CALLABLE CONVERTIBLE BONDS UNDER LIQUIDITY
CONSTRAINTS
DAVID HOBSON, GECHUN LIANG, HAODONG SUN*

Abstract. This paper provides a complete solution to the callable convertible bond studied in
[Liang and Sun, Dynkin games with Poisson random intervention times, SIAM Journal on Control
and Optimization, 57(4): 2962–2991, 2019], and corrects an error in Proposition 6.2 of that paper. The
callable convertible bond is an example of a Dynkin game, but falls outside the standard paradigm
since the payoffs do not depend in an ordered way upon which agent stops the game. We show how
to deal with this non-ordered situation by introducing a new technique which may of interest in its
own right, and then apply it to the bond problem.

Key words. Constrained Dynkin game, callable convertible bond, order condition, saddle point.

AMS subject classifications. 60G40, 91A05, 91G80, 93E20.

1. Introduction. The holder of a perpetual bond receives a coupon from the
firm indefinitely. If the bond is convertible, the bondholder has the addi-
tional opportunity to exchange the bond for a fixed number of units of the firm’s stock at a
moment of the bondholder’s choosing. If the convertible bond is callable then the
firm has the option to call the bond on payment of a fixed surrender price to the
bondholder. The problem of pricing the callable convertible bond involves finding the
value of the bond and the optimal stopping rules for conversion (by the bondholder)
and call (by the firm).

The callable convertible bond is an example of a Dynkin game. A Dynkin game [3]
is a game played by two agents, each of whom chooses a stopping time. The game
involves a payment from the second player to the first. If the first player is first to
stop (at \(\tau\)) then the payment is \(L_\tau\); if the second player is first to stop (at \(\sigma\)) then the
payment is \(U_\sigma\); under a tie (\(\tau = \sigma\)) then the payment is \(M_\tau\). Here, \((L_t)_{t \geq 0}\), \((U_t)_{t \geq 0}\) and
\((M_t)_{t \geq 0}\) are adapted stochastic processes. For stopping rules \(\tau\) and \(\sigma\), the expected
value of the payment is

\[ J(\sigma, \tau) = E[L_\tau 1_{\tau < \sigma} + U_\sigma 1_{\sigma < \tau} + M_\tau 1_{\tau = \sigma}] \]

The objective of Player 1 is to maximise \(J\) whilst the objective of Player 2 is to
minimise \(J\) and this leads to two problem values

\[ v = \inf_{\sigma} \sup_{\tau} J(\sigma, \tau) \quad \text{and} \quad w = \sup_{\tau} \inf_{\sigma} J(\tau, \sigma) \]

(respectively the upper and lower value) depending on whether we take the perspective of the first or second player. Trivially \(v \leq w\): of great importance
is whether \(v = w\) in which case the Dynkin game is said to have a value \(v = w = \bar{v}\). See
[6] and [10] for general treatments using the backward stochastic differential equation
approach and the Markovian setup, respectively, and [13] for an extensive survey with
applications to financial game options. One of the main ideas is to find a saddle point,
i.e. a pair of stopping times \((\sigma^*, \tau^*)\) such that

(i) \(J(\sigma^*, \tau) \leq J(\sigma^*, \tau^*)\) for all \(\tau\) and

(ii) \(J(\sigma^*, \tau^*) \leq J(\sigma, \tau^*)\) for all \(\sigma\); then it is straightforward to show that the game
has a value and \((\sigma^*, \tau^*)\) are optimal for Player 2 and Player 1 respectively.

Historically, the relative order of the payoff processes \(L\), \(U\) and \(M\) in a Dynkin
game has been important in proving that the game has a value. When \(M \equiv L\),
[3] proved that a Dynkin game has a value under the Mokobodzki condition which
states that there exist two supermartingales whose difference lies between \(L\) and \(U\).
Such a condition was later relaxed in [10], see Kifer [13, Theorem 1] for a statement

of the result under the order condition $L \leq M \leq U$ and an integrability condition. Subsequently, the order condition was further relaxed in [14, 19, 23] by extending the class of stopping strategies to randomized stopping times. [14] shows the game has a value under fairly general conditions on the various payoffs, provided that agents are allowed to use randomised strategies. In particular the players can use these strategies to ‘hide’ their stopping time from the opposing player. One important result is that the game is always terminated (i.e. at least one player chooses to stop) at or before the first moment $t$ that $L_t > U_t$.

In general, the information structure is a crucial element in Dynkin games. See, for example, [7, 8] for the treatment of asymmetric/incomplete information and [1] for a robust version of a Dynkin game in which the players are ambiguous about their probability model. Moving beyond the classical set-up in a different direction, Liang and Sun [18] introduced a constrained Dynkin game in which the players’ stopping strategies are constrained to be event times of an independent Poisson process. The constrained Dynkin game is an extension of the Dynkin game in the same way that the constrained optimal stopping problem of [9] is an extension of a classical optimal stopping problem. When the problem involves a time-homogeneous payoff, a time-homogeneous diffusion process and an infinite time-horizon, the use of a Poisson process to determine the set of possible stopping times maximises the tractability of the constrained problem. Then under the order condition $L = M \leq U$ on the payoffs [18] prove existence of a constrained game value.

The Dynkin game formulation of the perpetual callable convertible bond was first introduced in [20] (see also [21] for the finite horizon counterpart). They reduced the problem from a Dynkin game to an optimal stopping problem, and discussed when call precedes conversion and vice versa. A key element of the problem specification in [20] is that the firm’s stock price is calculated endogenously. Extensions of this convertible bond model include, for example, [2] which considered the problem of the decomposition of a convertible bond into a bond component and an option component, [5] which studied the convertible bond with call protection, and [4] which added the tax benefit and bankruptcy cost to the convertible bond.

In contrast to the abovementioned works on convertible bonds, [18] introduced a constraint on the players’ stopping strategies by assuming that both bondholder and firm may only stop at times which are event times of an independent Poisson process. The idea is that the existence of liquidity constraints may restrict the players’ abilities to stop at arbitrary stopping times. [18] assumes that the firm’s share price is exogeneous, and then the analysis is an extension of [9, 11, 12, 15] and [17] which study optimal stopping problems under a liquidity constraint and their applications. In the same way that the classical callable convertible problem is related to a Dynkin game, the problem with liquidity constraints can be related to a Dynkin game under a condition that the stopping times lie in a restricted set.

The callable convertible bond was studied in [18] but, unfortunately, one of the calculations in Proposition 6.2 of [18] is incorrect. [18] first reduced the original problem from the state space $x \in (0, \infty)$ to $(0, \tilde{x}^\lambda]$ with $\tilde{x}^\lambda$ to be endogenously determined, and argued that the order condition $L \leq U$ would hold in the domain $x \in (0, \tilde{x}^\lambda]$, whereas the game would stop at the earliest Poisson arrival time after the firm’s stock price $X_x$ exceeds $\tilde{x}^\lambda$. However, the threshold $\tilde{x}^\lambda$ in Proposition 6.2 of [18] was incorrectly calculated, making the remaining analysis for the optimal stopping strategies of the convertible bond in [18] void. It turns out $\tilde{x}^\lambda$ cannot be endogenously determined because the game will not automatically stop after $X_x$ exceeds $\tilde{x}^\lambda$. One way to
correct this error is to enforce this stopping condition by assuming \( \bar{x}_\lambda \) is exogenously given (e.g. \( \bar{x}_\lambda := K/\gamma \)) and introducing a forced conversion condition: conversion is assumed to automatically occur at the earliest Poisson arrival time after the stock price process \( X^x \) first exceeds \( \bar{x}_\lambda \). See [22 Chapter 2.5] for further details. However, one significant drawback of the above modification is that there is a possibility that the stock price \( X^x \) drops below any small number \( \varepsilon > 0 \) at the moment \( T_M \) when the forced conversion is taking place, that is \( \mathbb{P}^{x}(X^x_{T_M} < \varepsilon) > 0 \). This is obviously against the interest of both the firm and the bondholder as neither of them would have incentive to stop in such a situation. Moreover, the new convertible bond (with forced conversion) is different from the original convertible bond that we are interested in.

One of the difficulties in the callable convertible bond problem is that, although it can be recast in the standard form of a Dynkin game, the upper payoff process \( U \) does not necessarily dominate the lower payoff process \( L \). As a result the general existence results for Dynkin games (see [16] or [13]) and especially the existence theorem in the Poisson (constrained) case ([18 Theorem 2.3]) do not apply. One possibility is to try to remove the order condition in the Poisson case as in [14] [19] [23], but at best that would give us an existence result, and we would like an explicit solution. Instead therefore, we take a different approach. The idea is to replace the original problem with a modified problem for which the order condition is satisfied (in both the standard case with unconstrained stopping times, and the illiquid case where stopping times are constrained to be event times of a Poisson process) and to which the theory applies. We then use a saddle-point argument to find the (explicit) solution to this modified problem, and a further (general) argument to show that this saddle-point is also a saddle-point for the original (constrained) perpetual callable convertible bond problem.

2. The extended saddle point result. Recall the classical formulation of a Dynkin game: for \( L = (L_t)_{t \geq 0}, U = (U_t)_{t \geq 0}, M = (M_t)_{t \geq 0} \) and

\[
J^{U,M,L}(\sigma, \tau) = \mathbb{E}[L_\tau 1_{\{\tau < \sigma\}} + U_\sigma 1_{\{\sigma < \tau\}} + M_\tau 1_{\{\tau = \sigma\}}],
\]

define the upper and lower values

\[
\mathcal{V} \equiv \mathcal{V}^{U,M,L}(\mathcal{T}) = \inf_{\sigma \in \mathcal{T}} \sup_{\tau \in \mathcal{T}} J^{U,M,L}(\sigma, \tau), \quad \mathcal{V} = \mathcal{V}^{U,M,L}(\mathcal{T}) = \sup_{\tau \in \mathcal{T}} \inf_{\sigma \in \mathcal{T}} J^{U,M,L}(\tau, \sigma),
\]

where \( \mathcal{T} \) is a set of stopping times. If \( \underline{v} = \mathcal{V} \) then we say the game has a value \( v = v^{U,M,L}(\mathcal{T}) \) where \( v = \underline{v} = \mathcal{V} \).

The Dynkin game was analysed in [3] and [16] (amongst others, see [13] for a comprehensive survey). Often this analysis is under a condition that the payoffs are given (e.g. \( \bar{v} \equiv \mathcal{V} \mathcal{M} \mathcal{L} \equiv \mathcal{V}^{U,M,L}(\mathcal{T}) = \sup_{\tau \in \mathcal{T}} \inf_{\sigma \in \mathcal{T}} J^{U,M,L}(\tau, \sigma) \)).

Example 2.1. Suppose that \( L_t = M_t = 1_{\{t > 1\}} \) and \( U_t = 1_{\{t \leq 1\}} \). Then, \( J^{U,M,L}(\sigma, \tau) = 1_{\{1 < \tau \leq \sigma\}} + 1_{\{\sigma < \tau, \sigma \leq 1\}} \). It is clear that \( \mathcal{V} = \inf_{\sigma} \sup_{\tau} J^{U,M,L}(\sigma, \tau) = 1 \), as, given \( \sigma \), Player 1 who maximizes \( J \) can choose a stopping strategy \( \tau^* = \sigma + 1_{\{\sigma \leq 1\}} \) (or more generally any stopping time for which \( \tau \in (\sigma, \infty) \) on \( \sigma \leq 1 \) and \( \tau \in (1, \sigma] \) on \( \sigma > 1 \)). On the other hand, \( \underline{v} = \sup_{\sigma} \inf_{\tau} J^{U,M,L}(\sigma, \tau) = 0 \), as Player 2 who minimizes \( J \) can choose a stopping strategy \( \sigma^* \) with \( \sigma^* \in (1, \tau) \) on \( \tau > 1 \) and \( \sigma^* \geq \tau \) on \( \tau \leq 1 \).

