SPECTRAL RECIPROCITY FOR $GL(n)$ AND SIMULTANEOUS NON-VANISHING OF CENTRAL $L$-VALUES

SUBHAJIT JANA AND RAMON NUNES

Abstract. We prove a reciprocity formula for the average of the product of Rankin–Selberg $L$-functions $L(1/2, \Pi \times \overline{\sigma})L(1/2, \sigma \times \overline{\pi})$ as $\sigma$ varies over automorphic representations of $PGL(n)$ over a number field $F$, where $\Pi$ and $\pi$ are cuspidal automorphic representations of $PGL(n+1)$ and $PGL(n-1)$ over $F$, respectively. If $F$ is totally real, and $\Pi$ and $\pi$ are tempered everywhere, we deduce simultaneous non-vanishing of these $L$-values for certain sequences of $\sigma$ with conductor tending to infinity in the level aspect and bearing certain local conditions.

1. Introduction

Recently, there has been some interest in reciprocity formulæ. These are spectral identities between sums of $L$-functions. One can point out at least two good reasons for this interest. The first one is a purely aesthetic one. The formulæ are often hard to visualize and they connect families of $L$-functions which apparently seem to be not connected. The second one is one of the most important reason from the viewpoint
of analytic theory of \( L \)-functions. The reciprocity formul\ae\ allow one to understand averages of \( L \)-functions without (or only mildly) dealing with the geometric side of a trace formula. Instead the formul\ae\ arrange it so that complexity of the families of \( L \)-functions drops from one side to the other side of the reciprocity formula. This helps, for instance, estimate the \( L \)-functions with high complexity by the means of other family with lower complexity.

Even though it is foreseeable that not all problems involving \( L \)-functions can be dealt with this technique, it is still exciting to find out how further one can push its boundaries. There is in particular eagerness for results in high-rank groups where the geometric side can often be very cumbersome.

To demonstrate the complications of studying the geometric side of a trace formula in high-rank groups, it suffices to look at the Kuznetsov trace formula. While in GL(2), there’s a good deal of literature dedicated to the sums of Kloosterman sums and many applications thereof, for GL(3) the study of these objects is no easy matter, as can be perceived, for example, from the works of Blomer and Buttcane, e.g. [8]. Some applications can be seen in [6, 10, 9]. For larger \( n \) we refer to [20, 7] as examples of application of Kuznetsov formula where geometric sides needed careful analysis.

1.1. A primer on Reciprocity formul\ae\.

**Different groups: Motohashi and generalizations.** Motohashi’s formula is the first kind of spectral identity which is probably the most studied and has several interesting applications. The story starts with the work of Motohashi [37], where he proved a formula of the shape

\[
\int_{\mathbb{R}} |\zeta(1/2 + it)|^4 h(t) \, dt = \sum_f L(1/2, f)^3 \tilde{h}(t_j) + (\ldots),
\]

where the sum on the right-hand side runs over cusp forms of PGL(2). We have have swept under the symbol (\ldots) the contribution of the Eisenstein series and some degenerate terms. Moreover, the relations \( h \rightsquigarrow h \) are explicitly-given via some integral transformations. This allowed him to give an asymptotic formula for the fourth-power moment of the Riemann zeta function. A few years later, Ivić showed (under some restrictions) how to reverse the integral transformation \( \tilde{h} \rightsquigarrow h \), leading to a strong subconvex bound for \( L(1/2, f) \) in terms of the spectral parameters of \( f \). Around the same time, Conrey and Iwaniec [18] studied a similar problem on the \( q \) aspect, with forms twisted by quadratic Dirichlet characters. Even though they did not phrase their results in terms of reciprocity formula, one can guess one from their proof. An \textit{almost} exact formula (with an error term) was later found by Petrow [40]. More recently Petrow and Young (\textit{cf.} [42] and [41]) have vastly generalized Conrey and Iwaniec’s work to general Dirichlet characters. Here, again there’s no effort in producing exact
formulæ but one can notice that an underlying version of Motohashi’s formula is used (in both directions!). A bit later, and with a different application in mind, Blomer et al. [11] have yet another form of the identity and finally, Nelson [38] gave a period theoretic approach, which in fact was previously sketched by Michel and Venkatesh in [34]. As a matter of fact [38] allows, at least conceptually, to see all the previous results as particular cases of a certain master identity.

Same group: $GL(4) \times GL(2) \rightsquigarrow GL(4) \times GL(2)$. In this case, we talk about a formula where in both sides we average over (possibly different) families of automorphic representations of the same group, namely $GL(2)$. Moreover the degree of the $L$-functions is also the same, namely 8. We divide them, however, in three different cases according to how the $L$-function factorizes and this corresponds to the number of partitions of 4 as a sum of two positive integers.

(1) $4 = 2 + 2$. This is probably the most natural situation. It amounts to studying the fourth moment of $L(1/2, \sigma)$ or the second moment of $L(1/2, \sigma \times \sigma_0)$ over a family of $\sigma$, where $\sigma_0$ is a fixed automorphic form of $GL(2)$. If one is to be rigorous, this does not exactly fit the description above as we may have to deal with certain periods which are only related to $L$-functions up to taking its square (cf. [23]). A reciprocity formula, in this case, is implicit in [34], and, to our knowledge, the first instance of such an equality is in [1]. Later, a period approach to the equality was developed by Zacharias in [50] and [51]. The latter also deals with regularization and contain a strong subconvex bound for $L(1/2, \sigma)$, where $\sigma$ is a PGL(2) cuspidal representation of prime level tending to infinity.

We may think the above example as the $n = 2$ case for a general reciprocity formula $GL(2n) \times GL(n) \rightsquigarrow GL(2n) \times GL(n)$. For $n > 2$, one can see a certain glimpse of a reciprocity formula in the works of Blomer [5] and first named author [29]. Here one has to be even more flexible when employing the term “reciprocity” as on one side of the formula the periods are neither known nor expected to be related to $L$-functions. Nevertheless these results fit in the overall strategy where one can bypass the need of a delicate study of geometric side (in the sense of the trace formula).

(2) $4 = 3 + 1$. Here we are concerned with averages of

$$L(1/2, \Pi \times \hat{\sigma})L(1/2, \sigma),$$

where $\Pi$ is a fixed representation of $GL(3)$. In this particular case, the first appearances are in the works of Blomer and Khan (cf. [12] and [13]). In both papers, by taking $\Pi$ to be an Eisenstein series, the authors find applications leading to strong exponents in the subconvexity problem for $GL(2)$. In [39], the second named author proved a version of the main result in [12] for number fields,
but via a period theoretic approach. This is not a complete generalization for two reasons, it does not allow for general weight functions and the fixed GL(3) representation needs to be cuspidal.

(3) \( 4 = 4 \). Let \( \Pi \) be a fixed automorphic representation of GL(4), then we are interested in studying the first moment of \( L(\Pi \times \sigma) \) as \( \sigma \) varies. A reciprocity formula was found by Blomer, Li and Miller [14]. This case is the hardest one as it involves the least factorable \( L \)-function. In order to grasp on the difficulty, we only mention that the authors of [14] do not have applications to sub convexity. Their only application is to non-vanishing and it is important to mention that their analysis is finer than usual as they only win by a logarithmic power, instead of the more usual polynomial saving.

In this work, we give a generalization of the work in [39] (hence of [12, 13]) to a spectral sum over GL\( p \) \( n \) with \( L \)-functions of degree \( 2n^2 \), such as in [29] but in a more unbalanced situation.

1.2. Main results. Let \( F \) be a number field and \( S \) be a finite set of places of \( F \) containing all the archimedean places. Let \( \Pi \) and \( \pi \) be cuspidal automorphic representations for GL\( (n + 1) \) and GL\( (n - 1) \) over \( F \), respectively, with trivial central characters and be unramified outside \( S \). Let \( \Phi \in \Pi \) and \( \phi \in \pi \) be cusp forms. Also, let \( s = (s_1, s_2) \) be a pair of complex numbers. Our main object of study is the following average of \( L \)-functions.

\[
\mathcal{M}(s, \Phi, \phi) := \int_{\text{gen}} \frac{L(s_1, \Pi \times \overline{\sigma})L(s_2, \sigma \times \overline{\pi})}{L^S(\sigma)} \mathcal{H}_S(\sigma) \, d\sigma,
\]

where the integral is taken with respect to an automorphic Plancherel measure over the generic automorphic spectrum of GL\( (n) \) with trivial central character (cf. §4.2 for a discussion on the measure \( d\sigma \)). The factor \( \mathcal{H}_S(\sigma) := \mathcal{H}_S(\sigma; \Phi, \phi, s) \) is a certain weight function depending on the \( S \)-adic components of \( \Phi, \phi, \) and \( \sigma \). We refer to §6.1 for the definition. The factor \( L^S(\sigma) \) is certain harmonic weight which appear in e.g. the Kuznetsov formula, see (21) for the definition. For example, if \( \sigma \) is cuspidal then \( L^S(\sigma) \) is proportional to \( L^S(1, \sigma, \text{Ad}) \).

Finally, for any pair of complex numbers \( s = (s_1, s_2) \), we shall write

\[
\tilde{s} = (\tilde{s}_1, \tilde{s}_2) := \left( \frac{1 + (n - 1)s_2 - s_1}{n}, \frac{(n + 1)s_1 + s_2 - 1}{n} \right). \tag{2}
\]

We also write \( \Pi(w^*)\Phi \) as \( \tilde{\Phi} \) where

\[
w^* := \begin{pmatrix} I_{n-2} & \vdots & 1 \\ \vdots & \vdots & \vdots \\ 1 & \vdots & 1 \end{pmatrix}, \tag{3}
\]

Our first main result is the following reciprocity formula.
Theorem 1. Let $s \in \mathbb{C}^2$ such that
\[
\frac{1}{2} \leq \Re(s_1), \Re(s_2), \Re(\bar{s}_1), \Re(\bar{s}_2) \leq 1.
\]
Then, we have the equality
\[
\mathcal{M}(s, \Phi, \phi) = \mathcal{N}(s, \Phi, \phi) + \mathcal{M}(\bar{s}, \bar{\Phi}, \bar{\phi})
\]
where
\[
\mathcal{N}(s, \Phi, \phi) = \mathcal{R}(\bar{s}, \bar{\Phi}, \bar{\phi}) + \mathcal{D}(\bar{s}, \bar{\Phi}, \bar{\phi}) - \mathcal{R}(s, \Phi, \phi) - \mathcal{D}(s, \Phi, \phi).
\]
and $\mathcal{R}(s, \Phi, \phi)$ and $\mathcal{D}(s, \Phi, \phi)$ are given by (42) and (26), respectively.

As in [39], we can choose the vectors $\Phi$ and $\phi$ in a such a way that the left-hand side picks up forms of conductors up to certain height and the right-hand side can be asymptotically computed.

Theorem 2. Let $n \geq 3$. We assume that $F$ is totally real, and $\Pi$ and $\pi$ are unramified and tempered at every non-archimedean place. Let $p_0$ be a prime not dividing the discriminant of $F$ and $\tau$ be a supercuspidal representation of $\text{GL}_n(F_{p_0})$ with trivial central character. Then for every $\delta > 0$ there is an $\eta > 0$ so that for any integral ideal $q$ of the finite adeles of norm $q^{-1}$ such that $q$, $p_0$, and the discriminant of $F$ are pairwise coprime, we have
\[
\sum_{\sigma \text{ cuspidal}, \sigma_{p_0} = \tau \atop C(\sigma_t) \mid q, |C(\sigma_t)|^{-1} \geq q^{1/2 - \delta}} \frac{L(1/2, \Pi \times \bar{\sigma})L(1/2, \sigma \times \bar{\pi})}{L^\delta(1, \sigma, \text{Ad})} H_q(\sigma) h_\infty(\sigma)
\]
\[
= \Delta_F^{-d_n} D_\infty \frac{\zeta_q(n)/\zeta_q(1)}{\varepsilon_{p_0}(1, \tau \otimes \bar{\pi})} \frac{L^{p_0} (1, \Pi \otimes \bar{\pi}) L^{p_0} (n/2, \bar{\Pi})}{L^{p_0} (1 + n/2, \bar{\pi})} + O(q^{-\eta}),
\]
where $d_n$ only depends on $n$ and the implied constant may depend on $\Pi$ and $\pi$. Here $H_q(\sigma)$ and $h_\infty(\sigma)$ are certain test functions at the $q$-adic places and $\infty$-adic places defined in (46.1) and (32), respectively. The harmonic weight is the adjoint $L$-value at one excluding the $q$-adic Euler factors. On the other hand, $D_\infty = 1$ depends on the archimedean component of the test vectors and $\zeta_q := \prod_{v \mid q} \zeta_v$.

The analogous theorem for $n = 2$ is done in [39]. Our proof also works for $n = 2$, but certain care is needed to compute the degenerate terms.

In particular, we have the following corollary.

Corollary 3. Let $F$, $q$, $p_0$, $\tau$, $\Pi$, and $\pi$ be as above. For any sufficiently large $q$ there exists at least one cuspidal representation $\sigma$ with trivial central character, such that $\sigma_{p_0} = \tau$ and $C(\sigma_t) \mid q$ with $|C(\sigma_t)| \geq q^{1/2 - \delta}$ so that both $L(1/2, \Pi \times \bar{\sigma})$ and $L(1/2, \sigma \times \bar{\pi})$ do not vanish.
We would like to point out that our result shows simultaneous non-vanishing of \( L \)-functions whose combined degree is \( 2n^2 \). In particular, if one manages to generalize the result to non-cuspidal representations, this would lead to a simultaneous non-vanishing of the \( L\left(\frac{1}{2} + it, \sigma\right) \) at \( 2n \) different values of \( t \). For comparison, The main result in [47] shows simultaneous non-vanishing at \( n^2 \) different values.

1.3. Sketch of the proof: Strong Gelfand formations. Before we proceed to proving our results, we would like to present another point of view on spectral reciprocity formulæ, which is due to Reznikov [44]. The key concept here is that of a Strong Gelfand Formation. First, we say that a pair of reductive groups \( (G, H) \) over a number field is a strong Gelfand pair if for every place \( v \) and every pair of irreducible (admissible) representations \( \Pi \) and \( \sigma \) of \( G \) and \( H \), respectively, we have that the space of \( H \)-invariant maps from \( \Pi \) to \( \sigma \) is at most one-dimensional. Now let \( G, H_1, H_2 \) and \( J \) be reductive groups with natural embeddings

\[
\begin{array}{ccc}
G & \rightarrow & H_1 \\
\downarrow & & \downarrow \\
H_2 & \rightarrow & J
\end{array}
\]

Then we say that \( (G, H_1, H_2, J) \) is a Strong Gelfand formation if the pairs \( (G, H_i) \) and \( (H_i, J) \) are strong Gelfand pairs, for \( i = 1, 2 \).

It is well-known that if \( (G, H) \) is a Gelfand pair, \( \Pi \) and \( \sigma \) are automorphic representations of \( G \) and \( H \), respectively, and \( \Phi \in \Pi \) and \( \xi \in \sigma \) are automorphic forms then the period

\[
\int_{[H]} \Phi(h) \overline{\xi}(h) \, dh,
\]

where \([H] := H(F) \backslash H(\mathbb{A})\), can often be linked to an \( L \)-function. Therefore, in order to obtain a reciprocity formula one might consider \( \Phi \in \Pi \) and \( \phi \in \pi \) automorphic forms of \( G \) and \( J \), respectively, and consider the period \( \int_{[J]} \Phi(j) \overline{\phi}(j) \, dj \). Expanding the vector \( \Phi \) in the spaces of automorphic forms in \( H_1 \) and \( H_2 \), one should get

\[
\sum_{\xi_1} \left( \int_{[H_1]} \Phi \overline{\xi_1} \right) \left( \int_{[J]} \xi_1 \overline{\phi} \right) = \sum_{\xi_2} \left( \int_{[H_2]} \Phi \overline{\xi_2} \right) \left( \int_{[J]} \xi_2 \overline{\phi} \right),
\]

where \( \xi_i \) runs through an orthonormal basis of automorphic forms for \( H_i \).

The reciprocity formula which we prove here can be seen as a special case of the above discussion where take \( G = \text{GL}(n + 1) \), \( H_1 = \text{GL}(n) \), \( J = \text{GL}(n - 1) \), and \( H_2 = \text{GL}(n) \) for the purpose of the sketch we assume that such quotients are compact.
w*GL(n)w^{*-1}$, with $w^*$ as in (3). For these groups, inclusion is given by $h \mapsto \begin{pmatrix} h & \varepsilon \\ \varepsilon^{-1} & 1 \end{pmatrix}$ which is an embedding of $GL(n)$ inside $GL(n + 1)$.

1.4. **A closely related work.** While this article was at the final stage of preparation, a preprint by Miao [33] has been posted in arXiv, obtaining a similar reciprocity formula to our Theorem 1. The author starts, as we do, from the identity in Proposition 5.1. The author also predicts an application of the reciprocity formula to non-vanishing. We decided nevertheless to keep our own proof of the reciprocity formula as we could not match our degenerate term to any term in [33] and that term is the source of the main term in Theorem 2.

1.5. **What’s next?**

1.5.1. **Global.**

(1) The question of generalizing the above results to $\Pi$ and $\pi$ that are general (not necessarily cuspidal) automorphic representations is a quite natural one. The difficulty comes from the fact that, in that case, the period $P(s, \Phi, \phi)$, defined in (24) and from whose properties we deduce the reciprocity in Theorem 1, does not converge. A remedy to this lack of convergence should follow from a suitable notion of regularization and the works of Ichino–Yamana [24] and Zyodor [52] could be of help in finding out this suitable notion. It is important to remark that we do not require simply the conclusion from these papers. Instead we need to understand how the various truncation operators interact when averaged over the spectrum of $GL(n)$.

(2) An important distinction between the present and [39, Corollary 1.3] is the need for an auxiliary prime at which our representations are supercuspidal. This difference is necessary for $n \geq 3$ as we cannot easily bound the contribution of the continuous spectrum. The same kind of restriction also appears in [29] and [47].

(3) Finally, after staring at the list of different reciprocity formulæ for $GL(2)$ one might wonder whether we could have a general reciprocity formulæ for the average of

$$L(1/2, \Pi \otimes \tilde{\sigma})L(1/2, \sigma \otimes \tilde{\pi}),$$

where, now, for given $n \geq r \geq 2$, $\Pi$ and $\pi$ are automorphic representations of $GL(n + r)$ and $GL(n - r)$, respectively. Unfortunately, it is not clear to us how to generalize our method in any straightforward way. The main reason is the more complicated nature of Rankin-Selberg zeta integrals for $GL(n) \times GL(m)$ when $n - m > 1$, which involves extra integration over unipotent groups.
1.5.2. Local.

(1) Recall the local weight factors $\mathcal{H}_S(\sigma)$ and corresponding weight factor $\tilde{\mathcal{H}}_S(\sigma)$ in the dual side of the reciprocity formula in Theorem 1. There is an implicit integral transform which relates $\mathcal{H}$ and $\tilde{\mathcal{H}}$ governed by the Weyl element in (3). For various analytic question in automorphic forms we often would need nice properties of this test functions e.g. non-negativity and richness, see [37, 38].

(2) Blomer–Khan [12] explicitly determined the integral transform relating the local weight functions in both sides of the reciprocity formula via the classical methods e.g. Kuznetsov, Voronoi. It is natural to wonder whether one can deduce the same in our higher rank case via the method of integral representations. The test functions are essentially related to the local Whittaker functions of the test vectors as in Theorem 1. We think one can produce the transform via the analysis of certain local Bessel distribution, in particular, the local $\text{GL}(n + 1) \times \text{GL}(n - 1)$ functional equation which is governed by the Weyl element (3). However, we are unable to produce that in this article. The reason, partly, seems to be that we are dealing with a period of $\text{GL}(n + 1) \times \text{GL}(n - 1)$ which does not resemble the $\text{GL}(n + 1) \times \text{GL}(n - 1)$ zeta integral.

(3) On the other hand, via the theory of Kirillov model one will be able to show that the family of local weights is quite abundant, in the sense of [38].

(4) More importantly, we would like to construct test vectors which produce a non-negative local weight. This seems to be difficult due to the unbalanced (that is, correlation of $L$-functions of degrees $n(n+1)$ and $n(n-1)$) nature of the moment considered in Theorem 1, unlike the balanced moment (that is, correlation of $L$-functions of degree $2n$) as considered in [29] where non-negativity of the local weight was immediate.

(5) Finally, we may wonder if we can obtain a similar result as in Theorem 3 in the archimedean aspect as well. One of the main ingredient to prove Theorem 3 is the classical non-archimedean newvector theory of [26] which allows us to pick up the family considered in Theorem 3. In principle we can, at least at the real places, via the analogous archimedean newvector theory as in [31]. However, we do not pursue that in this article.

1.6. Structure of the paper. We fix notations and conventions that are used throughout the text in §2. Preliminaries on automorphic forms, Whittaker models and integral representations of $L$-functions in the local and global settings are recalled in §3 and §4 respectively.

In §4 we use spectral theory and the theory of integral representations of $L$-functions to relate the average of $L$-functions $\mathcal{M}(s, \Phi, \phi)$ to a period of $\Phi$ and $\phi$ (essentially) over $\text{GL}(n - 1)$ up to a degenerate term coming from regularizing the zeta integral on the
smaller group. It becomes clear that the reciprocity formula follows from a certain identity of periods, also deduced in the same section.

Everything up until this point works for general vectors \( \Phi \) and \( \phi \). In §6, we briefly describe our choices of local vectors used in the proof of Theorem 2. For these choices, we study in §7 and §8 the local factors appearing the original and dual sides, respectively. We use these vectors to pick up the family of representations considered in Theorem 2. This is one of the most technical parts of the paper.

In §9, we show a meromorphic continuation of the term \( \mathcal{M}(s, \Phi, \phi) \) to a neighborhood of \( s = \left( \frac{1}{2}, \frac{1}{2} \right) \). This adds an extra term \( \mathcal{R}(s, \Phi, \phi) \), called the residue term (since it appears after an application of the residue theorem) and we estimate its contribution with vectors as in §6.

In §10, we show that the degenerate term can be factored into a product of local integral and study these local factors. First the unramified computation and later with the choices from §6. This is the source of the main term in Theorem 2. The estimates to the residue and degenerate terms are only given for the term in the dual side since they vanish in the original side, which we show in §11. We also give the proofs of the main results in §11.

