 
Figure 93. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 25, \beta \in [0, 5]$ and $h = 0$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L_2$-diverginess for thee given parameters and used the same start value for all $\beta$.

Figure 94. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 25, \beta \in [0, 5]$ and $h = 0.5$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L_2$-diverginess for thee given parameters and used the same start value for all $\beta$. 
Figure 95. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 25, \beta \in [0, 5]$ and $h = 1$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L_2$-diverginess for the given parameters and used the same start value for all $\beta$.

Figure 96. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 100, \beta \in [0, 5]$ and $h = 0$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L_2$-diverginess for the given parameters and used the same start value for all $\beta$. 
Figure 97. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 100, \beta \in [0,5]$ and $h = 0.5$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L_2$-diverginess for thee given parameters and used the same start value for all $\beta$.

Figure 98. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 100, \beta \in [0,5]$ and $h = 1$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L_2$-diverginess for thee given parameters and used the same start value for all $\beta$. 
Figure 99. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 500, \beta \in [0, 5]$ and $h = 0$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L_2$-diverginess for thee given parameters and used the same start value for all $\beta$.

Figure 100. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 500, \beta \in [0, 5]$ and $h = 0.5$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L_2$-diverginess for thee given parameters and used the same start value for all $\beta$. 
Figure 101. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 500, \beta \in [0, 5]$ and $h = 1$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L^2$-diverginess for the given parameters and used the same start value for all $\beta$.

Figure 102. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 1000, \beta \in [0, 5]$ and $h = 0$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L^2$-diverginess for the given parameters and used the same start value for all $\beta$. 
Figure 103. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 1000, \beta \in [0,5]$ and $h = 0.5$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L^2$-diverginess for thee given parameters and used the same start value for all $\beta$.

Figure 104. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 1000, \beta \in [0,5]$ and $h = 1$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L^2$-diverginess for thee given parameters and used the same start value for all $\beta$. 
Figure 105. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta \in [0, 5]$ and $h = 0$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L_\infty$-distance–diverginess for thee given parameters and used the same start value for all $\beta$.

Figure 106. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta \in [0, 5]$ and $h = 0.5$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L_\infty$-distance–diverginess for thee given parameters and used the same start value for all $\beta$.

6.1.2. $L_\infty$-distance divergence.
Figure 107. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 10, \beta \in [0, 5]$ and $h = 1$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L_\infty$-distance–diverginess for thee given parameters and used the same start value for all $\beta$.

Figure 108. 1000 iterations of the $\varepsilon$-Banach algorithm for $N = 25, \beta \in [0, 5]$ and $h = 0$. We simulated one uniform in the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$. We plotted the $L_\infty$-distance–diverginess for thee given parameters and used the same start value for all $\beta$.

We plotted the $L_2$-norms for the given parameters and used the same 1000 start values for all $\varepsilon$ and Two-Step-Banach.

Figure 188. 1000 iterations of the $\varepsilon$-Banach and the Two-Step-Banach algorithm for $N = 500$, $\beta = 3$ and $h = 0.5$. We simulated 1000 uniform in the corners of the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$ and Two-Step-Banach. We plotted the plefka-values for the given parameters and used the same 1000 start values for all $\varepsilon$ and Two-Step-Banach.
Figure 189. 1000 iterations of the $\varepsilon$-Banach and the Two-Step-Banach algorithm for $N = 500, \beta = 3$ and $h = 0.5$. We simulated 1000 uniform in the corners of the hypercube distributed start value for $\varepsilon = -0.9, -0.7, -0.45, 0.45, 0.7, 0.9$ and Two-Step-Banach. We plotted the TAP-free-energy values for all iterations ending inside the corners of the hypercube for the given parameters and used the same 1000 start values for all $\varepsilon$ and Two-Step-Banach.
6.5. **Short summary.** We see that the depended on the start values is much stronger for negative $\varepsilon$ than for positive $\varepsilon$. For Banach Two Step everything seems to depend on the start values. It’s quite interesting that for a given TAP free energy level there seems to be a range of optimal $\varepsilon$ and also a few values of $\varepsilon$ which won’t give us solutions with the desired level of TAP free energy. (That seems true also for plefka and the $L_2$-norm.) It seems to be true that for negative $\varepsilon$ we have that for smaller $\varepsilon$ the dependence on the start value is much stronger. This is probably because of the fact that for negative $\varepsilon$ the iterations spend some time outside the hypercube.