Notwithstanding the above example, in any given problem the pragmatic approach to finding a solution is to find a saddle point, i.e. to find a pair \( (\sigma^*, \tau^*) \in \mathcal{T} \times \mathcal{T} \)
such that $J^{U,M,L}(\sigma^*, \tau) \leq J^{U,M,L}(\sigma^*, \tau^*) \leq J^{U,M,L}(\sigma, \tau^*)$ for all $(\sigma, \tau) \in T \times T$. Then, 
$$\overline{v}^{U,M,L}(T) \leq \sup_{\tau \in T} J^{U,M,L}(\sigma^*, \tau) \leq J^{U,M,L}(\sigma^*, \tau^*) \leq \inf_{\sigma \in T} J^{U,M,L}(\sigma, \tau^*) \leq \underline{v}^{U,M,L}(T).$$

Since trivially $\underline{v}^{U,M,L}(T) \leq \overline{v}^{U,M,L}(T)$, we conclude that $\underline{v}^{U,M,L}(T) = \overline{v}^{U,M,L}(T)$ and the game has a value.

Note that the existence of a saddle-point gives a direct proof of the existence of a game value, but leaves us no nearer to finding the game value unless we can identify the optimisers $\sigma^*$ and $\tau^*$. Nonetheless our first key result is an extension of this argument.

**Proposition 2.2.** Suppose $L \leq U \leq \overline{U}, M \leq \overline{M}, \underline{L} \leq L \leq \overline{L}$ and let $T$ be a set of stopping times.

Suppose that there exists a pair of stopping times $(\sigma^*, \tau^*) \in T \times T$ such that

(i) $J^{U,M,L}(\sigma^*, \tau^*) = J^{U,M,L}(\sigma^*, \tau^*) = J^{U,M,L}(\sigma^*, \tau^*)$;

(ii) $J^{U,M,L}(\sigma^*, \tau) \leq J^{U,M,L}(\sigma^*, \tau^*)$ for any $\tau \in T$;

(iii) $\bar{J}^{U,M,L}(\sigma^*, \tau^*) \leq \bar{J}^{U,M,L}(\sigma^*, \tau^*)$ for any $\sigma \in T$.

Then, $\overline{v}^{U,M,L}(T) = \overline{v}^{U,M,L}(T) = J^{U,M,L}(\sigma^*, \tau^*)$ and the game for payoff triple $(U, M, L)$ and stopping time set $T$ has a value. Moreover $(\sigma^*, \tau^*)$ is a saddle point for the game with payoffs $(U, M, L)$.

**Proof.** Since $T$ remains constant throughout, to economise on notation we omit the label $T$. It follows from monotonicity of the payoffs and (i)-(iii) that

$$J^{U,M,L}(\sigma^*, \tau) \leq J^{U,M,L}(\sigma^*, \tau^*) \leq J^{U,M,L}(\sigma^*, \tau^*),$$

and

$$J^{U,M,L}(\sigma, \tau^*) \geq J^{U,M,L}(\sigma, \tau^*) \geq J^{U,M,L}(\sigma, \tau^*).$$

Hence, $(\sigma^*, \tau^*)$ is indeed a saddle-point for the game with payoffs $(U, M, L)$. □

**Remark 2.3.** Under the hypotheses of Proposition 2.2, $(\sigma^*, \tau^*)$ is also a saddle-point for the games with payoffs $(\overline{U}, \overline{M}, \overline{L})$ and $(\underline{U}, \underline{M}, \underline{L})$ and these games also have value $J^{U,M,L}(\sigma^*, \tau^*)$. Indeed, we have

$$J^{\overline{U},\overline{M},\overline{L}}(\sigma, \tau^*) \geq J^{U,M,L}(\sigma, \tau^*)$$

$$\geq J^{U,M,L}(\sigma^*, \tau^*) = J^{\overline{U},\overline{M},\overline{L}}(\sigma^*, \tau^*),$$

which, when combined with (ii) of Proposition 2.2 gives the desired result for the game with payoff triple $(\overline{U}, \overline{M}, \overline{L})$.

Conversely, $J^{\underline{U},\underline{M},\underline{L}}(\sigma^*, \tau^*) \leq J^{U,M,L}(\sigma^*, \tau^*) \leq J^{U,M,L}(\sigma^*, \tau^*) = J^{\underline{U},\underline{M},\underline{L}}(\sigma^*, \tau^*)$, and the corresponding results follow for $(\underline{U}, \underline{M}, \underline{L})$.

For general triples $(\overline{U}, U, \overline{U}), (\overline{M}, M, \overline{M})$ and $(\underline{L}, L, \overline{L})$ we cannot expect to find stopping times satisfying the conditions of the proposition. But, the following special case will prove to be exactly what we need for the callable convertible bond. The key point is that it translates a problem where the ordering condition $L \leq U$ is violated to a problem where it is satisfied, and then the general theory of [13] can be applied. In particular, the existence theorem for constrained games ([13], Theorem 2.3) is valid for problems where the ordering constraint is satisfied.
Recall $U \lor L$ is the process given by $(U \lor L)_t = \max\{U_t, L_t\}$.

**Corollary 2.4.** Suppose that there exists a pair of stopping times $(\sigma^*, \tau^*) \in T \times T$ such that

(i) $J^{U \lor L, L, L}(\sigma^*, \tau^*) = J^{U, L, L}(\sigma^*, \tau^*)$;

(ii) $J^{U \lor L, L, L}(\sigma^*, \tau) \leq J^{U \lor L, L, L}(\sigma^*, \tau^*)$ for any $\tau \in T$;

(iii) $J^{U \lor L, L, L}(\sigma^*, \tau^*) \leq J^{U \lor L, L, L}(\sigma, \tau^*)$ for any $\sigma \in T$.

Then $J^{U, L, L}(T) = J^{U, L, L}(T) = J^{U, L, L}(\sigma, \tau^*)$ and the game for payoff triple $(U, L, L)$ and (constrained) stopping time set $T$ has a value $v^{U, L, L} = J(\sigma^*, \tau^*)$.

**Proof.** Take $\bar{U} = U \lor L$, $\bar{L} = U$, $\bar{L} = L = \bar{M} = M = \bar{M}$ in Proposition 2.2.

**Example 2.5.** Suppose that $L_t = M_t = 1_{\{t \geq 1\}}$ and $U_t = 1_{\{t < 1\}}$. (Note the different treatment of $t = 1$ when compared with Example 2.1.) Then, $J^{U, L, L}(\sigma, \tau) = 1_{\{1 \leq \sigma \leq \tau\}} + 1_{\{\sigma < \tau, \sigma < 1\}}$. Although $U \geq L$ is not satisfied, it is still possible to find a saddlepoint in the sense of Corollary 2.4. Indeed, $(\sigma^*, \tau^*) = (\text{any value in } T, \tau^*) = \inf\{t : t \geq 1, t \in T\}$ is a saddle point. To see this, for $\bar{U} = U \lor L = 1$, $J^{U, L, L}(\sigma, \tau) = 1_{\{1 \leq \tau \leq \sigma\}} + 1_{\{\sigma < \tau\}}$. It is clear that

$$J^{U, L, L}(\sigma^*, \tau^*) \leq J^{U, L, L}(\sigma^*, \tau^*) = J^{U, L, L}(\sigma^*, \tau^*) = J^{U, L, L}(\sigma^*, \tau^*) = J^{U, L, L}(\sigma^*, \tau^*) = 1,$$

so the extended saddle point conditions in Corollary 2.4 are satisfied. Hence the game has a value, and that value is 1.

### 3. The callable convertible bond: problem specification.

From the bondholder’s viewpoint, the discounted payoff of a perpetual callable convertible bond issued by a firm has the form

$$P(\sigma, \tau) = \int_0^{\sigma \land \tau} e^{-ru} c \, du + e^{-\gamma \tau} \gamma X_\tau^x \mathbb{1}_{\tau \leq \sigma} + e^{-\gamma \sigma} K \mathbb{1}_{\sigma < \tau}.$$

Here $X^x$ represents the stock price process starting from $X_0^x = x$. The firm issues convertible bonds as perpetuities with a constant coupon rate $c \geq 0$. The investor then purchases a share of this convertible bond at initial time $t = 0$. By holding the convertible bond, the investor will continuously receive the coupon rate $c$ from the firm until the contract is terminated: (i) if first, (i.e. $\sigma < \tau$) the firm calls the bond at some stopping time $\sigma$, the bondholder will receive a pre-specified surrender price $K$ at time $\sigma$; (ii) if first (i.e. $\tau < \sigma$) the investor chooses to convert their bond at some stopping time $\tau$, the bondholder will obtain $\gamma X_\tau^x$ at time $\tau$ from converting their bond to $\gamma$ shares of firm’s stock with a pre-specified conversion rate $\gamma$. If bondholder and firm choose to stop the contract simultaneously (i.e. $\sigma = \tau$) then the bondholders act takes priority and the bondholder will obtain $\gamma X_\tau^x$.

Note that $P(\sigma, \tau)$ can be rewritten using integration by parts as

$$P(\sigma, \tau) = \left\{ \frac{c}{\tau} + e^{-\gamma \tau} \left( \gamma X_\tau^x - \frac{c}{\tau} \right) \right\} \mathbb{1}_{\{\tau \leq \sigma\}} + \left\{ \frac{c}{\tau} + e^{-\gamma \sigma} \left( K - \frac{c}{\tau} \right) \right\} \mathbb{1}_{\{\sigma < \tau\}}.$$

This is exactly the form in (2.1) with $L_t = M_t = \frac{c}{\tau} + e^{-\gamma \tau} \left( \gamma X^x_\tau - \frac{c}{\tau} \right)$ and $U_t = \frac{c}{\tau} + e^{-\gamma \tau} \left( K - \frac{c}{\tau} \right)$. Note that we do not have $L \leq U$: in particular if $X^x_\tau > \frac{K}{\gamma}$ then $L_t > U_t$. Then $J^x(\sigma, \tau) := \mathbb{E}^x[P(\sigma, \tau)]$ is given by

$$J^x(\sigma, \tau) = \mathbb{E}^x \left[ \left\{ \frac{c}{\tau} + e^{-\gamma \tau} \left( \gamma X_\tau^x - \frac{c}{\tau} \right) \right\} \mathbb{1}_{\{\tau \leq \sigma\}} + \left\{ \frac{c}{\tau} + e^{-\gamma \sigma} \left( K - \frac{c}{\tau} \right) \right\} \mathbb{1}_{\{\sigma < \tau\}} \right].$$

We work under the following assumption on the stock price process $X^x$:
STANDING ASSUMPTION 3.1. The price process $X^x$ of the firm’s stock follows

$$X^x_t = x + \int_0^t (r - q)X^x_s ds + \int_0^t \sigma X^x_s dW_s,$$

where the constants $r, q, \sigma$ (with $\sigma > 0$) represent the risk-free interest rate, the dividend rate and the stock’s volatility, and $W$ is a Brownian motion.