Acknowledgements

We would like to thank Paul Nelson for various discussion and feedback. We would like to thank Farrell Brumley for providing us reference [19] which became quite helpful in many parts of the paper. We also would like to thank Valentin Blomer for his interest in this work and encouragement. Part of the work has been carried out at the Max-Planck-Institute für Mathematik in Bonn. We are grateful towards the MPI for its excellent working environment.

2. General Notations

The letter \( F \) denotes a local of global number field. In the beginning of each section we define \( F \) explicitly. For any place \( v \) of a global field \( F \) by \( F_v \), we denote the localization of \( F \) at \( v \). Similarly, for any global object \( \mathfrak{G} \) (e.g. an \( L \)-function) we denote the \( v \)-adic component (if defined) of \( \mathfrak{G} \) by \( \mathfrak{G}_v \) (e.g. a \( v \)-adic \( L \)-factor). If clear from the context, we suppress the subscript \( v \) from the notation \( \mathfrak{G}_v \). We denote the adele ring \( F \) by \( \mathbb{A} \).

For any \( n \geq 1 \) by \( G_n \) we denote the algebraic group \( \text{GL}(n) \). We embed \( G_n \hookrightarrow G_{n+1} \) in the upper left corner. We denote the subgroup of upper triangular unipotent matrices in \( G_n \) by \( N_n \). Also, by \( Z_n \) we denote the center of \( G_n \). We have \( Z_n(R) \cong \mathbb{R}^\times \cong G_1(R) \), so often we identify \( Z_n(R) \) with \( G_1(R) \). We denote the long Weyl element of \( G_n \) by \( w_n \).

We fix Haar measures on \( G_n(R) \), \( N_n(R) \), and \( G_1(R) \) (whenever exists) which we denote by \( dg \), \( dn \), and \( d^\times z \), respectively. We also fix \( G_n(R) \)-invariant quotient measures
on $\mathbb{Z}_n(R) \backslash G_n(R)$ and $N_n(R) \backslash G_n(R)$ which, abusing notations, we denote by $dg$. Again, if clear from the context, we suppress the index $n$ from the notations.

Let $A_n$ be the group of diagonal matrices in $G_n$. If $F$ is a local field then we denote by $K_n$ the standard maximal compact subgroup of $G_n(F)$. We have the Iwasawa decomposition $G_n(F) = N_n(F)A_n(F)K_n$. Using Iwasawa parametrization we can write

$$dg = \delta^{-1}(a) \, dn \, d^x a \, dk,$$

where $\delta$ is the modular character,

$$d^x a = \prod_{i=1}^n d^x a_i, \quad a = \text{diag}(a_1, \ldots, a_n)$$

and $dk$ is a Haar measure on $K_n$.

We follow $\epsilon$-convention, as usual in analytic number theory, which allows us to change the values of $\epsilon$ from line to line. We also adopt the usual Vinogradov notations $\ll$, $\gg$, and $\sim$. Our convention is that the implied constants in the Vinogradov notations are allowed to depend on the global field and the ambient group.

3. Local Preliminaries

In this section we work over a general local field $F$ of characteristic zero, archimedean or non-archimedean, without mentioning the field explicitly. If $F$ is non-archimedean we denote $\mathfrak{o}$ to be its ring of integers, $\mathfrak{p}$ to be the maximal ideal in $\mathfrak{o}$, and $p$ to be the order of its residue field.

For the group $G_n(F)$ we mostly write $G$, and sometimes write $G_n$ if there is a source of confusion. The letter $\pi$ will denote an irreducible admissible representation of $G$.

3.1. Measure normalizations. On $F$ we fix a Lebesgue measure $dx$ so that if $F$ is non-archimedean then $\text{vol}(\mathfrak{o}) = 1$. We fix $d^x x := \zeta_F(1) \frac{dx}{|x|}$ to be the Haar measure on $F^\times$.

Finally, if $K_m$ is the standard maximal compact subgroup $G_m$ we normalize $dk$ to be the probability measure on $K_m$.

3.2. Additive character. We fix an additive character $\psi_0$ of $F$. We define an additive character of $N$ by

$$\psi(n(x)) := \psi_0 \left( \sum_{i=1}^{n-1} x_{i,i+1} \right), \quad n(x) := (x_{i,j})_{i,j} \in N.$$

We denote restriction of $\psi$ to smaller unipotent subgroups also by the same letter.\footnote{Note that $p$ does not, regrettably, necessarily denote a prime number.}
3.3. **Gamma factors and analytic conductors.** For every irreducible representation \( \pi \) we can attach local \( \gamma, L, \varepsilon \) factors which are related by

\[
\gamma(s, \pi) := \varepsilon(s, \pi) \frac{L(1-s, \tilde{\pi})}{L(s, \pi)},
\]

where \( \tilde{\pi} \) is the contragredient of \( \pi \). We refer to [17, §3] for the description of the local factors.

We can also attach a local analytic conductor \( C_p \) to \( \pi \). If \( F \) is archimedean one defines \( C(\pi) \) via the Langlands parameters of \( \pi \), see [25]. If \( F \) is non-archimedean then one defines \( C(\pi) \) via the invariance property under the congruence subgroups, as in [26], see §3.8. We record that if \( F \) is non-archimedean and \( \pi \) is unramified then \( C(\pi) = 1 \).

If \( \pi_i \) are representations of \( G_{n_i} \) for \( i = 1, 2 \) then one has

\[
C(\pi_1 \otimes \pi_2) \ll C(\pi_1)^{n_2}C(\pi_2)^{n_1}
\]  \hspace{1cm} (4)

where the implied constant is absolute, see [22].

One can analytically relate the local \( \gamma \) factor and the analytic conductor of a representation (see [31] for some discussion on this). We have the asymptotic expansion

\[
\gamma(1/2 + s, \pi) = \gamma(1/2, \pi) C(\pi)^{-s} + O_\pi(s),
\]

as \( s \to 0 \). In particular,

\[
\gamma(1/2 + s, \pi) = C(\pi \otimes | \det |^\beta(s))^{-R(s)},
\]  \hspace{1cm} (5)

as long as \( s \) is away from the poles and zeros of the \( \gamma \) factor.

3.4. **Sobolev norms.** We follow [34, §2.3.3] to define a Sobolev norm on unitary representations. First, we define a Laplacian \( \mathfrak{D} \) on \( G \).

If \( F \) is archimedean then we define

\[
\mathfrak{D} := 1 - \sum_X X^2,
\]

where \( \{X\} \) is a basis of the Lie algebra of \( G \).

Let \( F \) be non-archimedean. Let \( K[m] \) denote the principal congruence subgroup of level \( m \) and \( e[m] \) denote the orthogonal projector on the orthogonal complement of \( K[m-1] \)-invariant vectors inside the space of \( K[m] \) invariant vectors. If \( F \) is non-archimedean we define the Laplacian by

\[
\mathfrak{D} := \sum_{m=0}^{\infty} p^m e[m].
\]

Note that \( \sum_{m=0}^{\infty} e[m] \) is the identity operator. We also note that \( \mathfrak{D} \) is invertible and a large enough power of \( \mathfrak{D}^{-1} \) is of trace class.
Finally, we define the order $d$ Sobolev norm of $v \in \pi$ by
\[ S_d(v) := \| \mathcal{D}^d v \|_\pi. \]
We refer to \[34, \S 2.4\] for properties of the Sobolev norm.

**Lemma 3.1.** For each $d_1, d_2 > 0$ there is an $L > 0$ such that
\[ \int_G C(\pi)^{d_1} \sum_{v \in B(\pi)} S_{d_2}(v) S_{-L}(v) \, d\mu^{\text{loc}}(\pi) < \infty. \]
Here $B(\pi)$ is an orthonormal basis of $\pi$ consisting of eigenvectors of $\mathcal{D}$.

**Proof.** If $F$ is archimedean the proof can exactly be done as in \[31, \text{Lemma 3.3}\]. Let $F$ be non-archimedean. We choose $B(\pi)$ to be a $\mathcal{D}$-eigenbasis, i.e., a $K$-type basis. We denote $c(\pi)$ to be the conductor exponent of $\pi$. Using \[34, 2.6.3 \text{Lemma}\] we see that the quantity in the lemma is bounded by
\[ \int_G p^{d_1 c(\pi)} \sum_{m=0}^{\infty} p^{m(d_2-L)} p^{md_3} \, d\mu^{\text{loc}}(\pi), \]
for some $d_3 > 0$. For any $L' > 0$ there is a large $L > 0$ such that the inner sum is $O(p^{-L'c(\pi)})$. Thus it is enough to prove that
\[ \int_G p^{-Ac(\pi)} \, d\mu^{\text{loc}}(\pi) < \infty, \]
for large enough $A > 0$. This follow from the fact that the Plancherel volume of the set of representations with conductors equal to $X$ is at most $X^{O(1)}$. \[ \square \]

### 3.5. Whittaker and Kirillov model.
For the details of this subsection we refer to \[3\] for non-archimedean case and \[28, \S 3\] for archimedean case.

We recall the notion of genericity for an irreducible representation $\pi$ of $G$. We call $\pi$ to be generic if
\[ \text{Hom}_G(\pi, \text{Ind}_K^G(\psi)) \neq 0. \]
We also know that $\pi$ is generic then the above Hom-space is one-dimensional. We always identify $\pi$ with its image under a non-zero element of the Hom-space, which we call the Whittaker model of $\pi$ under $\psi$.

The theory of Kirillov model asserts that the restriction
\[ W \ni \left\{ g \mapsto W \left[ \begin{pmatrix} g \\ 1 \end{pmatrix} \right] \right\} \]
is injective. Furthermore, for any $\phi \in C^\infty_c(N_{n-1}\backslash G_{n-1}, \psi)$ there is a unique $W_\phi \in \pi$ such that
\[ W_\phi \left[ \begin{pmatrix} g \\ 1 \end{pmatrix} \right] = \phi(g), \]
and the map \( \phi \mapsto W_\phi \) is continuous.

If \( \pi \) is unitary then we can write a unitary inner-product \( \pi \) as

\[
\langle W_1, W_2 \rangle := \int_{\mathcal{N}_{n-1}\backslash G_{n-1}} W_1 \left( \begin{pmatrix} g & \vdots \\ 1 & \end{pmatrix} \right) W_2 \left( \begin{pmatrix} g & \vdots \\ 1 & \end{pmatrix} \right)^\dagger \, dg,
\]

for any two \( W_1, W_2 \in \pi \).

We recall the Langlands classification of the unitary representations of \( G \). Let \( P \) be any parabolic subgroup of \( G \) attached to the partition \( n = \sum_{i=1}^k n_i \) be any partition. Let \( \pi_i \) be any square-integrable representation of \( G_{n_i} \). For any tuple \( (s_1, \ldots, s_k) \in \mathbb{C}^k \) we consider the unitarily normalized induction \( \text{Ind}_{P}^{G} \bigotimes_{i=1}^{k} \pi_i \otimes \mid \det \mid ^{s_i} \). Then any unitary representation \( \pi \) of \( G \) is the unique irreducible constituent of such an induction and is denoted by \( \mathbb{H}^{k}_{1} \pi_i \otimes \mid \det \mid ^{s_i} \). We call \( \pi \) to be \( \theta \)-tempered (resp. tempered) if \( \max_{i=1}^{k} \mid \Re(s_i) \mid = \theta \) (resp. 0).

We need the following bound for Whittaker functions. The bound may be available in the literature in a scattered way, although, we are unable to find a proper reference to the result in the \( \theta \)-tempered case for general local fields. We state the result here and prove it after developing necessary tools.

**Lemma 3.2.** Let \( W \in \pi \) be \( \theta \)-tempered. If \( g = ak \) with \( a = \text{diag}(a_1, \ldots, a_n) \) then for any large \( N > 0 \) and small \( \eta > 0 \)

\[
W(g) \ll_{N, \eta} \mid \det(a/a_n) \mid ^{-\theta} \delta^{1/2-\eta}(a) \prod_{i=1}^{n-1} \min(1, |a_i/a_{i+1}|^{-N}) S_d(W),
\]

for some \( d > 0 \) depending only on \( N \) and the group.

This result is proved at the real place in [31, Lemma 5.2] (tempered case) and in [29, Lemma 7.2] (\( \theta \)-tempered case).

### 3.6. Whittaker–Plancherel formula

We record the relevant formulation of the Whittaker–Plancherel formula. We refer to [48, Chapter 5] for archimedean case and [4, Theorem 2.3.2] for the non-archimedean case.

Let \( \hat{G} \) be the unitary dual of \( G \) i.e. \( \hat{G} \) is the isomorphism class of unitary irreducible representations of \( G \). We can equip \( \hat{G} \) with the local Plancherel measure \( d\mu^\text{loc} \) which is compatible with the Haar measure \( dg \) on \( G \). It is known that \( d\mu^\text{loc} \) is supported only on the tempered representation of \( G \). Let \( \xi \in L^2(\mathbb{N} \backslash G, \psi) \) smooth and with sufficient decay at infinity. Then we absolutely convergent representation

\[
\xi(g) = \int_{\hat{G}} \sum_{W \in B(\pi)} W(g) \int_{\mathbb{N} \backslash G} \xi(h) \overline{W(h)} \, dh \, d\mu^\text{loc}(\pi),
\]
where $B(\pi)$ is an orthonormal basis of $\pi$. The above sum over $B(\pi)$ does not depend on the choice of $B(\pi)$.

3.7. Local zeta integral and functional equation. For this subsection we refer to [17, §3] for detailed discussion.

Let $\Pi$ and $\pi$ be irreducible generic representations of $G_{n+1}$ and $G_n$, respectively such that $\Pi$ and $\pi$ are realized in the Whittaker models with respect to the same additive character. For $\Re(s)$ sufficiently large, we define the local zeta integral of $W \in \pi$ and $V \in \Pi$ by

$$\Psi(s, V, W) := \int_{N_n \backslash G_n} V \left[ \begin{pmatrix} g & \cdot \\ & 1 \end{pmatrix} \right] W(g) |\det(g)|^{s-1/2} dg. \quad (7)$$

If $\Pi$ and $\pi$ are unitary then the above is defined for $\Re(s)$ large enough. One can then meromorphically continue $\Psi$ to the whole complex plane.

Let $\omega_\pi$ be the central character of $\pi$. We have the local functional equation

$$\Psi(1-s, \widetilde{V}, \widetilde{W}) = \omega_\pi(-1)^n \gamma(s, \Pi \otimes \bar{\pi}) \Psi(s, V, W), \quad (8)$$

where $\widetilde{W} \in \widetilde{\pi}$ denotes the contragredient of $W$ defined by $\widetilde{W}(g) := W(w_n g^{-1})$, similar for $\widetilde{V}$.

**Lemma 3.3.** Let $V \in \Pi$ and $W \in \pi$ such that both $\Pi$ and $\pi$ are varying over some families with growing conductors. Also let $s \in \mathbb{C}$ be away from a pole of the zeta integral $\Psi(\cdot, V, W)$. Then for each $d > 0$ there is a $d' > 0$ such that

$$\Psi(1/2 + s, V, W) \ll_s S_{d'}(V) S_{-d}(W),$$

where the dependency of the implicit constant on $s$ is at most polynomial.

**Proof.** We use the standard fact that any Whittaker function decays rapidly along any positive root: if $a = \text{diag}(a_1, \ldots, a_n)$

$$W(a) \ll_N \prod_{i=1}^{n-1} \text{min}(1, |a_i/a_{i+1}|^{-N}) S_d(W), \quad (9)$$

for some $d > 0$. The proof uses $N$-equivariance and smoothness of the Whittaker function.

If $F$ is archimedean we may choose an element $Y$ (depending on $N_1, \ldots, N_{n-1}$) in the Lie algebra of $G_n$ such that

$$d\pi(Y)W(a) = \prod_{i=1}^{n-1} (a_i/a_{i+1})^{N_i} W(a).$$

The claim follows from the Sobolev embedding that $d\pi(Y)W(a) \ll S_d(W)$ for some $d > 0$. 
If $F$ is non-archimedean then the invariance of $W$ under some maximal compact implies that
\[ W(a) = 0, \quad \text{if } |a_i| > c|a_{i+1}| \text{ for some } i, \tag{10} \]
where $c$ depends only on $W$ via its level, i.e. its some Sobolev norm. The claim follows again from Sobolev embedding.

Now let $\Re(s)$ be large enough so that we can write $\Psi(1/2+s,V,W)$ as the absolutely convergent integral
\[
\int_{\mathbb{N}_n \backslash G_n} V \left[ \left( \begin{array}{c} g \\ 1 \end{array} \right) \right] |W(g)|^s \det(g)^s \, dg.
\]
Let $\omega_\pi$ be the central character of $\pi$.

Let $F$ be archimedean. We integrate by parts with respect to $\mathcal{D}$ sufficiently many, say $d$, times to obtain that the above equals
\[
\int_{\mathbb{N}_n \backslash G_n} \mathcal{D}^d \left[ V \left[ \left( \begin{array}{c} g \\ 1 \end{array} \right) \right] \right] (\det(g))^s \mathcal{D}^{-d}W(g) \, dg.
\]
It is straightforward to check that $\mathcal{D} |\det(g)|^s = p(s) |\det(g)|^s$ for certain polynomial $p(s)$. We use Iwasawa coordinates in $\mathbb{N}_n \backslash G_n$ to write the above integral as
\[
p(s) \int_{\mathbb{N}_n \backslash G_{n-1} \times K_n} \mathcal{D}^d \left[ \left( \begin{array}{c} z \\ a \\ 1 \end{array} \right) \right] \left( \begin{array}{c} a \\ 1 \end{array} \right)^k \left( \begin{array}{c} k \\ 1 \end{array} \right) |\det(a)|^s |z|^{ns} \omega_\pi(z)
\]
\[
\mathcal{D}^{-d}W \left[ \left( \begin{array}{c} a \\ 1 \end{array} \right) \right] d^x z \, d^x a \, d\hat{\chi}(a) \, dk.
\]
We change variable $k \mapsto \left( \begin{array}{c} k' \\ 1 \end{array} \right) k$ and integrate of $k' \in K_{n-1}$ to obtain that the above up to an absolute constant equals to
\[
p(s) \int_{\mathbb{N}_{n-1} \backslash G_{n-1} \times K_n} \mathcal{D}^d \left[ \left( \begin{array}{c} z \\ h \\ 1 \end{array} \right) \right] \left( \begin{array}{c} h \\ 1 \end{array} \right)^k \left( \begin{array}{c} k \\ 1 \end{array} \right) |\det(h)|^{s-1} |z|^{ns} \omega_\pi(z)
\]
\[
\mathcal{D}^{-d}W \left[ \left( \begin{array}{c} h \\ 1 \end{array} \right) \right] d^x z \, dh \, dk.
\]
We do Cauchy–Schwarz on the $h$-integral and use unitarity of $\pi$ to obtain that the above is bounded by
\[
|p(s)| S_{-d}(W) \left( \int_{\mathbb{N}_n \backslash G_n} \mathcal{D}^d \left[ \left( \begin{array}{c} z \\ h \\ 1 \end{array} \right) \right] \left( \begin{array}{c} h \\ 1 \end{array} \right)^k \right]^2 |\det(h)|^{2\Re(s)-2} |z|^{2n\Re(s)} \, d^x z \, dh \, dk \right)^{1/2}.
\]
Using rapid decay estimate of $V$ from (9) we see that the above integral is absolutely convergent for $\Re(s)$ large enough. Noting that $S_d(\Pi(k)V) = K_n S_d(V)$ for any $k \in K_n$ we conclude.

Now let $F$ be non-archimedean and $\Re(s)$ be sufficiently large. First, we assume that $V$ and $W$ are a $K$-type vectors, i.e., a $\mathfrak{D}$-eigenvectors. Then if the level of $V$ is smaller than that of $W$, the zeta integral vanishes and the assertion follows.

Now let the level of $V$ be larger than that of $W$. We write the zeta integral in the Iwasawa coordinates as
\[
\int_{K_n} \int_{A_n} \prod \left( \begin{array}{cc} k & 1 \\ 1 & 1 \end{array} \right) V \left( \begin{array}{c} a \\ 1 \end{array} \right) \pi(k)W(a) |\det(a)|^s \frac{d^\times a}{\delta(a)} dk.
\]

Using rapid decay of $V$ as in (10) we may restrict the above $A_n$ integral on $a_1 \ll \cdots \ll a_n$ where the implied constants depend only on $S_d(V)$ polynomially for some $d$. We use Sobolev embedding to bound $\pi(k)W(a) \ll K_n S_{d'}(W)$ for some $d' > 0$. So the zeta integral becomes absolutely convergent for some large $\Re(s)$ and bounded by $S_d(V)S_{d'}(W)$. Thus the claim follows for $V, W$ being $\mathfrak{D}$-eigenvectors. The general claim now follows from [34, S4d].

So far we have proved that for a general local field $F$ and $\Re(s)$ sufficiently positive the assertion in the lemma follows. Now if $\Re(s)$ is sufficiently negative then we use the local functional equation (8), and the bounds in (5) and (4) to conclude that $\Psi(1/2 + s, V, W)$ satisfies the claim in the lemma (by absorbing the powers of the conductor into the Sobolev norms). We conclude our proof by an application of the Phragmén–Lindelöf convexity principle.

**Proof of Lemma 3.2.** We follow the proofs in [29, 31]. Using [34, S1b] we reduce to the case of $k = 1$.

We run an induction on $n$. The $n = 2$ case is in [34, Proposition 3.2.3]. We prove the inductive case.

Note that in the archimedean case there exists a differential operator $Y$ such that
\[ d\pi(Y)W(a) = (a_{n-1}/a_n)W(a). \]

We define $W_1 := d\pi(Y^N)W$. Thus it is enough to show that
\[ W_1(a) \ll_{N,\eta} |\det(a)|^{-\delta^{1/2-\eta}}(a) \prod_{i=1}^{n-2} \min(1, |a_i/a_{i+1}|^{-N}) S_d(W_1), \]
as $S_d(W_1) \ll S_{d'}(W)$ for some $d' > d$.

