GEOMETRY AND ANALYSIS OF CONTACT INSTANTONS AND ENTANGLEMENT OF LEGENDRIAN LINKS I

YONG-GEUN OH

Abstract. We introduce the class of tame contact manifolds $(M, \lambda)$, which includes compact ones but not necessarily compact, and establish uniform a priori $C^0$-estimates for the nonlinear elliptic boundary value problem of Hamiltonian-perturbed contact instantons with the Legendrian boundary condition introduced in [Oh21b]. We study the problem of estimating the untangling energy of one Legendrian submanifold from the Reeb flow trace of another, and formulate a particularly designed parameterized moduli space for the study of the problem. We establish the Gromov-Floer-Hofer type convergence result for Hamiltonian-perturbed contact instantons of finite energy and construct its compactification of the moduli space, first by defining the correct energy and then by proving a uniform a priori energy bounds in terms of the oscillation of the relevant contact Hamiltonian. Using this, we prove that the self Reeb-untangling energy of a compact Legendrian submanifold $R$ in any tame contact manifold $(M, \lambda)$ is greater than that of the period gap $T_\lambda(M, R)$ of the Reeb chords of $R$. Then applying the operation of the Legendrianization of contactomorphisms we prove a conjecture of Sandon and Shelukhin: there exists a translated point for any contactomorphism isotopic to the identity whose oscillation norm is smaller than the period gap of the contact manifold $(M, \lambda)$, and at least $\dim H_\ast(M, \mathbb{Z}_2)$ translated points if the contactomorphism is nondegenerate in addition.

1. Introduction

The general Lagrangian Floer theory in symplectic geometry concerns intersections of Lagrangian submanifolds which largely relies on the study of the moduli spaces of solutions of Hamiltonian-perturbed pseudoholomorphic curves under the Lagrangian boundary condition with finite energy (and of bounded image in addition when the ambient space is noncompact).

In this paper and its sequels, we develop a contact analog to such a theory for the study of contact dynamics which concerns entanglement of Legendrian links which relies on the study of the moduli spaces of Hamiltonian-perturbed contact instantons under the Legendrian boundary condition. This nonlinear elliptic boundary value problem was introduced by the present author in [Oh21b] which is based on the analytic study of contact instantons provided in [OW18a, OW18b, Oh21b]. More importantly in ibid, we proved a fundamental vanishing result of the asymptotic charge for finite $\pi$-energy contact instantons with Legendrian boundary conditions, which eliminates the phenomenon of the occurrence of spiraling cusp instantons along a Reeb core. This enables us to carry out the Gromov-Floer-Hofer style compactification and the relevant Fredholm theory of the associated moduli space. The present paper and its sequels [Oh], [OY] are based on this geometric analysis of perturbed contact instantons and the relevant contact geometry and Hamiltonian calculus.

Remark 1.1. The equation (with $H = 0$) itself, what we call the contact instanton equation, was first introduced by Hofer [Hof00, p.698] and utilized in [ACH05], [Abb11] in their attempts to attack Weinstein’s conjecture in three dimensions. The way how they used the equation is different from ours in that they still lifted the equation to the symplectization of the contact manifold and use the machinery of perturbed pseudoholomorphic curves in symplectic geometry, while we directly work with the equation on the contact manifold without involving symplectization. (See [OW14, OW18a] for the closed string case and [Oh21b] for the open string case for the basic coercive regularity estimates and the subsequence convergence results in this framework.) We need to systematically use contact Hamiltonian calculus and coordinate free tensorial calculations in an optimal way for this purpose.

Along the way, we also develop the analytic machinery of Hamiltonian-perturbed contact instantons and illustrate its application to a quantitative study of contact dynamics. Leaving a full systematic study of perturbed contact instantons and the aforementioned quantitative entanglement study of general Legendrian links in future works, we utilize contact instantons with Legendrian boundary conditions as its probes, and prove a conjecture of Sandon [San12] and Shelukhin [She17] as a sample quantitative investigation of self-entanglement of a compact Legendrian submanifold. Our study provides a flexible analytic tool for general systematic quantitative study of the contact dynamics and topology through the geometric analysis of perturbed contact instantons.

1.1. Entanglement of Legendrian links. We will always consider cooriented contact manifolds $(M, \xi)$ which admits associated contact forms $\lambda$ satisfying $\ker \lambda = \xi$. We denote by

$$\mathcal{C}(\xi) = C(M, \xi)$$

(1.1)

the set of contact forms $\lambda$ of $\xi$, i.e., of those satisfying $\ker \lambda = \xi$ and $\lambda \wedge (d\lambda)^n$ is a volume form of $M = M^{2n+1}$. 

Contact manifolds equipped with a contact form carry canonical background Reeb dynamics: When $\lambda$ is a contact form of $\xi$, it uniquely defines a contact vector field $R_\lambda$ called the Reeb vector field by the defining condition

$$R_\lambda|d\lambda = 0, \ R_\lambda|\lambda = 1.$$  

Unlike the Lagrangian submanifolds in symplectic background, the generic characteristic of a Legendrian link is its entanglement structure relative to this background dynamics. We refer readers to [She19], [ENS18] for an illustration of the power of the study of such a (quantum) entanglement structure in which the authors provide a complete invariant of knots by studying the entanglement of a two-component Legendrian link in the unit cotangent bundle of $\mathbb{R}^3$ associated to a knot. Note that the unit cotangent bundle of $\mathbb{R}^3$ is also contactomorphic to the one-jet bundle of $S^2$.

**Remark 1.2.** Our adoption of the term ‘entanglement’ rather than ‘linking’ is motivated by the observation that the former describes ‘dynamical state’ while the latter ‘static state’ and our study of untangling of Reeb chords is a dynamical phenomenon. It is also partially motivated by our wish that the study shall be connected to the story of ‘quantum entanglement’ in the information theory and Chern-Simons theory in physics. (See [HHHH09] for some nice review.) It appears to us that there are at least combinatorial similarity between the structure of ‘total morphisms’ in the Fukaya-type categories (to be constructed via contact instanton moduli spaces) and the ‘total density matrix’ of the relevant physical state in the theory of topological entanglement. (See [KP06, FFN07], for example.) Investigation towards this direction is a subject of future study.

One of the purposes of the present paper is to make the first step towards a systematic quantitative study of this entanglement structure. With this long-term goal of investigation in our minds, we formulate the general problem in this introduction in the scope wider than that of what we actually investigate in the present paper which mainly deals with a two-component link of the type $(\psi(R), R)$ for an arbitrary contactomorphism $\psi$.

A Legendrian link is a finite disjoint union

$$R = \bigsqcup_{i=1}^\ell R_i$$

of connected Legendrian submanifolds $R_i$. We call each $R_i$ a component of the link $R$.

**Definition 1.3.** Consider a co-oriented contact manifold $(M, \xi)$ and a Legendrian link $R$. Let $\lambda \in \mathcal{C}(\xi)$. A curve $\gamma : [0, T] \to M$ satisfying

$$\begin{cases} \gamma' = R_\lambda(\gamma(t)), \\ \gamma(0), \gamma(T) \in R \end{cases}$$

is called a Reeb chord of $R$. We call $\gamma$ a self-chord if its initial and final points land at the same component, and a trans-chord otherwise. We denote by $\mathfrak{Reeb}(R)$ the set of Reeb chords of $R$.

Here is the simplest form of nontrivial entanglement.

**Definition 1.4.** Let $(M, \xi)$ be a contact manifold.
(1) We say a Legendrian link $R$ is dynamically $\lambda$-entangled if there exists a Reeb chord of $R$.

(2) We just say dynamically Reeb-entangled (or just dynamically entangled) if there exists a contact form $\lambda \in \mathcal{C}(\xi)$ such that $\Reeb(\lambda) \neq \emptyset$.

We say a chord $\gamma$ primary if $\gamma((0,T))$ does not intersect $R$.

**Definition 1.5.** For a given Legendrian link $R$, we define the $\lambda$-chord period gap (or simply a $\lambda$-chord gap) $T(M,\lambda;R)$ of $R$ is defined by

$$T(M,\lambda;R) := \inf \{ T | \exists (T,\gamma) \in \Reeb(R), \gamma \text{ is primary} \}.$$ 

Obviously if $R$ is compact, $T(M,\lambda;R) > 0$.

This definition is a direct generalization to the links of the following standard definition $T(M,\lambda)$ below in contact geometry.

**Definition 1.6.** Let $\lambda$ be a contact form of contact manifold $(M,\xi)$ and $R \subset M$ a connected Legendrian submanifold. Denote by $\Reeb(R)$ (resp. $\Reeb(R;\lambda)$) the set of closed Reeb orbits (resp. the set of self Reeb chords of $R$).

(1) We define $\text{Spec}(M,\lambda)$ to be the set

$$\text{Spec}(M,\lambda) = \left\{\int_{\gamma} \lambda \mid \lambda \in \Reeb(M,\lambda)\right\}$$

and call the action spectrum of $(M,\lambda)$.

(2) We define the period gap to be the constant given by

$$T(M,\lambda) := \inf \left\{\int_{\gamma} \lambda \mid \lambda \in \Reeb(M,\lambda)\right\} > 0.$$ 

We define $\text{Spec}(M,R;\lambda)$ and the associated $T(M,\lambda;R)$ similarly using the set $\Reeb(M,R;\lambda)$ of Reeb chords of $R$.

We set $T(M,\lambda) = \infty$ (resp. $T(M,\lambda;R) = \infty$) if there is no closed Reeb orbit (resp. no $(R_0,R_1)$-Reeb chord). Then we define

$$T_\lambda(M,R) := \min \{T(M,\lambda), T(M,\lambda;R)\}$$

and call it the (chord) period gap of $R$ in $M$.