Following [13] (and also [9] and others) the liquidity constraint is modelled as follows. Instead of allowing $\sigma$ and $\tau$ to be any stopping times we assume that $\sigma, \tau \in \mathcal{T} = \mathcal{R}(\lambda)$, where

$$\mathcal{R}(\lambda) = \{\eta: \eta \text{ is a } \mathcal{G}\text{-stopping time such that } \eta(\omega) = T_N(\omega) \text{ for some } N \geq 1\}.$$

Herein, $\mathcal{G}$ is the filtration generated by the underlying Brownian motion $W$ (with its natural filtration $\mathbb{F}^W$) and an exogenous Poisson process (with its natural filtration $\mathbb{H}$ and jump times $\{T_N\}_{N \geq 1}$), i.e. $\mathcal{G} = \mathbb{F}^W \lor \mathbb{H}$. Then, in summary, we work on a filtered probability space $(\Omega, \mathcal{F}, \mathcal{G}, \mathbb{P})$ which supports a Brownian motion $W$ driving the price process and a Poisson process, and $\mathcal{T}$ is the set of $\{T_N\}_{N \geq 1}$-valued stopping times.

It turns out that it is useful to consider the (upper and lower) value of the callable convertible bond as functions of the initial value of the stock price. Then, with the superscript $\lambda$ denoting the rate of the Poisson process we define the upper and lower value of the convertible bond with liquidity constraint via

$$\mathcal{V}^{\lambda}_{\text{ca}}(x) = \inf_{\sigma \in \mathcal{R}(\lambda)} \sup_{\tau \in \mathcal{R}(\lambda)} J^x(\sigma, \tau),$$

$$\mathcal{U}^{\lambda}_{\text{ca}}(x) = \sup_{\tau \in \mathcal{R}(\lambda)} \inf_{\sigma \in \mathcal{R}(\lambda)} J^x(\sigma, \tau),$$

where $J^x$ is as given in (3.2). In the case where there are no liquidity constraints on the stopping times, the superscript $\lambda$ is omitted. Our goal is first to show that $\mathcal{V}^{\lambda}_{\text{ca}} = \mathcal{U}^{\lambda}_{\text{ca}}$ as functions of $x$ and hence that the game value $v^{\lambda}_{\text{ca}}$ is well defined, and second to give an explicit form for $v^{\lambda}_{\text{ca}}$.

A key element of the financial specification of the callable convertible bond is that if the firm calls at the same time as the bondholder then the bondholder’s actions take priority. In particular, $M \equiv L$. A second key element is that if the firm calls then the bondholder is given a final opportunity to preempt the call, and to convert. Effectively then, the payoff when the firm calls is given by $U \lor L$ (and not $U$). This suggests that we should consider the problem with modified payoffs $(\hat{U}, \hat{M}, \hat{L})$ given by $(\hat{U}, \hat{M}, \hat{L}) = (U \lor L, L, L) = (\hat{r} + e^{-rt} (K \lor \gamma X^x_t - \frac{\hat{r}}{r}), \hat{r} + e^{-rt} (K - \hat{r})), \hat{r} + e^{-rt} (K - \hat{r}))$, for which the ordering condition holds. We aim to find a saddle-point for this modified problem, and then to use Corollary 2.4 to deduce that it provides a solution to the original problem.

For future reference, let $\alpha_\lambda > 1$ and $\beta_\lambda < 0$ be the two characteristic roots of the differential operator

$$\mathcal{L}_\lambda f := \frac{1}{2} \sigma^2 x^2 f'' + (r - q)xf' - (r + \lambda)f, \quad f \in C^2(\mathbb{R}_+).$$

That is, $(\alpha_\lambda, \beta_\lambda)$ are the roots of $Q_\lambda(z) = 0$ with $Q_\lambda(z) := \frac{1}{2} \sigma^2 z^2 + (r - q - \frac{1}{2} \sigma^2)z - (r + \lambda)$. For simplicity, we also write $\alpha := \alpha_0$, $\beta := \beta_0$, $\mathcal{L} := \mathcal{L}_0$ and $Q := Q_0$.

**Lemma 3.2.** For $r \neq q$ and $\lambda \geq 0$ we have $Q_\lambda(\frac{\lambda + \alpha_\lambda}{r - q}) > 0$. Then, if $q < r$, $\frac{\lambda + \alpha_\lambda}{r - q} > 1$ and $\alpha_\lambda \in (1, \frac{\lambda + \alpha_\lambda}{r - q})$ (and $\alpha \in (1, \frac{\lambda + \alpha}{r - q})$). Conversely, if $q > r$ then $\frac{\lambda + \alpha_\lambda}{r - q} < 0$ and $\beta_\lambda \in (\frac{\lambda + \alpha_\lambda}{r - q}, 0)$. 

Further, we have \( \alpha \lambda < \alpha \left( \frac{\lambda + r}{r} \right) \) and hence \( \frac{\alpha \lambda}{\lambda + r} < \alpha \).

Proof. We have \( Q(\frac{\lambda + r}{r}) = \frac{1}{2} \sigma^2 \left( \frac{\lambda + r}{r} \right)^2 - \left( \frac{\lambda + r}{r} \right) \). If \( q > r \) then this is immediately positive; if \( q < r \) then it is positive since \( \frac{\lambda + r}{r - q} > 1 \). The final result follows similarly. \( \square \)

4. Two auxiliary optimal stopping problems. In this section, we solve the optimal stopping problems of the bondholder and the firm separately. They will serve as the building blocks for the construction of the optimal stopping strategies for the convertible bond in the next section.

4.1. Optimal stopping of the bondholder. Consider the following optimal stopping problem

\[
(4.1) \quad v^\lambda_{co}(x) = \sup_{\tau \in \mathcal{R}(\lambda)} \mathbb{E}^x \left[ \int_0^\tau e^{-ru}c \, du + e^{-r\tau}X^x_\tau \right].
\]

This is the problem facing the bondholder in the absence of any callable feature for the firm. We aim to find \( \tau^* \in \mathcal{R}(\lambda) \) to maximize the above expected discounted payoff of the bondholder. For later use, we also introduce an equivalent formulation, under which the bondholder finds an optimal number of Poisson jumps, i.e.

\[
(4.2) \quad v^\lambda_{co}(x) = \sup_{N \in \mathcal{N}(\lambda)} \mathbb{E}^x \left[ \int_0^{T_N} e^{-ru}c \, du + e^{-rT_N}X^x_{T_N} \right],
\]

where

\[ \mathcal{N}(\lambda) = \{ \tilde{\mathcal{G}}\text{-stopping time } N \text{ for } N \geq 1, \text{ with } \tilde{\mathcal{G}} = \{ \mathcal{G}_{T_n} \}_{n \geq 1} \}. \]

Define \( x^*_{co,\lambda} \) by

\[
(4.3) \quad x^*_{co,\lambda} = \frac{c(\lambda + q)(\alpha(\lambda + r) - \beta_\lambda r)}{\gamma r(\lambda + r)(\alpha(\lambda + q) - \lambda - \beta_\lambda q)}.
\]

It will turn out that \( x^*_{co,\lambda} \) is a critical threshold both in the problem under consideration, and for the callable convertible bond. The subscripts \( co \) and \( \lambda \) are intended to convey that the quantity arises in the convertible bond problem under a liquidity constraint based on the Poisson process with rate \( \lambda \).

Lemma 4.1. Assume that \( r > 0 \) and \( q > 0 \). Let \( x^*_{co,\lambda} \) be given as in \((4.3)\). Then \( x^*_{co,\lambda} \max \{ \frac{c}{\gamma r}, \frac{c \lambda + q}{\gamma q \lambda + r} \} \) and \( x^*_{co,\lambda} < \frac{c}{\gamma r} \frac{\alpha}{\alpha - 1} \).

Proof. Given the formula \((4.3)\), \( x^*_{co,\lambda} > \frac{c}{\gamma r} \) is equivalent to \( \beta_\lambda(r - q) < \lambda + r \). If \( r \geq q \) this is immediate, and if \( r < q \) it follows from Lemma 3.2.

Moreover, \( x^*_{co,\lambda} > \frac{c \lambda + q}{\gamma q \lambda + r} \) is equivalent to \( r > \alpha(r - q) \). If \( r \leq q \) this is immediate. Otherwise, it follows from Lemma 3.2.

Finally, after some algebra it can be shown that \( x^*_{co,\lambda} < \frac{\alpha r}{\gamma r - \alpha - 1} \) is equivalent to \( \beta_\lambda((\lambda + q)r + \alpha \lambda(q - r)) < \alpha(\lambda + r)q. \)

Given the signs of \( \beta_\lambda \) and \( \alpha \), it is sufficient to argue that \((\lambda + q)r + \alpha \lambda(q - r) > 0 \). But if \( q \geq r \) this is immediate, and if \( q < r \) then since \( \alpha < \frac{r}{r - q} \), we have \((\lambda + q)r + \alpha \lambda(q - r) = \ldots \)
\( \lambda(r + \alpha(q - r)) + qr > qr > 0. \)  

**Lemma 4.2.** Suppose that \( r > 0 \) and \( q > 0. \) Then, the value function \( v^\lambda_{co}(x) \) has the explicit expression

\[
(4.4) \quad v^\lambda_{co}(x) = \begin{cases} 
\frac{c}{r} + \left[ \frac{\gamma x^*_{co,\lambda} - c}{x^*_{co,\lambda}} \right] & x < x^*_{co,\lambda}; \\
\frac{c}{\lambda + r} + \frac{q\gamma x^*_{co,\lambda} - c}{\lambda + q} + \frac{q\gamma x^*_{co,\lambda} - c}{\lambda + q} + \frac{\gamma x^*_{co,\lambda} - c}{x^*_{co,\lambda}} \frac{x^\beta_{co,\lambda}}{(x^*_{co,\lambda})^\beta_{co,\lambda}}, & x \geq x^*_{co,\lambda}.
\end{cases}
\]

The optimal stopping time for (4.1) is given by \( \tau^* = T_{N_{x^*_{co,\lambda}}} \) with \( N_y \) defined as

\[
(4.5) \quad N_y = \inf\{n \geq 1 : X^n_T \geq y\}.
\]

**Proof.** Following along similar arguments in Theorem 1 of [9], it can be shown that the value function \( v^\lambda_{co}(x) \) satisfies the recursive equation

\[
(4.6) \quad v^\lambda_{co}(x) = \mathbb{E}^x \left[ \int_0^{T_1} e^{-r u} c \, du + e^{-r T_1} \max \{ v^\lambda_{co}(X^x_{T_1}), \gamma X^x_{T_1} \} \right] = \mathbb{E}^x \left[ \int_0^{\infty} e^{-(r+\lambda) u} (c + \lambda \max \{ v^\lambda_{co}(X^x_u), \gamma X^x_u \}) \, du \right],
\]

which, in turn, implies that \( v^\lambda_{co} \) is a solution of the HJB equation

\[
\mathcal{L} \lambda V(x) + c + \lambda \max \{ V(x), \gamma x \} = 0.
\]

(Moreover, \( v^\lambda_{co} \) is the solution which is bounded at zero, and of linear growth at infinity).