In the non-archimedean case, we reduce to showing the above by appealing to the invariance of $W$ under sum open-compact subgroup and $N$-equivariance.
Let $\omega_{\pi}$ be the central character of $\pi$ and $\tilde{a} := \text{diag}(a_1, \ldots, a_{n-1})$. Using the Whittaker–Plancherel formula (6) we write

$$|\det(a/a_n)|^s W_1(a) = \omega_{\pi}(a_n) W_1(a/a_n) |\det(\tilde{a}/a_n)|^s =$$

$$\omega_{\pi}(a_n) \sum_{G_{n-1}} \int_{W' \in B(\pi')} W''(\tilde{a}/a_n) \Psi(1/2 + s, W_1, W) \, d\mu_{\text{loc}}(\pi'),$$

which is valid for some $\Re(s) > 0$.

The RHS is absolutely convergent which can be seen applying Lemma 3.3 and Lemma 3.1, thus is analytic in $s$ in some right half plane. Note that the poles of the integrand in the RHS as a function of $s$ may at most come from the poles of the zeta integral as the Whittaker functions are analytic [27]. It is known that (see e.g. [17, Theorem 3.5]) the rightmost pole of $\Psi(1/2 + s, W_1, W')$ is the same of the local $L$-factor $L(1/2 + s, \pi \otimes \pi')$. As $\pi$ is $\theta$-tempered and $\pi'$ is tempered, the $L$-factor is holomorphic for $\Re(s) > -1/2 + \theta$. So we may analytically continue the integrand of the RHS until $\Re(s) = -1/2 + \theta + \eta$ for any $\eta > 0$.

We apply inductive hypothesis on $W'$ (note that $\pi'$ is tempered) that

$$W''(\tilde{a}/a_n) \ll_{N, \eta} \delta^{1/2-\eta}(\tilde{a}) \prod_{i=1}^{n-2} \min(1, |a_i/a_{i+1}|^{-N}) S_{d'}(W'),$$

for some $d' > 0$. We use

$$\delta(a) = |\det(\tilde{a}/a_n)| \delta(\tilde{a}/a_n)$$

and Lemma 3.3 to obtain that

$$W_1(a) \ll_{N, \eta} \prod_{i=1}^{n-2} \min(1, |a_i/a_{i+1}|^{-N})$$

$$\int_{G_{n-1}} \sum_{W' \in B(\pi')} S_{d' - L}(W') S_d(W_1) \, d\mu_{\text{loc}}(\pi'),$$

where $d$ depends on $L, N$. Making $L$ large enough and applying Lemma 3.1 we see the that last integral is convergent and we conclude.

**Remark 3.1.** From the proof of Lemma 3.2 it can be noted that the exponent $\theta$ of $|\det|$ in the bound of $W$ as in the statement of the lemma, can be modified to $-\hat{\theta}$ where $\hat{\theta}$ is the minimum of the magnitudes of the real parts of the Langlands parameters of $\pi$. If $\pi$ is unramified, this follows similar to the proof of Lemma 3.2 - by noting the Langlands parameters of $\pi \otimes \pi'$ and by bounding $W' \in \pi'$. For other $\pi$ one can similarly work out, however, as we do not need this result in this paper we are not giving a full proof.
3.8. **Newvectors.** Let $F$ be non-archimedean and $\pi$ be any generic irreducible representation of $G_n(F)$. Let $K_0(p^j)$ be the congruence subgroup of $G_n$ consisting of matrices in $G_n(o)$ whose last row modulo $p^j$ is congruent to $(0, \ldots, 0, *)$.

Let $c(\pi)$ be the minimal non-negative integer $j$ such that $\pi^{K_0(p^j)}$ is non-zero. It is a theorem by Casselman (for $n = 2$) [16] and Jacquet–Piatetski-Shapiro–Shalika (for general $n$) [26] that $\pi^{K_0(p^{c(\pi)})}$ is one dimensional. Any non-zero vector in this fixed space is called a newvector. Also, $c(\pi)$ and $C(\pi) := p^{c(\pi)}$ are called the conductor exponent and (analytic) conductor of $\pi$, respectively.

In this paper we denote the newvector $W \in \pi$ such that $W(1) = 1$ by $W_\pi$. Newvectors often serve the purpose of test vectors for the Rankin–Selberg periods. In this paper we use two such instances, hence record them here.

Let $\sigma$ and $\Pi$ be any irreducible generic representation of $G_n$ and $G_{n+1}$, respectively. Further assume that at least one of $\Pi$ and $\sigma$ is unramified. We consider the vector $W_\Pi^{(c(\sigma))}$, given by (29). from [15, Theorem 1.1], we have

$$
\Psi(s, W_\Pi^{(c(\sigma))}, W_\sigma) = \frac{L(s, \Pi \otimes \bar{\sigma})}{[G_n(o) : K_0(p^{c(\sigma)})]},
$$

(11)

Note that, this generalizes the classical test vector result in [26] which considers the case of unramified $\sigma$.

The $L$-functions attached to $\pi$ can be given by

$$
L(s, \pi) = \prod_{i=1}^n (1 - p^{-s} \alpha_i)^{-1},
$$

for certain $\alpha := \{\alpha_i\} \in \mathbb{C}^n$. If $\pi$ is also unramified then $\alpha_i \neq 0$ and are called the Satake parameters attached to $\pi$. We record the description of $W_\pi$ which is due to Shintani [46] for unramified $\pi$ and Miyauchi [35] for general $\pi$.

Let $\pi$ be unramified for now. Let $m := (m_1, \ldots, m_n) \in \mathbb{Z}^n$ and

$$
a = \text{diag}(y_1, y_2, \ldots, y_n),
$$

with $v(y_i) = m_i$. Then

$$
W_\pi(a) = \begin{cases} 
\delta^{1/2}(a) \lambda_\pi(m), & \text{if } m_1 \geq \cdots \geq m_n \\
0, & \text{otherwise},
\end{cases}
$$

(12)

where $\lambda_\pi(m)$ is the Schur polynomial with index $m$ and evaluated at $\alpha$. i.e.

$$
\lambda_\pi(m) := \frac{\det([\alpha_j^{m_i+n-i}]_{1 \leq i, j \leq n})}{\det([\alpha_j^{n-i}]_{1 \leq i, j \leq n})}.
$$
If $\pi$ is $\theta$-tempered then $\max_i \{|\alpha_i|\} = p^\theta$. Consequently, it follows from the highest weight theory for $U(n)$ that

$$\lambda_{\pi}(m) \ll p^{\theta \sum_i m_i},$$

where the implied constant is absolute.

We also record that if $\pi$ is also unitary then

$$\|W_\pi\|^2 = \frac{L(1, \pi \otimes \overline{\pi})}{\zeta(n)},$$

which can be proved directly calculating the $L^2$-norm using the description in (12).

4. **Global Preliminaries**

In this section, we let $F$ to be a number field with the adele ring $\mathbb{A}$. By $G_n$ we denote the algebraic group $GL(n)$ over $F$. For any subgroup $H < G_n$ defined over $F$ by $[H]$ we denote the quotient $H(F)Z_H(\mathbb{A})/H(\mathbb{A})$ where $Z_H$ is the center of $H$. We fix the $G_n(\mathbb{A})$ invariant probability measure on $[G_n]$ and denote it by $dg$. When there is no confusion we usually suppress the index $n$ from the notation.

4.1. **Classification of automorphic spectrum.** We give a quick description of the standard automorphic representations i.e. which appear in the spectral decomposition of $L^2(G)$. We refer to [34, §2.2.1] and [36] for details.

Let $Y(G)$ be the set of pairs $(M, \sigma)$ where $M$ is the Levi part of a standard parabolic subgroup $G$ and $\sigma$ is an isomorphism class of discrete series of $M\mathbb{A}$. Here by discrete series we mean the automorphic forms on $M(F)\backslash M(\mathbb{A})$ such that for all $\varphi \in \sigma$ the integral

$$\|\varphi\|^2_\sigma := \int_{Z_M(\mathbb{A})M(F)\backslash M(\mathbb{A})} |\varphi(x)|^2 \, dx$$

is finite.

We let $X(G)$ be the quotient of $Y(G)$ by the equivalence relation defined as follows: $(M, \sigma) \sim (M', \sigma')$ if there exists a Weyl element $w$ such that $wMw^{-1} = M'$ and $w\sigma w^{-1} \simeq \sigma'$. For every $\chi \in X(G)$ we denote $I(\chi)$ to be the unitarily normalized induction $\text{Ind}_{G(\mathbb{A})}^{\tilde{M}(\mathbb{A})}\tilde{\chi}$ where $N_M$ is the unipotent radical attached to $M$. Langlands' classification asserts that any standard automorphic representation is isomorphic to the unique irreducible constituent $\tilde{\chi}$ of the induction $I(\chi)$.

Furthermore, we start with a cuspidal data $\chi = (M, \sigma)$, i.e. $\sigma$ being a cuspidal automorphic representation of $M(\mathbb{A})$, and proceed with the same construction as above to obtain $\tilde{\chi}$. Another theorem of Langlands asserts that any generic automorphic representation is isomorphic to such a $\tilde{\chi}$. 
4.2. Spectral decomposition. We define a norm on $I^p(\chi)$ by
\[
\|f\|_{I^p(\chi)}^2 := \int_K \|f(k\sigma_d)\|^2 dk,
\]
where $dk$ is the probability Haar measure on $K$. Finally, we define a natural intertwiner (by averaging over $P(F)\backslash G(F)$ and analytic continuation)
\[
Eis : I^p(\chi) \to C^\infty([G]).
\]
Then for any element $\xi \in C^\infty([G])$ with sufficiently rapid decay at the cusp (e.g. a cusp form) we have the pointwise Plancherel decomposition
\[
\xi(x) = \int_{X(G)} \sum_{f \in \widehat{B}(I^p(\chi))} \frac{\langle \xi, Eis(f) \rangle_{L^2([G])}}{\langle f, f \rangle_{I^p(\chi)}} Eis(f)(x) d\mu^{\text{aut}}(\chi). \tag{15}
\]
Here $\widehat{B}(I^p(\chi))$ denotes an orthogonal basis of $I^p(\chi)$ and $d\mu^{\text{aut}}(\chi)$ denotes the Plancherel measure on $X(G)$ compatible with $dg$. The RHS above does not depend on the choice of orthonormal basis $B$. Also, the RHS converges absolutely and uniformly on compacta. For more details we refer to [34, §2.2.1].

Often, we shorthand (15) as
\[
\xi(x) = \int_{\text{aut}} \sum_{\varphi \in \widehat{B}(\pi)} \frac{\langle \xi, \varphi \rangle}{\|\varphi\|^2} \varphi(x) d\pi.
\]
In practice, we mostly vary $\pi$ over the generic spectrum only, in which case we replace $\int_{\text{aut}}$ above by $\int_{\text{gen}}$.

4.3. Fourier expansion of automorphic forms. Let $\psi_0 : F \backslash A \to C^\times$ be an additive character, which, for concreteness, we chose $\psi_0$ as in [34] to be the additive character $e_Q \circ \text{tr}$, where $e_Q$ is the only additive character of $Q \backslash A_Q$ whose restriction to $\mathbb{R}$ is $x \mapsto e^{2\pi ix}$ and $\text{tr} : A \to A_Q$ is the adelic version of $\text{tr} : F \to Q$. We extend $\psi_0$ to a character $\psi$ of $N(A)$ as in [34]. We define the $\psi$-Whittaker space by
\[
W(\psi) := \{W \in C^\infty(G(A)) \mid W(n g) = \psi(n) W(g), n \in N(A), g \in G(A)\}
\]
on which $G(A)$ acts by right translation.

We define an intertwiner $\pi \mapsto W(\psi)$ by
\[
\pi \ni \varphi \mapsto W_\varphi := \int_{[N]} \varphi(n) \overline{\psi(n)} dn.
\]
We call $\pi$ to be generic if the above intertwiner does not vanish identically. The theory of Whittaker model asserts that if $\pi$ is irreducible generic then the above intertwiner is unique up to scalars and in fact is a $G(A)$-equivariant embedding. We call the image

\[ W(\pi, \psi) \] of \( \pi \) under the above intertwiner to be the Whittaker model of \( \pi \). For generic \( \pi \) we identify \( \pi \) with its Whittaker model.

Given an automorphic form \( \varphi \) in a generic representation \( \pi \) of \( G(\mathbb{A}) \) we can write its Fourier expansion using \( W_\varphi \). For example, if \( \varphi \) is cuspidal then we can write (see [17, Theorem 1.1])

\[
\varphi(g) = \sum_{\gamma \in N_n(F) \backslash P_n(F)} W_\varphi(\gamma g) = \sum_{\gamma' \in N_{n-1}(F) \backslash G_{n-1}(F)} W_\varphi \left[ \begin{pmatrix} \gamma' \\ 1 \end{pmatrix} g \right].
\]

(16)

The above Fourier expansions converge absolutely and uniformly on compacta. Here \( P_n \) is the standard Mirabolic subgroup of \( GL_p \) defined by \( GL(n-1) \times U_n \) and \( U_n \) is the unipotent radical of the parabolic in \( GL(n) \) attached to the partition \( n = (n-1) + 1 \).

In other words, \( P_n \) is the stabilizer of \( (0, \ldots, 0, 1) \) of the right action of \( G_n \) on the row vectors, thus consists of matrices in \( GL(n) \) with last row being \( (0, \ldots, 0, 1) \).

If \( \varphi \) is non-cuspidal then the Fourier expansion of \( \varphi \) is more complicated. We do not need full Fourier expansion for non-cuspidal automorphic form, interested readers may look at [24, Proposition 4.2]. However, we do need a partial Fourier expansion with respect to the unipotent subgroup \( U_n \). From abelian Fourier theory we have

\[
(\varphi - \varphi_{U_n})(g) = \sum_{\gamma \in P_{n-1}(F) \backslash G_{n-1}(F)} W_{\varphi_{U_n}} \left[ \begin{pmatrix} \gamma \\ 1 \end{pmatrix} g \right].
\]

(17)

Here \( \varphi_{U_n} \) is the the constant term of \( \varphi \) along \( U_n \) defined by

\[
\varphi_{U_n}(g) := \int_{[U_n]} \varphi(ug) \, du,
\]

and \( W_{\varphi_{U_n}} \) is a partial Whittaker function defined by

\[
W_{\varphi_{U_n}}(g) := \int_{[U_n]} \varphi(ug)\overline{\psi(u)} \, du = \int_{[U_n]} (\varphi(ug) - \varphi_{U_n}(ug))\overline{\psi(u)} \, du,
\]

(18)

which follows as \( \varphi_{U_n} \) is left \( U_n \)-invariant.

4.4. Global Zeta Integral and \( L \)-functions. We give a quick description of global theory \( GL(n+1) \times GL(n) \) zeta integrals, for details see [17, §2]. Let \( \Pi \) and \( \pi \) be generic representations of \( G_{n+1}(\mathbb{A}) \) and \( G_n(\mathbb{A}) \), respectively. Let \( \Phi \in \Pi \) and \( \varphi \in \pi \) be two automorphic forms with Whittaker functions \( W_\Phi \) and \( W_\varphi \), respectively. We define global zeta integral between \( \Phi \) and \( \varphi \) by

\[
\Psi(s, W_\Phi, W_\varphi) := \int_{N_n(\mathbb{A}) \backslash G_n(\mathbb{A})} W_\Phi \left[ \begin{pmatrix} g \\ 1 \end{pmatrix} \right] W_\varphi(g) |\det(g)|^{s-1/2} \, dg.
\]
The above converges absolutely for sufficiently large $\Re(s)$. If $\Phi$ and $\varphi$ are factorizable vectors then the global zeta integral factors into local zeta integrals as

$$\Psi(s, W_\Phi, W_\varphi) = \prod_v \Psi_v(s, W_{\Phi,v}, W_{\varphi,v}),$$

where the local zeta integral $\Psi_v$ is defined as in (7), and $W_\Phi = \prod_v W_{\Phi,v}$, similarly for $W_\varphi$. The product converges absolutely again for large real $\Re(s)$.

If $\Phi$ and $\psi$ are unramified at the places outside of a finite set $S$, and further, if $W_{\Phi,v} = W_\Pi_v$ and $W_{\varphi,v} = W_\pi_v$ for $v \notin S$ then (see [17, Theorem 3.3])

$$\Psi(s, W_\Phi, W_\varphi) = L(s, \Pi \otimes \pi) \prod_{v \in S} \Psi_v(s, W_{\Phi,v}, W_{\varphi,v}),$$

(19)

where $L_v$ denotes the $v$-adic local $L$-factor and $\Lambda$ denotes the global completed Rankin–Selberg $L$-function of $\Pi \otimes \pi$. We refer to [17, Theorem 4.2] for meromorphic properties of the Rankin–Selberg $L$-functions.

We write $\Lambda^S$ for the partial $L$-function removing all $v$-adic Euler factors for $v \in S$. If $S = \{v \mid \infty\}$ then we write, as usual in analytic number theory, $L$ for $\Lambda^S$.

We can attach a global analytic conductor $C(\pi)$ to an automorphic representation $\pi$, analogously to its $L$-function $\Lambda(s, \pi) := \Lambda(s, \pi \otimes 1)$. If $\pi$ is unramified at the places outside of a finite set $S$. Then $C(\pi) = \prod_{v \in S} C(\pi_v)$ where $C(\pi_v)$ is the local conductor as defined in §3.3.

We also have the convexity bound

$$L(1/2, \pi) \ll \epsilon C(\pi)^{1/4+\epsilon},$$

(20)

which follows from the functional equation of $\Lambda(s, \pi)$ and the Phramén–Lindelöf convexity principle.

If $\Phi$ is cuspidal then the integral

$$\int_{[GL(n)]} \Phi \left[ \begin{pmatrix} g & \cdot \\ \cdot & 1 \end{pmatrix} \right] \frac{\overline{\varphi(g)}}{|\det(g)|^{s-1/2}} \, dg$$

converges absolutely for any $\varphi$. Moreover, if $\varphi$ is generic then the above equals to $\Psi(s, W_\Phi, W_\varphi)$. This way we may analytically continue $\Psi(s, W_\Phi, W_\varphi)$ for any cuspidal $\Phi$.

However, if $\Phi$ is not cuspidal then the above integral is not convergent. One needs to regularize the integral, as in [24], to give it a meaning and then the regularized integral will again be equal to the global zeta integral.

In this paper we do not need the general regularization scheme but only need to regularize the above integral when $\varphi$ is cuspidal. This “naive” regularization is comparatively easier and we describe it below.
4.5. Harmonic weights. We describe the harmonic weights that appear in the Kuznetsov trace formula. The harmonic weights relate the unitary products on a generic unitary automorphic representation and that of its Whittaker model.

Let \( \pi \) be a unitary generic irreducible automorphic representation such that \( \pi \) is unramified outside a finite set of places \( S \). Let \( \varphi_1, \varphi_2 \in \pi \) so that \( W_{\varphi_1, v} = W_{\varphi_2, v} = W_{\pi, v} \) for all \( v \not\in S \). Then by Schur’s lemma there exists a positive constant \( L_S(\pi) \) such that

\[
\langle \varphi_1, \varphi_2 \rangle_\pi = L_S(\pi) \prod_{v \in S} \langle W_{\varphi_1, v}, W_{\varphi_2, v} \rangle_{\pi, v} = L(\pi) \prod_{v \in S} \frac{\langle W_{\varphi_1, v}, W_{\varphi_2, v} \rangle_{\pi, v} \zeta_v(n)}{L_v(1, \pi_v \otimes \overline{\pi_v})}. \tag{21}
\]

If \( \pi \) is cuspidal then a standard Rankin–Selberg argument shows that

\[
L_S(\pi) = \Lambda^S(1, \pi, \text{Ad}) \prod_{v \in S} \frac{\zeta_v(n)}{\zeta_v(1)}. \tag{22}
\]

If \( \pi \) is non-cuspidal then one can also show that \( L_S(\pi) \) is proportional to the first non-zero Laurent coefficient of \( \Lambda^S(s, \pi \otimes \overline{\pi}) \) around \( s = 1 \).

**Lemma 4.1.** Let \( M \) be a Levi of \( G \) attached to the partition \( n = n_1 + \cdots + n_k \) and \( \pi := \bigotimes_{i=1}^k \pi_i \) be a cusp form on \( M \) such that \( \pi_i \)'s are pairwise non-isomorphic. Let \( \Pi := \bigotimes_{i=1}^k \pi_i \) be the Eisenstein representation attached to the cuspidal data \((M, \pi)\). Then

\[
L^S(\Pi) = \lim_{s \to 1} \frac{\Lambda^S(s, \Pi \otimes \overline{\Pi})}{\xi_F(s)^k} \prod_{v \in S} \zeta_v(n),
\]

where \( \xi_F(s) \) is the Dedekind zeta function attached to \( F \).

If \( \pi_i \) are not pairwise non-isomorphic then \( L^S(\Pi) \) will be proportional to \( \lim_{s \to 1} (s - 1)^{k'} \Lambda^S(s, \Pi \otimes \overline{\Pi}) \) where \( k' \) is the order of the pole of \( \Lambda^S(s, \Pi \otimes \overline{\Pi}) \) at \( s = 1 \). However, we do not need that result here, so we do not prove it.

For \( \pi \) as in Lemma 4.1 we define the global Casselman–Shalika factor

\[
\text{cs}(\pi) = \prod_{1 \leq i < j \leq k} \Lambda(1, \pi_i \otimes \overline{\pi_j}).
\]

Note that as \( \pi_i \) are pairwise non-isomorphic the above quantity is well-defined. Similarly, we define the partial factor \( \text{cs}^S(\pi) \) and the local factor \( \text{cs}(\pi_v) \). Note that, we can also write assertion of Lemma 4.1 as

\[
L^S(\Pi) = |\text{cs}^S(\pi)|^2 \prod_{i=1}^k \Lambda^S(1, \pi_i, \text{Ad}) \prod_{v \in S} \frac{\zeta_v(n)}{\zeta_v(1)}.
\]

This result is probably well-known to the experts. However, we are unable to find a reference which points us to the constant with the precision we need (e.g. to define (42)). The result can be extracted from [19], but we give a sketch for convenience.
Proof. Let $f \in \mathcal{I}(M, \pi)$ be any nonzero element and $\text{Eis}(f)$ be the corresponding Eisenstein series. Then from [45, Proposition 7.3.1] we have
\[
W_{\text{Eis}}(f) = \prod_v W_{\text{Eis}}(f,v), \quad W_{\text{Eis}}(f,v) = W_{f_v}^{\text{Jac}},
\]
where $f_v \in \text{Ind}_{M(F_v)}^{G(F_v)}(\pi_v)$ and $\pi_v$ is realized in its Whittaker model. Here, $W_{f_v}^{\text{Jac}}$ is the Jacquet’s functional as defined in [19, §1.4].