**1.2. Legendrian isotopy and Reeb chords.** In relation to our solution to the conjecture of Sandon and Shelukhin [San12], [She17], we consider the pair $(R_0,R_1)$ of the type $R_0 = \psi(R)$, $R_1 = R$ for a contactomorphism $\psi$ and prove a result in the simplest level of dynamical entanglement, the existence of a Reeb chord of a two-component link $(\psi(R),R)$, by studying the moduli space of contact instantons intertwining the link, and give its application to the aforementioned conjecture. In [OY], we systematically develop this analytic package for the case of one-jet bundles and give a Floer-theoretic construction of Legendrian spectral invariants. We will investigate the higher level entanglement structure involving the Fukaya category-type construction of in a sequel [Oh].

We denote by

$$\text{Leg}(M,\xi)$$

the set of Legendrian submanifold and by $\text{Leg}(M,\xi;R)$ its connected component containing $R \in \text{Leg}(M,\xi)$, i.e, the set of Legendrian submanifolds Legendrian isotopic to $R$. We denote by

$$\mathcal{P}(\text{Leg}(M,\xi))$$
the monoid of Legendrian isotopies \([0, 1] \to \text{Leg}(M, \xi)\). We have natural evaluation maps

\[
ev_0, \ev_1 : \mathcal{P}(\text{Leg}(M, \xi)) \to \text{Leg}(M, \xi)
\]

and denote by

\[
\mathcal{P}(\text{Leg}(M, \xi), R) = \ev_0^{-1}(R) \subset \mathcal{P}(\text{Leg}(M, \xi))
\]

and

\[
\mathcal{P}(\text{Leg}(M, \xi), (R_0, R_1) = (\ev_0 \times \ev_1)^{-1}(R_0, R_1) \subset \mathcal{P}(\text{Leg}(M, \xi)).
\]

**Notation 1.7.** Let \(H = H(t, x)\) be a given contact Hamiltonian.

1. We denote by

\[
\psi_H : t \mapsto \psi_H^t
\]

the contact Hamiltonian path generated by \(H\).

2. When \(\psi \in \text{Cont}(M, \xi)\), we denote by

\[
H \mapsto \psi
\]

when \(\psi = \psi_H^1\).

3. When \(R_0 = R\) and \(R_1 = \psi(R)\) for a contactomorphism contact isotopic to the identity, the Hamiltonian path \(\psi_H\) defines a natural Legendrian isotopy

\[
\mathcal{R}_{H;R} : t \mapsto \psi_H^t(R).
\]

We denote by

\[
\mathcal{P}(\text{Leg}(M, \xi), R; H) \subset \mathcal{P}(\text{Leg}(M, \xi), (\psi(R), R))
\]

the set of Legendrian isotopies which is homotopic to the path \(\mathcal{R}_{H;R}\) relative to the ends.

Now we specify what kind of contact manifolds we will take as the background geometry in the present paper. Our introduction of the following class of contact manifolds is largely motivated to make the relevant contact manifolds amenable to the maximum principle in the study of contact instantons, which will include compact contact manifolds, the one-jet bundles \(J^1B\) for general compact manifolds \(B\) and, most importantly for the purpose of current paper, the product \((Q \times Q \times \mathbb{R}, \mathcal{A})\),

\[
\mathcal{A} = -e^{\pi_1} \pi_2^* \lambda + \pi_2^* \lambda
\]

is tame for any compact contact manifold \((Q, \lambda)\).

We first introduce the following type of barrier functions.

**Definition 1.8 (Reeb-tame functions).** Let \((M, \lambda)\) be contact manifold. A function \(\psi : M \to \mathbb{R}\) is called \(\lambda\)-tame at infinity if \(\mathcal{L}_R d\psi = 0\) on \(M \setminus K\) for a compact subset \(K\).

We will most just say ‘tame’ omitting ‘at infinity’ unless there is a need to emphasize the latter.

**Definition 1.9 (Contact \(J\)-convexity).** Let \(J\) be a \(\lambda\)-adapted CR almost complex structure. We call a function \(\psi : M \to \mathbb{R}\) contact \(J\)-convex if there exists a compact subset \(K \subset M\) such that

\[
-d(d\psi \circ J) \geq 0 \quad \text{on } \xi,
\]

\[
R_\lambda d(d\psi \circ J) = 0
\]

on \(M \setminus K\). We call such a pair \((\psi, J)\) a contact pseudoconvex pair.
Here the inequality (1.4) needs some explanation: We recall a CR almost complex structure is an endomorphism $J(\xi) \subset \xi$ that satisfies

$$J(R\lambda) = 0 \quad J^2 = -\text{id}|_{\xi} \oplus 0.$$ 

In particular $J(TM) \subset \xi$. The meaning of (1.4) is that

$$-d(d\psi \circ J) = h d\lambda \quad (1.6)$$

on $\xi$ for some nonnegative function $h \geq 0$.

**Remark 1.10.** In other words, the two form $-d(d\psi \circ J)$ we are considering in (1.4) corresponds to the real almost complex version of the standard Levi-form in several complex variables, when $M$ is a CR manifold of the hypersurface-type. The condition (1.4) then corresponds to pseudoconvexity of the hypersurface. The condition (1.5) is an additional requirement that involves contact geometry. This is responsible for our naming of ‘contact $J$-convexity’ and ‘contact pseudoconvex pairs’. Similar notion of such a pair is also utilized in [Oh21c] in the study of Liouville sectors introduced in [GPS17, GPS18].

The upshot of introducing this kind of barrier functions on contact manifold is the following amenability of the maximum principle to the pair $(\psi, J)$ in the study of contact instantons.

**Theorem 1.11.** Let $(M, \xi)$ be a contact manifold and consider the contact triad $(M, \lambda, J)$ associated to it. Let $\psi$ be a $\lambda$-tame contact $J$-convex function. Then for any contact instanton $w: \Sigma \to M$ for the triad $(M, \lambda, J)$, the composition $\psi \circ w$ is a subharmonic function, i.e., satisfies

$$\Delta(\psi \circ w) \geq 0.$$

Motivated by this analytical fact, we introduce the following class of contact manifolds for which uniform $C^0$ bounds for the (perturbed) contact instantons will be available.

**Definition 1.12** (Tame contact manifolds). We call a contact form $\lambda$ tame if $(M, \lambda)$ admits a pair $(\psi, J)$ of a $\lambda$-adapted CR almost complex structure $J$ and a $\lambda$-tame contact $J$-convex exhaustion function $\psi$. We call a contact manifold $(M, \lambda)$ tame if $\lambda$ is tame (at infinity).

We will show in [OY] that the standard contact form of any one-jet bundles $J^1B$ for compact $B$ is tame, and in Proposition 11.7 that the contact form

$$\mathcal{A} = -e^\eta \pi_1^* \lambda + \pi_2^* \lambda$$

is tame on $M_Q := Q \times Q \times \mathbb{R}$ with for any compact contact manifold $(Q, \lambda)$.

The first main result of the present paper is the following existence theorem of Reeb chords between $\psi(R)$ and $R$ for any compact Legendrian submanifold $R$ on tame contact manifolds, as an application of the analytic framework of perturbed contact instantons.

**Theorem 1.13** (Theorems 10.5 & 10.6). Let $(M, \xi)$ be a contact manifold equipped with a tame contact form $\lambda$. Let $\psi \in \text{Cont}_0(M, \xi)$ and consider any Hamiltonian $H = H(t, x)$ with $H \mapsto \psi$. Assume $R$ is any compact Legendrian submanifold of $(M, \xi)$. Then the following hold:
(1) Provided $\|H\| \leq T_\lambda(M,R)$, we have
$$\#\Reeb(\psi(R), R) \neq \emptyset.$$  

(2) Provided $\|H\| < T_\lambda(M,R)$ and $\psi = \psi_H^1$ is nondegenerate to $(M,R)$, then
$$\#\Reeb(\psi(R), R) \geq \dim H^*(R; \mathbb{Z}_2).$$

(See Corollary 4.8 for the meaning of nondegeneracy of $\psi$ relative to $(M,R)$.)

1.3. Translated points and the Sandon-Shelukhin conjecture. As an application, we investigate the dynamics of contactomorphisms, especially the existence question on the translated points of contactomorphisms, whose explanation is now in order. This notion was introduced by Sandon [San12] in the course of her applications of Legendrian spectral invariants to the problem of contact nonsqueezing initiated by Eliashberg-Kim-Polterovich [EKP06] and further studied by [Chi17], [Fra16].

For each given coorientation preserving contact diffeomorphism $\psi$ of $(M,\xi)$, we call the function $g$ appearing in $\psi^*\lambda = e^g\lambda$ the conformal exponent for $\psi$ and denote it by $g = g_\psi$ [Oh21b].

Definition 1.14 (Sandon [San12]). Let $(M,\xi)$ be a contact manifold equipped with a contact form $\lambda$. A point $x \in M$ is called a $\lambda$-translated point of a contactomorphism $\psi$ if $x$ satisfies
$$\begin{cases} g_\psi(x) = 0 \\ \psi(x) = \phi_R^\eta x(x) \text{ for some } \eta \in \mathbb{R}. \end{cases}$$

We denote the set of $\lambda$-translated points of $\psi$ by $\Fix^\text{trn}_\lambda(\psi)$.

Using the Legendrianization [Che96], [Bhn01] of contactomorphism $\psi$ followed by the Legendrian version of Darboux-Weinstein neighborhood and the generating function method, Sandon [San12] observed that if the contactomorphism $\psi$ is $C^1$-small, then it has at least $\dim H_*(M,\mathbb{Z}_2)$ translated point of any contactomorphisms provided a suitable nondegeneracy hypothesis holds. (See [She17] or Definition 1.15 of the present paper for the definition of relevant nondegeneracy.) She then asked the question whether the Arnold conjecture-like result holds for the translated points of contactomorphisms.

The following definition is a slight variation of the one given by Shelukhin in [She17, Section 1.2].