From the structure of the stopping problem, we expect that there is a continuation region \((0, z)\) with \( V > \gamma x \) and a stopping region \([z, \infty)\) with \( V \leq \gamma x \). On \((0, z)\), \( v^\lambda_{co} \) solves \( \mathcal{L} \lambda V + c + \lambda V = \mathcal{L} V + c = 0 \) and on \([z, \infty)\), it solves \( \mathcal{L} \lambda V + (c + \gamma \lambda x) = 0 \), together with boundary conditions that \( V(0) = c/r \) and \( V(x) \) is of linear growth. In addition we expect value matching and smooth fit at \( z \) (and that \( V(z) = \gamma z \)).

We find that with \( z \) replaced by the optimal threshold \( x^*_{co,\lambda} \), on \((0, x^*_{co,\lambda})\),

\[
(4.7) \quad v^\lambda_{co}(x) = \frac{c}{r} \left[ 1 - \frac{x^\alpha}{(x^*_{co,\lambda})^\alpha} \right] + \gamma x^*_{co,\lambda} \frac{x^\alpha}{(x^*_{co,\lambda})^\alpha} = \frac{c}{r} \left[ \gamma x^*_{co,\lambda} - \frac{c}{r} \right] \frac{x^\alpha}{(x^*_{co,\lambda})^\alpha},
\]

and on \([x^*_{co,\lambda}, \infty)\)

\[
(4.8) \quad v^\lambda_{co}(x) = \frac{c}{\lambda + r} + \frac{\gamma x}{\lambda + q} + \frac{q\gamma x^*_{co,\lambda} - c}{\lambda + q} + \frac{\gamma x^*_{co,\lambda} - c}{\lambda + r} \frac{x^\beta_{co,\lambda}}{(x^*_{co,\lambda})^\beta_{co,\lambda}}.
\]

Furthermore, first order smooth fit gives that

\[
\frac{\alpha}{x^*_{co,\lambda}} \left[ \gamma x^*_{co,\lambda} - \frac{c}{r} \right] = \frac{\gamma x^*_{co,\lambda} - \frac{c}{\lambda + q}}{\lambda + q} + \frac{\beta x^*_{co,\lambda}}{\lambda + r} \left[ q\gamma x^*_{co,\lambda} - c \right] \frac{x^\beta_{co,\lambda}}{(x^*_{co,\lambda})^\beta_{co,\lambda}}.
\]

This can be solved to give

\[
x^*_{co,\lambda} = \frac{c(\lambda + q)(\alpha(\lambda + r) - \beta r)}{\gamma r(\lambda + r)(\alpha(\lambda + q) - \lambda - \beta q)}.
\]
Given the lower bounds on $x_{co,\lambda}$ of Lemma 4.2 it is clear from (4.7), (4.8) and the smooth fit at $x_{co,\lambda}$ that $v_{co,\lambda}^\gamma(x)$ is increasing and convex in $x$. Then, since \[ \lim_{x \to 0} v_{co,\lambda}^\gamma(x) = \frac{\gamma}{\lambda} > 0 , \quad \text{and} \quad \lim_{x \to \infty} \frac{v_{co,\lambda}^\gamma(x)}{x} = \frac{\lambda x}{\lambda + \eta} < \gamma \] it follows that $v_{co,\lambda}^\gamma$ crosses the line $\gamma x$ exactly once on $(0, \infty)$. In particular, $v_{co,\lambda}^\gamma(x) > \gamma x$ on $x \in (0, x_{co,\lambda})$ and $v_{co,\lambda}^\gamma(x) \leq \gamma x$ on $x \in [x_{co,\lambda}, \infty)$. Hence, $N_{x_{co,\lambda}} = \{ n \geq 1 : v_{co,\lambda}^\gamma(X_{T_n}^x) \leq \gamma X_{T_n}^x \}$.

Finally, consider $Y = (Y_n)_{n \geq 1}$ given by
\[ Y_n = \int_0^{T_n} e^{-ru_c} du + e^{-rT_n} \max\{v_{co,\lambda}^\gamma(X_{T_n}^x), \gamma X_{T_n}^x \} . \]

Using arguments similar to those in Theorem 1 of [1] it can be shown that $Y$ is a $\bar{G}$-supermartingale, and a $\bar{G}$-martingale when $n$ is replaced by $n \wedge N_{x_{co,\lambda}}$. In turn, for any $N \in \mathcal{N}(\lambda)$,
\[ \max\{v_{co,\lambda}^\gamma(X_{T_1}^x), \gamma X_{T_1}^x \} \geq E X_{T_1}^x \left[ \int_{T_1}^{T_N} e^{-r(u-T_1)} c du + e^{-r(T_N-T_1)} \max\{v_{co,\lambda}^\gamma(X_{T_n}^x), \gamma X_{T_n}^x \} \right] \]
\[ \geq E X_{T_1}^x \left[ \int_0^{T_N} e^{-ru_c} du + e^{-rT_N} \gamma X_{T_N}^x \right] . \]

Substituting the above inequality into the recursive equation (4.6) yields that
\[ v_{co,\lambda}^\gamma(x) \geq E X^x \left[ \int_0^{T_N} e^{-ru_c} du + e^{-rT_N} \gamma X_{T_N}^x \right] . \]

The above inequality will become an equality with $N = N_{x_{co,\lambda}}$. This proves the optimality of $T_{N_{x_{co,\lambda}}}$. \[ \square \]

Lemma 4.2 implies that the whole region $(0, \infty)$ can be divided into the continuation region $(0, x_{co,\lambda})$ and the stopping region $[x_{co,\lambda}, \infty)$. Furthermore, we have the following properties of the value function $v_{co,\lambda}^\gamma(x)$ and the optimal stopping time $\tau^\gamma$.

**Corollary 4.3.** Suppose that $r > 0$ and $q > 0$ and that the surrender price satisfies $K \geq \gamma x_{co,\lambda}$. Then, the value function satisfies $v_{co,\lambda}^\gamma(x) \leq K$ for $x \leq x_{co,\lambda}$.

**Proof.** Since $v_{co,\lambda}^\gamma(x)$ is increasing in $x$, we have $v_{co,\lambda}^\gamma(x) \leq v_{co,\lambda}^\gamma(x_{co,\lambda})$ for $x \leq x_{co,\lambda}$. On the other hand, by the value matching at $x_{co,\lambda}$, we have $v_{co,\lambda}^\gamma(x_{co,\lambda}) = \gamma x_{co,\lambda}$. The conclusion then follows from the assumption $\gamma x_{co,\lambda} \leq K$. \[ \square \]

**Proposition 4.4.** The value function satisfies the dynamic programming equation
\[ (4.9) \quad v_{co,\lambda}^\gamma(x) = E X^x \left[ \int_0^\eta e^{-ru_c} du + e^{-r\eta} v_{co,\lambda}^\gamma(X_\eta^x) \mathbb{1}_{\{\eta < \tau^\gamma\}} + e^{-r\tau^\gamma} \gamma X_{\tau^\gamma}^x \mathbb{1}_{\{\tau^\gamma = \eta\}} \right] \]

for any $x \in \mathcal{R}(\lambda)$ with $x \leq \tau^\gamma$.

**Proof.** First, integration by parts yields
\[ v_{co,\lambda}^\gamma(x) = \frac{c}{r} + E X^x \left[ e^{-r\tau^\gamma} \left( \gamma X_{\tau^\gamma}^x - \frac{c}{r} \right) \right] . \]

Next, for any stopping time $\eta \in \mathcal{R}(\lambda)$ with $\eta \leq \tau^\gamma$, by conditioning on $X_\eta^x$, we have
\[ v_{co,\lambda}^\gamma(x) = \frac{c}{r} + E X^x \left[ e^{-r\eta} E X_\eta^x \left[ e^{-r(\tau^\gamma - \eta)} \left( \gamma X_{\tau^\gamma}^x - \frac{c}{r} \right) \right] \right] \]
\[ = \frac{c}{r} + E X^x \left[ e^{-r\eta} \left\{ \mathbb{1}_{\{\eta < \tau^\gamma\}} E X_\eta^x \left[ e^{-r(\tau^\gamma - \eta)} (\gamma X_{\tau^\gamma}^x - \frac{c}{r}) \right] + \mathbb{1}_{\{\eta = \tau^\gamma\}} \left( \gamma X_{\tau^\gamma}^x - \frac{c}{r} \right) \right\} \right] \]
\[ = \frac{c}{r} + E X^x \left[ e^{-r\eta} \left\{ \mathbb{1}_{\{\eta < \tau^\gamma\}} \left( v_{co,\lambda}^\gamma(X_\eta^x) - \frac{c}{r} \right) + \mathbb{1}_{\{\eta = \tau^\gamma\}} \left( \gamma X_{\tau^\gamma}^x - \frac{c}{r} \right) \right\} \right] . \]
Then, the dynamic programming equation \((4.9)\) follows since \(\int_0^\infty e^{-ru} \, du = \frac{1}{r}(1 - e^{-r\eta})\).

### 4.2. Optimal stopping of the firm.

For \(K \in (\frac{r}{\gamma}, \gamma x_{ca,\lambda}^*)\), consider the following optimal stopping problem

\[
(4.10) \quad v^\lambda_f(x) = \inf_{\sigma \in \mathcal{R}(\lambda), \sigma \leq T_{N_{K/\gamma}}} \mathbb{E}^x \left[ \int_0^\sigma e^{-ru} \, du + e^{-r\sigma} \max\{\gamma X_{\sigma}^f, K\} \right],
\]

where \(N_y\) is as defined in \((4.3)\). Taking the perspective of the firm we aim to find \(\sigma\) to minimize the modified expected discounted payoff of the bondholder, where the bondholder is not allowed to make any stopping decisions, except that at \(\sigma\) the bondholder may choose to preempt and to receive shares in preference to a cash payment. In line with \((4.2)\), the optimal stopping problem \((4.10)\) also has an equivalent formulation

\[
(4.11) \quad v^\lambda_f(x) = \inf_{N \in \mathcal{N}(\lambda), N \leq N_{K/\gamma}} \mathbb{E}^x \left[ \int_0^{TN} e^{-ru} \, du + e^{-rT_{N}} (K \mathbb{1}_{\{N < N_{K/\gamma}\}} + \gamma X_{T_{N_{K/\gamma}}}^f \mathbb{1}_{\{N = N_{K/\gamma}\}}) \right],
\]

where we used the stopping condition that the bond is forced to stop at \(T_{N_{K/\gamma}}\), and that \(\gamma X_{T_{N_{K/\gamma}}}^f < K\) if \(N < N_{K/\gamma}\).