7. **Finding good solutions in high temperature: $\beta = 3, h = 0.5$**

We simulated 100,000 realizations of the disorder, if we talk about $n$ of them we talk about the first $n$ of them. We only accepted solutions satisfying the plefka condition and being inside of the hypercube.
7.1. **100 realizations of disorder and 50 start values and 21 ε-values.**

The following plots concern the same iterations with the same realizations, same start values. We only accepted solutions satisfying the plefka condition and being inside of the hypercube.

For $N = 25, \beta = 3, h = 0.5$ we simulated 100 realizations of the disorder and 50 start values used for all of them. For $\varepsilon = -0.705 - 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1,000 iterations of the Banach-ε-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all realizations we plotted the $L_\infty$ distance to the first solution of the realization we found.
For $N = 25, \beta = 3, h = 0.5$ we simulated 100 realizations of the disorder and 50 start values used for all of them. For $\varepsilon = -0.705 - 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all $\varepsilon$ we plotted the $L_\infty$ distance to the first solution of the realization we found.

For $N = 25, \beta = 3, h = 0.5$ we simulated 100 realizations of the disorder and 50 start values used for all of them. For $\varepsilon = -0.705 - 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all realizations we plotted the diverginess of the $L_2$-norms of the solutions found in the respective realization.
Figure 193. For $N = 25, \beta = 3, h = 0.5$ we simulated 100 realizations of the disorder and 50 start values used for all of them. For $\varepsilon = -0.705 - 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all $\varepsilon$ we plotted the diverginess of the $L_2$-norms of the solutions found with the respective $\varepsilon$.

Figure 194. For $N = 25, \beta = 3, h = 0.5$ we simulated 100 realizations of the disorder and 50 start values used for all of them. For $\varepsilon = -0.705 - 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all solutions we found we plotted a point with $x$ coordinate specifying the used $\varepsilon$ and $y$ coordinate the concerning realization.
Figure 195. For $N = 25$, $\beta = 3$, $h = 0.5$ we simulated 100 realizations of the disorder and 50 start values used for all of them. For $\varepsilon = -0.705 - 0.001 \cdot k$, $k = 0, \ldots, 20$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all realizations we plotted the number of good solutions.

Figure 196. For $N = 25$, $\beta = 3$, $h = 0.5$ we simulated 100 realizations of the disorder and 50 start values used for all of them. For $\varepsilon = -0.705 - 0.001 \cdot k$, $k = 0, \ldots, 20$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all $\varepsilon$ we plotted the plefka values found with this $\varepsilon$. 
Figure 197. For $N = 25, \beta = 3, h = 0.5$ we simulated 100 realizations of the disorder and 50 start values used for all of them. For $\varepsilon = -0.705 - 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all realizations we plotted the plefka values found in the concerning realization.

Figure 198. For $N = 25, \beta = 3, h = 0.5$ we simulated 100 realizations of the disorder and 50 start values used for all of them. For $\varepsilon = -0.705 - 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For $\varepsilon = 0.705 + 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all realizations we plotted the number of good solutions.

For $N = 25, \beta = 3, h = 0.5$ we simulated 1000 realizations of the disorder and 500 start values used for all of them. For $\varepsilon = 0.705 + 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all $\varepsilon$ we plotted the plefka values found with this $\varepsilon$. 
For $N = 25$, $\beta = 3$, $h = 0.5$ we simulated 1000 realizations of the disorder and 500 start values used for all of them. For $\varepsilon = 0.705 + 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all realizations we plotted the Plefka values found in the concerning realization.

For $N = 25$, $\beta = 3$, $h = 0.5$ we simulated 1000 realizations of the disorder and 500 start values used for all of them. For $\varepsilon = 0.705 + 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all $\varepsilon$ we plotted the TAP free energy values found with this $\varepsilon$. 

Figure 236.

Figure 237.
For $N = 25, \beta = 3, h = 0.5$ we simulated 1000 realizations of the disorder and 500 start values used for all of them. For $\varepsilon = 0.705 + 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all realizations we plotted the TAP free energy values found for the concerning realization.

Figure 239. For $N = 25, \beta = 3, h = 0.5$ we simulated 1000 realizations of the disorder and 500 start values used for all of them. For $\varepsilon = 0.705 + 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. Just a histogram of the TAP free energy values found.
For $N = 25, \beta = 3, h = 0.5$ we simulated 1000 realizations of the disorder and 500 start values used for all of them. For $\varepsilon = 0.705 + 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all $\varepsilon$ we plotted the $L_2$-norms found with this $\varepsilon$.