Definition 1.15 (Compare with Definition 1 [She17]). Let $\psi : M \to M$ be a contactomorphism and let $(x, \eta)$ be a translated point.

(1) We say a translated point $(x, \eta)$ of $\psi$ is nondegenerate if the differential
d$$d(\phi_{R^\eta}^\psi)(x) : T_xM \to T_xM$$
of the map $\phi_{R^\eta}^\psi$ at $x$ does not have an eigenvector with eigenvalue 1 that lies in $\xi_x(= \ker d\lambda(x))$, i.e.,
$$\ker d(\phi_{R^\eta}^\psi)(x) \cap \xi_x = \{0\}.$$  

(2) We say a contactomorphism $\psi$ is nondegenerate if all its translated points are nondegenerate.
It is easy to see that a generic contact Hamiltonian \( H = H(t, x) \) is nondegenerate. (See [AM13], [She17, Lemma 3], and [Oh21b, Appendix] and Definition 3.14 for its intersection analog.)

Using Theorem 1.13 and the Legendrianization of contactomorphism [Che96], [Bhu01], we give the proof of the following conjecture of Sandon and Shelukhin [San12], [She17] in Section 11.

**Remark 1.16.** In fact, Shelukhin stated a stronger conjecture [She17, Conjecture 31] which replaces to \( \|H\| \) below by \( 2\|H\| \). However, from the way how our proof goes and from the corresponding result from [Che98, Oh97] in symplectic geometry, we suspect that the theorem below is all we can prove and should be a more plausible conjecture than that [She17, Conjecture 31] in general.

**Theorem 1.17** (Compare with Conjecture 31, [She17]). Assume \((M, \lambda)\) be a compact contact manifold. Let \( T(M, \lambda) > 0 \) be the minimal period of closed Reeb orbits of \( \lambda \). Then we have the following:

1. Provided \( \|H\| \leq T(M, \lambda) \), we have
   \[
   \# \text{Fix}_\text{trn}^\text{in}(\psi) \neq \emptyset
   \]
2. Provided \( \|H\| < T(M, \lambda) \) and \( H \) is nondegenerate, we have
   \[
   \# \text{Fix}_\text{trn}^\text{in}(\psi) \geq \dim H^*(M; \mathbb{Z}_2).
   \]

Albers-Merry proved this result in [AM13] for the case of contact manifolds with a strong exact filling utilizing the technique of Rabinowitz Floer homology which is in turn based on the result of Albers-Frauenfelder [AF10] about the leafwise intersection points. On the other hand, our proof is of purely contact geometric nature, without the presence of symplectic background, based on the combination of contact geometry and dynamics by taking as its probe the analytic package of (perturbed) contact instantons developed in [OW18a, Oh21b] as well as in the present paper.

Obviously Theorem 1.17 implies that the existence results hold for all Hamiltonian \( H \), if \((M, \lambda)\) carries no closed Reeb orbits, i.e., for any \((M, \lambda)\) for which Weinstein conjecture fails to hold. It will be very interesting to see if our method can be improved to remove the smallness hypothesis put in the statement of Theorem 1.17 as in the case of Arnold’s conjecture in symplectic geometry. This will be a subject of future study.

### 1.4. Hamiltonian-perturbed contact instantons

Recall a contact form \( \lambda \) admits a decomposition \( TM = \xi \oplus \mathbb{R}(R_\lambda) \). We denote the associated projection to \( \xi \) by \( \pi : TM \to \xi \) and decompose
\[
v = v^\pi + \lambda(v) R_\lambda, \quad v^\pi := \pi(v).
\]
In terms of this splitting the contact Hamilton’s equation can be decomposed
\[
\dot{x} = X_H(t, x) \iff \begin{cases} (\dot{x} - X_H(t, x))^\pi = 0 \\ \gamma^*(\lambda + H dt) = 0 \end{cases}
\]
with \( \gamma : \Omega^{(1, 0)} \to \mathcal{D}_{\xi} \) into the \( \xi \)-component and the Reeb component of the equation. (See [Oh21b].)

**Definition 1.18** (Contact triad [OW14]). Let \((M, \xi)\) be a contact manifold, and \( \lambda \) be a contact form of \( \xi \). An endomorphism \( J : TM \to TM \) is called a \( \lambda \)-adapted CR-almost complex structure if it satisfies

\[
\begin{aligned}
\langle dx^\alpha \wedge dv^\beta, J(v^\gamma, \xi) \rangle &= 0, \\
\langle dx^\alpha \wedge dv^\beta, \xi \rangle &= 0, \\
\langle dx^\alpha \wedge dv^\beta, dv^\gamma \rangle &= 0, \\
\langle dx^\alpha \wedge dv^\beta, dx^\gamma \rangle &= 0,
\end{aligned}
\]
(1) $J(\xi) \subset \xi$, $JR_\lambda = 0$ and $J^2_r = -id|_\xi$.
(2) $g_\xi := d\lambda(\cdot, J|_\xi \cdot)|_\xi$ defines a Hermitian vector bundle $(\xi, J|_\xi, g_\xi)$.

We call the triple $(M, \lambda, J)$ a contact triad.

For given such a triad, we first decompose any $TM$-valued one-form $\Xi$ on a Riemann surface $(\Sigma, j)$ into
\[
\Xi = \Xi^\pi + \lambda(\Xi),
\]
and then we further decompose $\Xi^\pi$ into $J$ linear and $J$ anti-linear parts of $\Xi^\pi$.

We now consider $(M, \lambda, J)$ is a contact triad for the contact manifold $(M, \xi)$, and equip with it the contact triad metric $g = d\lambda(\cdot, J\cdot) + \lambda \otimes \lambda$.

The following perturbed contact instanton equation is introduced in [Oh21b] as the contact counterpart of the celebrated Floer’s Hamiltonian-perturbed Cauchy-Riemann equation in symplectic geometry.

**Definition 1.19** ([Oh21b]). Let $(M, \lambda)$ be contact manifold equipped with a contact form, and consider the (time-dependent) contact triad $(M, \lambda, J) = \{J_t\}_{t \in [0, 1]}$.

Let $H = H(t, x)$ be a time-dependent Hamiltonian. We say $u : \mathbb{R} \times [0, 1] \to M$ is a $X_H$-perturbed Legendrian Floer trajectory if it satisfies
\[
\begin{cases}
(du - X_H \otimes dt)^\pi(0, 1) = 0, \\
(d(e^{g_H(u)}(u^*\lambda + H dt) \circ j)) = 0
\end{cases}
\quad (1.8)
\]
where the function $g_H : \mathbb{R} \times [0, 1] \to \mathbb{R}$ is defined by
\[
g_H(t, x) := g_{\psi_H^{-1}}(\psi_H^{-1}(u(t, x))).
\quad (1.9)
\]

Here we refer to Subsection 6.1 for the explanation and the perspective of the transformation $u \mapsto \overline{u}$ where
\[
\overline{u}(\tau, t) := (\psi_H^{-1}(\psi_H^{-1})^{-1}(u(t, x))) = \psi_H^{-1}(\psi_H^{-1})^{-1}(u(t, x))
\]
which we apply above in (1.9). This kind of coordinate change from the **dynamical version** to the **intersection theoretic version** of the Floer homology has been systematically utilized by the present author in the symplectic Floer theory. (See [Oh05, Oh99, Oh05] and the book [Oh15b, Section 12.7].) To motivate this transformation, we will provide the general perspective associated to it in Subsection 6.1.

1.5. **Definition of horizontal and vertical energies.** As in the study of the moduli space of Floer trajectories, especially the kind of parameterized nonautonomous Floer trajectories appearing in the study of displacement energy of Lagrangian submanifolds presented in [Oh97], one needs to develop the whole analytic package for the study of the moduli space of solutions of (1.8) such as the a priori coercive estimates, Fredholm theory and compactification of the moduli spaces. The first has been established in [OW18a, OW18b] for the closed string case, and then in [Oh21b] for the open string case of Legendrian boundary conditions. The
Fredholm theory and the first step of compactification for the closed string case is carried out in [Oh21a] under the asymptotic charge vanishing hypothesis. The present author then proved in [Oh21b] that this asymptotic charge always vanishes for the open string case of Legendrian boundary condition. In these works, precise tensorial calculations utilizing the canonical connection of the contact triad introduced in [OW14] play an important role.

In Part 3, we establish all these ingredients for this moduli space up to the level of what are needed to complete the proof of Theorem 1.13. We leave a full account of the Fredholm theory and the compactification of general contact instanton moduli spaces in a sequel.

To make the study of Gromov-Floer-Hofer type compactness result, it is crucial to identify a correct choice of energy in the framework of contact instantons. Such an identification of the Hofer-type energy is given in [Oh21a] for the closed string case of contact instantons. (See also [OS21] for such a study in the context of lcs-instantons on locally conformal symplectic manifolds.) We adapt this study to the open-string context of Legendrian boundary conditions for the perturbed equation, and prove an a priori energy bound and develop the relevant bubbling argument and $C^1$-estimates in Part 3.

It turns out that the correct choice of the horizontal part of the energy, which we call the $\pi$-energy, is the following.

**Definition 1.20** (The $\pi$-energy of perturbed contact instanton). Let $(J, H)$ be as in Definition 1.19. Let $u : \mathbb{R} \times [0, 1] \to M$ be any smooth map. We define

$$E_{J,H}^\pi(u) := \frac{1}{2} \int e^{g_H(u)} |(du - X_H(u) \otimes dt)|_J^2$$

call it the off-shell $\pi$-energy, where $g_H(u)$ is the function given in (1.9).