If $\phi \in \pi$ we assume that $W_{\phi,v} = W_{\pi_v}$ when $v$ is an unramified place. Then it follows from [45, Proposition 7.1.4] that
\[
W_{f_v}^{\text{Jac}}(1) = \text{cs}(\pi_v)^{-1}. \quad \text{Hence, using (14) we have}
\]
\[
\|W_{f_v}^{\text{Jac}}\|_v^2 = \frac{L_v(1, \Pi \otimes \Pi_v(n))}{\zeta_v(n)|\text{cs}(\pi_v)|^2} = \frac{L_v(1, \pi_{i,v} \otimes \bar{\pi}_{i,v})}{\zeta_v(n)} \tag{23}
\]
for all $v \not\in S$.

Moreover, we have a factorization [19, §11]
\[
W_{\text{Eis}(\text{cs}^S(\pi)f)} = \text{cs}^S(\pi)W_{\text{Eis}(f)} = \prod_{v \not\in S} \text{cs}(\pi_v)W_{f_v}^{\text{Jac}} \prod_{v \in S} W_{f_v}^{\text{Jac}}.
\]
We choose $\varphi_1 = \varphi_2 = \text{Eis}(\text{cs}^S(\pi)f)$ in (21).

Using the definition of harmonic weights in (21) we have
\[
\|f(g)\|_v^2 = \frac{1}{\prod_{i=1}^k \mathcal{L}(\pi_i)} \prod_v \frac{\zeta_v(n_i)\|f_i(g_v)\|_{\pi_v}^2}{L_v(1, \pi_{i,v} \otimes \bar{\pi}_{i,v})} \, dg.
\]
From [19, Proposition A.2] we have
\[
\zeta_v(n)\|W_{f_v}^{\text{Jac}}\|_v^2 = \prod_i \zeta_v(n_i) \int_{P(F_v) \backslash G(F_v)} \|f_v(g_v)\|_{\pi_v}^2 \, dg_v.
\]
Thus using (23) we obtain
\[
\|f\|_{\mathcal{I}(M,\pi)}^2 = \int_{P(k) \backslash G(k)} \|f(g)\|_\pi^2 \, dg = \prod_{i=1}^k \mathcal{L}(\pi_i) \prod_{v \not\in S} \|W_{f_v}^{\text{Jac}}\|_v^2 \zeta_v(n) \frac{\zeta_v(n_i)\|f_i(g_v)\|_{\pi_v}^2}{L_v(1, \pi_{i,v} \otimes \bar{\pi}_{i,v})}.
\]
Replacing $f$ by $\text{cs}^S(\pi)f$ we obtain
\[
\|\text{cs}^S(\pi)f\|_{\mathcal{I}(M,\pi)}^2 = \prod_{i=1}^k \mathcal{L}(\pi_i)|\text{cs}^S(\pi)|^2 \prod_{v \not\in S} \|W_{f_v}^{\text{Jac}}\|_v^2 \zeta_v(n) \frac{\zeta_v(n_i)\|f_i(g_v)\|_{\pi_v}^2}{L_v(1, \pi_{i,v} \otimes \bar{\pi}_{i,v})}.
\]
Finally, using description of $\mathcal{L}(\pi_i)$ for cuspidal $\pi_i$ as in (22) we conclude. \qed
4.6. **Regularization.** To prove the reciprocity formula in Theorem 1 we need to express the global $L$-function of $\sigma \otimes \pi$ on $\text{GL}(n) \times \text{GL}(n - 1)$ while $\sigma$ is non necessarily cuspidal. In this case, the usual zeta integral which is divergent. This is why we need to regularize the global zeta integral to relate it with the Rankin–Selberg $L$-functions.

**Proposition 4.1.** Let $\varphi$ be an generic automorphic form on $G_n(\mathbb{A})$ and $\phi$ be a cusp form on $G_{n-1}(\mathbb{A})$ with trivial central character. Then for $s \in \mathbb{C}$ with $\Re(s)$ sufficiently large

$$\int_{[\text{GL}(n-1)]} (\varphi \left( \begin{pmatrix} g & x \\ 1 & 1 \end{pmatrix} \right) - \varphi_{U_n} \left( \begin{pmatrix} g & x \\ 1 & 1 \end{pmatrix} \right) \overline{\phi(g)}) \mid \det(g) \mid^{s-1/2} dg$$

is absolutely convergent and equals to $\Psi(s, W_{\varphi}, W_{\phi})$.

To prove this proposition we need some preparatory result on the decay properties of $W_{U_n}$ which will be used to deal with several convergence issues.

**Lemma 4.2.** Let $\varphi$ be any vector in a generic automorphic representation $\pi$ of $G_n(\mathbb{A})$ and $\varphi_{U_n}$ be its constant term along $U_n$. Let $X$ be any element in the universal enveloping algebra of $\mathfrak{g}_{n-1}(\mathbb{A})$. Then for $z \in Z_{n-1}(\mathbb{A})$ and $g \in G_n(\mathbb{A})$ we have for all large $N$

$$d\pi(X) (\varphi - \varphi_{U_n}) \left( \begin{pmatrix} z & x \\ 1 & 1 \end{pmatrix} g \right) \ll_{X,N,g} |z|^{-N},$$

where the dependency on $g$ is at most polynomial in $|g|$.

**Proof.** This is a special case/reformulation of [36, Lemma I.2.10].

**Lemma 4.3.** Let $z \in Z_{n-1}(\mathbb{A})$, $g \in G_{n-1}$ and $\gamma \in P_{n-1}(F) \backslash G_{n-1}(F)$. Then for all large $M, N$

$$W_{\varphi}^{U_n} \left( \begin{pmatrix} z \gamma g & x \\ 1 & 1 \end{pmatrix} \right) \ll_{M,N,g} |z|^{-N}|\gamma|^{-M}$$

where the dependency on $g$ is at most polynomial in $|g|$.

**Proof.** We use the formulation in (18) to write

$$W_{\varphi}^{U_n} \left( \begin{pmatrix} z \gamma g & x \\ 1 & 1 \end{pmatrix} \right) = \int_{F_{n-1} \backslash A_{n-1}} (\varphi - \varphi_{U_n}) \left( \begin{pmatrix} I_{n-1} & x \\ 1 & 1 \end{pmatrix} \begin{pmatrix} z \gamma g & x \\ 1 & 1 \end{pmatrix} \right) \psi_0(\epsilon_{n-1}^t x) dx,$$

where $\epsilon_{n-1}$ is the vector $(0, \ldots, 0, 1)^t \in A_{n-1}$. Conjugating, using automorphic of $\varphi$, and changing variables we write the above as

$$\mid \det(z) \mid \int_{F_{n-1} \backslash A_{n-1}} (\varphi - \varphi_{U_n}) \left( \begin{pmatrix} z & x \\ 1 & 1 \end{pmatrix} \begin{pmatrix} g & x \\ 1 & 1 \end{pmatrix} \right) \overline{\psi_0(\epsilon_{n-1}^t \gamma x)} dx.$$

From Abelian Fourier theory and Lemma 4.2 we deduce that the above integral is bounded by

$$|z|^{-N} |\epsilon_{n-1}^t \gamma|^{-M}$$
for all large $M, N$. We conclude the proof by noting that $e_{n-1}^t \gamma$ uniquely determines $\gamma \in P_{n-1}(F) \backslash G_{n-1}(F)$.

\textbf{Proof of Proposition 4.1.} Rapid decay of the cusp form $\phi$ on $[G_{n-1}]$ and Lemma 4.2 yield the absolute convergence in the Lemma for sufficiently large $\Re(s)$.

To prove that equality we first, using (17), write the integral as

$$
\int_{[\text{GL}(n-1)]} \sum_{\gamma \in P_{n-1}(F) \backslash G_{n-1}(F)} W_{U_n}^{\varphi} \left( \begin{pmatrix} g & 1 \\ 1 & 1 \end{pmatrix} \right) \overline{\phi(g)} |\det(g)|^{s-1/2} \, dg.
$$

Again rapid decay of $\phi$ on $[G_{n-1}]$ and Lemma 4.3 yield absolute convergence of the above joint integral and sum for large $\Re(s)$. This allows us to unfold and write the above as

$$
\int_{P_{n-1}(F) \backslash G_{n-1}(\mathbb{A})} W_{U_n}^{\varphi} \left( \begin{pmatrix} g & 1 \\ 1 & 1 \end{pmatrix} \right) \sum_{\gamma \in N_{n-1}(F) \backslash P_{n-1}(F)} \overline{W_{\phi}(\gamma g)} |\det(g)|^{s-1/2} \, dg.
$$

Now we insert the Fourier expansion of $\phi$ as in (16) into the above equation to write the same as

$$
\int_{P_{n-1}(F) \backslash G_{n-1}(\mathbb{A})} W_{U_n}^{\varphi} \left( \begin{pmatrix} g & 1 \\ 1 & 1 \end{pmatrix} \right) \sum_{\gamma \in N_{n-1}(F) \backslash P_{n-1}(F)} \overline{W_{\phi}(\gamma g)} |\det(g)|^{s-1/2} \, dg.
$$

Once again, applying Lemma 4.3 for $W_{U_n}^{\varphi}$ along with Lemma 3.2 for $W_{\phi}$ we deduce that the above joint sum and integral converge absolutely. This allows us to unfold once again to and write the above as

$$
\int_{N_{n-1}(F) \backslash G_{n-1}(\mathbb{A})} W_{U_n}^{\varphi} \left( \begin{pmatrix} g & 1 \\ 1 & 1 \end{pmatrix} \right) \overline{W_{\phi}(g)} |\det(g)|^{s-1/2} \, dg.
$$

Finally, using $N_{n-1}(\mathbb{A})$-equivariance of $W_{\phi}$ we can fold the above integral as

$$
\int_{N_{n-1}(\mathbb{A})} \int_{[N_{n-1}]} W_{U_n}^{\varphi} \left( \begin{pmatrix} ng & 1 \\ 1 & 1 \end{pmatrix} \right) \overline{\psi(n)W_{\phi}(g)} |\det(g)|^{s-1/2} \, dn \, dg.
$$

We conclude by noting that the inner integral evaluates to $W_{\varphi} \left[ \begin{pmatrix} g & 1 \\ 1 & 1 \end{pmatrix} \right]$. □

\section{5. Global Set-up}

In this section we work globally and adopt the notations as in the beginning of §4. Let $\Pi$ and $\pi$ be cuspidal automorphic representations of $G_{n+1}(\mathbb{A})$ and $G_{n-1}(\mathbb{A})$, respectively, with trivial central characters. Let $\Phi \in \Pi$ and $\phi \in \pi$ be two cusp forms.
5.1. **Reciprocity as a period identity.** We first show an identity between two periods of the automorphic forms $\Phi$ and $\phi$. This identity is the point of departure for the reciprocity formula.

For $s \in \mathbb{C}^2$ we define

$$\mathcal{P}(s, \Phi, \phi) := \int_{[G_{n-1}]} \int_{[G_1]} \Phi \left( \begin{pmatrix} h & z \\ z & 1 \end{pmatrix} \right) \bar{\phi}(h) |\det(h)|^{s_1 + s_2 - 1} |z|^{n(s_1 - 1/2)} d^x z dh.$$  

(24)

As $\Phi$ is cuspidal, rapid decay of $\Phi$ ensures that the above converges absolutely for any $s \in \mathbb{C}^2$.

**Proposition 5.1.** For any $s \in \mathbb{C}^2$ we have

$$\mathcal{P}(s, \Phi, \phi) = \mathcal{P}(\tilde{\Phi}, \phi, \tilde{s}),$$

for $\tilde{\Phi} := \Pi(w^*) \Phi$ where $w^*$ and $\tilde{s}$ are given by (3) and (2), respectively.

**Proof.** This is a straightforward generalization of [39, Proposition 5.1] and the proof follows the same lines. Indeed, by making use of the automorphicity of $\Phi$ we have

$$\Phi \left( \begin{pmatrix} hz & z \\ z & 1 \end{pmatrix} \right) = \tilde{\Phi} \left( \begin{pmatrix} hz & 1 \\ 1 & 1 \end{pmatrix} \left( z^{-1} I_n \right) \right).$$

We plug-in the above in the integral in (24). Then using the central invariance of $\Phi$ and $\phi$, along with the change of variables $h \mapsto h z^{-1}$ followed by $z \mapsto z^{-1}$, we arrive at the conclusion. \qed

5.2. **Spectral decomposition of the period.** Recall that $\Phi$ is a cusp form on $G_{n+1}(\mathbb{A})$. We start by projecting $\Phi$ to the space of center invariant automorphic forms on $G_n(\mathbb{A})$. For $s \in \mathbb{C}$ we define

$$\mathcal{A}_s \Phi(g) = |\det(g)|^{s-1/2} \int_{[G_1]} \Phi \left( \begin{pmatrix} zg & 1 \\ 1 & 1 \end{pmatrix} \right) |z|^{n(s-1/2)} d^x u, \quad g \in G_n(\mathbb{A}).$$

Once again the above converges absolutely due to the rapid decay of $\Phi$.

Note that $\mathcal{A}_s \Phi(g)$ is $Z_n(\mathbb{A})G_n(F)$-left invariant. We also notice that since $\Phi$ is smooth and of rapid decay, then so is $\mathcal{A}_s \Phi$ on $G_n(\mathbb{A})$. We spectrally decompose $\mathcal{A}_s \Phi$ over $\widehat{G_n}$ as in (15) to obtain

$$\mathcal{A}_s \Phi(g) = \int_{\mathcal{B}(\sigma)} \sum_{\varphi \in \mathcal{B}(\sigma)} \frac{\langle \mathcal{A}_s \Phi, \varphi \rangle}{\|\varphi\|^2} \varphi(g) d\sigma.$$
It follows directly from the definition of $A_s$ that we have
\[
\langle A_s \Phi, \varphi \rangle = \int_{[G_n]} \Phi \left( \begin{pmatrix} g & 1 \\ 0 & 1 \end{pmatrix} \right) |\varphi(g)| \det(g)|^{s-1/2} dg,
\]
which, due to rapid decay of $\Phi$, converges absolutely for all $s \in \mathbb{C}$. Using Fourier expansion of $\Phi$ as in (16), expression above vanishes unless $\sigma$ is generic which can be seen similarly [29, Lemma 4.1]. In this case it equals $\Psi(s, W_\Phi, W_\varphi)$, see §4.4. As a consequence, we may rewrite the spectral decomposition of $A_s \Phi$ as
\[
A_s \Phi(g) = \int_{\text{gen}} \sum_{\varphi \in \mathcal{B}(\sigma)} \frac{\Psi(s, W_\Phi, W_\varphi)}{||\varphi||^2} \varphi(g) d\sigma.
\]
The above is entire as a function of $s \in \mathbb{C}$.

Let $\tilde{U}_n$ be the image of $U_n$ under the embedding $G_n \hookrightarrow G_{n+1}$ and $\Phi_{\tilde{U}_n}$ is the constant term along $\tilde{U}_n$, that is,
\[
\Phi_{\tilde{U}_n}(g) := \int_{[U_n]} \Phi \left( \begin{pmatrix} u & 1 \\ 0 & 1 \end{pmatrix} \right) g, \quad g \in G_{n+1}(\mathbb{A}).
\]
Note that $\tilde{U}_n$ is not a unipotent radical of any parabolic of $G_{n+1}$, so the above integral may not vanish identically. As $[U_n]$ is compact, working as above, we can spectrally decompose $A_s \Phi_{U_n}$ to obtain
\[
A_s \Phi(g) - A_s \Phi_{U_n}(g) = \int_{\text{gen}} \sum_{\varphi \in \mathcal{B}(\sigma)} \frac{\Psi(s, W_\Phi, W_\varphi)}{||\varphi||^2} (\varphi(g) - \varphi_{U_n}(g)) d\sigma.
\]
Once again the above converges absolutely and hence is entire as a function of $s \in \mathbb{C}$.

Recall that $\phi \in \pi$ is a cusp form. Let $s := (s_1, s_2) \in \mathbb{C}^2$ with $\Re(s_2)$ being sufficiently large. We take $g = \left( \begin{pmatrix} h & 1 \\ 0 & 1 \end{pmatrix} \right)$ for $h \in G_{n-1}(\mathbb{A})$ in the above equation and integrate the both sides against $|\phi| \det |g|^{s_2-1/2}$ over $h \in [G_{n-1}]$. Using Lemma 4.1 we can write that
\[
\int_{[G_{n-1}]} \left( A_{s_1} \Phi \left( \begin{pmatrix} h & 1 \\ 0 & 1 \end{pmatrix} \right) - A_{s_1} \Phi_{U_n} \left( \begin{pmatrix} h & 1 \\ 0 & 1 \end{pmatrix} \right) \right) |\phi(h)| \det(h)|^{s_2-1/2} dh = \int_{\text{gen}} \sum_{\varphi \in \mathcal{B}(\sigma)} \frac{\Psi(s_1, W_\Phi, W_\varphi)\Psi(s_2, W_\varphi, W_\phi)}{||\varphi||^2} d\sigma. \quad (25)
\]
Both sides are absolutely convergent for any $s \in \mathbb{C}^2$ with sufficiently $\Re(s_2)$ and thus entire in $s_1$ and holomorphic in $s_2$ in a right half plane.
We define the degenerate term by
\[ D(s, \Phi, \phi) := \int_{[G_n]} \int_{[G_{n-1}]} \Phi_{U_n} \left[ \begin{pmatrix} z h \\ z \end{pmatrix} \right] \overline{\phi(h)} |\det(h)|^{s_1 + s_2 - 1} |z|^{n(s_1 - 1/2)} dh dz, \]  \hspace{1cm} (26)

Once again, rapid decay of \( \Phi \) ensures that the integral in (26) converges absolutely for any \( s \in \mathbb{C}^2 \).

**Proposition 5.2.** Let \( \Phi \in \Pi, \phi \in \pi, \) and \( s \in \mathbb{C}^2 \) be such that \( R(s_2) \) is sufficiently large. Recall \( P, D, \) and \( L \) from (24), (26), and (21), respectively. Let \( S \) be a finite set of places such that both \( \Phi \) and \( \phi \) are unramified at all \( v \not\in S \). Moreover, let \( W_{\Phi,v} = W_{\Pi_v} \) and \( W_{\phi,v} = W_{\sigma_v} \) for \( v \not\in S \). Then
\[ P(s, \Phi, \phi) - D(s, \Phi, \phi) = \mathcal{M}(s, \Phi, \phi) \]
where \[ \mathcal{M}(s, \Phi, \phi) := \int_{\text{gen}} \Lambda(s_1, \Pi \otimes \overline{\sigma}) \Lambda(s_2, \sigma \otimes \overline{\pi}) \mathcal{L}^2(\sigma) \mathcal{H}_S(\sigma; W_{\Phi,v}, W_{\phi,v}, s) d\sigma, \] and \( \mathcal{H}_S(\sigma; W_{\Phi}, W_{\phi}, s) \) is as defined in §6.1.

**Proof.** Note that \( P \) as in (24) can be written as
\[ \int_{G_n} A_{s_1} \Phi \left[ \begin{pmatrix} h \\ 1 \end{pmatrix} \right] \overline{\phi(h)} |\det(h)|^{s_2 - 1/2} dh. \]

Similarly, we can write (26) as
\[ D(s, \Phi, \phi) = \int_{G_n} A_{s_1} \Phi_{U_n} \left[ \begin{pmatrix} h \\ h \end{pmatrix} \right] \overline{\phi(h)} |\det(h)|^{s_2 - 1/2} dh. \]

We also choose \( \overline{B}(\sigma) \) in (25) so that \( W_{\phi,v} = W_{\sigma_v} \). Finally, using (21) and (19) we conclude the proof. \( \square \)

6. **Choice of the Vectors in the Local Factors**

6.1. **The local factor.** Let \( \Pi \) and \( \pi \) be generic automorphic representations of \( G_{n+1}(\mathbb{A}) \) and \( G_{n-1}(\mathbb{A}) \), respectively. Let \( \sigma \) be a generic unitary automorphic representation of \( G_n(\mathbb{A}) \).

Let \( S \) be a finite set of places of \( F \). Let \( v \in S \). For \( W_1 \in \Pi_v \) and \( W_2 \in \pi_v \), and \( s \in \mathbb{C}^2 \) we define
\[ H_v(\sigma_v) = H_v(\sigma_v; W_1, W_2, s) := \sum_{W \in \mathcal{G}(\sigma_v)} \Psi_v(s_1, W_1, \overline{W}) \Psi_v(s_2, W_2, W_2) \mathcal{L}_v(s_1, \Pi_v \otimes \overline{\sigma}_v) \mathcal{L}_v(s_2, \sigma_v \otimes \overline{\pi}_v), \]  \hspace{1cm} (28)
Here $B(\sigma_v)$ is an orthonormal basis of $\sigma_v$. The RHS does not depend on a choice of $B(\sigma_v)$. We also define

$$h_v(\sigma_v) = L_v(s_1, \Pi_v \otimes \overline{\sigma_v})L_v(s_2, \sigma_v \otimes \overline{\sigma_v})H_v(\sigma_v) = \sum_{w \in B(\sigma_v)} \Psi_v(s_1, W_1, \overline{W})\Psi_v(s_2, W, \overline{W}).$$

Finally, we define

$$H_S(\sigma) := \prod_{v \mid \mathfrak{S} \text{ non-archimedean}} H_v(\sigma_v) \prod_{v \in S \text{ archimedean}} h_v(\sigma_v),$$

which is the local factor used in Theorem 1.

Lemma 3.3 and Lemma 3.1 imply that the RHS of (28) is absolutely convergent for sufficiently large $\Re(s)$. As a function of $s$ the function $H(\sigma; W_1, W_2, s)$ can be analytically continued to all of $\mathbb{C}$ which follows from the fact that

$$\frac{\Psi_v(s, W_1, \overline{W})}{L_v(s, \Pi_v \otimes \overline{\sigma_v})} = \frac{\Psi_v(s, W, \overline{W})}{L_v(s, \sigma_v \otimes \overline{\sigma_v})}$$

are entire functions of $s$.

6.2. Choice of vectors. Let $\mathfrak{q}$ be an ideal of $\prod_{v < \infty} \mathfrak{o}_v$ and $\mathfrak{p}_0$ be a fixed prime such that $\mathfrak{q}$, $\mathfrak{p}_0$, and the discriminant $\Delta_F$ of $F$ are pairwise coprime. We let

$$S := \{\mathfrak{p}_0\} \cup \{v \mid \mathfrak{q}\} \cup \{v \mid \Delta_F\} \{v \mid \infty\}.$$

We assume that $\Pi$ and $\pi$ are unramified at all $v < \infty$.