**Lemma 4.5.** Suppose that \(r > 0\), \(q > 0\) and \(K \in (\frac{r}{\gamma}, \gamma x_{ca,\lambda}^*)\). Then, the value function \(v^\lambda_f(x)\) has the explicit expression

\[
(4.12) \quad v^\lambda_f(x) = \begin{cases} 
\frac{1}{\lambda + r} \left( x - \frac{K}{\gamma} \right)^2, & 0 < \frac{K}{\gamma} < x; \\
\frac{1}{\lambda + r} \left( x - \frac{K}{\gamma} \right)^2 + A + B \left( \frac{\gamma x_{ca,\lambda}^*}{\gamma x_{ca,\lambda}^*} \right)^2, & x \leq \frac{K}{\gamma} < x; \\
\frac{1}{\lambda + r} \left( x - \frac{K}{\gamma} \right)^2 + C, & x < \frac{K}{\gamma}; \\
\frac{1}{\lambda + r} \left( x - \frac{K}{\gamma} \right)^2 + D, & x \leq \frac{K}{\gamma}; \\
\frac{1}{\lambda + r} \left( x - \frac{K}{\gamma} \right)^2 + E, & x < \frac{K}{\gamma};
\end{cases}
\]

where the unknowns \(A, B, C\) and the optimal threshold \(x_{ca,\lambda}^*\) are given by

\[
(4.13) \quad A = \frac{K - \frac{r}{\gamma}}{\alpha - \beta}, \quad \alpha - \beta > 0; \\
(4.14) \quad B = \frac{K - \frac{r}{\gamma}}{\alpha - \beta} \left( \frac{\gamma x_{ca,\lambda}^*}{\gamma x_{ca,\lambda}^*} \right), \quad \alpha - \beta < 0; \\
(4.15) \quad x_{ca,\lambda}^* = \frac{K}{\gamma} \left( \frac{1}{(K - \frac{r}{\gamma})} \frac{\lambda + r}{\alpha - \beta} \right) - \frac{\lambda K}{\alpha - \beta} \left( \frac{1 - (r - q)\beta}{\alpha - \beta} \right)^{-1}; \\
(4.16) \quad C = \frac{\alpha \lambda}{\beta} \left( \frac{K}{\gamma x_{ca,\lambda}^*} \right)^{\alpha - \beta} + B \left( \frac{K}{\gamma x_{ca,\lambda}^*} \right)^{\beta - \frac{\lambda K}{\beta}} - \frac{\lambda K}{\alpha - \beta} \left( \frac{1}{\alpha - \beta} \right).
\]

The optimal stopping time for \((4.10)\) is given by \(\sigma^* = T_{N_{K/\gamma}}\) with \(N_o\) defined in \((4.9)\).

The optimal threshold \(x_{ca,\lambda}^*\) for this problem will turn out to be an optimal threshold for the callable convertible bond with liquidity constraint (for moderate values of surrender value \(K\)) which justifies the subscripts \(ca\) and \(\lambda\).

**Proof.** Similar to Lemma \((4.2)\), it can be shown that the value function \(v^\lambda_f(x)\)
satisfies the recursive equation
\[
v^*_f(x) = \mathbb{E}^x \left[ \int_0^{T_1} e^{-ru} c \, du + e^{-rT_1} (\min\{v^*_f(X^T_0), K\} \mathbb{1}_{\{X_{T_1} < K/\gamma\}} + \gamma X^T_0 \mathbb{1}_{\{X_{T_1} \geq K/\gamma\}}) \right]
\]
which in turn implies that \(v^*_f(x)\) is a solution of the HJB equation
\[
\mathcal{L}_\lambda V + c + \lambda (\min\{V(x), K\} \mathbb{1}_{\{x < K/\gamma\}} + \gamma x \mathbb{1}_{\{x \geq K/\gamma\}}) = 0.
\]
Moreover, \(v^*_f\) is bounded at zero and of linear growth.

To solve the above equation, we first consider \(x < K/\gamma\). For small \(x\), we expect that the firm will continue, so \(v^*_f < K\) and \(v^*_f\) solves \(\mathcal{L}_\lambda V + c = 0\) subject to \(V(0) = \frac{c}{\gamma}\).

For moderate \(x\), we expect that the firm will choose to call, so \(v^*_f > K\) and \(v^*_f\) solves \(\mathcal{L}_\lambda V + (c + \lambda K) = 0\). Next, we consider \(x \geq K/\gamma\). The firm will be forced to stop in this situation, so \(v^*_f\) solves \(\mathcal{L}_\lambda V + (c + \lambda K x) = 0\) subject to \(V\) being of linear growth.

The boundary between small and moderate \(x\) occurs at \(x\) where \(V(x) = K\). The boundary between moderate and large \(x\) occurs at \(x\) where \(\gamma x = K\). We expect value matching and first order smooth fit at both boundaries, which lead to the expression (4.12) and (writing \(\theta = \frac{K}{\gamma x_{ca,\lambda}}\), the four algebraic equations

\[
(4.18) \quad K = \frac{c + \lambda K}{\lambda + r} + A + B;
\]
\[
(4.19) \quad \left( K - \frac{c}{\gamma} \right) \frac{\alpha}{x_{ca,\lambda}} = A \frac{\alpha}{x_{ca,\lambda}} + B \frac{\beta}{x_{ca,\lambda}};
\]
\[
(4.20) \quad \frac{c + \lambda K}{\lambda + r} + A \theta^\alpha + B \theta^\beta = \frac{c}{\lambda + r} + \frac{\lambda K}{\lambda + q} + C;
\]
\[
(4.21) \quad \frac{\gamma}{K} A \theta^\alpha + \frac{\gamma}{K} B \theta^\beta = \frac{\lambda \gamma}{\lambda + q} + C \beta \gamma.
\]

We next solve (4.18)-(4.21). Multiplying (4.19) by \(x^*_{ca,\lambda}\) eliminates \(x^*_{ca,\lambda}\), and then (4.18) and the modified (4.19) can be solved to give expressions for \(A\) and \(B\) in (4.13) and (4.14), respectively. Note that since \(K > \frac{c}{\gamma}\) we have \(A > 0\) and \(B < 0\) by Lemma 3.2 (4.20) and (4.21) can then be solved for \(C\) and \(\theta\). Indeed, we have
\[
C = \frac{\lambda K (q - r)}{(\lambda + r)(\lambda + q)} + A \theta^\alpha + B \theta^\beta = \frac{A \theta^\alpha}{\beta} + B \theta^\beta - \frac{\lambda K}{\lambda + q} \frac{1}{\beta}.
\]

We can use the last equality to find \(x^*_{ca,\lambda}\) given in (4.15), and then this gives \(C\) in (4.16).

We are left to show \(x^*_{ca,\lambda} < \frac{c}{\gamma}, \) \(v^*_f(x) < K\) on \(x \in (0, x^*_{ca,\lambda})\) and \(v^*_f(x) > K\) on \(x \in (x^*_{ca,\lambda}, \infty)\). The first statement will be proved in Proposition 4.6 below. The second and third statements follow from the increasing property of \(v^*_f(x)\) in \(x\) and the value matching condition \(v^*_f(x^*_{ca,\lambda}) = K\). (In particular, it is easily checked that \(\frac{d}{dx} v^*_f > 0\) on \((0, x^*_{ca,\lambda})\) \(\cup (x^*_{ca,\lambda}, K/\gamma)\), where for the second statement we use that \(A \theta^\alpha > 0\) and \(B \theta^\beta > 0\). Finally, on \((K/\gamma, \infty)\) we have that, irrespective of the sign \(C, \) \(\frac{d}{dx} v^*_f\) is monotonic in \(x\), since the values of the derivative are positive at both ends of the interval, it must be positive throughout.) The three statements then imply that
\[
N_{x^*_{ca,\lambda}} = \{n \geq 1 : v^*_f(X^n_T) \geq K\} \leq N_{K/\gamma}.
\]
Finally, note that
\[
\left(\int_0^{T_n} e^{-ru}cdu + e^{-rT_n} \min\{v^*_N(X_{T_n}^{\pi}), K\} \mathbb{I}_{\{n < N_{K/\gamma}\}} + \gamma X_{T_n}^{\pi} \mathbb{I}_{\{n = N_{K/\gamma}\}}\right)_{1 \leq n \leq N_{K/\gamma}}
\]
is a \(\tilde{G}\)-submartingale, and a \(\tilde{G}\)-martingale with \(n\) replaced by \(n \wedge N_{x^{*}_{ca,\lambda}}\). The proof is similar to the one in Lemma 4.2 (see also Theorem 1 in [3]), and is therefore omitted. In turn, for any \(N \in \mathcal{N}(\lambda)\) such that \(N \leq N_{K/\gamma}\), since \(\{1 < N_{K/\gamma}\} = \{X_{T_1} < K/\gamma\}\), by the submartingale property we have
\[
\min\{v^*_N(X_{T_n}^{\pi}), K\} \mathbb{I}_{\{X_{T_n} < K/\gamma\}} + \gamma X_{T_n}^{\pi} \mathbb{I}_{\{X_{T_n} \geq K/\gamma\}}
\]
\[
\leq \mathbb{E}^{X_{T_1}} \left[ \int_{T_1}^{T_n} e^{-r(u-T_1)}cdu + e^{-r(T_n-T_1)} \min\{v^*_N(X_{T_n}^{\pi}), K\} \mathbb{I}_{\{N < N_{K/\gamma}\}} + \gamma X_{T_n}^{\pi} \mathbb{I}_{\{N = N_{K/\gamma}\}} \right]
\]
\[
\leq \mathbb{E}^{X_{T_1}} \left[ \int_{T_1}^{T_n} e^{-r(u-T_1)}cdu + e^{-r(T_n-T_1)} (K \mathbb{I}_{\{N < N_{K/\gamma}\}} + \gamma X_{TN_{K/\gamma}}^{\pi} \mathbb{I}_{\{N = N_{K/\gamma}\}}) \right].
\]

Substituting the above inequality into the recursive equation (4.17) yields that
\[
v^*_N(x) \leq \mathbb{E}^{x} \left[ \int_0^{T_n} e^{-ru}cdu + e^{-rT_n} (K \mathbb{I}_{\{N < N_{K/\gamma}\}} + \gamma X_{TN_{K/\gamma}}^{\pi} \mathbb{I}_{\{N = N_{K/\gamma}\}}) \right].
\]
The above inequality turns out to be an equality with \(N = N_{x^{*}_{ca,\lambda}}\), which shows the optimality of \(T_{N_{x^{*}_{ca,\lambda}}}\).

Lemma 4.5 implies that the whole region \((0, \infty)\) can be divided into the continuation region \((0, x^{*}_{ca,\lambda})\) and the stopping region \([x^{*}_{ca,\lambda}, \infty)\). The next proposition provides a relationship between the optimal thresholds \(x^{*}_{ca,\lambda}\) in Lemma 4.2 and \(x^{*}_{ca,\lambda}\) in Lemma 4.3, which also completes the proof of Lemma 4.5.

**Proposition 4.6.** Suppose that \(r > 0, q > 0\) and \(K \in (\frac{q}{\gamma}, \gamma x^{*}_{ca,\lambda})\). Then, \(x^{*}_{co,\lambda} > \frac{K}{\gamma}\) if and only if \(x^{*}_{ca,\lambda} < \frac{K}{\gamma}\).

**Proof.** Recall the definition \(\theta = \frac{K}{\gamma x^{*}_{ca,\lambda}}\). Hence, \(x^{*}_{ca,\lambda} < \frac{K}{\gamma}\) is equivalent to \(\theta > 1\).

In turn, (4.10) implies
\[
\theta > 1 \iff \frac{1}{A(\alpha - \beta)} - \frac{\lambda q}{\lambda + q} \left(1 - \frac{(r - q)\beta}{\lambda + r}\right) > 1
\]
\[
\iff \left(\frac{\lambda K}{\lambda + q} - \frac{\lambda q}{\lambda + r} \right) \left(K - \frac{c}{r}\right) < \frac{\lambda K}{\lambda + q} \left(1 - \frac{(r - q)\beta}{\lambda + r}\right)
\]
\[
\iff (\lambda + r)K[\alpha(\lambda + r) - \lambda q\beta] < \frac{c}{r}[\lambda + q][\alpha(\lambda + r) - \lambda q\beta].
\]

On the other hand, it follows from (4.12) that this is equivalent to \(x^{*}_{co,\lambda} > \frac{K}{\gamma}\).