We apply the gauge transformation $\Phi_H^{-1}$ to define a map $\overline{\pi}$ by

$$\overline{\pi}(\tau, t) = (\psi_H^t(\psi_H^1)^{-1})^{-1}(u(\tau, t)) = \psi_H^1(\psi_H^t)^{-1}(u(\tau, t)) \quad (1.10)$$

and

$$J' = \{J'_t\}, \quad J'_t = (\psi_H^t(\psi_H^1)^{-1})^* J, \quad (1.11)$$

$$\lambda' = (\psi_H(\phi_H^1)^{-1})^* \lambda. \quad (1.12)$$

Then for the given contact triad $(M, \lambda, J)$, the triple

$$(M, \{\lambda'_t\}, \{J'_t\})$$

forms a $t$-dependent family of contact triads. We denote the associated contact triad metric by

$$g'_t = (\psi_H(\phi_H^1)^{-1})^* g.$$

The upshot of this coordinate change is that if $u$ satisfies (1.8) with respect to $J_t$, then $\overline{\pi}$ is a nonautonomous contact instanton that satisfies

$$\overline{\partial}_{J'_t} \overline{\pi} = 0,$$

with the boundary condition

$$\overline{\pi}(\tau, 0) \in \psi_H^1(R_0), \quad \overline{\pi}(\tau, 1) \in R_1,$$

where we have

$$(\overline{\partial}_{J'_t} \overline{\pi})(\tau, t) = (d\overline{\pi})^\pi_{J'_t} (0, 1)(\tau, t).$$
The following identity justifies the presence of weight function $e^{\varphi_H(u)}$ in (6.8).
(See also Remark 7.3 for its naturality and further necessity of the presence of the weight factor in the definition.)

**Proposition 1.21** (Proposition 7.2). *Let $u : \mathbb{R} \times [0, 1] \to M$ be any smooth map and $\varphi$ be as above. Then*

$$E_{\varphi,H}^*(u) = E_{\varphi,j}^*(\varphi) = \int \varphi^* \lambda. \quad (1.13)$$

Another crucial component of Hofer-type energy, the vertical part of energy, is more nontrivial to describe. We refer readers to Section 13, Part 3 for the details of its construction, which we denoted by $E_{\varphi_{\perp},J,K,H}(u)$.
(See [Oh21a] also for the same definition considered in the closed string context.) We will show in Part 3 that these two energies will govern the convergence behavior of perturbed contact instantons, similarly as in the case of pseudoholomorphic curves in the symplectization [Hof93, BEHZ03].

1.6. **Cut-off Hamiltonian-perturbed contact instanton equation.** For the purpose of relating the existence question of Reeb chords between the pair $(\psi(R), R)$ to the oscillation norm of the Hamiltonian $H \mapsto \psi$, we will adapt the scheme laid out in [Oh97] to the context of perturbed contact instantons with Legendrian boundary conditions in contact manifolds and prove Theorem 1.13: The scheme of [Oh97] was used for the study of displacement energy of Lagrangian submanifolds on symplectic manifolds.

We consider the perturbed contact instanton with *moving Legendrian boundary condition*, and set-up the deformation-cobordism framework of parameterized moduli space of perturbed contact instantons by adapting a similar parameterized Floer moduli spaces used in [Oh97].

We will be particularly interested in the case for which the domain dependent Hamiltonian arises as

$$H_K(\tau, t, x) := H(\chi_K(\tau), t, x) \quad (1.14)$$

where $\chi_K : \mathbb{R} \times [0, 1] \to [0, 1]$ is the family of cut-off functions used in [Oh97]. (See Section 8 for the definition.) Especially, we will concern the two-parameter family $H$ of the form $H(s, t, x) = sH(t, x)$ for the compact family $(s, t) \in [0, 1]^2$.

**Notation 1.22** (The family $(H^s, J^s)$). Consider the two parameter family of CR-almost complex structures and Hamiltonian functions:

$$J = \{J(s,t)\}, \quad H = \{H(s,t)\} \quad \text{for } (s, t) \in [0, 1]^2.$$ We denote by $H^s$ the time-dependent Hamiltonian given by $H^s(t, x) := H(s, t, x)$ and $J^s$ given by $J^s(t, x) = J(s, t, x)$.

Note that $[0, 1]^2$ is a compact set and so $J, H$ are compact families. We will be particularly interested in the case:

$$J(s, t, x) = (\psi_H^s(\psi_H^1)^{-1})_s J_0, \quad J_0 \in \mathcal{J}(M, \xi) \quad (1.15)$$

**Remark 1.23.** If we write $J^s = (\psi_H^1)^{-1})_s J_0$, then we can write

$$J(s, t, x) = (\psi_H^s)_s J^s, \quad s \in [0, 1].$$
Therefore we have a family of $s$-dependent contact triads, one autonomous
\[(M, \lambda^s, J^s)\]
and the other non-autonomous
\[(M, \{\lambda^s_t\}, \{J^s_t\})\]
which are related by the one-parameter family of gauge transformations
\[\Phi_{H^s}, \quad s \in [0, 1].\]

For each $K \in \mathbb{R}_+ = [0, \infty)$, we take the one-parameter family of cut-off functions
\[\chi_K : \mathbb{R} \to [0, 1]\]
and define a $\Theta_{K+1}$-family of contactomorphisms
\[\psi_{H^s, \chi_K(t)} (\tau) = \psi_{H^s, \chi_K(t)} (\psi_{H^s, \chi_K(t)}^{-1})^{-1}, \quad (\tau, t) \in \Theta_{K+1} \subset \mathbb{R} \times [0, 1],\]
and associate the $\Theta_{K+1}$-family of contact triads
\[(M, \{\psi_{H^s, \chi_K(t)} (\tau)\}, \{\psi_{H^s, \chi_K(t)} (\tau) J^0\})\]
where the family $\{\Theta_{K+1}\}$ is a nested family of disc-like domains such that
\[\bigcup_{K \in (0, \infty)} \Theta_{K+1} = \mathbb{R} \times [0, 1].\]
(See Section 8 for the precise definition of the domain $\Theta_{K+1}$.) We denote the associated parameterized moduli space by
\[M_{\text{para}}^{[0, K_0]}(M, R, J, H) = \bigcup_{K \in [0, K_0]} \{K\} \times M_{\text{para}}(M, R, J, H)\]
for a sufficiently large $K_0 > 0$. (See Section 9 for the precise definition thereof.) Denote by $M(M; \alpha_j)$ (resp. $M(M, R; \beta_k)$) the moduli space of contact instantons on the plane $\mathbb{C}$ with $\alpha_j$ as its asymptotic Reeb orbits (resp. that of contact instantons on the half plane $\mathbb{H}$ with boundary in $R$ and with $\beta_k$ as its asymptotic Reeb chord).

Then we prove the following fundamental a priori energy bounds

**Theorem 1.24** (Propositions 8.6 & 8.7). Assume $(M, \lambda)$ be a tame contact manifold. Let $(K, u) \in M_{\text{para}}^{[0, K_0]}(M, \lambda; J, H)$ be any element. Then we have

1. **[The horizontal energy bound]**
   \[E_{H^K, H}^H(u) \leq \|H\|.\]
2. **[The vertical energy bound]**
   \[E_{J^K, H}^J(u) \leq \|H\|.\]

We would like to emphasize that the proofs of these a priori bounds much rely on the particular form of Hamiltonian-perturbed contact instanton equation (1.8) under the Legendrian boundary condition and utilize the calculations based on the contact Hamiltonian calculus. (See Proposition 12.2 and Proposition 15.1 respectively.) These calculi are systematically developed and organized in [Oh21b, Section 2] with coherent signs, notations and conventions, and further developed in Subsection 2 of the present paper.

Then the following is a sample Gromov-Floer-Hofer type convergence result that we use in the proof of Theorem 1.13.
Theorem 1.25 (Theorem 16.1). Consider the moduli space $M^{\text{para}}(M; R; J, H)$. Then one of the following alternatives holds:

1. There exists some $C > 0$ such that
   \[ |d\pi|_{C^0; \mathbb{R} \times [0, 1]} \leq C \] (1.16)
   where $C$ depends only on $(M, R; J, H)$ and $\lambda$.

2. There exists a sequence $u_\alpha \in M^{K_\alpha}(M; R; J, H)$ with $K_\alpha \to K_\infty \leq K_0$ and a finite set $\{ \gamma_j^+ \}$ of closed Reeb orbits of $(M, \lambda)$ such that $u_\alpha$ weakly converges to the union
   \[ u_\infty = u_0 + \sum_{j=1}^{\infty} v_j + \sum_{k} w_k \]
   in the Gromov-Floer-Hofer sense, where
   \[ u_0 \in M^{K_\infty}(M; R; J, H), \]
   \[ v_j \in M(M, J'_z; \alpha_j); \quad \alpha_j \in \Reeb(M, \lambda'_z), \]
   and
   \[ w_k \in M(M, \psi^{-1}_z(R), J'_z; \beta_k); \quad \beta_k \in \Reeb(M, \lambda; R). \]

Here the domain point $z_j$ is the point at which the corresponding bubble is attached.

The proof of this theorem will occupy Part 3. Its content will be also the foundation of the analysis of contact instantons with Legendrian boundary condition used in the sequel [Oh]. It is also the analytic basis for the Floer theoretic construction of Legendrian spectral invariants via contact instanton Floer-type homology given in [OY] for the one-jet bundle.

1.7. Reeb-untangling energy of pairs of subsets. Theorem 1.13 and 1.17 motivate us to introduce the following notion of Reeb-untangling energy of one subset from the Reeb trace of the other: We call the following union
   \[ Z_S := \bigcup_{t \in \mathbb{R}} \phi^t_{R_{\lambda}}(S) \] (1.17)
the Reeb trace of a subset $S \subset M$.

Definition 1.26. Let $(M, \xi)$ be a contact manifold, and let $S_0, S_1$ of compact subsets $(M, \xi)$.