We choose factorizable cusp forms $\Phi \in \Pi$ and $\phi \in \pi$ by specifying their local Whittaker components $W_{\Phi,v} \in \Pi_v$ and $W_{\phi,v} \in \pi_v$. For all $v \not\in S$ we choose $W_{\Phi,v} = W_{\Pi_v}$ and $W_{\phi,v} = W_{\pi_v}$. The choices at $v \in S$ are described below.

6.2.1. At the places $v \mid \mathfrak{q}$. For any $f \in \mathbb{Z}_{\geq 0}$ and any prime $\mathfrak{p}$ we define

$$W_{\Pi_v}^{(f)}(g) := p^{-(n-1)f} \int_{F_{\mathfrak{p}}^{n-1}} W_{\Pi_v} \left( g \left( \begin{array}{cc} I_{n-1} \beta \\ 1 \end{array} \right) \right) 1_{\mathfrak{p}^{n-1}(\beta \mathfrak{p}^f)} d\beta,$$

for $g \in G_{n+1}(F_{\mathfrak{p}})$.

We let $\mathfrak{p}_v$ the maximal ideal of $\mathfrak{o}_v$. Let $\mathfrak{q} = \prod_{v \mid \mathfrak{q}} \mathfrak{p}_v^{f_v}$ For all $v \mid \mathfrak{q}$ we choose $W_{\Phi,v} = W_{\Pi_v}^{(f_v)}$.

On the other hand, for all $v \mid \mathfrak{q}$ we choose $W_{\phi,v} = W_{\pi_v}$.

---

3We do not require $\Pi$ and $\pi$ to be unramified at any place other than the place $\mathfrak{p}$. We may assume some bounded ramification at an arbitrary finite set of fixed places and analyse the corresponding local factors as we do for the archimedean places. However, we assume unramifiedness as this will not bring in some unimportant non-archimedean local factors.
6.2.2. At the places \( v \mid \Delta_F \). At these places we need a little care due to the fact that our additive character is not unramified. That is, \( \psi_v(x) = \psi_{F_v}(\lambda x) \) for some \( \lambda \in F_v \), such that \( |\lambda|_v^{-1} = \Delta_v \) is the \( v \)-part of the discriminant \( \Delta_F \) and \( \psi_{F_v} \) is an unramified additive character of \( F_v \), i.e. trivial on \( \mathfrak{o}_v \). Let
\[
a_r(\lambda) = \begin{pmatrix} 
\lambda^{r-1} & \lambda^{r-2} & \cdots & \lambda \\
1 & 1 & \cdots & 1
\end{pmatrix}, \quad (\lambda \in F_v^\times, \ r \geq 1).
\]

Then, we take
\[
W_{\Phi,v}(g) := W_{\Pi,v}(a_{n+1}(\lambda)g), \ W_{\phi,v}(a_{n-1}(\lambda)g) := W_{\pi_v}(g), \quad (30)
\]
where \( W_{\Pi,v} \) and \( W_{\pi_v} \) are the usual newvectors, i.e., with respect to \( \psi_{F_v} \). It is a direct computation to see that \( W_{\Phi,v} \) and \( W_{\phi,v} \) are indeed left-invariant by \( \psi_v \).

6.2.3. At the place \( v = p_0 \). Let \( \tau \) be a fixed supercuspidal representation of \( G_n(F_v) \) with trivial central character. For normalization purpose we choose \( \tau \) so that
\[
L_v(s, \tau \otimes \overline{\tau}) = \zeta_{p_0}(ns).
\]
Such a \( \tau \) exists, see [49, §2.1].

It is known that \( W_{\tau} \in C_c^\infty(Z_n(F_v)N_n(F_v)\backslash G_n(F_v), \psi_v) \). We choose \( W_{\Phi,v} \) so that
\[
W_{\Phi,v} \left[ \begin{pmatrix} zh \\ 1 \end{pmatrix} \right] := \mathbf{1}_{z \in Z_n} W_{\tau}(h), \quad z \in G_1(F_v), h \in Z_n(F_v)\backslash G_n(F_v). \quad (31)
\]
Note that the (31) uniquely determines \( W_{\Phi,v} \) due to the theory of Kirillov model, see [31.5]

Once again, we choose \( W_{\phi,v} = W_{\pi_v} \).

6.2.4. At the archimedean places \( v \mid \infty \). Again using the theory of Kirillov model, for each \( v \mid \infty \) we choose \( W_{\Phi,v} \in \Pi_v \) so that \( W_{\Phi,v} \mid_{G_n(F_v)} \) is given by a fixed element in \( C_c^\infty(N_n(F_v)\backslash G_n(F_v), \psi_v) \) which is sufficiently concentrated near the identity and \( W_{\Phi,v}(1) = 1 \). In the language of [31] such vectors are called analytic newvectors of \( \Pi_v \).

Also, for each \( v \mid \infty \) we choose \( W_{\phi,v} \) to be an analytic newvector of \( \pi_v \). We will specify support conditions of these vectors in Lemma [10.5].

We shorthand
\[
H_q(\sigma) := \prod_{v \mid \mathfrak{q}} H_v(\sigma_v; W_{\Pi_v}^{(f_q)}, W_{\pi_v}, \left( \frac{1}{2}, \frac{1}{2} \right)), \quad (32)
\]
if \( \mathfrak{q} = \prod_{v \mid \mathfrak{q}} \mathfrak{p}_v^{e_v} \). We also shorthand \( h_{\mathfrak{q}}(\sigma) := \prod_{v \mid \mathfrak{q}} h_v(\sigma_v) \).
7. Local Weight Function: Original Moment

In this section, let \( v \) be a non-archimedean place and \( F \) be the corresponding local field whose ring of integer is \( \mathfrak{o} \) with maximal ideal \( \mathfrak{p} \). The letters \( \Pi, \sigma, \) and \( \pi \) denote irreducible generic unitary representations of \( G_{n+1}(F), G_n(F), \) and \( G_{n-1}(F) \), respectively. Similarly, \( L, \gamma, \ldots \) etc. denote local \( L \)-factor, local \( \gamma \)-factor... etc. We drop \( F \) from the notations if there is no confusion.

We fix a \( 0 \leq \vartheta < 1/2 \). Further assume that \( \Pi \) and \( \pi \) are tempered and unramified. Also, let \( \sigma \) be a \( \vartheta \)-tempered representation of \( G_n \) with conductor exponent \( c_p^\sigma \).

The goal of this section is to analyse \( H_v^\sigma \) for the choices of the local vectors as in \( \S 6 \) at the non-archimedean places \( p \) and \( p_0 \).

7.1. At the places \( v \mid q \). We first state the main proposition of this subsection. We devote this subsection to prove this proposition. Recall the definition of the local factor \( H_v \) from (28).

**Proposition 7.1.** Recall the choices of test vectors from \( \S 6 \) for \( v \mid q \). We have

\[
H_v(\sigma_v; W_{\Phi,v}, W_{\phi,v}, s) = \begin{cases} 
\ll \epsilon \frac{p_v^{c(\sigma_v)} \epsilon + c(\sigma_v) - n c(\sigma_v) + t_v}{p_v} & \text{if } c(\sigma_v) < f_v \\
\frac{1}{\eta(p_v^{f_v}) \| W_v \|^2} & \text{if } c(\sigma_v) = f_v \\
0 & \text{if } c(\sigma_v) > f_v 
\end{cases}
\]

for \( \Re(s) = \left( \frac{1}{2}, \frac{1}{2} \right) \). Here \( \eta(p^f) := [G_n(\mathfrak{o}) : K_0(p^f)] = |p^f|^{-(n-1)} \).

For the rest of this subsection we suppress the notation for the place \( v \). From \( \S 6 \) we have

\[
H_v(\sigma_v; W_{\Phi,v}, W_{\phi,v}, s) = H(\sigma; W^{(f)}_\Pi, W_\pi, s).
\]

First we explicitly write \( W^{(f)}_\Pi \) defined in (29) as follows. Note that the Fourier transform of \( 1_{\mathfrak{o}^v} \) is itself. Thus,

\[
W^{(f)}_\Pi \begin{bmatrix} g \\ 1 \end{bmatrix} = W_\Pi \begin{bmatrix} g \\ 1 \end{bmatrix} \mathbf{1}_{\mathfrak{o}^{n-1}}(\ell(g)p^{-f}),
\]

where \( \ell(g) \) denotes the row vector constructed from the first \( n - 1 \) elements of the last row of \( g \).

**Lemma 7.1.** Let \( c(\sigma) \) be the conductor exponent of \( \sigma \) and let \( W \in \sigma \) with \( W(1) = 1 \). Then

\[
\Psi(s_1, W^{(f)}_\Pi, W) = \begin{cases} 
L(s_1, \Pi \otimes \sigma) & \text{if } c(\sigma) = f \\
\eta(p^f) & \text{if } c(\sigma) > f 
\end{cases}
\]

where \( \eta(p^f) \) is as in Proposition 7.1.
Proof. Let \( \Re(s) \) be sufficiently large. Using (33) and sphericality of \( W_\Pi \) we can write the zeta integral in Iwasawa coordinates as

\[
\int_{A_n} W_\Pi \begin{pmatrix} a & \varepsilon \\ 1 & 1 \end{pmatrix} \left| \det(a) \right|^{s_1-1/2} \int_{K_n} 1_{\sigma_0} \ell(k) a_n p^{-f} W(ak) \frac{d\chi a}{\delta(a)}.
\]

Recall from the description of the spherical Whittaker function in (12) that the above is zero unless \( a_n \in \mathfrak{o} \). Hence the inner \( K_n \)-integral projects onto \( \sigma_0 \Pi(p\max(0, f-v(s))) \). Using the classical newvector theory, as described in §3.8, the space \( \sigma_0 \Pi(p\max(0, f-v(s))) \) is zero unless \( c(\sigma) \leq f \).

In the case of \( c(\sigma) = f \) it follows from the the above discussion and §3.8 that \( W \) must be a newvector of \( \sigma \). Finally, (11) and the normalization of \( W \) yields this case. We conclude by meromorphic continuation. \( \square \)

Lemma 7.2. Let \( \sigma \) be a \( \vartheta \)-tempered representation with conductor exponent \( c(\sigma) \). Then

\[
\gamma(1/2 - s, \sigma) \ll p^{c(\sigma)\Re(s)} (1 + p^{n(\Re(s)-1/2+\vartheta)}),
\]

for \( s \) away from the poles of the above \( \gamma \)-factor.

Proof. Recall that

\[
\gamma(1/2 - s, \sigma) = \epsilon(1/2 - s, \sigma) \frac{L(1/2 + s, \sigma)}{L(1/2 - s, \sigma)},
\]

with

\[
\epsilon(1/2 - s, \sigma) = \epsilon(1/2, \sigma) p^{c(\sigma)s},
\]

and \( |\epsilon(1/2, \sigma)| = 1 \).

Also, there exist \( \{\alpha_i\}_{i=1}^m, \{\beta_i\}_{i=1}^m \in \mathbb{C}^m \) with \( m \leq n \) such that \( \max\{|\alpha_i|, |\beta_i|\} = p^\vartheta \).

\[
L(s, \sigma) = \prod_{i=1}^m (1 - p^{-s} \alpha_i)^{-1}, \quad L(s, \sigma) = \prod_{i=1}^m (1 - p^{-s} \beta_i)^{-1}
\]

Compiling all the bounds we conclude. \( \square \)

Note that if \( \pi' \) is a tempered unramified representation of \( \text{PGL}(r) \) with Langlands (or Satake) parameters \( \{\nu_i\}_{i=1}^r \) such that \( \Re(\nu_i) = 0 \) then

\[
\gamma(s, \pi' \otimes \sigma) = \prod_{i=1}^r \gamma(s + \nu_i, \sigma).
\]

Hence Lemma 7.2 implies that

\[
\gamma(1/2 - s, \pi' \otimes \sigma) \ll p^{c(\sigma)\Re(s)} (1 + p^{nr(\Re(s)-1/2+\vartheta)}),
\]

whenever \( s \) is away from the poles of the gamma factor.
Lemma 7.3. Fix $\vartheta < 1/2$ and let $\sigma$ be $\vartheta$-tempered. Fix $\varepsilon \geq c(\sigma)$ and let $W \in \sigma$ be any $K_0(p^e)$-invariant unit vector. Then the zeta integral

$$\Psi(1/2 + s_2, W, \overline{W}) \ll p^{(\varepsilon - c(\sigma))\varepsilon},$$

for $\Re(s_2) = 0$.

Proof. Let $\Re(s_2) > 0$. Note that $K_0(p^e)$ invariance of $W$ implies that if $W \left[ \begin{array}{c} h \\ 1 \end{array} \right]$ is nonzero then $e_{n-1}h \in \mathfrak{a}$. Thus the integral of $\Psi(1/2 + s_2, W, W_2)$ can be written as absolute convergent integral (follows from Lemma 3.2)

$$\int_{N_{n-1}\backslash G_{n-1}} W \left[ \begin{array}{c} h \\ 1 \end{array} \right] 1_{\gamma_{n-1}}(e_{n-1}h)W_\pi(h) \det(h)^{\varepsilon_2} dh.$$ 

We use Cauchy–Schwarz and unitarity of $W$ to conclude that the above is bounded by square root of

$$\int_{N_{n-1}\backslash G_{n-1}} 1_{\gamma_{n-1}}(e_{n-1}h)|W_\pi(h)|^2 \det(h)^{2\Re(s_2)} dh.$$ 

Lemma 3.2 confirms that the above integral converges absolutely as $\Re(s_2) > 0$ and equals to $L(2\Re(s_2), \pi \otimes \tilde{\pi})$ [17, Theorem 3.3]. Thus we have $\Psi(s_2, W, W_\pi) \ll 1$ for $\Re(s_2) > 0$.

Now we focus on $\Psi(1/2 - s_2, W, W_\pi)$ where we also assume that $s_2$ is away from a pole of the zeta integral $\Psi(1/2 - s_2, W, W_\pi)$. We apply $G_n \times G_{n-1}$ local functional equation to obtain the $\Psi(1/2 - s_2, W, W_\pi)$ equals to

$$\omega_\pi(-1)^{n-1}\gamma(1/2 + s_2, \tilde{\sigma} \otimes \pi) \int_{N_{n-1}\backslash G_{n-1}} \tilde{W} \left[ \begin{array}{c} h \\ 1 \end{array} \right] \overline{W_\pi(h)} \det(h)^{\varepsilon_2} dh,$$

where $\omega_\pi$ is the central character of $\pi$. The above integral is absolutely convergent. Also from (33) we obtain that the above gamma factor is bounded by $p^{-\Re(s_2)(n-1)c(\sigma)}$.

We note that $K_0(p^e)$-invariance of $W$ implies that $\tilde{W} \left[ \begin{array}{c} h \\ 1 \end{array} \right]$ is nonzero then $e_{n-1}h \in p^{-\varepsilon}$. So the above integral can be written as

$$\int_{N_n \backslash G_n} \tilde{W} \left[ \begin{array}{c} h \\ 1 \end{array} \right] 1_{\gamma_{n-1}}(e_{n-1}hp^e)\overline{W_\pi(h)} \det(h)^{\varepsilon_2} dh.$$ 

We again apply Cauchy–Schwarz on the $h$ integral and use unitarity of $W$ to obtain the above is bounded by the square root of

$$\int_{N_{n-1}\backslash G_{n-1}} 1_{\gamma_{n-1}}(e_{n-1}hp^e)|\overline{W_\pi(h)}|^2 \det(h)^{2\Re(s_2)} dh.$$
The above is $p^{2(n-1)\Re(s_2)r} L(2\Re(s_2), \pi \otimes \pi)$. Thus for $\Re(s_2) > 0$ we have
\[
\Psi(1/2 - s_2, W, W) \ll p^{(n-1)\Re(s_2)(e-c(\sigma))}.
\] (35)
Using Phragmén–Lindelöf with $\Re(s_2) = \epsilon$ we may conclude. □

**Lemma 7.4.** Let $\xi$ be any irreducible generic tempered unramified representation of $G_{n-1}$. Let $\chi$ be any unitary character of $F^\times$ and $l \in \mathbb{Z}_{>0}$. Then the integral
\[
\int_{v(z) = l} \chi(z) \int_{A_{n-1}} W_{\Pi} \left[ \begin{pmatrix} az & z \\ 1 & 1 \end{pmatrix} \right] |W_{\xi}(a)| \det(a)^{s-1} \frac{d^r a}{\delta(a)} d^r z,
\]
is absolutely convergent for $\Re(s) > 0$ and is $O(p^{-nl/2})$.

**Proof.** Note that as $\xi$ is tempered and $\Re(s) > 0$ Lemma 3.2 implies absolute convergence of the integral in the lemma.

Using Shintani’s formula (12) we can bound the above integral as
\[
p^{-nl/2} \sum_{m_1 \geq \ldots \geq m_{n-1} \geq l} |\lambda_{\Pi}(m, l, 0)\lambda_{\xi}(m)| p^{-\Re(s)\sum m_i},
\]
Temperedness of $\Pi$ and (13) implies that $\lambda_{\Pi}(m, l, 0) \ll 1$ and similarly, $\lambda_{\xi}(m) \ll 1$. Thus we obtain that the above infinite sum is convergent if $\Re(s) > 0$ and is bounded. □

**Lemma 7.5.** Let $W \in \sigma^{K_0(p^e)}$ be any unit vector for some $e \geq 0$. Also let $\xi$ be as in Lemma 7.4. Then the integral
\[
\int_{v(z) = l} W_{\Pi} \left[ \begin{pmatrix} a & z \\ 1 & 1 \end{pmatrix} \right] |W_{\xi}(a)| \det(a)^{s} \frac{d^r a}{\delta(a)} \chi(p z) d^r z,
\]
is absolutely convergent for $0 < \Re(s) < 1/2 - \vartheta$ and is $O(p^{\Re(s)(n-1)(e-c(\sigma))})$.

**Proof.** This follows from the proof of Lemma 7.3 in particular, from (35). □

**Lemma 7.6.** Let $W \in \sigma^{K_0(p^e)}$ be any unit vector for some $e \geq 0$. Let $l \in \mathbb{Z}_{>0}$ and $\omega_\sigma$ be the central character of $\sigma$. Then for $\Re(s) = 0$ the integral
\[
\int_{v(z) = l} \left| z \right|^{ns} \omega_\sigma(z) \int_{A_{n-1}} W_{\Pi} \left[ \begin{pmatrix} az & z \\ 1 & 1 \end{pmatrix} \right] W \left[ \begin{pmatrix} a & 1 \\ 1 & 1 \end{pmatrix} \right] |\det(a)|^{s} \frac{d^r a}{\delta(a)} |\det(a)| d^r z,
\]
is absolutely convergent and is $O(p^{-nl/2+e(e-c(\sigma))})$.

**Proof.** Absolute convergence follows from Lemma 3.2.
We choose some \(0 < \eta < 1/2 - \vartheta\). We use non-archimedean Kontorovich–Lebedev–Whittaker transform \([21]\) to write the integral as

\[
\frac{1}{(n-1)!} \int_{\tau \in (S^1)^{n-1}} \int_{v(z) = t} |z|^{n_\sigma(z)} \omega_\sigma(z) \int_{A_{n-1}} W_\Pi \left[ \begin{pmatrix} a' & z \\ z & 1 \end{pmatrix} \right] \frac{W_\tau(a')}{\det(a')} |\det(a')|^{\eta + s - 1} \frac{d^\times a'}{\delta(a')} d^\times z
\]

\[
\int_{A_{n-1}} W \left[ \begin{pmatrix} a'' \\ 1 \end{pmatrix} \right] W_\tau(a'') |\det(a'')|^{-\eta} \frac{d^\times a}{\delta(a'')} \prod_{i \neq j} (\tau_i - \tau_j) \frac{d\tau_1}{\tau_1} \cdots \frac{d\tau_{n-1}}{\tau_{n-1}}.
\]

Here for \(\tau := (\tau_1, \ldots, \tau_{n-1}) \in (S^1)^{n-1}\) by \(\tau^{-1}\) we mean \((\tau_1^{-1}, \ldots, \tau_{n-1}^{-1}) \in (S^1)^{n-1}\), and by \(d\tau_j\) we denote the \(2\pi i\)-normalized Lebesgue measure on \(S^1\).