**Proposition 4.7.** Suppose that \(r > 0, q > 0\) and \(K \in (\frac{q}{\gamma}, \gamma x^{*}_{ca,\lambda})\). Then, the value function satisfies \(v^*_N(x) \geq \gamma x\) for \(x \leq x^{*}_{ca,\lambda}\).

**Proof.** Note that \(v^*_N(x)\) is increasing in \(x\), \(v^*_N(0) = \frac{q}{\gamma} > 0\) and \(v^*_N(x^{*}_{ca,\lambda}) = K > \gamma x^{*}_{ca,\lambda}\), so it is sufficient to show that \(v^*_N\) does not cross \(\gamma x\) on \((0, x^{*}_{ca,\lambda}]\). In turn, this
will follow if \( (v^J)’(y) < \gamma \) at any crossing point \( y \in (0, x_{ca,\lambda}^*) \) — then \( v^J \) may cross down below \( \gamma x \) but cannot cross back above.

Let \( y \in (0, x_{ca,\lambda}^*) \) be such that \( v^J(y) = \gamma y \). Then \( \hat{\gamma} + (K - \hat{\gamma}) \left( \frac{y}{x_{ca,\lambda}^*} \right)^{\alpha} = \gamma y \) and

\[
(v^J)’(y) < \gamma \Leftrightarrow \frac{\alpha}{y} \left( \gamma y - \frac{c}{r} \right) < \gamma \Leftrightarrow y < \frac{\alpha}{\gamma - \frac{c}{r}}.
\]

The last inequality in the above follows from Lemma 4.1 since we have \( y < x_{ca,\lambda}^* < \frac{K}{\gamma} < x_{co,\lambda}^* < ? \). This proves the claim \( \blacksquare \).

To conclude this section, we provide the dynamic programming equation for the optimal stopping problem (4.10). The proof follows along similar arguments in Proposition 4.4 and is thus omitted.

**Proposition 4.8.** The value function satisfies the dynamic programming equation

\[
(4.22)
\]

\[
v^J(x) = \mathbb{E}^x \left[ \int_0^{\sigma^\tau} e^{-ru}cdu + e^{-r\sigma^*} \max \{ \gamma X_{\sigma^*}, K \} \mathbb{I}_{\sigma^* = \eta} + e^{-r\eta}v^J(X_{\eta}) \mathbb{I}_{\eta < \sigma^*} \right].
\]

for any \( \eta \in \mathcal{R}(\lambda) \) with \( \eta < \sigma^* \).

5. **Pricing the callable convertible bond.** We divide our analysis into three cases according to the value of the surrender price \( K \). Observe that \( \int_0^\infty e^{-ru}cdu = \hat{\xi} \) is the value of the corresponding perpetuity if the bond is never converted nor called.

Define \( J^x \) and \( \tilde{J}^x \) by

\[
(5.1) \quad J^x(\sigma, \tau) = \mathbb{E}^x \left[ \int_0^{\sigma^\tau} e^{-ru}cdu + e^{-r\tau} \gamma X_{\tau}^{\sigma^*} \mathbb{I}_{\tau \leq \sigma} + e^{-r\tau} K \mathbb{I}_{\sigma < \tau} \right].
\]

and

\[
(5.2) \quad \tilde{J}^x(\sigma, \tau) = \mathbb{E}^x \left[ \int_0^{\sigma^\tau} e^{-ru}cdu + e^{-r\tau} \gamma X_{\tau}^{\sigma^*} \mathbb{I}_{\tau \leq \sigma} + e^{-r\tau} \max \{ \gamma X_{\tau}^\sigma, K \} \mathbb{I}_{\sigma < \tau} \right].
\]

5.1. **Case \( K \leq \hat{\xi} \).** In this case, since the surrender price \( K \) is smaller than the corresponding perpetuity value \( \hat{\xi} \), the firm will choose to call at the first opportunity. On the other hand, the bondholder will preempt the firm’s stopping action by converting the bond if \( \gamma X_{T_1} > K \).

**Theorem 5.1.** Suppose that \( r > 0, q > 0 \) and \( K \leq \hat{\xi} \). Then, \( (\sigma^*, \tau^*) = (T_1, T_{N_{K/\gamma}}) \) is a saddle point for \( J^x \) in (3.3)-(3.4), and the game value is given by

\[
(5.3) \quad v^J_{ca}(x) = \begin{cases} \frac{\alpha K}{\lambda + r} + A \left( \frac{\alpha}{\lambda + r} \right)^{\alpha}, & x < K/\gamma; \\ \frac{c}{\lambda + r} + \frac{\lambda \gamma}{\lambda + q} + B \left( \frac{\lambda}{\lambda + q} \right)^{\beta}, & x \geq K/\gamma, \end{cases}
\]

with \( A > 0 \) and \( B > 0 \) given by

\[
A = \frac{(\lambda + r) - \beta_\lambda (r - q)}{(\alpha_\lambda - \beta_\lambda)} \frac{\lambda K}{(\alpha_\lambda - \beta_\lambda)}; \quad B = \frac{(\lambda + r) - \alpha_\lambda (r - q)}{(\alpha_\lambda - \beta_\lambda)} \frac{\lambda K}{(\alpha_\lambda - \beta_\lambda)}.
\]
Proof. The signs of $A$ and $B$ follow from Lemma 5.1. For the main result it is sufficient to verify the conditions (i)-(iii) in Corollary 2.4 to show $(\sigma^*, \tau^*)$ is a saddle point for $J^z$ in (5.3)-(5.4) where $J^z$ and $\tilde{J}^z$ are as in (5.1) and (5.2) respectively.

First, we apply integration by parts to $\tilde{J}^z$ to obtain

$$
\tilde{J}^z(\sigma^*, \tau^*) = \frac{c}{r} + E^z \left[ e^{-rT_1} \left\{ h(\gamma X^z_{\tau^*}) 1_{\{\tau^*=T_1\}} + h(\max\{\gamma X^z_{T_1}, K\}) 1_{\{\tau^*>T_1\}} \right\} \right]
$$

where to save space we write $h(z) = z - \xi$. By the definitions of $T_{N_K/\gamma}$, $\max\{\gamma X^z_{T_1}, K\} = K$ on the event $\{\tau^*>T_1\}$. Hence,

$$
\tilde{J}^z(\sigma^*, \tau^*) = \frac{c}{r} + E^z \left[ e^{-rT_1} \left\{ h(\gamma X^z_{\tau^*}) 1_{\{\tau^*=T_1\}} + h(K) 1_{\{\tau^*>T_1\}} \right\} \right]
$$

which verifies (i). To show (ii), for any $\tau \in \mathcal{R}(\lambda)$, we have

$$
\tilde{J}^z(\sigma^*, \tau) = \frac{c}{r} + E^z \left[ e^{-rT_1} \left\{ h(\gamma X^z_{\tau^*}) 1_{\{\tau^*=T_1\}} + h(\max\{\gamma X^z_{T_1}, K\}) 1_{\{\tau^*>T_1\}} \right\} \right]
$$

Then, (ii) follows by observing that

$$
\tilde{J}^z(\sigma^*, \tau^*) = J^z(\sigma^*, \tau^*) = \frac{c}{r} + E^z \left[ e^{-rT_1} \left( \max\{\gamma X^z_{T_1}, K\} - \frac{c}{r} \right) \right].
$$

For (iii), we have, for any $\sigma \in \mathcal{R}(\lambda)$,

$$
J^z(\sigma, \tau^*) = \frac{c}{r} + E^z \left[ e^{-r(\sigma^\wedge \tau^*)} \left\{ h(\gamma X^z_{\tau^*}) 1_{\{\tau^*\leq\sigma\}} + h(K) 1_{\{\tau^*>\sigma\}} \right\} \right]
$$

$$
= \frac{c}{r} + E^z \left[ 1_{\{\tau^*=T_1\}} e^{-rT_1} h(\gamma X^z_{T_1}) 1_{\{\tau^*\leq\sigma\}} + 1_{\{\tau^*>T_1\}} e^{-r(\tau^*-T_1)} h(\gamma X^z_{\tau^*}) 1_{\{\tau^*\leq\sigma\}} + e^{-r(\tau^*-T_1)} h(K) 1_{\{\tau^*>\sigma\}} \right].
$$

Since $\gamma X^z_{T_1} \geq K$ and $K - \frac{c}{r} \geq 0$, we further obtain

$$
J^z(\sigma, \tau^*) \geq \frac{c}{r} + E^z \left[ 1_{\{\tau^*=T_1\}} e^{-rT_1} \left( \gamma X^z_{T_1} - \frac{c}{r} \right) + 1_{\{\tau^*>T_1\}} e^{-rT_1} \left( K - \frac{c}{r} \right) \right]
$$

which verifies (iii).

To calculate the game value $v^\lambda_{ga}(x) = J^z(\sigma^*, \tau^*)$ in (5.4), we may use the exponential distribution of $T_1$ to rewrite (5.4) as

$$
v^\lambda_{ga}(x) = E^x \left[ \int_0^\infty e^{-(r+\lambda)u} (c + \gamma \max\{\gamma X^z_u, K\}) du \right].
$$

which, in turn, implies that $v^\lambda_{ga}(x)$ is the solution of the following HJB equation

$$
L_x V + c + \gamma \max\{\gamma x, K\} = 0
$$
such that $V$ is bounded at zero, and of linear growth at infinity. It is immediate that, on $[0, K/\gamma)$

$$V(x) = \frac{c + \lambda K}{\lambda + r} + A \left(\frac{\gamma x}{K}\right)^{\alpha \lambda} ,$$

and on $[K/\gamma, \infty)$

$$V(x) = \frac{c}{\lambda + r} + \frac{\lambda \gamma x}{\lambda + q} + B \left(\frac{\gamma x}{K}\right)^{\beta \lambda} .$$

where $A$ and $B$ are constants to be determined. Value matching and first order smooth fit at $K/\gamma$ give that $A$ and $B$ solve

$$\frac{\lambda K}{\lambda + r} + A = \frac{\lambda K}{\lambda + q} + B;$$

$$A \alpha \lambda \frac{\gamma x}{K} = \frac{\lambda \gamma}{\lambda + q} + B \beta \lambda \frac{\gamma}{K},$$

which yield the expressions of $A$ and $B$ in the theorem, and we conclude. \(\Box\)

**Fig. 5.1.** The convertible bond value $v_{ca}^\lambda$ for Case $K \leq \gamma x^*.$

**5.2. Case $\gamma x^* < K < \gamma x_{co,\lambda}^*.$** In this case, since the surrender price is larger than the value of the perpetuity, the firm will not seek to call the bond when the stock price is low; nor will the bondholder seek to convert in this case. Conversely, when the stock price is large both the firm will seek to call, and the bondholder will seek to convert, with the bondholder’s action taking precedence. Finally, when the stock price is moderate the firm will seek to call. The bondholder would prefer that the bond is not called and would not choose to convert of their own volition, but, given that the bond is being called, may elect to convert.