1. We define
   \[ e^{\text{trn}}(S_0, S_1) := \inf_H \{ \| H \| \mid \psi^1_H(S_0) \cap Z_{S_1} = \emptyset \}. \] (1.18)
   We put $e^{\text{trn}}(S_0, S_1) = \infty$ if $\psi^1_H(S_0) \cap Z_{S_1} \neq \emptyset$ for all $H$. We call $e^{\text{trn}}(S_0, S_1)$ the $\lambda$-untangling energy of $S_0$ from $S_1$ or just of the pair $(S_0, S_1)$.

2. We put
   \[ e^{\text{trn}}(S_0, S_1) = \sup_{\lambda \in \mathcal{E}(\xi)} e^{\text{trn}}(S_0, S_1). \] (1.19)
   We call $e^{\text{trn}}(S_0, S_1)$ the Reeb-untangling energy of $S_0$ from $S_1$ on $(M, \xi)$.

We mention that the quantity $e^{\text{trn}}(S_0, S_1)$ is not symmetric, i.e., $e^{\text{trn}}(S_0, S_1) \neq e^{\text{trn}}(S_1, S_0)$ in general. Theorem 1.13 implies
\[ e^{\text{trn}}(R, R) \geq T_{\lambda}(M, R) > 0 \]
for all compact Legendrian submanifolds $R$. Existence of generating functions [Vit92, Thé95] proves $e^{\text{trn}}_{\lambda}(R, R) = \infty$ if

$$\lambda = \lambda_{\text{can}} := dz - pdq, \quad R = 0_{J^1B}.$$ 

In this regard, the following is an interesting open question to ask, which is the contact analog to the Arnold-like conjectures in symplectic geometry.

**Question 1.27.** Which class of compact Legendrian submanifolds $R$ have $e^{\text{trn}}_{\lambda}(R, R) = \infty$ in the following classes of contact manifolds?

- on a closed $M$,
- on a one-jet bundle $(J^1B, \lambda_{\text{can}})$ for a compact manifold $B$.

Similarly, we can define the $\lambda$-untangling energy of contact form $\lambda$ on a contact manifold $(M, \xi)$.

**Definition 1.28.** Let $(M, \xi)$ be a contact manifold. For each contact form $\lambda$ of $\xi$, we define

$$e^{\text{trn}}_{\lambda}(M, \xi) := \inf_{\psi \in \text{Cont}^0(M, \xi)} \{ \| \psi \|_{\text{osc}}^\lambda \mid \text{Fix}^{\text{trn}}_{\lambda}(\psi) = \emptyset \}$$

and

$$e^{\text{trn}}(M, \xi) := \sup_{\lambda \in \mathcal{C}(\xi)} e^{\text{trn}}_{\lambda}(M, \xi).$$

We call $e^{\text{trn}}_{\lambda}(Q)$ (resp. $e^{\text{trn}}(M, \xi)$) the $\lambda$-untangling energy of the contact form $\lambda$ (resp. the Reeb-untangling energy of contact structure $\xi$).

By definition, we have

$$e^{\text{trn}}(M, \xi) \geq e^{\text{trn}}_{\lambda}(M, \xi)$$

for all $\lambda \in \mathcal{C}(\xi)$ and $e^{\text{trn}}(M, \xi)$ is an invariant of the contact structure $\xi$.

Theorem 1.17 implies

$$e^{\text{trn}}_{\lambda}(M, \xi) \geq T(M, \lambda) > 0.$$ 

The following is an interesting open question.

**Question 1.29.** Is $e^{\text{trn}}(M, \xi) < \infty$? If not, what is a condition of the contact manifold $(M, \xi)$ for it to hold?

One natural avenue to pursue in the future is to amplify our quantitative study given in the present paper to define the contact instanton spectral invariants of general Legendrian links and investigate their entanglement structure. We also hope to further apply this machinery to problems of contact topology and thermodynamics. (See [BLMN15, MNSS90], for example, in the midst of many articles on contact geometric formulation of thermodynamics in physics literature. Entov and Polterovich applied ideas from contact dynamics to a problem of non-equilibrium thermodynamics in a recent article [EP21].) Some steps toward this goal and further applications will be given in [OY] and [Oh].

**Remark 1.30.** Throughout the paper, neither symplectization nor pseudoholomorphic curves in symplectic geometry is involved. In Appendix A, we compare the Hamiltonian-perturbed contact instanton equation and the projection of the standard Hamiltonian-perturbed Floer trajectory equation of the homogeneous lifting $\tilde{H}$ on the symplectization $SM$ of the contact Hamiltonian $H$ on $M$. While they
coincide when \( H = 0 \), the two equations provide two different elliptic systems of perturbed contact instanton equations. The perturbed equation considered in the present paper is not the reduction of the Floer trajectory equation on the symplectization. Further comparison will be given in [Oh21d] where we establish the coercive elliptic estimates for the perturbed equation (6.15) for the family \( J' \) not necessarily of the type given in (1.11) so that one cannot convert to the (unperturbed) contact instanton equations by the gauge transformation \( \Phi_H \).

**Acknowledgement:** We would like to thank Bhupal and Sandon for patient explanation on the generating function techniques on the Legendrian spectral invariants and their applications at the time of ideas on the current research starting to form, which helped the author to appreciate differences between contact dynamics and symplectic Hamiltonian dynamics. We also thank Rui Wang for her collaboration in the very beginning of our study of contact instantons, and for helping us on the calculations given in Appendix A.1.

**Convention and Notations:**
- **(Contact Hamiltonian)** We define the contact Hamiltonian of a contact vector field \( X \) to be \(-\lambda(X)\).
- For given time-dependent function \( H = H(t, x) \), we denote by \( X_H \) the associated contact Hamiltonian vector field whose associated Hamiltonian \(-\lambda(X_t)\) is given by \( H = H(t, x) \), and its flow by \( \psi_H^t \).
- When \( \psi = \psi_H^1 \), we say \( H \) generates \( \psi \) and write \( H \mapsto \psi \).
- **(Developing map)** \( \text{Dev}(t \mapsto \psi_t) \): denotes the time-dependent contact Hamiltonian generating the contact Hamiltonian path \( t \mapsto \psi_t \).
- **(Reeb vector field)** We denote by \( R_\lambda \) the Reeb vector field associated to \( \lambda \) and its flow by \( \phi_t^{R_\lambda} \).
- **(Contact instanton homology)** We denote by \( CI^*_\lambda(R_0, R_1) \) the \( \lambda \)-contact instanton complex and \( HI^*_\lambda(R_0, R_1) \) its cohomology, when defined. (See Subsection 10.2 for the definition.)
- **(\( \Sigma, j \))**: a punctured Riemann surface (with boundary) and \((\Sigma, j)\) the associated compact Riemann surface.
- We always regard the tangent map \( du \) as a \( u^*TM \)-valued one-form and write \( du = d^\nu u + u^*\lambda \otimes R_\lambda \) with respect to the decomposition \( TM = \xi \oplus \mathbb{R}(R_\lambda) \).
- \( g_H(u) \): the function defined by \( g_H(u)(\tau, t) := g_{\psi^t_H(\psi^1_H)^{-1}}(u(\tau, t)) \).
- \( T(M, \lambda) \): the infimum of the action of closed \( \lambda \)-orbits.
- \( T(M, \lambda; R) \): the infimum of the action of self \( \lambda \)-chords.
- \( T_\lambda(M, R) = \min\{T(M, \lambda), T(M, \lambda; R)\} \).

2. **Summary of contact Hamiltonian calculus**

In this section, we summarize basic contact Hamiltonian calculus we are going to use. We follow the exposition of [Oh21b, Section 2] and its sign conventions, and amplify the calculus further which will be needed for the purpose of the present paper and its sequels. We will always assume that \((M, \lambda)\) is cooriented.

**Definition 2.1.** For given coorientation preserving contact diffeomorphism \( \psi \) of \((M, \xi)\) we call the function \( g \) appearing in \( \psi^*\lambda = e^g\lambda \) the **conformal exponent** for \( \psi \) and denote it by \( g = g_{\psi} \).
**Definition 2.2.** Let $\lambda$ be a contact form of $(M, \xi)$. For each contact vector field $X$, the associated function $H$ is given by

$$H = -\lambda(X) \quad (2.1)$$

is called the $\lambda$-contact Hamiltonian of $X$. We also call $X$ the $\lambda$-contact Hamiltonian vector field associated to $H$.

When $(M, \xi)$ is cooriented, the line bundle $L = \mathbb{R}_M$ is trivial and the associated Jacobi bracket is also called the Lagrange bracket in some literature. (See [AG01].) When a contact form $\lambda$ is given the map $X \mapsto -\lambda(X)$ induces a Lie algebra isomorphism, which does not necessarily satisfy the Leibnitz rule. Partly due to different sign conventions literature-wise, we fix the sign convention of the bracket following that of [Oh21b].

**Proposition 2.3** (Compare with Proposition 5.6 [LOTV18], Proposition 9 [dLLV19]). Let $(M, \xi)$ be cooriented and $\lambda$ be an associated contact form. Define a bilinear map

$$\{\cdot, \cdot\} : C^\infty(M) \times C^\infty(M) \to C^\infty(M).$$

by

$$\{H, G\} := -\lambda([X_H, X_G]). \quad (2.2)$$

Then it satisfies Jacobi identity and the assignment $X \mapsto -\lambda(X)$ defines a Lie algebra isomorphism $\mathfrak{X}(M, \xi)$ to $C^\infty(M)$.

Under our sign convention, the $\lambda$-Hamiltonian $H$ of the Reeb vector field $R_\lambda$ as a contact vector field becomes the constant function $H = -1$.

Next let $\psi^t \xi$ be a contact isotopy of $(M, \xi = \ker \lambda)$ with $\psi^t\xi = e^{t\lambda}$ and let $X_t$ be the time-dependent vector field generating the isotopy. Let $H : [0, 1] \times M \to \mathbb{R}$ be the associated time-dependent contact Hamiltonian $H_t = -\lambda(X_t)$.