Note that choice of \(\eta\) ensures absolute convergence of all the integrals. We use Lemma 7.4 to bound the outer \(A_{n-1} \times \mathcal{F}^\times\)-integral by \(p^{-nd/2}\) and Lemma 7.5 to bound the inner \(A_{n-1}\)-integral by \(p^{(n-1)(e-(\varepsilon - \epsilon)(\sigma))}\). Bounding the \((S^1)^{n-1}\)-integral trivially we conclude. \(\square\)

**Lemma 7.7.** Let \(c(\sigma)\) be the conductor exponent of \(\sigma\) and \(W \in \sigma\) be any unit vector. Then the zeta integral

\[
\Psi(1/2 + s_1, W_\Pi^{(f)}, W) \ll p^{c(\sigma) + \epsilon f} p^{-\frac{\omega(\sigma)+\epsilon}{2}},
\]

for \(\Re(s_1) = 0\)

**Proof.** Using (33) and Iwasawa coordinates we write

\[
\Psi(1/2 + s_1, W_\Pi^{(f)}, W) = \int_{\hat{p}^\times} \omega_\sigma(z) \int_{A_{n-1}} W_\Pi \left[ \begin{pmatrix} a & z \\ z & 1 \end{pmatrix} \right] \frac{d^\times a}{\delta(a)} \det(a) \prod_{i \neq j} (\tau_i - \tau_j) \frac{d\tau_1}{\tau_1} \cdots \frac{d\tau_{n-1}}{\tau_{n-1}}.
\]

In the inner \(K_n\)-integral support condition of \(1_{\omega_n}\) forces \(l(k) \in (\mathfrak{p}^e)^{n-1}\) where \(e := \max(0, f - v(z))\). Hence that integral can be written as

\[
\int_{K_0(\mathfrak{p}^e)} W_\Pi \left[ \begin{pmatrix} a \\ 1 \end{pmatrix} k \right] dk.
\]

The above lies in \(\hat{\sigma}^{K_0(\mathfrak{p}^e)}\). Hence, the integral vanishes identically unless \(c(\sigma) \leq e\) in which case the integral can be written as

\[
c_e(W) W^{(e)} \left[ \begin{pmatrix} a \\ 1 \end{pmatrix} \right].
\]
for some unit vector \( W'(e) \in \sigma^{K_0(p^e)} \) and
\[
c_e(W)^2 := \int_{N_{n-1} \setminus G_{n-1}} \left| \int_{K_0(p^e)} W \left[ \begin{pmatrix} h \\ 1 \end{pmatrix} k \right] dk \right|^2 dh.
\]
We apply Cauchy–Schwarz and apply unitarity of \( W \) to obtain that
\[
c_e(W) \leq \text{vol}(K_0(p^e)) = p^{-e(n-1)}.
\]
Thus we can write \( \Psi(1/2 + s_1, W^{(f)}_\Pi, W) \) as
\[
\sum_{e=c(\sigma)} c_e(W) \int_{\nu(z) = f-e} \omega_\sigma(z) \int_{A_{n-1}} W_\Pi \left[ \begin{pmatrix} az \\ z \\ 1 \end{pmatrix} \right]
 \frac{W(e) \left[ \begin{pmatrix} a \\ 1 \end{pmatrix} \right]}{||z||n \det(a)|^{s_1} \frac{d^x a}{|\delta(a)| \det(a)}} d^x z
+ \frac{\delta_{c(\sigma)=0}}{c(W_\sigma)} \int_{z \in p^{f+1}} \omega_\sigma(z) \int_{A_{n-1}} W_\Pi \left[ \begin{pmatrix} az \\ z \\ 1 \end{pmatrix} \right]
 \frac{W_\sigma \left[ \begin{pmatrix} a \\ 1 \end{pmatrix} \right]}{||z||n \det(a)|^{s_1} \frac{d^x a}{|\delta(a)| \det(a)}} d^x z.
\]
From (14) we have \( c(W_\sigma) = ||W_\sigma||_\sigma = 1. \)

We let \( \Re(s_1) = 0. \) Using Lemma 7.6 bound the first summand by
\[
\sum_{e=c(\sigma)}^f p^{-(n-1)e} p^{-(n-f-e)/2} p^{e-c(\sigma)} \ll p^{-nf/2-(n/2-1)c(\sigma)+f},
\]
and the second summand by
\[
\delta_{c(\sigma)=0} \sum_{l=f+1}^\infty p^{-nl/2} \ll \delta_{c(\sigma)=0} p^{-n(f+1)/2}.
\]
Compiling, we conclude the proof.

Proof of Proposition 7.1. The case of \( c(\sigma) < f \) follows from Lemma 7.7 and Lemma 7.3, combining with the facts that the dimension of \( \sigma^{K_0(p^f)} \) is a polynomial in \( c(\pi) \) and \( f \) \([43]\) and for \( \Re(s_1) = \Re(s_2) = 1/2 \)
\[
L(s_1, \Pi \otimes ^{\vartheta} \pi), L(s_2, \sigma \otimes \pi) = 1,
\]
as \( \Pi, \pi \) are tempered and \( \sigma \) is \( \vartheta \)-tempered with \( \vartheta < 1/2 \). Lemma 7.4 implies the case \( c(\sigma) > f \) immediately.
In the case of $c(\sigma) = f$ we choose a basis $\mathcal{B}(\sigma)$ containing the vector $\frac{W_\sigma}{\|W_\sigma\|}$ where $W_\sigma$ is the newvector of $\sigma$ with $W_\sigma(1) = 1$. Thus we obtain

$$H(\sigma; W^{(f)}_\Pi, W_\pi, s) = \frac{\|W_\sigma\|^2 \Psi(s_2, W_\sigma, \overline{W_\pi}) \Psi(s_1, W_{\Pi_\Pi}, \overline{W_\sigma})}{L(s_1, \Pi \otimes \overline{\sigma}) L(s_2, \sigma \otimes \overline{\pi})}. $$

It follows from [35] that $W_\sigma |_{G_{n-1}(F)}$ is $G_{n-1}(\mathfrak{o})$-invariant, consequently, $\|W_\sigma\| \gg 1$. Finally, applying Lemma 7.1 we conclude the proof.

7.2. At the places $v | \Delta_F$. Recall the choices in [30]. Since our vectors differ from the spherical ones only by a multiplication on the left, it follows that $W_{\phi,v}$ is right invariant by $\binom{k}{1}$, $k \in K_n$. Therefore, for $W \in \sigma_v$ the zeta integral $\Psi(s_1, W_{\phi,v}, \overline{W})$ vanishes unless $W$ is spherical. Hence, $H_v(\sigma_v; W_{\phi,v}, W_{\phi,v}, s)$ vanishes unless $\sigma_v$ is unramified in which case $H_v(\sigma_v)$ has only one summand. The vector corresponding to this summand has to be given, up to normalization, by a left translate of $W_{\sigma_v}$, the newvector for the unramified character. More precisely, we have

$$H(\sigma; W_{\phi,v}, W_{\phi,v}, s) = \frac{W(g) := W_{\sigma_v}(a_n(\lambda)g).}{\|W\|^2 \Psi(s_1, W_{\phi,v}, \overline{W}) \Psi(s_2, W, \overline{W}_{\phi,v})}$$

where

$$\|W\|^2 = |\lambda|^\mu \|W_\sigma\|^2 = \Delta_\mu^\mu L_v(1, \sigma_v \times \overline{\sigma}_v)/\zeta_v(n),$$

where $\mu_1$ and $\mu_2$ are affine functions whose complex coefficients only depend on $n$ and $\mu$ is a constant also only depending on $n$. Altogether, we get that

$$H_v(\sigma_v; W_{\phi,v}, W_{\phi,v}, s) = \frac{\Delta_\mu^\mu(s)}{L_v(1, \sigma_v \times \overline{\sigma}_v)/\zeta_v(n)},$$

where $\mu_H$ is an affine functions whose complex coefficients depend only on $n$.

7.3. At the place $v = p_0$. Recall the choice of the local test vectors at $v = p_0$ from [36].

**Proposition 7.2.** We have

$$H_v(\sigma_v; W_{\phi,v}, W_{\phi,v}, s) = \begin{cases} \varepsilon(1, \tau \otimes \overline{\tau}) & \text{if } \sigma_v = \tau; \\ 0 & \text{otherwise.} \end{cases}$$
for $s = \left(\frac{1}{2}, \frac{1}{2}\right)$. Here $\varepsilon$ denotes the local epsilon factor.

The proof of this lemma is essentially contained in [30, §6.2]. We give a sketch of the proof for the sake of completeness.

**Proof.** For $W \in \mathcal{B}(\sigma_v)$ using (31) we write

$$\Psi(1/2, W_{\Phi,v}, \overline{W}) = \int_{Z_n N_n \backslash G_n} W_\tau(g) \overline{W}(g) \, dg.$$ 

The above integral is absolutely convergent as $W_\tau$ is compactly supported in $Z_n N_n \backslash G_n$. Thus it defines a $G_n$-invariant pairing between $\tau$ and $\sigma_v$. By Schur’s lemma, this pairing must vanish identically unless $\sigma_v = \tau$. In the latter case the pairing is proportional to the unitary product in $\tau$ as defined in §3.5.

If $\sigma_v \neq \tau$ we choose an orthonormal basis $\mathcal{B}(\sigma_v)$ containing $W_\tau$. As $\Psi(1/2, W_{\Phi,v}, \overline{W})$ vanishes for $W$ orthogonal to $W_\tau$ we obtain

$$H_v(\sigma_v; W_{\Phi,v}, W_{\phi,v}, s) = \|W_\tau\|^{-2} \int_{Z_n N_n \backslash G_n} |W_\tau(g)|^2 \, dg.$$ 

The above follows from (11) and the fact that $L_v(s, \Pi \otimes \tilde{\tau}) = 1$. We evaluate the above integral appealing to [30, Lemma 6.2] and conclude. $\square$

### 8. Local Weight Function: Dual Moment

In this section we adopt the same notations as in §7. In particular, $\sigma$ is irreducible generic unitary $\vartheta$-tempered representation of $G_n(F)$ for some $0 \leq \vartheta < 1/2$.

Recall $w^*$ from the statement of Proposition 5.1. Let $W_1 \in \Pi$ and $W_2 \in \pi$, and $s \in \mathbb{C}^2$. We define the dual local factor by

$$\tilde{H}(\sigma) = \tilde{H}(\sigma; W_1, W_2, s) := H(\sigma; \Pi(w^*)W_1, W_2, s)$$

where $H(\sigma)$ is as in (28).

The goal of this section is to analyse $\tilde{H}(\sigma)$, as in Proposition 8.1 for the choices of the local vectors as in §7 at the places $v \mid q$ and $v \mid \Delta_F$.

#### 8.1. At the places $v \mid q$

We suppress the subscript $v$ as usual.

For $W \in \sigma$ we define

$$\tilde{W}^{(f)}(g) = p^{-(n-1)f} \int_{F^{n-1}} W \left[ g \left( \begin{array}{c} 1_{n-1} \\ 1 \end{array} \right) \right] 1_{\varrho^{n-1}}(\beta p^f) \, d\beta.$$ 

Clearly, for $g \in G_{n-1}$

$$\tilde{W}^{(f)} \left[ \left( \begin{array}{c} g \\ 1 \end{array} \right) \right] = W \left[ \left( \begin{array}{c} g \\ 1 \end{array} \right) \right] 1_{\varrho^{n-1}}(e_{n-1} g p^{-f}),$$

where $e_{n-1}$ is the standard row vector $(0, \ldots, 0, 1)$. 

Lemma 8.1. Recall the vector $W_{\Pi}^{(f)}$ from \(\text{(29)}\). Then $\tilde{H}(\sigma; W_{\Pi}^{(f)}, W_\pi, s)$ vanishes unless $\sigma$ is unramified in which case

$$
\tilde{H}(\sigma; W_{\Pi}^{(f)}, W_\pi, s) = \|W_\sigma\|^{-2} \frac{\Psi(s_2, \tilde{W}_\sigma^{(f)}, \tilde{W}_\pi)}{L(s_2, \sigma \otimes \tilde{\pi})},
$$

where $\tilde{W}_\sigma^{(f)}$ is defined as in \(\text{(37)}\).

Proof. As $W_{\Pi}$ is spherical on $G_{n+1}$ we can write

$$
W_{\Pi}^{(f)}(gw^*) = p^{-(n-1)f} \int_{F^{n-1}} W_{\Pi} \left[ gw^* \begin{pmatrix} I_{n-1} & \beta \\ 1 & 1 \end{pmatrix} \right] 1_{\sigma^{n-1}}(\beta p^f) \, d\beta
$$

$$
= p^{-(n-1)f} \int_{F^{n-1}} W_{\Pi} \left[ g \begin{pmatrix} I_{n-1} & \beta \\ 1 & 1 \end{pmatrix} \right] 1_{\sigma^{n-1}}(\beta p^f) \, d\beta.
$$

Let $\Re(s_1)$ and $\Re(s_2)$ be sufficiently large. Changing variable we can write $\Psi(s_1, \Pi(w^*)W_{\Pi}^{(f)}, \tilde{W})$ as

$$
p^{-(n-1)f} \int_{N_n \setminus G_n} W_{\Pi} \left[ \begin{pmatrix} g & 1 \\ 1 & 1 \end{pmatrix} \right] \int_{F^{n-1}} W \left[ g \begin{pmatrix} I_{n-1} & -\beta \\ 1 & 1 \end{pmatrix} \right] 1_{\sigma^{n-1}}(\beta p^f) \, d\beta.
$$

Next we construct the basis $\left\{ \sigma \left( \begin{pmatrix} I_{n-1} & -\beta \\ 1 & 1 \end{pmatrix} \right) W \right\}_{W \in B(\sigma)}$ in the definition of $\tilde{H}$. This yields that

$$
\tilde{H}(\sigma) = \sum_{W \in B(\sigma)} \frac{\Psi(s_1, W_{\Pi}, \tilde{W}) \Psi(s_2, \tilde{W}_\sigma^{(f)}, \tilde{W}_\pi)}{L(s_1, \Pi \otimes \tilde{\sigma}) L(s_2, \sigma \otimes \tilde{\pi})}.
$$

Finally, we choose $B(\sigma)$ consisting of $K$-type basis. Sphericality of $W_{\Pi}$ implies that $\Psi(s_1, W_{\Pi}, W)$ vanishes unless $\sigma$ is unramified and $W \in \sigma$ is spherical. In this case we take $W$ to be $W_\sigma$. Applying \(\text{(11)}\) and meromorphic continuation we conclude the proof. \(\square\)

Lemma 8.2. We have

$$
\Psi(1/2 + s_2, \tilde{W}_\sigma^{(f)}, \tilde{W}_\pi) \ll p^{-f(n-1)(1/2 - \vartheta)},
$$

for $\Re(s_2) = 0$

Proof. Using Lemma 3.2 we can write the zeta integral as the absolutely convergent integral

$$
\int_{N_{n-1} \setminus G_{n-1}} W_{\sigma}^{(f)} \left[ \begin{pmatrix} g & 1 \\ 1 & 1 \end{pmatrix} \right] \tilde{W}_\pi(g) \left| \det(g) \right|^{s_2} \, dg.
$$
Using (38) and sphericity of the vectors $W_\sigma$ and $W_\pi$ we can write the above as
\[
\int_{A_{n-1}} W_\sigma \left[ \begin{array}{cc} a & 1 \\ \end{array} \right] (a) |\text{det}(a)|^{s_2} \int_{K_{n-1}} 1_{a_{n-1}} (e_{n-1}ka_{n-1}p^{-f}) \text{d}k \frac{\text{d}^\times a}{\delta(a)}.
\]
The inner $K_{n-1}$-integral evaluates to the characteristic function of $v(a_{n-1}) \geq f$. Using Shintani’s formula (12) for the spherical vectors we may write the above as
\[
\sum_{\mathfrak{z} \in \mathfrak{Z} \geq 0 \atop m_{n-1} \geq f} \lambda_\sigma(m,0) \lambda_\pi(m)p^{-(1/2+s_2)\Sigma_i m_i}.
\]
Using (13) we obtain
\[
\lambda_\sigma(m,0) \ll p^{\vartheta \Sigma_i m_i},
\]
and temperedness of $\pi$ implies that $\lambda_\pi(m) \ll 1$. Thus we get $\Psi(1/2+s_2, \tilde{W}_\sigma^{(f)}, \tilde{W})$ is bounded by
\[
\sum_{m_1 \geq \ldots m_{n-1} \geq f} p^{-(1/2-\vartheta)\Sigma_i m_i} \ll p^{-f(n-1)(1/2-\vartheta)},
\]
which follows as $\vartheta < 1/2$. □

**Proposition 8.1.** Fix $0 \leq \vartheta < 1/2$ and let $\sigma$ be a $\vartheta$-tempered representation. Then $\tilde{H}(\sigma; W_\Pi^{(f)}, W_\pi, s)$ vanishes unless $\sigma$ is unramified in which case
\[
\tilde{H}(\sigma; W_\Pi^{(f)}, W_\pi, s) \ll p^{-f(n-1)(1/2-\vartheta)},
\]
for $\Re(s) = (\frac{1}{2}, \frac{1}{2})$.

**Proof.** As $\pi$ is tempered and $\sigma$ is $\vartheta$-tempered with $\vartheta < 1/2$ we have $L(s_2, \sigma \otimes \tilde{\pi}) = 1$ for $\Re(s_2) = 1/2$. Also, (14) implies $\|W_\sigma\| = 1$. We conclude using Lemma 8.1 and Lemma 8.2. □

8.2. **At the places** $v \mid \Delta_F$. Recall the choices (30). As we observed in §7.2 $W_{\Phi,v}$ is spherical, thus it is invariant by the action of the Weyl element $w^*$. Therefore, we have
\[
\tilde{H}_v(\sigma_v) = H(\sigma_v) = \frac{\Delta_v^{-\mu_H(s)}}{L_v(1, \sigma_v \times \bar{\sigma}_v)/\zeta_v(n)},
\]
which follows from (36).

9. **The Residue Term: Dual Side**

Recall $M(s, \Phi, \phi)$ in (27) which is originally defined for sufficiently large $\Re(s)$. The goal of this section is to meromorphically continue $M(s, \Phi, \phi)$ on the right of $\Re(s) = (\frac{1}{2}, \frac{1}{2})$. Our aim is to prove the following proposition.
Proposition 9.1. Recall $P, D, M,$ and $R$ from (24), (26), (27), and (42), respectively. Let $\Phi, \phi$ are as in Proposition (5.2). Then we have

$$P - D = M + R$$

where all of the above are evaluated at $(s, \Phi, \phi)$ with $\Re(s) \geq 1/2$ and are holomorphic in this region. Moreover, if the local components of $\Phi$ and $\phi$ are chosen as in §6 then

$$R \left( \frac{1}{2}, \frac{1}{2} \right), \Phi, \phi \right) \ll_{\Pi, \pi} p^{-f(n-2)/2},$$

where $\bar{\Phi}$ is as in Proposition 5.1.

9.1. Analytic continuation. We recall the definition $M$ below where the objects are as in Proposition 5.2

$$M(s, \Phi, \phi) = \int_{\text{gen}} \frac{\Lambda(s_1, \Pi \otimes \bar{\sigma}) \Lambda(s_2, \sigma \otimes \bar{\pi})}{L^S(\sigma)} \mathcal{H}_S(\sigma) \, d\sigma.$$

Using the parametrization of the generic spectrum via cuspidal data (cf. §4.1) we can decompose $M = M_0 + M_1$, where $M_1$ corresponds to the contribution coming from the parabolic $Q$ attached the partition $n = (n - 1) + 1$ and $M_0 = M - M_1$. We can further decompose $M_1 = M_2 + M_\pi$ where $M_\pi$ corresponds to the the Eisenstein spectrum attached to

$$\sigma(\pi, z) := \mathcal{I} \left( M, \pi \otimes | z \otimes |^{-|z|^{-1}} \right), \quad z \in i\mathbb{R},$$

where $M \cong G_{n-1} \times G_1$ is the Levi of $Q$. In other words,

$$M_\pi(s, \Phi, \phi) := c_Q \int \frac{\Lambda(s_1, \Pi \otimes \bar{\sigma}(\pi, z)) \Lambda(s_2, \sigma(\pi, z) \otimes \bar{\pi})}{L^S(\sigma(\pi, z))} \mathcal{H}_S(\sigma(\pi, z)) \, dz,$$

where $c_Q$ is a positive constant depending only on $Q$ (see [2, Main Theorem]) and $dz$ is the $2\pi i$-normalized Lebesgue measure on $i\mathbb{R}$.

Note that $\Lambda(s, \Pi \otimes \bar{\sigma})$ and $\Lambda(s, \sigma \otimes \bar{\pi})$ are entire functions in $s$ if $\sigma$ is not of the form (40), which follows from [17, Theorem 4.2]. Applying positivity of $L^S(\sigma)$ for unitary $\sigma$ (see §4.5) and entireness of of $\mathcal{H}_S(\sigma)$ as a function of $s$ (see §6.1) we obtain that $M_0$ and $M_2$ are entire functions in $s$.

The above argument also implies that $M$ as defined in (27) is also holomorphic for $s_1 \in \mathbb{C}$ and $1/2 \leq \Re(s_2) < 1$.

We now perform the meromorphic continuation of $M_\pi(s, \Phi, \phi)$ which is originally defined for large $\Re(s)$ to $\Re(s) \geq 1/2$. The argument is a generalization of [39, Proposition 9.1].

---

4 Actually, we already analytically continued $M_\pi(s, \Phi, \phi)$ in $s_1$ to all of $\mathbb{C}$ but we are not assuming that here.
Lemma 9.1. Let any \( v \in S \) and \( W_1 \in \Pi_v \) and \( W_2 \in \pi_v \). Then the local factor \( H_v(\sigma(\pi_v, z); W_1, W_2, s) \), originally defined for \( z \in i\mathbb{R} \) and large \( \mathbb{R}(s) \), can be analytically continued as a function of \( z, s_1, s_2 \) to all of \( \mathbb{C}^3 \).

The proof can be extracted from [19]. We prove it here for completeness and reader’s convenience.

Proof. From the definition of the local weight in (26) we know that \( H_v(\sigma_v) \) does not depend on the choice of basis \( B(\sigma_v) \). We construct a basis \( B(\sigma_v(z)) \) for \( z \in i\mathbb{R} \) via the flat sections, as follows.

Let \( \tau_{\pi_v}^{\cap M} \) be the restriction of \( \tau_{\pi_v} \) := \( \pi_v \otimes |z|^{-(n-1)} \) to \( K \cap M \). Thus \( \tau_{\pi_v}^{\cap M} = \tau_{\pi_v}^{\cap M}(z) \) is independent of \( z \). We construct \( \tau_{\pi_v}^{K} := \text{Ind}_{K \cap M}^{K} \tau_{\pi_v}^{\cap M} \) which is, consequently, independent of \( z \). We choose an orthonormal basis \( B(\tau_{\pi_v}^{K}) \) of \( \tau_{\pi_v}^{K} \). For all \( \eta \in B(\tau_{\pi_v}^{K}) \) we choose a function \( \xi_{\pi_v, z, \eta} \) on \( G(F_v) \) which satisfy

\[
\xi_{\pi_v, z, \eta}(nmk) = \zeta_Q^{1/2} \eta(k), \quad n \in N_M, m \in M, k \in K,
\]

where \( N_M \) is the unipotent radical attached to \( M \).

Let \( W_{\text{Jac}} \) be the Jacquet’s functional from the induced model to the Whittaker model, see [19, §1.4], [27]. Then it is known from [19, Proposition A.2] that

\[
\langle W_{\text{Jac}}^{\xi_{\pi_v, z, \eta_1}}, W_{\text{Jac}}^{\xi_{\pi_v, z, \eta_2}} \rangle = \zeta \langle \xi_{\pi_v, z, \eta_1}, \xi_{\pi_v, z, \eta_2} \rangle = \langle \eta_1, \eta_2 \rangle,
\]

where \( \zeta \) is an absolute constant. In particular, \( \|W_{\text{Jac}}^{\xi_{\pi_v, z, \eta}}\|^2 \) is never zero as a function of \( z \).