In particular, there are no circumstances where the bondholder wants to convert and the firm does not want to call. Hence the game option reduces to an optimal stopping problem for the firm (subject only to the fact that the bondholder may choose to pre-empt the call to receive $\gamma X^*_t$ rather than $K.$) The resulting optimal stopping problem is precisely the problem we studied in Section 12. Then $\sigma^* = T_{X^*_{co,\lambda}}$ is the candidate optimal stopping time of the firm. Moreover, Proposition 14.7 implies that in the continuation region (for the firm), the value function $v^\lambda_f(x)$ dominates
the conversion payoff $\gamma x$. This confirms that indeed, there is no incentive for the bondholder to convert even if they were given such an opportunity. Instead, if we define another stopping time $\tau^* = T_{N_{K/\gamma}}$, then since $K/\gamma > x^*_{ca,\lambda}$ we have that

$$\tau^* = T_{N_{K/\gamma}} \geq T_{N_{x^*_{ca,\lambda}}} = \sigma^*.$$  

The idea is to show in that $(\sigma^*, \tau^*)$ is a saddle point for $J$ in (5.6). 

**Theorem 5.2.** Suppose that $r > 0$, $q > 0$ and $\frac{r}{\bar{d}} < K < \gamma x^*_{ca,\lambda}$. Then, $(\sigma^*, \tau^*) = (T_{N_{x^*_{ca,\lambda}}}, T_{N_{K/\gamma}})$ is a saddle point for $J^x$ in (5.3), and the game value is given by $v^x_{\gamma}(x) = v^x_{\gamma}(x)$, with $v^x_{\gamma}(x)$ given in Lemma 4.7.

**Proof.** Recall the definitions of $J^x$ and $\tilde{J}^x$ from (5.1) and (5.2). We want to show that (i)-(iii) of Corollary 2.4 are satisfied.

By Proposition 4.4, we know that $x^*_{ca,\lambda} < K/\gamma$. This means $\sigma^* \leq \tau^*$. In turn, the definition of $T_{N_{K/\gamma}}$ implies that

$$\tilde{J}^x(\sigma^*, \tau^*) = \frac{c}{r} + E^x \left[ e^{-\sigma^* \gamma} \{ h(\gamma X^*_{\tau^*}) \mathbb{1}_{\{\tau^* = \sigma^*\}} + h(\max\{\gamma X^*_{\sigma^*}, K\}) \mathbb{1}_{\{\tau^* > \sigma^*\}} \} \right]$$

$$= \frac{c}{r} + E^x \left[ e^{-\sigma^* \gamma} \{ h(\gamma X^*_{\tau^*}) \mathbb{1}_{\{\tau^* = \sigma^*\}} + h(K) \mathbb{1}_{\{\tau^* > \sigma^*\}} \} \right] = J^x(\sigma^*, \tau^*).$$

Moreover, integration by parts yields

$$J^x(\sigma^*, \tau^*) = \frac{c}{r} + E^x \left[ e^{-\gamma \sigma^*} \left( \max\{\gamma X^*_{\sigma^*}, K\} - \frac{c}{r} \right) \right]$$

$$= E^x \left[ \int_0^{\sigma^*} e^{-\gamma \sigma u} c du + e^{-\gamma \sigma^*} \max\{\gamma X^*_{\sigma^*}, K\} \right] = v^x_{\gamma}(x),$$

where we used Lemma 4.5 in the last equality. This shows condition (i) and that $v^x_{\gamma}(x)$ is the game value.

To verify condition (ii), note that, for any $\tau \in R(\lambda)$,

$$\tilde{J}^x(\sigma^*, \tau) = \frac{c}{r} + E^x \left[ e^{-\gamma (\sigma^* \wedge \tau)} \left( \gamma X^*_{\tau} \mathbb{1}_{\{\tau \leq \sigma^*\}} + \max\{K, \gamma X^*_{\tau}\} \mathbb{1}_{\{\tau < \sigma^*\}} - \frac{c}{r} \right) \right]$$

$$= \frac{c}{r} + E^x \left[ e^{-\gamma (\sigma^* \wedge \tau)} \left( \gamma X^*_{\tau} \mathbb{1}_{\{\tau < \sigma^*\}} + \gamma X^*_{\tau} \mathbb{1}_{\{\tau = \sigma^*\}} + \max\{K, \gamma X^*_{\tau}\} \mathbb{1}_{\{\sigma^* < \tau\}} - \frac{c}{r} \right) \right].$$

Using $X^*_{\tau} < x^*_{ca,\lambda}$ on the event $\{\tau < \sigma^*\}$, whence $\gamma X^*_{\tau} \leq v^x_{\gamma}(X^*_{\tau})$ on $\{\tau < \sigma^*\}$ by Proposition 4.7 we obtain

$$\tilde{J}^x(\sigma^*, \tau) \leq \frac{c}{r} + E^x \left[ e^{-\gamma \sigma^*} \{ h(\gamma X^*_{\tau}) \mathbb{1}_{\{\tau < \sigma^*\}} + e^{-\gamma \sigma^*} \{ h(\gamma X^*_{\tau}) \mathbb{1}_{\{\tau = \sigma^*\}} + h(\max\{K, \gamma X^*_{\tau}\}) \mathbb{1}_{\{\sigma^* < \tau\}} \} \right]$$

$$\leq \frac{c}{r} + E^x \left[ e^{-\gamma \sigma^*} \{ h(\gamma X^*_{\tau}) \mathbb{1}_{\{\tau < \sigma^*\}} + e^{-\gamma \sigma^*} \{ h(\gamma X^*_{\tau}) \mathbb{1}_{\{\tau = \sigma^*\}} + \max\{K, \gamma X^*_{\tau}\} \mathbb{1}_{\{\sigma^* < \tau\}} \} \right]$$

$$= E^x \left[ \int_0^{\sigma^*} e^{-\gamma \sigma u} c du + e^{-\gamma \sigma^*} v^x_{\gamma}(X^*_{\tau}) \mathbb{1}_{\{\tau < \sigma^*\}} + e^{-\gamma \sigma^*} \max\{\gamma X^*_{\sigma^*}, K\} \mathbb{1}_{\{\sigma^* < \tau\}} \right]$$

$$= v^x_{\gamma}(x),$$

where the last equality follows from Proposition 4.8 with $\eta = \sigma^* \wedge \tau$. Then

$$\tilde{J}^x(\sigma^*, \tau) \leq v^x_{\gamma}(x) = J(\sigma^*, \tau^*) = \tilde{J}(\sigma^*, \tau^*),$$

$$J(\sigma^*, \tau^*) = J^x(\sigma^*, \tau^*) = \tilde{J}(\sigma^*, \tau^*),$$

$$\tilde{J}(\sigma^*, \tau^*) = J(\sigma^*, \tau^*).$$
Callable convertible bonds under liquidity constraints

where we used (5.6) in the second last equality.

Next we prove (iii). Let \( \sigma \in R(\lambda) \). With \( \hat{\sigma} := \sigma \wedge \tau^* \), and using \( \gamma X_{\hat{\sigma}} \geq K \) so that \( \gamma X_{\hat{\sigma}} \mathbb{1}_{(\sigma = \tau^*)} + K \mathbb{1}_{(\sigma < \tau^*)} = \max \{ \gamma X_{\hat{\sigma}}, K \} \), we have

\[
J_x^x(\sigma, \tau^*) = \frac{c}{r} + E^x \left[ e^{-\lambda(\sigma \wedge \tau^*)} \left( \gamma X_{\hat{\sigma}} \mathbb{1}_{(\sigma \geq \tau^*)} + K \mathbb{1}_{(\sigma < \tau^*)} - \frac{c}{r} \right) \right]
\]

\[
= \frac{c}{r} + E^x \left[ e^{-\lambda \hat{\sigma}} \left( \gamma X_{\hat{\sigma}} \mathbb{1}_{(\hat{\sigma} = \tau^*)} + K \mathbb{1}_{(\hat{\sigma} < \tau^*)} - \frac{c}{r} \right) \right]
\]

\[
= \frac{c}{r} + E^x \left[ e^{-\lambda \hat{\sigma}} \left( \max \{ \gamma X_{\hat{\sigma}}, K \} - \frac{c}{r} \right) \right].
\]

By (4.10) and Lemma 4.5, we further have

\[
J_x^x(\sigma, \tau^*) \geq \inf_{\eta \in R(\lambda), \eta \leq T_{NK/\gamma}} E^x \left[ \int_0^{\eta} e^{-ru} d\eta + e^{-r \eta} \max \{ \gamma X_{\eta}, K \} \right]
\]

\[
= v_{\lambda}^x(\eta) = J_x^x(\sigma^*, \tau^*),
\]

where we used (5.6) in the last equality. This completes the proof. \( \square \)

---

**Fig. 5.2. The convertible bond value \( v_{\lambda}^x \) for Case \( \frac{c}{r} < K < \gamma x^*_{co,\lambda} \).**

### 5.3. Case \( K \geq \gamma x^*_{co,\lambda} \)

In this case, since the surrender price is very high, the firm will postpone their call time to avoid paying \( K \) unless the stock price is very high. On the other hand, in the region where the firm does want to call, the bondholder already wants to convert, and therefore, the callable feature has no impact. This means that the game problem for a callable convertible bond reduces to an optimal stopping problem without the callable feature, i.e. the first auxiliary problem we studied in Section 4.

Recall that in Section 4.1 we defined the (optimal) stopping time \( \tau^* = T_{N_{x^*_{co,\lambda}}} \).

Now define another stopping time \( \sigma^* = T_{N_{x}} \) where the level \( z \) is such that \( v_{\lambda}^{x_{co}}(z) = K \).

Since \( \frac{K}{\gamma} \geq x^*_{co,\lambda} \), \( \frac{K}{\gamma} \) is in the stopping region, meaning that \( v_{\lambda}^{x_{co}}(\frac{K}{\gamma}) \leq \gamma \frac{K}{\gamma} = K \). In turn, \( z \geq \frac{K}{\gamma} \geq x^*_{co,\lambda} \), and

\[
\tau^* = T_{N_{x^*_{co,\lambda}}} \leq T_{N_{x}} = \sigma^*.
\]
THEOREM 5.3. Suppose that $r > 0$, $q > 0$ and $K \geq \gamma x_{co, \lambda}^\ast$. Let $z$ be such that $v_{co}^\lambda(z) = K$. Then, $(\sigma^\ast, \tau^\ast) = (T_{N_z}, T_{N_z, \co, \lambda}^\ast)$ is a saddle point for $J$ in (3.3)-(3.4), and the game value is given by $v_{co}^\lambda(x) = v_{co}^\lambda(x)$, with $v_{co}^\lambda(x)$ given in Lemma 4.2.

Proof. By (5.7), we know that $\tau^\ast \leq \sigma^\ast$. In turn, Lemma 4.2 implies that

$$J^\ast(\sigma^\ast, \tau^\ast) = \mathbb{E}^x \left[ \int_0^{\tau^\ast} e^{-ru} \mu du + e^{-r \tau^\ast} \gamma X_{\tau^\ast}^x \right]$$

(5.8)

This shows condition (i) and that $v_{co}^\lambda(x)$ is the game value.