We denote by $\text{Cont}_0(M, \xi)$ the identity component of the group $\text{Cont}(M, \xi)$ of (orientation-preserving) contactomorphisms. We denote by

$$\mathcal{P}(\text{Cont}(M, \xi))$$

the groupoid of (Moore) paths of contactomorphisms $\ell : [0, T] \to \text{Cont}(M, \xi)$. We call an element thereof a contact Hamiltonian path. We have three obvious maps, the assignment $\ell \to T$ of the domain length of $\ell$, and the source and the target map

$$s, t : \mathcal{P}(\text{Cont}(M, \xi)) \to \text{Cont}(M, \xi); \quad s(\ell) = \ell(0), \; t(\ell) = \ell(T) \quad (2.3)$$

as usual. (When we consider an element of Moore path $\ell$, one often writes it as a pair $(T, \ell)$.)

When $(M, \xi)$ is equipped with a contact form $\lambda$ and we consider a path on $[0, 1]$, i.e., with $T = 1$, we can associated another map the $\lambda$-developing map

$$\text{Dev}_\lambda : \mathcal{P}(\text{Cont}(M, \xi)) \to C^\infty([0, T] \times M, \mathbb{R})$$

by assigning its $\lambda$-contact Hamiltonian functions

$$\text{Dev}_\lambda(\ell)(t, x) := -\lambda \left( \frac{\partial\ell}{\partial t}(t, \ell_t^{-1}(x)) \right). \quad (2.4)$$

**In the present paper, we will always assume $T = 1$ unless otherwise said.** Unravelling this definition, we have $\text{Dev}_\lambda(\ell)(t, x) = H(t, x)$ where $X_t$ is the vector field generating the path $\ell$, i.e.,

$$X_t(x) = \frac{\partial\ell}{\partial t}(t, \ell_t^{-1}(x)), \quad H = -\lambda(X_t).$$
We denote by $X \mapsto \psi$ if $\psi = \psi^1_H$.

The following formulae for the contact Hamiltonians can be derived by a straightforward calculation. (See [MS15] for its first appearance.)

**Lemma 2.4.** Let $\Psi = \{\psi_t\} \in P(\text{Cont}(M, \xi))$ be a contact isotopy satisfying $\psi^* \lambda = e^{\theta} \lambda$ with $g_{\Psi} := g(t, x)$ and generated by the vector field $X_t$ with its contact Hamiltonian $H(t, x) = H_t(x)$, i.e., with $\text{Dev}_\lambda(\Psi) = H$.

1. Then the (timewise) inverse isotopy $\Psi^{-1} := \{\psi_t^{-1}\}$ is generated by the (time-dependent) contact Hamiltonian
   \[
   \text{Dev}_\lambda(\Psi^{-1}) = -e^{-g_{\Psi} \circ \Psi} \text{Dev}_\lambda(\Psi)
   \]  
   where the function $e^{-g_{\Psi} \circ \Psi}$ is given by $e^{-g_{\Psi} \circ \Psi}(t, x) := \frac{\partial}{\partial t} (\psi_t^{-1}(x))$.

2. If $\Psi' = \{\psi'_t\}$ is another contact isotopy with conformal exponent $g_{\Psi'} = \{g'_t\}$, then the timewise product $\Psi \Psi'$ is generated by the Hamiltonian
   \[
   \text{Dev}_\lambda(\Psi' \Psi) = \text{Dev}_\lambda(\Psi') + e^{-g_{\Psi \circ \Psi'}^{-1}} \text{Dev}_\lambda(\Psi) \circ (\Psi')^{-1}.
   \]  

In particular, if $\Psi$ is a strict contactomorphism like the Reeb flow $\varphi_t^\lambda$, then we have

\[
\text{Dev}_\lambda(\Psi' \Psi) = \text{Dev}_\lambda(\Psi') + \text{Dev}_\lambda(\Psi) \circ (\Psi')^{-1}
\]

which is an immediate generalization of the symplectic case.

Now we prove the following contact analog of well-known Banyaga’s formula from [Ban78] in symplectic geometry. For the derivation of this contact counterparts, we need to employ somewhat different argument to derive these formulae, especially because the bracket $\{G, H\}$, called the Lagrange bracket [AG01], is defined differently from the symplectic Poisson bracket and carries different properties, e.g., that the bracket does not satisfy the Leibnitz rule any more. (See [LOT18, Proposition 5.6], [dLLV19, Proposition 9].)

**Proposition 2.5.** Let $\psi_{s,t}$ be a two-parameter family of contactomorphisms and $H$ and $G$ the $t$-Hamiltonian and the $s$-Hamiltonian respectively. Then we have

\[
\frac{\partial}{\partial s} H - \frac{\partial}{\partial t} G + \{G, H\} = 0,
\]

\[
\frac{\partial}{\partial t} (G(s, t, \psi^H_{s,t}(x))) = \frac{\partial}{\partial t} (s, t, \psi^H_{s,t}(x)).
\]

**Proof.** We first consider the map $\Phi : (-\delta, \delta) \times [0, T] \to M$ defined by $\Phi(s, t) = (s, t, \psi_{s,t}(x))$.

Then we have

\[
\frac{d\Phi}{ds} = \frac{\partial}{\partial s} \oplus X_G(\psi_{s,t}(x))
\]

\[
\frac{d\Phi}{dt} = \frac{\partial}{\partial t} \oplus X_H(\psi_{s,t}(x))
\]
on $(-\delta, \delta) \times [0, T] \oplus TM$. Therefore the vector fields

\[
\frac{\partial}{\partial s} \oplus X_G, \quad \frac{\partial}{\partial t} \oplus X_H
\]
on $(-\delta, \delta) \times [0, T] \times M$ are $\Phi$-related to $\frac{\partial}{\partial s}$ and $\frac{\partial}{\partial t}$ we have

\[
[\frac{\partial}{\partial s} \oplus X_G, \frac{\partial}{\partial t} \oplus X_H] = 0.
\]

By expanding the left hand side, we obtain

\[
\frac{\partial X_H}{\partial s} - \frac{\partial X_G}{\partial t} + [X_G, X_H] = 0.
\]
By evaluating the one-form $\lambda$ against the equation and recalling the definition of Lagrange bracket $\{G,H\}$ (see [Oh21b, Proposition 2.19] for the definition thereof with our sign convention)

$$\{G,H\} = -\lambda([X_G,X_H]),$$

the above is equivalent to

$$-\frac{\partial H}{\partial s} + \frac{\partial G}{\partial t} - \{G,H\} = 0.$$

This finishes the proof of (2.7).

For the proof of (2.8), we rewrite (2.9) as

$$0 = \frac{\partial X_H}{\partial s}(s,t,\psi^t_H(x)) - \frac{\partial X_G}{\partial t}(s,t,\psi^t_H(x)) - \mathcal{L}_{X_H} X_G(s,t,\psi^t_H(x))$$

for all $(s,t,x)$. We then apply the one-form $\lambda$ and get

$$-\frac{\partial H}{\partial s}(s,t,\psi^t_H(x)) + \frac{\partial G}{\partial t}(G(s,t,\psi^t_H(x))) = 0$$

which finishes the proof of (2.8). \qed

**Remark 2.6.** We would like to mention that in this contact case the equality (2.7) holds in the nose while in the symplectic case, we only have

$$-\frac{\partial H}{\partial s} + \frac{\partial G}{\partial t} - \{G,H\} = c(s,t)$$

for some function $c = c(s,t)$ depending only on the parameters $(s,t)$.

Using (2.8), we derive the following formula for the $s$-Hamitonian $\text{Dev}(s \mapsto \phi^t_{sH})$ of the two-parameter family of contactomorphisms

$$\mu(s,t) := \phi^t_{sH}$$

for any $t$-dependent Hamiltonian $H = H(t,x)$. Unlike the $t$-Hamiltonian which is manifest from the expression $\phi^t_{sH}$, the $s$-Hamiltonian is not manifest therefrom.

The following formula will play a fundamental role in our derivation of the optimal inequality that enters in our proof of the Sandon-Shelukhin conjecture. (See the proof of the $\pi$-energy identity stated in Proposition 12.2.)

**Lemma 2.7.** Let $L$ be the two-parameter Hamiltonian given by $L(s,t,x) = \text{Dev}(s \mapsto \phi^t_{sH})(s,x)$. Then

$$L(s,t,\psi^1_{sH}(x)) = \int_0^t H(r,\psi^{r}_{sH}(x)) \, dr.$$

(2.11)

In particular we have $L(s,0,x) \equiv 0$ and

$$L(s,1,\psi^1_{sH}(x)) = \int_0^1 H(r,\psi^{r}_{sH}(x)) \, dr.$$

(2.12)

**Proof.** We also denote the $t$-Hamiltonian of the family $\mu = \mu(s,t)$ by $F = F(s,t,x)$ such that

$$F = F(s,t,x) := \text{Dev}(t \mapsto \mu(s,t))(t,x)$$

which is nothing but

$$F(s,t,x) := sH(t,x).$$
Using (2.8), we compute the $\text{Dev}(s \mapsto \mu_{(s,t)})$ by integrating the following
\[ \frac{\partial}{\partial t} (L \circ \mu)(s,t,x) = \left( \frac{\partial F}{\partial s} \right)(s,t,\mu_{(s,t)}(x)) = H(t,\mu_{(s,t)}(x)) = H(t,\psi^t_{sH}(x)) \]
over $t$. Then we obtain
\[ L(s,t,\mu_{(s,t)}(x)) = \int_0^t \frac{\partial F}{\partial s}(s,r,\mu_{(s,r)}(x)) \, dr = \int_0^t H(r,\psi^r_{sH}(r,x)) \, dr \]
which proves (2.11). By substituting $t = 0$ and $t = 1$ respectively, we have finished the proof. \qed

Part 1. Co-Legendrian submanifolds, tame contact manifolds and contact instantons

3. CO-LEGENDRIAN SUBMANIFOLDS

The notion of pre-Lagrangian submanifolds was introduced in [EHS95] which we recall now. Let $SM = M \times \mathbb{R}$ be the (conical) symplectization of $M$ which is the $\mathbb{R}_+-$subbundle of $T^*M$ which is formed by contact forms compatible with the given co-orientation of $(M, \xi)$. We rephrase the definition given in [EHS95] as follows.