We rewrite the definition (28) of \( H_v(\sigma(\pi_v, z); W_1, W_2, s) \) as

\[
\sum_{\eta \in B(\tau_{\pi_v}^{K})} \frac{\Psi_v(s_1, W_1, W_{\text{Jac}}^{\xi_{\pi_v, z, \eta}}, W_{\text{Jac}}^{\xi_{\pi_v, z, \eta}}, W_2)}{\|W_{\text{Jac}}^{\xi_{\pi_v, z, \eta}}\|^2 L_v(s_1, \Pi_v \otimes \sigma(\bar{\pi}_v, -z)) L_v(s_2, \sigma(\pi_v, z) \otimes \bar{\pi}_v)}
\]

From [27] it is known that \( W_{\text{Jac}}^{\xi_{\pi_v, z, \eta}} \) is entire in \( z \). We work as in §6.1 to conclude entireness of \( H_v \) in \( z, s \).

We define the residue term \( \mathcal{R}(s, \Phi, \phi) \) to be

\[
\frac{c_Q}{\text{res}_{s=1} \xi_F(s)} \frac{\Lambda(s_1 + s_2 - 1, \Pi \otimes \bar{\pi}) \Lambda(s_1 + s_2 - 1 + n(1 - s_2), \Pi)}{\Lambda(1 + n(1 - s_2), \pi)} \prod_{v \in S} L_v(1, \pi_v \otimes \bar{\pi}_v) L_v(1 + n(1 - s_2), \pi_v) L_v(1 - n(1 - s_2), \bar{\pi}_v) H_v(\sigma(\pi_v, 1 - s_2)),
\]

where \( c_Q \) is as in (41).

Lemma 9.2. \( \mathcal{M}(s, \Phi, \phi) \), initially defined for large \( \mathbb{R}(s) \), admits a meromorphic continuation to \( \mathcal{R}(s) \geq \frac{1}{2} \) and is given by the sum of \( \mathcal{R}(s, \Phi, \phi) \) and the RHS of (11),
where $R(s, \Phi, \phi)$ is given by (12). In particular, both the summands are holomorphic on $\Re(s) = 1/2$.

**Proof.** Using (40) we rewrite (41) as

$$M_s(s, \Phi, \phi) = c_Q \int_{\Re(z) = 0} \Lambda(s_1 - z, \Pi \times \pi)(s_2 + z, \pi \times \pi)$$

$$\times \frac{\Lambda(s_1 + (n-1)z, \Pi)\Lambda(s_2 - (n-1)z, \pi)}{L^S(\sigma(\pi, z))} H_s(\sigma(\pi, z)) \, dz.$$ 

Let $\delta > 0$ be sufficiently small in terms of all parameters. We use the positivity of $L^S(\sigma(\pi, z))$ on $z \in \mathbb{R}$ to define a continuous function $\kappa : \mathbb{R} \to (0, \delta)$ so that $L^S(\sigma(\pi, z))$ does not vanish for $-2\kappa(\Im(z)) < \Re(z) < 0$.

We notice that we can **analytically continue** $M_s(s, \Phi, \phi)$ to $\Re(s) > 1$, since in that region, the integrand is holomorphic in $s$. Now, suppose that

$$1 < \Re(s) < 1 + \kappa(\Im(s)).$$

We shift the contour of the integral defining $M_s(s, \Phi, \phi)$ down to $\Re(z) = -\kappa(\Im(z))$. We pick up a simple pole in this process at $z = 1 - s_2$ which is from $\Lambda(s_2 + z, \pi \times \pi)$. This is due to the fact that $\Lambda(s_1 - z, \Pi \times \pi)$, $\Lambda(s_1 + (n-1)z, \Pi)$, and $\Lambda(s_2 - (n-1)z, \pi)$ are entire in $s$ and $z$. Moreover, Lemma 9.1 and choice of $\delta$ ensures that $H_s(\sigma(\pi, z))/L^S(\sigma(\pi, z))$ is holomorphic in $z$ in the $\delta$-neighbourhood of 0.

We call the residue at $z = 1 - s_2$ to be $R(s, \Phi, \phi)$ whose expression in (42) follows from

$$L^S(\sigma(\pi, z)) = (\res_{s=1} \zeta_F^S(s)) \Lambda^S(1, \pi, \Ad) \Lambda^S(1 + nz, \pi) \Lambda^S(1 - nz, \pi),$$

which follows Lemma 4.1. Here $\zeta_F$ is the Dedekind zeta function attached to $F$.

Moreover, we observe that in view of our choice of $\kappa$, the shifted integral defines a holomorphic function in the region

$$1 - \kappa(\Im(s)) < \Re(s) < 1 + \kappa(\Im(s)).$$

We now take $s$ satisfying $1 - \kappa(\Im(s)) < \Re(s) < 1$. We may shift the contour back to the line $\Re(z) = 0$, picking no poles in the process. This proves the desired formula for

$$1 - \kappa(\Im(s)) < \Re(s) < 1.$$

We note from (41) that $M$ is holomorphic in $1/2 - \epsilon < \Re(s) < 1$. This follows from the holomorphy of the Rankin–Selberg $L$-functions and of the local weight $H_s$ which follows from Lemma 9.1. Similarly, meromorphicity (and holomorphy on $\Re(s) = 1/2$) of $R$, as in (42), in the same region follows from that of the local $L$-factors. □
9.2. Local computations for the residue term at \( v \mid q \). Recall the choice of the test vectors at \( v \mid q \) from \( \S 6 \). In this subsection we analyse the \( v \)-adic local components in the residue term in (42) for \( s = \left( \frac{1}{2}, \frac{1}{2} \right) \) and \( \Phi \) replaced by \( \tilde{\Phi} \) which is defined in Proposition 5.1. In the rest of this subsection we will only work \( v \)-adically and suppress the subscript \( v \).

Once again, we analytically continue \( \tilde{H}(\sigma(\pi, z)) \) for these choices from \( z \in iR \) to \( z \in \mathbb{C} \). However, the method is different than that in the proof of Lemma 9.1.

**Lemma 9.3.** We have

\[
L(1, \pi \otimes \tilde{\pi})L(1 - n/2, \tilde{\pi})L(1 + n/2, \pi)\tilde{H}(\sigma(\pi, 1/2); W_{\Pi}^{(f)}, W_{\pi}, s) = \frac{\zeta(n)}{\zeta(1)} \frac{\Psi(s, \tilde{W}_{\sigma(\pi, 1/2)}^{(f)}, W_{\pi})}{\zeta(1) L(s, \sigma(\pi, 1/2) \times \tilde{\pi})},
\]

where \( \tilde{W}^{(f)} \) is given by (37).

**Proof.** Let \( z \in iR \) so that \( \sigma(\pi, z) \) is unitary. We apply Lemma 8.1 to obtain

\[
\tilde{H}(\sigma(\pi, 1/2); W_{\Pi}^{(f)}, W_{\pi}, s) = \|W\|_{\sigma(\pi, z)}^{-2} \frac{\Psi(s, \tilde{W}_{\sigma(\pi, z)}^{(f)}, W_{\pi})}{L(s, \sigma(\pi, z) \times \tilde{\pi})}.
\]

Using (14)

\[
\|W_{\sigma(\pi, z)}\|^2 = \frac{L(1, \sigma(\pi, z) \otimes \sigma(\tilde{\pi}, z))}{\zeta(n)}.
\]

Finally, using definition of \( \sigma(\pi, z) \) from (40) and analytically continuing we conclude. \( \square \)

We need the following strengthened version of Lemma 8.2.

**Lemma 9.4.** Let \( \sigma \) be any unramified representation of \( G_n(F) \) and \( W^{(f)} \) be given as in (37). Then, we have

\[
\frac{\Psi(s, \tilde{W}_{\sigma(\pi, z)}^{(f)}, W_{\pi})}{L(s, \sigma \otimes \tilde{\pi})} = \sum_{k=0}^{\min(f, n-1)} \frac{(-1)^k e_k(A_\pi) \lambda_\sigma(f-k, 0, \ldots, 0)}{p^{f(n-1)+k}s},
\]

for any \( s \in \mathbb{C} \). Here \( e_k(A_\pi) \) denotes the \( k \)-th symmetric polynomial on the Satake parameters \( A_\pi \) of \( \pi \).

**Proof.** By entireness of the ratio in the LHS above it is enough to prove the formula for large \( \Re(s) \).

Using (38) we have

\[
\Psi(s, \tilde{W}_{\sigma(\pi, z)}^{(f)}, W_{\pi}) = \int_{a \in A_\pi \atop v(a_n) \geq f} W_{\sigma} \left( \begin{bmatrix} a & 1 \\ \sigma(a) & 1 \end{bmatrix} \right) \tilde{W}_{\pi}(a) \det(a)^{s-1/2} \frac{q^s a}{\delta(a)}.
\]
We now apply Shinatni's formula (12), leading to
\[ \Psi(s, W'_\sigma(f), W_\pi) = \sum_{m_1 \geq \ldots \geq m_{n-1} \geq f} \frac{\lambda_\sigma(m, 0)\lambda_{\tilde{\pi}}(m)}{p^{s} \sum_i m_i}. \]  

(43)

Developing the determinant in the numerator of \( \lambda_\sigma \) along the bottom row and using well-known formula for the Vandermonde determinant, we deduce that

\[ \lambda_\sigma(m, 0) = \sum_{j=1}^{n} \frac{\lambda_{\sigma(j)}(m)\alpha_j^{-1}}{\prod_{i \neq j}(\alpha_i - \alpha_j)}, \]

where \( \{\alpha_j\}_j \) are the Satake parameters of \( \sigma \) and \( \sigma^{(j)} \) is the local representation whose Satake parameters are those of \( \sigma \) with \( \alpha_j \) omitted. Moreover, notice that

\[ \lambda_{\sigma(j)}(m) = \alpha_j^{-f}\lambda_{\sigma(j)}(m_1 - f, \ldots, m_{n-1} - f) \]

Applying this and the equality

\[ \sum_{m_1 \geq \ldots \geq m_{n-1} \geq 0} \frac{\lambda_{\sigma(j)}(m)\lambda_{\tilde{\pi}}(m)}{p^{s} \sum_i m_i} = L(s, \sigma^{(j)} \otimes \tilde{\pi}) \]

to (13) gives

\[ \Psi(s, W'_\sigma(f), W_\pi) = \sum_{j=1}^{n} \frac{\alpha_j^{-f-1}L(s, \sigma^{(j)} \otimes \tilde{\pi})}{p^{f(n-1)s} \prod_{i \neq j}(\alpha_i - \alpha_j)}, \]

Since \( \sigma \) is unramified, we have the factorization

\[ L(s, \sigma \otimes \tilde{\pi}) = L(s, \sigma^{(j)} \otimes \tilde{\pi})L(s, \tilde{\pi} \otimes \chi_j) \]

where \( \chi_j \) is the character for which \( \chi_j(p) = \alpha_j \). Therefore,

\[ \Psi(s, W'_\sigma(f), W_\pi) = L(s, \sigma \otimes \tilde{\pi}) \sum_{j=1}^{n} \frac{\alpha_j^{-f-1}L(s, \tilde{\pi} \otimes \chi_j)^{-1}}{p^{f(n-1)s} \prod_{i \neq j}(\alpha_i - \alpha_j)}. \]

Expanding \( L(s, \tilde{\pi} \otimes \chi_j)^{-1} \) and changing the order of summation, we deduce that

\[ \Psi(s, W'_\sigma(f), W_\pi) = L(s, \sigma \otimes \tilde{\pi}) \sum_{k=0}^{n-1} \frac{(-1)^k e_k(A_{\tilde{\pi}})}{p^{f(n-1)s+k}} \sum_{j=1}^{n} \frac{\alpha_j^{k-f-1}}{\prod_{i \neq j}(\alpha_i - \alpha_j)} \]

Notice that the inner-sum equals

\[ \sum_{j=1}^{n} \frac{(\alpha_j^{-1})^{f-k+n-1}}{\prod_{i \neq j}(\alpha_i^{-1} - \alpha_j^{-1})}, \]

which, for \( f \geq k \), we might identify with

\[ \lambda_{\tilde{\pi}}(f-k, 0, \ldots, 0) \]
by developing the numerator of the Schur polynomial along the top row. Otherwise, we have \(0 \leq f - k + n - 1 < n - 1\) and using the very same idea we may relate this sum to a quotient of two determinants and where the numerator has two equal rows and thus it vanishes.

Altogether this leads to

\[
\Psi(s, \tilde{W}_\sigma^{(f)}, \tilde{W}_\pi) = L(s, \sigma \times \tilde{\pi}) \sum_{k=0}^{\min(f, n-1)} \frac{(-1)^k e_k(A_{\tilde{\pi}}) \lambda_{\tilde{\pi}}(f - k, 0, \ldots, 0)}{p(f(n-1)+k)s},
\]

which concludes the proof.

**Lemma 9.5.** We have

\[
L(1, \pi \otimes \tilde{\pi})L(1 + n/2, \pi)L(1 - n/2, \tilde{\pi})\tilde{H}(\sigma(\pi, 1/2); W^{(f)}_\Pi, W_\pi, s) \ll p^{-(n-2)/2}
\]

for \(s = (\frac{1}{2}, \frac{1}{2})\).

**Proof.** Using Lemma 9.3 and Lemma 9.4 for \(\sigma = \sigma(\pi, 1/2)\) and the given \(s\) we obtain

\[
\tilde{H}(\sigma(\pi, 1/2); W^{(f)}_\Pi, W_\pi, s) = \frac{\zeta(n)}{\zeta(1)} \sum_{k=0}^{\min(f, n-1)} \frac{(-1)^k e_k(A_{\tilde{\pi}}) \lambda_{\sigma(\pi, 1/2)}(f - k, 0, \ldots, 0)}{p(f(n-1)+k)/2}.
\]

Now it follows from the equality of \(L\)-functions

\[
L(s, \sigma(\pi, 1/2)) = L(s - 1/2, \tilde{\pi})\zeta(s + (n - 1)/2)
\]

that

\[
\lambda_{\sigma(\pi, 1/2)}(f - k, 0, \ldots, 0) = \sum_{j=0}^{f-k} \lambda_{\tilde{\pi}}(j, 0, \ldots, 0) |p^j|^{-1/2} |p^{f-k-j}|^{(n-1)/2} \ll p^{(f-k)/2}
\]

as \(\pi\) is tempered. \(\square\)

**9.3. Proof of Proposition 9.1.** The first assertion follows from Proposition 5.2 and Lemma 9.2 along with the discussion preceding it.

From the definitions (24) and (26), respectively, it is clear that \(P\) and \(D\) are entire in \(s\) as \(\Phi\) and \(\phi\) are cuspidal. The argument preceding Lemma 9.2 implies that \(M\) is entire in \(s_1\) and is holomorphic on the region \(1/2 \leq \Re(s_2) < 1\). This implies that \(R\) is holomorphic on the same region.

The final assertion on \(R\) follows from the definition of \(R\) in (42) upon applying Lemma 9.5 along with holomorphicity of the local weights as in Lemma 9.1 and the Rankin–Selberg \(L\)-functions.
10. THE DEGENERATE TERM: DUAL SIDE

In this section we use the same notations as in the beginning of §5. The goal of this section is to study the degenerate term defined in (26), as follows. The following proposition can be thought as a generalization of [39, Proposition 9.1].

**Proposition 10.1.** Let \( \Phi \) and \( \phi \) be given as in §6. Recall \( \tilde{\Phi} \) from Proposition 5.1. We have

\[
\mathcal{D} \left( \left( \frac{1}{2}, \frac{1}{2} \right), \tilde{\Phi}, \phi \right) = \Delta_F^{-c_\Omega} \mathcal{D}_\infty \frac{L^p(1, \Pi \times \tilde{\pi})L^p(n/2, \tilde{\Pi})}{L^p(1 + n/2, \tilde{\pi})},
\]

where \( c_\Omega \) is a constant depending only on \( n \) and \( \mathcal{D}_\infty \) is as defined in (45) with \( \mathcal{D}_\infty = 1 \).

First, we define a local factor which will be served as the local component of the degenerate term. For \( W_1 \in \Pi_v \) and \( W_2 \in \pi_v \) we define \( \Omega_v(s, W_1, W_2) \) by

\[
\int_{N_{n-1}(F_v) \cap G_{n-1}(F_v)} \int_{G_1(F_v)} W_1 \left[ \begin{pmatrix} zh & z \\ 1 & 1 \end{pmatrix} \right] W_2(h) |\det(h)|^{s_1 + s_2 - 1} |z|^{n(s_1 - 1/2)} d^x z dh,
\]

(44)

The RHS above is absolutely convergent for sufficiently large \( \Re(s) \).

We also define

\[
\mathcal{D}_\infty(s) = \mathcal{D}_\infty \left( s, \otimes_v \Omega, W_{\Phi,v}, \otimes_v \Omega W_{\phi,v} \right) := \prod_{v|\infty} \Omega_v(s, W_{\Phi,v}, W_{\phi,v}).
\]

(45)

We abbreviate \( \mathcal{D}_\infty \left( \frac{1}{2}, \frac{1}{2} \right) \) as \( \mathcal{D}_\infty \).

**Lemma 10.1.** Recall \( \tilde{s} \) from (2). Then for any \( \Phi \in \Pi \) and \( \phi \in \pi \) we have

\[
\mathcal{D}(s, \Phi, \phi) = \prod_v \Omega_v(\tilde{s}, W_{\Phi,v}, W_{\phi,v})
\]

for sufficiently large \( \Re(s) \).

**Proof.** Working as in the proof of Proposition 5.1 we may deduce that

\[
\mathcal{D}(s, \Phi, \phi) = \int_{[G_{n-1}]} \int_{[G_1]} \tilde{\Phi}^* \left[ \begin{pmatrix} zh & z \\ 1 & 1 \end{pmatrix} \right] \phi(h) |\det(h)|^{\tilde{s}_1 + \tilde{s}_2 - 1} |z|^{n(\tilde{s}_1 - 1/2)} d^x z dh,
\]

(46)

where \( \tilde{s} \) is as in (2) and

\[
\Phi^*(g) := \int_{\tilde{U}_n} \Phi(ug) du
\]
such that $\tilde{U}_n := w^*U_n w^*$ which consists of matrices of the form
\[
\begin{pmatrix}
1 & x \\
1 & 1
\end{pmatrix}, \quad x \in M_{(n-1) \times 1}.
\]

We first compute the Fourier–Whittaker expansion of $\tilde{\Phi}^\#$. Using (16) we write
\[
\tilde{\Phi}^\#(g) = \sum_{\gamma \in N_n(F) \backslash G_n(F)} \int [U_n] W_{\tilde{\Phi}} \left( \begin{pmatrix} \gamma \\ 1 \end{pmatrix} u g \right) du.
\]

We notice that for $\gamma \in G_n(F)$,
\[
W_{\tilde{\Phi}} \left( \begin{pmatrix} \gamma \\ 1 \end{pmatrix} \begin{pmatrix} I_{n-1} & x \\ 1 & 1 \end{pmatrix} \right) = \psi_0(\ell(\gamma)^t x) W_{\tilde{\Phi}} \left( \begin{pmatrix} \gamma \\ 1 \end{pmatrix} g \right),
\]
where $\ell(\gamma)$ denote the row matrix formed by the first $n - 1$ entries of the last row of $\gamma$. Integrating both sides above over $x$ in $(F \backslash A)^{n-1}$ we conclude in the above Fourier–Whittaker expansion of $\tilde{\Phi}^\#$ we must have $\ell(\gamma) = 0$, equivalently, $\gamma \in N_n(F) \backslash G_1(F) P_n(F)$. Using the isomorphism $N_n \backslash G_1 P_n \cong N_{n-1} \backslash G_{n-1} \times G_1$ thus we can write
\[
\tilde{\Phi}^\#(g) = \sum_{\gamma \in N_{n-1}(F) \backslash G_{n-1}(F)} \sum_{q \in G_1(F)} W_{\tilde{\Phi}} \left( \begin{pmatrix} q^\gamma \\ q \\ 1 \end{pmatrix} g \right).
\]

Plugging in the above expansion in (16) and executing an unfolding-folding we obtain that $D(s, \Phi, \phi)$ can be written as
\[
\int_{N_{n-1}(A) \backslash G_{n-1}(A)} \int_{G_1(A)} W_{\tilde{\Phi}} \left( \begin{pmatrix} zh \\ z \end{pmatrix} \right) \overline{W_{\tilde{\Phi}}(h)} |\det(h)|^\frac{s_1 + s_2 - 1}{2} |z|^n(s_1 - 1/2) d^\times z d h.
\]

The RHS above is absolutely convergent for sufficiently large $\Re(\tilde{s})$ which may be ensured by choosing $s$ with sufficiently large $\Re(s)$. The RHS is Eulerian and can be factored as $\prod_v \Omega_v(\tilde{s}, W_{\tilde{\phi}_v}, W_{\phi_v})$. \hfill $\Box$

In the next subsections we will analyse the local integrals $\Omega_v$ at various $v$ and for the test vectors chosen in $\textit{86}$.

10.1. \textbf{At the places} $v | q$. In this subsection, we mostly work at the place $v$ and unless otherwise stated the objects below are $v$-adic.

\textbf{Lemma 10.2.} Let $f \in \mathbb{Z}_{\geq 0}$. Recall $\Omega$ from (14) and $W_{II}^{(f)}$ from (29). We have
\[
\Omega(s, W_{II}^{(f)}, W_\pi) = \frac{L(s_1 + s_2, \Pi \times \tilde{\pi}) L(ns_1, \Pi)}{L \left( \left( n + 1 \right) s_1 + s_2, \tilde{\pi} \right)},
\]
for \( s \in \mathbb{C}^2 \) with large \( \Re(s) \).

**Proof.** First, it follows from (33) that for \( h \in G_{n-1} \) and \( z \in G_1 \), one has

\[
W_{\Pi}^{(f)} \left[ \begin{pmatrix} zh & \nu \\ z & 1 \end{pmatrix} \right] = W_{\Pi} \left[ \begin{pmatrix} zh & \nu \\ z & 1 \end{pmatrix} \right].
\]

Therefore, it suffices to take \( f = 0 \).