For $N = 25, \beta = 3, h = 0.5$ we simulated 1000 realizations of the disorder and 500 start values used for all of them. For $\varepsilon = 0.705 + 0.001 \cdot k, k = 0, \ldots, 20$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all realizations we plotted the $L_2$-norms found for the concerning realization.
7.5. 1000 realizations of disorder and 500 start values and 251 $\varepsilon$-values. The following plots concern the same iterations with the same realizations, same start values. We only accepted solutions satisfying the plefka condition and being inside of the hypercube.

Figure 242. For $N = 25, \beta = 3, h = 0.5$ we simulated 1000 realizations of the disorder and 500 start values used for all of them. For $\varepsilon = -0.505 + 0.001 \cdot k, k = 0, \ldots, 250$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all realizations we plotted the $L_\infty$ distance to the first solution of the realization we found.
For $N = 25, \beta = 3, h = 0.5$ we simulated 1000 realizations of the disorder and 500 start values used for all of them. For $\varepsilon = -0.505 + 0.001 \cdot k, k = 0, \ldots, 250$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all $\varepsilon$ we plotted the $L_\infty$ distance to the first solution of the realization we found.

For $N = 25, \beta = 3, h = 0.5$ we simulated 1000 realizations of the disorder and 500 start values used for all of them. For $\varepsilon = -0.505 + 0.001 \cdot k, k = 0, \ldots, 250$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all realizations we plotted the diverginess of the $L_2$-norms of the solutions found in the respective realization.
For $N = 25, \beta = 3, h = 0.5$ we simulated 1000 realizations of the disorder and 500 start values used for all of them. For $\varepsilon = -0.505 + 0.001 \cdot k; k = 0, \ldots, 250$ we made up to 1000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all $\varepsilon$ we plotted the diverginess of the $L_2$-norms of the solutions found with the respective $\varepsilon$.

For $N = 25, \beta = 3, h = 0.5$ we simulated 1000 realizations of the disorder and 500 start values used for all of them. For $\varepsilon = -0.505 + 0.001 \cdot k; k = 0, \ldots, 250$ we made up to 1000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all solutions we found we plotted a point with $x$ coordinate specifying the used $\varepsilon$ and $y$ coordinate the concerning realization.
Figure 247. For $N = 25, \beta = 3, h = 0.5$ we simulated 1000 realizations of the disorder and 500 start values used for all of them. For $\varepsilon = -0.505 + 0.001 \cdot k, k = 0, \ldots, 250$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all realizations we plotted the number of good solutions.

Figure 248. For $N = 25, \beta = 3, h = 0.5$ we simulated 1000 realizations of the disorder and 500 start values used for all of them. For $\varepsilon = -0.505 + 0.001 \cdot k, k = 0, \ldots, 250$ we made up to 1,000 iterations of the Banach-$\varepsilon$-algorithm where we stopped when we hit the target level of diverginess (measured with respect to the $L_\infty$ distance) of $10^{-7}$. For all $\varepsilon$ we plotted the plefka values found with this $\varepsilon$.

For all realizations we plotted the $L_2$-norms found for the concerning realization.
7.5.1. Different solutions found in 1000 realizations of disorder and with 500 start values and 251 \( \epsilon \)-values. We analyzed for each realization the number of different solutions found with the following algorithm:

\[
\text{FilteredSolutions} \leftarrow \text{empty array} \\
\text{FilteredSolutions}[1] \leftarrow \text{FoundSolutions}[1] \\
\text{for } k = 2, \ldots, \text{length(FoundSolutions)} \text{ do} \\
\quad f \leftarrow 0 \\
\quad \text{for } j = 1, \ldots, \text{length(FilteredSolutions)} \text{ do} \\
\quad \quad \text{if } \text{supnorm}(\text{FoundSolutions}[k] - \text{FilteredSolutions}[j]) < 10^{-7} \text{ then} \\
\quad \quad \quad f \leftarrow 1 \\
\quad \quad \text{end if} \\
\quad \text{end for} \\
\quad \text{if } f = 0 \text{ then} \\
\quad \quad \text{FilteredSolutions[length(FilteredSolutions)+1]} \leftarrow \text{FoundSolutions}[k] \\
\quad \text{end if} \\
\text{end for}
\]