**Definition 3.1.** Let $SM = M \times \mathbb{R}$ be the symplectization of $M$. A submanifold $K \subset M$ is called pre-Lagrangian if there is a Lagrangian section $\tilde{k} : K \to SM$.

By setting $\tilde{K} = \text{Image} \tilde{k}$ and $K = (\pi|_{\tilde{K}})^{-1}$, it can be easily seen that this definition is equivalent to the definition given in [EHS95] the condition of which reads that there is a Lagrangian lift $\tilde{K} \subset SM$ such that the restriction $\pi|_{\tilde{K}} : \tilde{K} \to K$ is a diffeomorphism.

We now introduce a more intrinsic notion of co-Legendrian submanifolds which does not involve symplectization and includes that of pre-Lagrangian submanifolds as a special case.

3.1. Definition of co-Legendrian submanifolds. We start with recalling the definition of coisotropic submanifolds in contact manifolds $(M, \xi)$. (We refer to [LOTV18] for the definition thereof in the general, not necessarily coorientable, case.) Majority of the discussion given in this subsection will not be directly relevant to the main purpose of the present paper except for the purpose of providing some general perspective for a future purpose with the Reeb trace of Legendrian submanifold. (We also find that the notion itself is interesting and so worthwhile to describe its geometry in some detail for a future purpose.) The Reeb traces of Legendrian submanifolds are the prototypes of co-Legendrian submanifolds and will enter in the intersection theoretic translation of Sandon’s translated points. (See Corollary 4.8.)

Recall by definition of $\lambda$ that $(M,d\lambda)$ is a presymplectic manifold.

**Definition 3.2.** Let $(M, \xi)$ be a contact manifold equipped with a contact form $\lambda$. A $(\lambda)$-coisotropic submanifold $C \subset M$ (with respect to $\lambda$) is one that satisfies
\[ (TC)^d\lambda \subset TC. \]

It is easy to show that this definition does not depend on the choice of contact forms $\lambda$ and depends only on the contact structure $\xi$. 

Lemma 3.3. Let $C$ be a coisotropic submanifold of $(M^{2n+1}, \lambda)$, and let $\lambda$ be any contact form of $\xi$.

1. $R_\lambda \in TC$.
2. We have a natural exact sequence vector bundles

$$0 \to \mathbb{R}(R_\lambda) \to (TC)^{d\lambda} \to TC \to TC/(TC)^{d\lambda} \to 0$$

where $TC/(TC)^{d\lambda} \to C$ is a symplectic vector bundle.

Proof. Since $R_\lambda \in \ker d\lambda$, we have

$$\mathbb{R}(R_\lambda) \subset (TC)^{d\lambda}.$$

Since $(TC)^{d\lambda} \subset TC$ by definition of coisotropic submanifolds, we derive that $R_\lambda$ is tangent to $C$. On the other hand, since $C$ is coisotropic, $TC/(TC)^{d\lambda}$ is symplectic. This finishes the proof. □

Definition 3.4. A coisotropic submanifold $C \subset (M, \lambda)$ is called co-Legendrian if $C$ is minimally coisotropic, i.e., if $TC/(TC)^{d\lambda}$ is symplectic.

Proposition 3.5. Let $Z$ be a co-Legendrian submanifold of $M$. Then we have $\dim Z = n + 1$, and

$$TZ = (TZ)^{d\lambda} = (\xi \cap TZ) \oplus \mathbb{R}(R_\lambda).$$

In particular, $\xi \cap TZ \subset TM|_Z$ is a Legendrian subbundle.

Proof. By Lemma 3.3, we know

$$\mathbb{R}(R_\lambda) \subset (TZ)^{d\lambda} = TZ.$$

The latter also implies $TZ/\mathbb{R}(R_\lambda) = (TZ/\mathbb{R}(R_\lambda))^{[d\lambda]}$ with respect to the induced fiberwise symplectic bilinear form $[d\lambda]$ on the quotient bundle $TM/\mathbb{R}(R_\lambda) \cong \xi$ of rank $2n$. In other words, $TZ/\mathbb{R}(R_\lambda)$ is a Lagrangian subbundle of the quotient and hence rank $TZ/\mathbb{R}(R_\lambda) = n$.

Combining the above, we have finished the proof. □

Remark 3.6. It is shown in [OP05], [Zam08] (for the symplectic case) and in [LOT18] (for the contact case) that the local deformation problem of general coisotropic submanifolds is obstructed. In particular the set of general coisotropic submanifolds is not a smooth (Frechet) manifold [Zam08]. However for the corresponding deformation problem of the co-Legendrian case, this obstruction vanishes and so the set of co-Legendrian submanifolds forms a smooth manifold: The quadratic term in the defining equation of coisotropic subspace given in [OP05, Proposition 2.2] vanishes for the co-Legendrian case!

Proposition 3.7. Any pre-Lagrangian submanifold is co-Legendrian for any contact form $\lambda$ of a given contact structure $(M, \xi)$ on $M$.

We need some preparation to start with the proof.

Let $\lambda$ be a contact form compatible to the co-orientation of $(M, \xi)$. Then we have canonical splitting

$$T_\alpha(SM) = \tilde{\xi} \oplus \mathbb{R}\left(\frac{\partial}{\partial r}\big|_{\alpha}\right) \oplus \mathbb{R}(\tilde{R}_\lambda(\alpha))$$

(3.1)

where $\tilde{R}_\lambda$ is the projectable vector field on $SM = M \times \mathbb{R}_+$ whose $\pi$-projection to $M$ is the Reeb vector field $R_\lambda$. Similarly $\tilde{\xi}$ is the lift of contact distribution $\xi$ of $M$. 
to $SM$. Both $\mathbb{R}\langle \frac{\partial}{\partial y} \big| \alpha \rangle \oplus \mathbb{R}\langle \hat{R}_\alpha \rangle$ and $\hat{\zeta}$ are symplectic subspaces of $T_\alpha(SM)$ with respect to the symplectic form $\omega = d(r\pi^*\lambda)$.

Let $K \subset M$ be any submanifold and let $\hat{k} : K \to SM$ be a section, i.e., a smooth map with $\pi \circ \hat{k} = id|_K$. We write the tangent vectors of $K$ at $y$ as

$$v = v' + aR_\lambda, \quad u = u' + bR_\lambda \in T_yK$$

for some $a, b \in \mathbb{R}$. At $\alpha \in \hat{k}^{-1}(y)$, we have canonical lifts $\hat{v}, \hat{u}$ thereof so that

$$dr(\hat{v}) = 0 = dr(\hat{u}), \quad \hat{v}', \hat{u}' \in \hat{\xi}_\alpha$$

by the splitting.

**Lemma 3.8.** Let $\alpha = r\pi^*\lambda_y \in \hat{k}^{-1}(y)$. Then for any $v, w \in T_yK$, we have

$$\omega(\hat{v}, \hat{u}) = rd\lambda(v, u). \quad (3.2)$$

**Proof.** We compute

$$\omega(\hat{v}, \hat{u}) = d(r\pi^*\lambda)(\hat{v}, \hat{u})$$

$$= (dr \wedge \pi^*\lambda + rd\pi^*\lambda)(\hat{v}', a\hat{R}_\lambda, \hat{u}', b\hat{R}_\lambda)$$

$$= r\pi^*d\lambda(\hat{v}', a\hat{R}_\lambda, \hat{u}', b\hat{R}_\lambda) = rd\lambda(v, u). \quad (3.3)$$

$\square$

We are now ready to give a proof of the proposition.

**Proof of Proposition 3.7.** Let $K$ be a pre-Lagrangian submanifold. Pick a Lagrangian section $\hat{k} : K \to SM$ and let $\hat{K}$ be its image. Then since $T_\alpha\hat{K}$ is Lagrangian, so is $(T_\alpha\hat{K})^\omega$ since $(T_\alpha\hat{K})^\omega = (T_\alpha\hat{K})$. Therefore

$$\omega(\hat{v}, \hat{u}) = 0$$

for all $\hat{v}, \hat{u}$ with $v, u \in (T_yK)^{d\lambda}$, since the latter implies $\hat{v}, \hat{u} \in T_\alpha\hat{K} = (T_\alpha\hat{K})^\omega$.

Therefore by (3.3) $d\lambda(v, u) = 0$ for all $v, u \in (T_yK)^{d\lambda}$ and hence $\hat{K}$ is isotropic with respect to $d\lambda$. Since dim $K = \text{dim} \hat{K} = n$, $K$ must be co-Legendrian. This finishes the proof. $\square$

The following proposition shows that none of closed (i.e., compact without boundary) co-Legendrian submanifold are pre-Lagrangian.

**Proposition 3.9.** No closed co-Legendrian submanifold is pre-Lagrangian.

**Proof.** Denote by $SM \to M$ the symplectization of $M$. Let $i : K \hookrightarrow M$ be a closed co-Legendrian submanifold. We need to show that no section $\hat{k} : K \to i^*SM$ can be Lagrangian.