Next, we verify condition (ii). Since $X_{\sigma^\ast}$ is in the stopping region of the optimal stopping problem (3.1), it follows that $K = v_{co}^\lambda(z) \leq v_{co}^\lambda(X_{\sigma^\ast}) \leq \gamma X_{\sigma^\ast}$. Hence, for any $\tau \in \mathcal{R}(\lambda)$,

$$J^\ast(\sigma^\ast, \tau) = \frac{c}{r} + \mathbb{E}^x \left[ e^{-r \tau} (\gamma X_{\tau}^x - \frac{c}{r}) \mathbb{I}_{\tau \leq \sigma^\ast} + e^{-r \sigma^\ast} \left( \max \{ K, \gamma X_{\sigma^\ast} \} - \frac{c}{r} \right) \mathbb{I}_{\tau > \sigma^\ast} \right]$$

$$\leq \frac{c}{r} + \mathbb{E}^x \left[ e^{-r \tau} (\gamma X_{\tau}^x - \frac{c}{r}) \mathbb{I}_{\tau \leq \sigma^\ast} + e^{-r \sigma^\ast} (\gamma X_{\sigma^\ast} - \frac{c}{r}) \mathbb{I}_{\tau > \sigma^\ast} \right]$$

$$= \frac{c}{r} + \mathbb{E}^x \left[ e^{-r (\tau \wedge \sigma^\ast)} (\gamma X_{\tau \wedge \sigma^\ast} - \frac{c}{r}) \mathbb{I}_{\tau \wedge \sigma^\ast} \right] \right].$$

It follows that

$$J^\ast(\sigma^\ast, \tau) \leq \sup_{\eta \leq 1} \mathbb{E}^x \left[ \int_0^\eta e^{-ru} \mu du + e^{-r \eta} \gamma X_{\eta}^x \right] = v_{co}^\lambda(x) = J^\ast(\sigma^\ast, \tau^\ast) = \tilde{J}^\ast(\sigma^\ast, \tau^\ast),$$

where we used (5.8) in the last two equalities.

Finally, using $X_{\sigma}^x < x_{co, \lambda}^\ast$ on the event $\{ \sigma < \tau^\ast \}$, whence $K \geq v_{co}^\lambda(X_{\sigma}^x)$ on $\{ \sigma < \tau^\ast \}$ by Corollary 4.3, we have

$$J^\ast(\sigma, \tau^\ast) = \frac{c}{r} + \mathbb{E}^x \left[ e^{-r (\tau \wedge \sigma)} \left( \gamma X_{\tau \wedge \sigma}^x, \mathbb{I}_{\tau \leq \sigma} + K \mathbb{I}_{\sigma < \tau^\ast} - \frac{c}{r} \right) \right]$$

$$\geq \frac{c}{r} + \mathbb{E}^x \left[ e^{-r (\tau \wedge \sigma)} \left( \gamma X_{\tau \wedge \sigma}^x, \mathbb{I}_{\tau \leq \sigma} + v_{co}^\lambda(X_{\sigma}^x) \mathbb{I}_{\sigma < \tau^\ast} - \frac{c}{r} \right) \right]$$

$$= \mathbb{E}^x \left[ \int_0^{\tau \wedge \sigma} e^{-ru} \mu du + e^{-r (\tau \wedge \sigma)} (\gamma X_{\tau \wedge \sigma}^x \mathbb{I}_{\tau \leq \sigma} + v_{co}^\lambda(X_{\sigma}^x) \mathbb{I}_{\sigma < \tau^\ast} \right]$$

for any $\sigma \in \mathcal{R}(\lambda)$. Then, using the dynamic programming equation (4.3) in Proposition 4.3 with $\eta = \sigma \wedge \tau^\ast$, we further have

$$J^\ast(\sigma, \tau^\ast) \geq v_{co}^\lambda(x) = J^\ast(\sigma^\ast, \tau^\ast)$$

where we used (5.8) in the last equality, which verifies condition (iii), and we conclude.
Callable convertible bonds under liquidity constraints

6. Comparison with convertible bonds with forced conversion/no liquidity constraints. In this section, we compare our results with two situations. The first one is with a forced conversion condition, and the second one is without liquidity constraints.

6.1. Comparison with convertible bonds with forced conversion. In [22], a forced conversion condition is introduced, i.e. the firm will force a conversion of the convertible bond to $\gamma$ shares of stock at the earliest Poisson arrival time after the stock price exceeds a predetermined threshold $K/\gamma$. By introducing the triggering and conversion times $H_{K/\gamma} := \inf\{u \geq 0 : X_u^x \geq K/\gamma\}$ and $T_M := \inf\{T_N \geq H_{K/\gamma} : N \geq 1\}$, the expected discounted payoff of the convertible bond at $H_{K/\gamma}$ can be calculated as

$$L^\lambda(X_{H_{K/\gamma}}^x) = \mathbb{E}^{X_{H_{K/\gamma}}^x} \left[ \int_{H_{K/\gamma}}^{T_M} e^{-r(u-H_{K/\gamma})} cdU + e^{-r(T_M-H_{K/\gamma})} \gamma X_{T_M}^x \right]$$

$$= c \frac{e^{\lambda r}}{r + \lambda} + \frac{\lambda q (\lambda + r)}{q (\lambda + r)} \gamma X_{H_{K/\gamma}}^x.$$ 

By introducing such a forced conversion condition, it is sufficient to solve the problem for $t \in [0, H_{K/\gamma})$, so the state space reduces from $x \in (0, \infty)$ to $x \in (0, K/\gamma]$ for which the upper payoff $U := K$ always dominates the lower payoff $L := \gamma x$ (so the existence theorem of constrained Dynkin games in [18] applies). See Chapter 2.5 in [22] for further details.

Although the forced conversion guarantees the order condition $L \leq U$, its drawback is significant: there is a possibility that the stock price $X_{T_M}^x$ drops below any small number $\varepsilon > 0$ when the forced conversion is taking place, i.e. $\mathbb{P}^x(X_{T_M}^x < \varepsilon) > 0$. Neither the firm nor the bondholder have incentive to stop in such a situation. In particular, the problem with forced conversion studied in [18] and [22] is not the true callable convertible bond problem as studied in this paper.

In the following table, we make a comparison between our results and the convertible bond with forced conversion in [22]. Note that ‘small’, ‘moderate’ and ‘large’ values of $K$ refer to different reference points in the two situations. They are $\frac{c}{r}$ and $\gamma x_{co,\lambda}^*$ without forced conversion, and $\frac{c}{r}$ and $\frac{c(\lambda + \rho)}{q(\lambda + r)}$ with forced conversion.

6.2. Comparison with convertible bonds without liquidity constraints.

Finally, we investigate the asymptotic behavior of the optimal stopping strategies and the convertible bond values when $\lambda \to \infty$. Intuitively, they will converge to their counterparts without liquidity constraints. Let us first recall a result from [24] (see also Proposition 7.1 in [18]) about the convertible bond without liquidity constraints.

Recall that $\alpha > 1$ is the positive root of $Q(z) = 0$ with $Q(z) = \frac{1}{2} \sigma^2 z^2 + (r - q - \frac{1}{2} \sigma^2) z - r$ and $H_y := \inf\{t \geq 0 : X_t \geq y\}$.

**Proposition 6.1.** Suppose that $r > 0$, $q > 0$ and that the admissible stopping times $\tau$ (of the firm) and $\sigma$ (of the bondholder) are chosen as $\mathbb{P}$-stopping times. Let

(6.1) $x^{*}_{co} := \left(\frac{\alpha}{\alpha - 1}\right) \frac{c}{\gamma r}$.

Then,

(i) Case $K \leq \frac{c}{\gamma}$: $(\sigma^*, \tau^*) = (0, H_{K/\gamma})$ and the convertible bond value is given as $v_{co}(x) = \max\{K, \gamma x\}$.

(ii) Case $\frac{c}{\gamma} < K < \gamma x^{*}_{co}$: $(\sigma^*, \tau^*) = (H_{K/\gamma}, H_{K/\gamma})$ and the convertible bond value is given as

$$v_{co}(x) = \begin{cases} \frac{c}{\gamma r} \left(\frac{x}{c}\right)^{\alpha} \left(\frac{K}{c} - \frac{x}{c}\right), & x < \frac{c}{\gamma}; \\ \gamma x, & x \geq \frac{c}{\gamma}. \end{cases}$$

(iii) Case $K \geq \gamma x^{*}_{co}$: $(\sigma^*, \tau^*) = (H_{K/\gamma}, H_{x^{*}_{co}})$ and the convertible bond value is given as

$$v_{co}(x) = \begin{cases} \frac{c}{\gamma r} \left(\frac{x}{x^{*}_{co}}\right)^{\alpha} \left(\frac{\gamma x^{*}_{co}}{x^{*}_{co}} - \frac{x}{x^{*}_{co}}\right), & x < x^{*}_{co}; \\ \gamma x, & x \geq x^{*}_{co}. \end{cases}$$

We conclude the paper with an asymptotic analysis for the case where the Poisson intensity $\lambda$ increases to $\infty$.

**Proposition 6.2.** When $\lambda \to \infty$, $x^{*}_{co, \lambda} \to x^{*}_{co}$, $x^{*}_{ca, \lambda} \to \frac{K}{\gamma}$, and $v_{co, \lambda}(x) \to v_{co}(x)$. Hence, the convertible bond with liquidity constraints will converge to its counterpart without liquidity constraints when $\lambda \to \infty$.

**Proof.** We prove the claims using Theorems 6.1-6.3 and Proposition 6.1. From the definitions of $\alpha_{\lambda}$ and $\beta_{\lambda}$ as roots of quadratics we have that as $\lambda \uparrow \infty$, $\alpha_{\lambda} \to \infty$, $\beta_{\lambda} \to \infty$, $\gamma_{\lambda} \to 1$, and $\gamma_{\lambda} - 1 \to 0$. This shows that the optimal stopping times and bond values converge to their counterparts without liquidity constraints as $\lambda \to \infty$. Therefore, the convertible bond with liquidity constraints will converge to its counterpart without liquidity constraints when $\lambda \to \infty$. 

Callable convertible bonds under liquidity constraints

$\frac{\partial \lambda}{\partial \lambda} \to 0, \beta_\lambda \to -\infty$ and $\frac{\partial \beta}{\partial \lambda} \to 0$. Moreover, from the expression for $x^*_{co,\lambda}$ in (6.1) and (6.1) we have $x^*_{co,\lambda} \to x^*_{co}$ and from Lemma 4.1, $x^*_{co,\lambda} < x^*_{co}$.

For Case $K \leq \frac{c}{c}$, from the properties of $\alpha_\lambda$ and $\beta_\lambda$ above we have $A, B \to 0$. Hence, $v^\lambda_{ca}(x) \to K$ for $x \leq K/\gamma$ and $v^\lambda_{ca}(x) \to \gamma x$ for $x > K/\gamma$, which means

$v^\lambda_{ca}(x) \to \max\{K, \gamma x\} = v_{ca}(x)$.

For Case $\frac{c}{c} < K < x^*_{co}$ we have that $K < x^*_{co,\lambda}$ for large enough $\lambda$. Then by the expressions for $x^*_{co,\lambda}$ and $A, B, C$ in (4.13) — (4.16) we have $x^*_{ca,\lambda} \to K/\gamma$ and $A, B, C \to 0$. Hence, from the expression for $v^\lambda_{ca}(x)$ in (4.12),

$v^\lambda_{ca}(x) = v^\lambda_{f}(x) \to v^\lambda_{ca}(x)$.

For case $K \geq x^*_{co,\lambda}$, the expression for $v^\lambda_{ca}(x)$ in (4.14) implies that

$v^\lambda_{ca}(x) = v^\lambda_{ca}(x) \to v^\lambda_{ca}(x)$,

and we conclude. □