We may use formula (12) and see that

\[
\Omega(s, W_{\Pi}, W_{\pi}) = \sum_{m_1 \geq \ldots \geq m_{n-1} \geq 0} \sum_{l \geq 0} \frac{\lambda_{\Pi}(m_1 + l, \ldots, m_{n-1} + l, l, 0) \lambda_{\mathbb{R}}(m)}{p^{(s_1 + s_2)\sum_i m_i + nls_1}},
\]

(47)

We now use the representation of \( \lambda_{\Pi} \) in terms of Schur polynomials and proceed much as in the proof of Lemma 9.3. We obtain

\[
\Omega(s, W_{\Pi}, W_{\pi}) = \sum_{j=1}^{n+1} L(s_1 + s_2, \Pi^{(j)} \times \pi) L(n_{js_1}, \chi_j^{-1}) \alpha_j^{-1} \prod_{i \neq j} (\alpha_i - \alpha_j),
\]

where \( \chi_j \) is the character of \( F \) such that \( \chi_j(p) = \alpha_j \). Since \( \Pi \) is unramified, we have the factorization

\[
L(s, \Pi \times \pi) = L(s, \Pi^{(j)} \times \pi) L(s, \pi \times \chi_j).
\]

Hence,

\[
\Omega(s, W_{\Pi}, W_{\pi}) = L(s_1 + s_2, \Pi \times \pi) \sum_{j=1}^{n+1} \frac{L(s_1 + s_2, \pi \times \chi_j)^{-1} L(n_{js_1}, \chi_j^{-1}) \alpha_j^{-1}}{\prod_{i \neq j} (\alpha_i - \alpha_j)}.
\]

Expanding the terms \( L(s_1 + s_2, \pi \times \chi_j) \) and \( L(n_{js_1}, \chi_j^{-1}) \) and changing the order of summation, the inner sum turns into

\[
\sum_{k=0}^{n} (-1)^k e_k(A_{\pi}) p^{k(s_1 + s_2)} \sum_{\nu \geq 0} p^{-n_{js_1}} \sum_{j=1}^{n+1} \frac{\alpha_j^{k-\nu-1}}{\prod_{i \neq j} (\alpha_i - \alpha_j)},
\]

where \( e_k(A_{\pi}) \) denotes the \( k \)-th symmetric polynomial on the Satake parameters \( A_{\pi} \) of \( \pi \). By Lagrange interpolation, the inner sum vanishes whenever \( 1 \leq k - \nu \leq n \). Since \( k - \nu \leq n \) always holds, we are only left with the cases where \( \nu \geq k \). In those cases, the inner sum can be rewritten as

\[
\sum_{j=1}^{n+1} \frac{(\alpha_j^{-1})^{\nu+n-k}}{\prod_{i \neq j} (\alpha_i^{-1} - \alpha_j^{-1})},
\]
which we recognize as $\lambda_\Pi^r(\nu - k, 0, \ldots, 0)$, again by referring to the Schur polynomials. From this, we deduce that

$$\Omega(s, W_\Pi, W_\pi) = L(s_1 + s_2, \Pi \times \tilde{\Pi})L(ns_1, \tilde{\Pi}) \sum_{k=0}^{n} (-1)^k e_k(A_\tilde{\pi})p^{-k(n_1+s_2)}$$

$$= \frac{L(s_1 + s_2, \Pi \times \tilde{\Pi})L(ns_1, \tilde{\Pi})}{L((n+1)s_1 + s_2, \tilde{\Pi})}.$$  \hspace{1cm} (48)

where, the last equality follows from

$$\prod_{i=1}^{n} \left(1 - \alpha_i p^{-s}\right) = \sum_{k=0}^{n} (-1)^k e_k(\alpha_1, \ldots, \alpha_n)p^{-ks}.$$  

Hence we conclude. \hspace{1cm} \Box

10.2. At the places $v \mid \Delta_F$. In this subsection, we only work at the places for which $v \mid \Delta_F$. Recall that in this case our choice of test vectors is given by (30), so that in this case $\Omega_v(s, W_\Phi, W_\phi, v)$ is given by

$$\int_{A_{n-1}} \int_{G_1} W_{\Pi_v} \left[ a_{n+1}(\lambda) \begin{pmatrix} za & z \\ n\pi_v(a_{n-1}(\lambda)a) & |\det(h)|^{s_1+s_2-1}\|z\|^{n(s_1-1/2)} \end{pmatrix} \right] \frac{d^n x \cdot d^n a}{\delta(a)}.$$  

Note that we may restrict the $\lambda$ integral on $A_{n-1}$ using sphericality of the vectors. Now it follows from the change of variables $\lambda a_{n-1}(\lambda) \lambda h \mapsto h$ and $\lambda z \mapsto z$ that the above is nothing but

$$|\lambda|^\mu_v(s) \Omega_v(s, W_\Pi, W_\pi),$$

where $\mu_v(s)$ is an affine function whose coefficients are complex numbers depending only on $n$. Recall that $|\lambda|^{-1} = \Delta_v$ is the $v$ part of the discriminant and notice that Lemma 10.2 also includes the unramified computation as a special case by simply taking $f = 0$. This allows us to deduce that

$$\Omega_v(s, W_\Phi, W_\phi, v) = \Delta_v^{-\mu_v(s)} \frac{L_v(s_1 + s_2, \Pi \times \tilde{\Pi})L_v(ns_1, \tilde{\Pi}_v)}{L_v((n+1)s_1 + s_2, \tilde{\Pi}_v)}. \hspace{1cm} (49)$$

We extend the definition of $\mu_v(s)$, which is constant in $v \mid \Delta_F$, to $v$ coprime with $\Delta_F$ by making it identically zero on such $v$.

10.3. A combined result. By putting together Lemma 10.2 and (49) and taking into consideration that both formulæ apply for the completely unramified cases $p \notin S$, we have the following lemma
Lemma 10.3. For large $\Re(s)$ we have
\[
\Omega_v(s, W_{\Phi,v}, W_{\phi,v}) = \Delta_v^{-\mu_v(s)} \frac{L_v(s_1 + s_2, \Pi \times \widehat{\pi}) L_v(ns_1, \widehat{\Pi}_v)}{L_v((n+1)s_1 + s_2, \widehat{\pi}_v)}
\]
for $v < \infty$ and $v \neq p_0$ where the local vectors are as in §6.

10.4. At the place $p_0$. In this subsection, we only work at the place $v = p_0$. Recall the choices of the test vectors at $v$ in §6.

Lemma 10.4. We have
\[
\Omega_v(s, W_{\Phi,v}, W_{\phi,v}) = 1
\]
for any $s \in \mathbb{C}^2$.

Proof. Let $\Re(s)$ be large enough. From (31) we have
\[
\Omega_v(s, W_{\Phi,v}, W_{\phi,v}) = \int_{G_{n-1}(F_v)} W_\tau \left[ \begin{pmatrix} h & \tau \pi_v \end{pmatrix} \right] \left| \det(h)^{s_1+s_2-1} \right| dh.
\]
From (11) we conclude that the above integral is $L_v(s_1 + s_2 - 1/2, \tau \times \widehat{\pi}_v)$. As $\tau$ is supercuspidal and $\pi_v$ is unramified this local $L$-factor equals to 1, which follows from §35. We conclude by analytic continuation.

10.5. At the archimedean places. Let $v | \infty$ be any place. Recall the choices of the test vectors at $v$ in §6.

Lemma 10.5. We have
\[
\Omega_v(s, W_{\Phi,v}, W_{\phi,v}) = 1
\]
for any $s \in \mathbb{C}^2$.

Proof. We specify the choices of the archimedean components as in §6. Fix $\epsilon > 0$ sufficiently small and $s \in \mathbb{C}^2$. As $W_{\phi,v}(1) = 1$ there is a neighbourhood $B = B(\epsilon, W_{\phi,v}, s) \subset N_n \setminus G_n$ around the identity such that
\[
|W_{\phi,v}(h) - 1|, \quad ||\det(h)|^{s_1+s_2-1} - 1|, \quad ||z|^{n(s_1-1/2)} - 1|
\]
are all smaller than $\epsilon$ whenever
\[
z \begin{pmatrix} h & \tau \pi_v \end{pmatrix} \in B.
\]
We choose $W_{\phi,v}$ such that $W_{\Phi,v} \mid_{N_n \setminus G_n}$ is supported on $B$ and
\[
\left| W_{\Phi,v} \begin{pmatrix} z & h \tau \pi_v \end{pmatrix} - 1 \right| < \epsilon.
\]
We conclude the proof with repeated use of the triangle inequality. \qed
10.6. **Proof of Proposition 10.1.** Let $\Re(s)$ be large enough. Using Lemma 10.1, Lemma 10.2 and Lemma 10.4 we obtain

$$D(\tilde{s}, \Phi, \phi) = \Delta_{\Re}^{-\mu(s)}D_{\sigma}(s)\frac{L^0(s_1 + s_2, \Pi \times \tilde{\Pi})L^0(ns_1, \tilde{\Pi})}{L^0((n+1)s_1 + s_2, \tilde{\Pi})},$$

where $D_{\sigma}(s)$ is defined in (45). Both sides above are holomorphic in $\Re(s) \geq \left(\frac{1}{2}, \frac{1}{2}\right)$ which follows from holomorphicity and non-vanishing of $L$-functions in the region of absolute convergence and Lemma 9.1. We conclude by plugging in $s = \left(\frac{1}{2}, \frac{1}{2}\right)$, defining $c_\Omega := \mu_\Omega \left(\frac{1}{2}, \frac{1}{2}\right)$, and appealing to Lemma 10.5.

11. **Proofs of the Main Results**

In this section we put together all of our previous efforts and finally prove our main Theorems. We shorthand $\mathcal{M}$ for $\mathcal{M}(s, \Phi, \phi)$ and $\tilde{\mathcal{M}}$ for $\mathcal{M}(\tilde{\Phi}, \tilde{\phi})$, where $\tilde{\Phi}$ and $\tilde{s}$ are given in Proposition 5.1. Similar notation is used for the functions $\mathcal{P}, \mathcal{D}$ and $\mathcal{R}$.

11.1. **Proof of Theorem 1.** From Proposition 9.1 we have

$$\mathcal{P} = \mathcal{M} + \mathcal{R} + \mathcal{D}$$

in the region $\Re(s) \geq 1/2$. Now, Proposition 5.1 tells us that

$$\mathcal{P} = \tilde{\mathcal{P}}.$$

We apply Proposition 9.1 on $\mathcal{P}$. Thus we obtain

$$\mathcal{M} = \tilde{\mathcal{M}} + \tilde{\mathcal{R}} + \tilde{\mathcal{D}} = \mathcal{R} + \mathcal{D}.$$

We write

$$\mathcal{H}_S(\sigma) = \prod_{v \in S, v \neq \infty} H_v(\sigma_v) \prod_{v \in S, v = \infty} h_v(\sigma_v)$$

which proves Theorem 1.

11.2. **A few lemmas.**

**Lemma 11.1.** Let $v$ be any place. Then for any $W_1 \in \Pi_v$ and $W_2 \in \pi_v$ we have

$$H_v(\sigma_v; W_1, W_2, s) \ll_{W_1, W_2, s} C(\sigma_v)^{-N}$$

for any $W_1 \in \Pi$, $W_2 \in \pi$, $s \in \mathbb{C}$.

This lemma allows us to truncate the Plancherel integral so the archimedean parameters have essentially bounded size.
Proof. We use Lemma 3.3 in the definition (28). We see that it suffices to show that for any \( N \) there is a \( M \) such that
\[
\sum_{W \in \mathcal{B}(\sigma_v)} S(M,W) \ll C(\sigma_v)^{-N}.
\]
If \( v \) is non-archimedean the proof of the above is contained in the proof of Lemma 3.1. If \( v \) archimedean then we argue as in the proof of [31, Lemma 3.3] and conclude via [34, Lemma 2.6.6]. \( \square \)

From now on let \( F \) be totally real.

Lemma 11.2. Let \( Q \) be an ideal of \( \prod_{v<\infty} \mathfrak{o}_v \) of norm \( q^{-1} \) and let \( X = (X_v)_{v|\infty} \) where \( X_v > 1 \) for \( v \mid \infty \). We define
\[
\mathcal{F}_{Q,X} := \left\{ \sigma \mid \sigma \text{ generic automorphic representation of } G_n(\mathbb{A}) \text{ with trivial central character} \mid C(\sigma_v) \mid q; C(\sigma_v) < X_v, v \mid \infty \right\}.
\]
Then
\[
\int_F \frac{1}{\mathcal{L}^{q,\infty}(\sigma)} d\sigma \ll_{\varepsilon} (qX)^{(n-1+\varepsilon)},
\]
where we write \( \mathcal{L}^{q,\infty} = \mathcal{L}^{(v|q), v|\infty} \) and \( X = \prod_{v|\infty} X_v \).

The proof is essentially the same as that of [31, Theorem 9], also see [30, Theorem 7]. We give a sketch of the proof for the sake of completeness.

Proof. We write momentarily \( S = \{v \mid q\} \cup \{v \mid \infty\} \). Then, for each non-archimedean \( v \in S \) we fix \( f_v \in \mathbb{Z}_{\geq 0} \). We construct a test function \( \alpha_v \) on \( G_n(\mathfrak{o}_v) \) which is an \( L^1 \)-normalized characteristic function of \( K_0(\mathfrak{p}_v^{f_v}) \) where \( K_0 \) denotes the Hecke congruence open-compact subgroup of \( G_n(\mathfrak{o}_v) \).

For each archimedean \( v \in S \) we choose \( X_v > 1 \) and \( \tau_v > 0 \), and construct and approximate archimedean congruence subset \( K_0(X_v, \tau_v) \subset G_n(\mathfrak{F}_v) \) as in [31, (1.4)]. We construct a test function \( \alpha_v \) on \( G_n(\mathfrak{F}_v) \) which is an \( L^1 \)-normalized smoothened characteristic function of \( K_0(X_v, \tau_v) \).

Let \( \alpha_v^* \) be the self-convolution of \( \alpha_v \). We define
\[
J_{\sigma_v}(\alpha_v^*) := \sum_{W \in \mathcal{B}(\sigma_v)} \sigma_v(\alpha_v^*)W(1)\overline{W(1)} = \sum_{W \in \mathcal{B}(\sigma_v)} |\sigma_v(\alpha_v)W(1)|^2 \geq 0.
\]
Classical non-archimedean newvector theory [26] and archimedean analytic newvector theory [31] imply that
\[
J_{\sigma_v}(\alpha_v^*) \gg 1, \quad \text{if } C(\sigma_v) = \begin{cases} p_v^{f_v}, & \text{for } v \text{ non-archimedean;} \\ X_v, & \text{for } v \text{ archimedean.} \end{cases}
\]
Let \( q' := \prod_{v|q} p_v^{f_v}. \) Now working as in the proof of [31, Theorem 9] we obtain
\[
\int_{C(\sigma_v) = q'} \frac{1}{L^S(\sigma)} d\sigma \ll \int_{\sigma} \prod_{v \in S} \frac{J_{\sigma_v}(\alpha_v^*)}{L^S(\sigma)} d\sigma = \prod_{v \in S} \int_{N_v(F_v)} \alpha_v^*(n_v) \psi_v(n_v) \, dn_v.
\]

The last integral can be bounded by \( |q'|^{1-n} \prod_{v|\infty} X_{v}^{n-1} \) using that \( \text{vol}(K_0(p_f^v))^{-1} = p_v^{n-1} \) and \( \text{vol}(K_0(X_v, \tau_v))^{-1} = X_v^{-1}. \) Summing over \( q' \mid q \) and breaking \([1, X_v]\) into dyadic intervals we conclude.

11.3. **Proof of Theorem**[2] We let \( q \) be an ideal of \( \prod_{v<\infty} \mathcal{O}_v \) of norm \( q^{-1}, \)
\[
S = \{ p_0 \} \cup \{ v \mid q \} \cup \{ v \mid \Delta_F \} \cup \{ v \mid \infty \}
\]
and \( S' = S \backslash \{ v \mid \Delta_F \}. \) Our point of departure is Theorem [1] with \( S \) as above, \( s = (\frac{1}{2}, \frac{1}{2}), \)
and cusp forms \( \Phi \) and \( \phi \) with local components as in \( \S 6. \) Once again, we suppress \( \Phi, \phi \)
and \( s \) from the notations. Since

**Lemma 11.3.** For all \( 0 < \delta \leq 1/2 \) we have a \( \delta' > 0 \) such that
\[
\mathcal{M} = \varepsilon_{p_0}(1, \tau \otimes \overline{\tau}) \Delta_F^{-c_H} \sum_{\sigma \text{ cuspidal: } \sigma_{p_0} = \tau} \frac{L(1/2, \Pi \times \overline{\sigma}) L(1/2, \sigma \times \overline{\sigma})}{\mathcal{L}^S(\sigma)} H_q(\sigma) h_{X}(\sigma) + O(q^{-\delta'}),
\]
for some absolute (depending only on \( n \)) \( c_H \) constant, where the implied constant in the
error term depends on the archimedean and \( p_0 \)-adic components of the test vectors.

**Proof.** Applying Proposition [7, 2] and (36) to the definition of \( \mathcal{M} \) in (27) we obtain
\[
\mathcal{M} = \sum_{\sigma \text{ cuspidal: } \sigma_{p_0} = \tau} \frac{L(1/2, \Pi \times \overline{\sigma}) L(1/2, \sigma \times \overline{\sigma})}{\mathcal{L}^S(\sigma)} H_q(\sigma) \varepsilon_{p_0}(1, \tau \otimes \overline{\tau}) \Delta_F^{-c_H} h_{X}(\sigma),
\]
where \( c_H = \mu_H((1/2, 1/2)). \) Using Proposition [7, 1] and Lemma [11, 1] we can truncate
the above sum at \( \varepsilon_{\sigma_v} \leq f_v \) for all \( v \mid q \) and \( C(\sigma_v) \ll q^2 \) for \( v \mid \infty. \) On the other hand, applying (20) and Proposition [7, 1] we can bound
\[
\sum_{\sigma \text{ cuspidal: } \sigma_{p_0} = \tau} \frac{L(1/2, \Pi \times \overline{\sigma}) L(1/2, \sigma \times \overline{\sigma})}{\mathcal{L}^S(\sigma)} H_q(\sigma) h_{X}(\sigma)
\ll \varepsilon q^{1/2 - \delta - n/2 + \epsilon} \sum_{\sigma \text{ cuspidal: } \sigma_{p_0} = \tau} \frac{1}{\mathcal{L}^S(\sigma)},
\]
where \( \epsilon \) is an absolute constant.
where the implied constants depend on $\Pi$ and $\pi$. We apply Lemma 11.2 to bound the RHS above by $O(q^{-\delta'})$ for some $\delta' > 0$ depending on $\delta$ after making $\epsilon$ sufficiently small.

**Lemma 11.4.** There exists some $\delta_1 > 0$ we have
\[
\tilde{M} \ll q^{-\delta''},
\]
where the implied constant in the error term depends on $\Pi$ and $\pi$.

**Proof.** Applying Proposition 8.1 and (39) to the definition of $\tilde{M}$ as in (27) we obtain
\[
\tilde{M} = \Delta_F^{-c_H} \int_{c(\sigma) = 0, \nu_0 \neq v < \infty} \frac{L(1/2, \Pi \times \tilde{s}) L(1/2, \sigma \times \tilde{\tau})}{L^{s'}(\sigma)} \tilde{H}_q(\sigma) \tilde{H}_{p_0}(\sigma_{p_0}) \tilde{h}_\mathcal{S}(\sigma) \, d\sigma.
\]
Once again, we use Proposition 8.1 and Lemma 11.1 to truncate the integral and apply (20) to bound
\[
\tilde{M} \ll q^{-(n-1)\eta} \int_{c(\sigma) = 0, \nu_0 \neq v < \infty} \frac{1}{L^{s'}(\sigma)} \, d\sigma,
\]
where $\eta$ is a uniform bound towards Ramanujan for $G_n$. For instance, we can take $\eta = (n^2 + 1)^{-1}$, see [32]. Here the implied constants depend on the local test vectors at the archimedean and $p_0$ places. Finally, we conclude by Lemma 11.2 and making $\epsilon$ small enough.

**Lemma 11.5.** We have $\mathcal{R} = 0 = \mathcal{D}$. Consequently, $\mathcal{P} = \mathcal{M}$.

**Proof.** Repeating the argument in §5.2 and of the proof of Proposition 7.2 we can write
\[
\mathcal{A}_{s_1, \Phi}(g) = \sum_{\sigma \text{ cuspidal}} \sum_{\varphi \in \mathcal{B}(\sigma)} \frac{\Psi(s_1, W_{\Phi, \varphi}, \tilde{W}_{\varphi})}{\|\varphi\|^2} \varphi(g).
\]
As before, the RHS is entire in $s_1$ and absolutely convergent. Moreover, as $\varphi$ are cusp forms we can now integrate the RHS term by term against $\phi \mid \det |s_j - 1/2$. Thus we obtain
\[
\mathcal{P}(s, \Phi, \phi) = \sum_{\sigma \text{ cuspidal}} \frac{L(s_1, \Pi \times \tilde{s}) L(s_2, \sigma \times \tilde{\tau})}{L^{s'}(\sigma)} \mathcal{H}_S(\sigma).
\]
The RHS is again entire in $s$ which follows from the analytic properties of Rankin–Selberg zeta integrals. Plugging-in $s = (\frac{1}{2}, \frac{1}{2})$ above and looking at the expression of $\mathcal{M}$ in the proof of Lemma 11.3 we obtain $\mathcal{P} = \mathcal{M}$.

On the other hand, from (42) we see that $\mathcal{R} = 0$ as $H_{p_0}(\sigma_{p_0}, z) = 0$ for any $z \in \mathbb{C}$ which follows from Lemma 9.1 and Proposition 7.2 for $z \in i\mathbb{R}$. Consequently, Proposition 9.1 implies that $\mathcal{D} = 0$.
Proof of Theorem 2. Theorem 1 and Lemma 11.3 imply that $\mathcal{M} = \tilde{\mathcal{M}} + \tilde{\mathcal{D}} + \tilde{\mathcal{K}}$. We apply Lemma 11.3, Lemma 11.4 bound of $\tilde{\mathcal{K}}$ from Proposition 9.1, expression of $L^S$ from from (22), and expression of $\tilde{\mathcal{D}}$ from Proposition 10.1. Thus we conclude the proof defining $d_n := c_\Omega - c_H$. □

Proof of Corollary 3. The main term in Theorem 2 is nonzero. This follows from Shahidi's result [45, Proposition 7.2.4] that the Rankin–Selberg $L$-values at 1 are non-zero and Proposition 10.1. Hence we conclude by making $q$ sufficiently large. □