Suppose to the contrary that there is a section $\hat{k} : K \to SM$ over $i$ whose image is a Lagrangian submanifold in $SM$. Note that any section $\hat{k}$ can be written as

$$\hat{k}(y) = (y, e^{g(y)}) \in K \times \mathbb{R}_+$$

for some function $g : K \to \mathbb{R}$. Since $\hat{k}$ is assumed to be Lagrangian,

$$d(e^{g} \hat{k}^*\pi^*i^*\lambda) = 0$$

on $K$, which is equivalent to

$$0 = dg \wedge (\pi \circ \hat{k})^*i^*\lambda + d(\pi \circ \hat{k})^*i^*\lambda = dg \wedge i^*\lambda + i^*d\lambda$$
on $K$. Since $K$ is assumed to be compact without boundary, $g$ must have at least one critical point $y_0 \in K$ where we have $dg(y_0) = 0$. Therefore $d\lambda|_{T_{y_0} K} = 0$ at $y_0$. In particular, we have

$$T_{y_0} K \subset \xi_{y_0}$$

and so $T_{y_0} K$ is isotropic in $\xi_{y_0}$. But this is a contradiction to the fact that $\dim K = n + 1$. Therefore there cannot be any Lagrangian section $\hat{k}$ of $SM \to M$. This finishes the proof. □

3.2. Examples of co-Legendrian submanifolds.

Example 3.10 (Conormal jets). The most natural examples of co-Legendrian submanifolds are the conormal one-jets $\tilde{\nu}^* N \subset J^1 B$ for any submanifolds $N \subset B$ where we define $\tilde{\nu}^* N$ by

$$\tilde{\nu}^* N := \pi^{-1}(\nu^* N) = \{(q,p,z) \mid (q,p) \in \nu^* N\}. \quad (3.4)$$

In fact, any co-Legendrian submanifold of general contact manifold is locally of this form.

We now show that the set of co-Legendrian submanifolds is strictly bigger than that of pre-Lagrangian submanifolds.

Example 3.11. We have only to provide an example of compact co-Legendrian submanifolds without boundary which then will not be pre-Lagrangian by Proposition 3.9. Consider the contact manifold $S^1 \times T^* S^1$ equipped with the contact one form

$$\lambda = dt - pdq$$

where $(q,p)$ is the coordinates of $T^* S^1 \cong S^1 \times \mathbb{R}$ and $t$ is the standard coordinate $S^1 \cong \mathbb{R}/\mathbb{Z}$. Then it is easy to see that $S^1 \times 0_{T^* S^1} \cong S^1 \times S^1$ is a co-Legendrian submanifold but it is not pre-Lagrangian by Proposition 3.9.

The next examples are the ones of our main interest in the present paper.

Example 3.12 (Reeb trace of Legendrian submanifolds). Let $R$ be any Legendrian submanifold of $(M,\lambda)$ and consider its sweeping locus under the Reeb flow

$$Z_R := \bigcup_{t \in \mathbb{R}} \phi^t_{\lambda_R}(R). \quad (3.5)$$

This is an immersed co-Legendrian submanifold in general. Under the hypothetical situation that there is no self Reeb chord of $R$ i.e., that Arnold’s Reeb chord conjecture fails for $R$, this immersion becomes a one-one immersion.

Remark 3.13 (Control manifolds). This class of submanifolds has been considered in the geometric formulation of thermodynamics and the information theory in the physics literature with the name of control manifold. (See [MNSS90], [BLM15], [BLMN15] for example.) (Strictly speaking, the control manifolds in these references are considered only in the one-jet bundle and also equipped with a (pseudo-)Riemannian metric in addition.) Co-Legendrian submanifolds are defined on general contact manifold, not just in the one-jet bundle case, without being equipped with a metric.

We now introduce the intersection theoretic version of translated fixed points.

Definition 3.14 (Translated intersection points). Let $(M,\xi)$ be a contact manifold. Let $(R_0, R_1)$ a pair of Legendrian submanifolds.
Let $\lambda \in \mathcal{C}(\xi)$. We call a pair $(x, \eta) \in R_0 \times \mathbb{R}_+$ a $\lambda$-translated intersection point of $R_0$ and $R_1$ if there is a Reeb chord $\gamma$ satisfying
\[ \gamma(0) \in R_0, \quad \gamma(\eta) = x \in R_1. \]
i.e., if $x \in R_0 \cap (\phi_R^\eta)^{-1}(R_1) \subset R_0 \cap Z_{R_1}$.

(2) We say the pair $(R_0, R_1)$ are dynamically $\lambda$-entangled if there is a Reeb chord of $\lambda$ from $R_0$ to $R_1$, and just dynamically Reeb-entangled if there is $\lambda \in \mathcal{C}(\xi)$ for which $\Reeb(M, \lambda; R) \neq \emptyset$.

By definition, for each given translated intersection point $(x, \eta)$ with $x \in \psi(R)$, there is a Reeb chord $\gamma_x : [0, \eta] \to M$ defined by
\[ \gamma_x(t) := \phi_{R_1}^{\eta}(x) \]
which satisfies
\[ \gamma_x(0) = x \in \psi(R), \quad \gamma_x(\eta) \in R \]
and vice versa.

We summarize the relationship between the set of translated intersection points between $R_0$ and $R_1$ and the intersection set $\psi(R_0) \cap Z_{R_1}$ in terms of the following general correspondence lemma.

**Lemma 3.15.** Let $(M, \lambda)$ be a contact manifold, and let $\psi : M \to M$ be a contactomorphism. Consider any compact subset $S_0, S_1$ of $M$.

\[ \psi(R) \cap Z_{S_1} = \emptyset \iff \psi(S_0) \cap S_1 = \emptyset \quad \& \quad \Reeb(\psi(S_0), S_1) = \emptyset. \]  

We remark that for Legendrian pair $(R_0, R_1)$, the condition $\psi(R_0) \cap R_1 = \emptyset$ holds for a generic contactomorphism $\psi$ by dimensional reason. This translation applied to a pair of compact Legendrian submanifolds $(R_0, R_1)$ will be what enables us to study the existence question of translated intersection points through the study of the moduli space of contact instantons with Legendrian boundary conditions which is the main analytical framework that we employ in the present paper.

### 4. Legendrianization of Contactomorphisms and Translated Points

A natural example of co-Legendrian submanifolds arises through the operation of Legendrianization of contactomorphisms. This construction was first employed by Bhupal [Bhu01] for his construction of spectral order on $\Cont_0(\mathbb{R}^{2n+1})$. (See also [Che96].) The following proposition is the contact analog to the fact that the graph of any symplectomorphism is a Lagrangian submanifold.

**Proposition 4.1.** Let $(Q, \xi)$ be any contact manifold. Define
\[ M_Q := Q \times Q \times \mathbb{R} \]
and by $\pi_i : M_Q \to Q$ be the projection to the $i$-th factor of the product for $i = 1, 2$, and $\eta : M_Q \to \mathbb{R}$ the projection to $\mathbb{R}$. Let a contact form $\lambda$ of the contact manifold $(Q, \xi)$ be given. Then the following hold:

(1) The one-form
\[ \mathcal{A} := -\epsilon^n \pi_1^* \lambda + \pi_2^* \lambda \]
on $M_Q$ defines a contact form.

(2) The Reeb vector field $R_{\mathcal{A}}$ is given by $(0, R_{\lambda}, 0)$. 

(3) For any contactomorphism $\psi$ of $(Q, \xi)$ with $\psi^* \lambda = e^{g_{\psi}} \lambda$, the map
\[
j_\psi(y) = (y, \psi(y), g_\psi(y))
\] (4.3)
is a Legendrian embedding of $Q$ into $(M_Q, \mathcal{A})$.

We denote by $\Gamma_\psi$ the image of the map $j_\psi$ and call it the Legendrianization of $\psi$.

Proof. Let $\dim Q = 2n + 1$. We compute
\[
d \mathcal{A} = -e^\eta (\pi_1^* d\lambda + d\eta \wedge \pi_1^* \lambda) + \pi_2^* d\lambda.
\]
We observe that the two form inside the parenthesis is the sum of two forms: one is
\[-e^\eta (\pi_1^* d\lambda + d\eta \wedge \pi_1^* \lambda)
\] and the other is $\pi_2^* d\lambda$. The first form is nondegenerate on $TQ \oplus \{0\} \oplus TR \subset TM_Q$ and the second form has rank $2n$ on $\{0\} \oplus TQ \oplus \{0\}$. Therefore $d \mathcal{A}$ has rank $2(2n + 1)$. Using this, one easily check that $\mathcal{A} \wedge (d \mathcal{A})^n$ is nowhere zero. (See the proof of [OS21, Proposition 2.4] for the details of its proof.) This proves $\mathcal{A}$ is a contact form on $M_Q = Q \times Q \times \mathbb{R}$.

Next (2) follows from the following lemma whose proof is a straightforward calculation and so omitted.

**Lemma 4.2.** The Reeb vector field of $\mathcal{A}$ is given by
\[R_\mathcal{A} = (0, R_\lambda, 0)\]
and its contact distribution given by
\[\ker \mathcal{A}|_{(x,y,\eta)} = \{(X,Y,a \frac{\partial}{\partial \eta}) \in TM \mid e^\eta \lambda(X) = \lambda(Y)\}.
\]

Finally for the proof of (3), we just compute $j_\psi^*(\mathcal{A})$
\[
j_\psi^*(\mathcal{A}) = -e^{g_{\psi}} \pi_1^* \lambda + j_\psi^* \pi_2^* \lambda
\]
\[
= -e^{g_{\psi}} \lambda + \psi^* \lambda = e^{g_{\psi}} \lambda + e^{g_{\psi}} \lambda = 0.
\]
This proves (3), which finishes the proof. \qed

Next we introduce the what we call the Legendrianization of contactomorphism $\psi$ in general.

**Definition 4.3 ($\Gamma_\psi$).** Let $\psi : Q \to Q$ be a contactomorphism with its conformal exponent function $g_\psi$. We define the contact graph
\[\Gamma_\psi := \{(x, y, \eta) \in Q \times Q \times \mathbb{R} \mid y = \psi(x), \eta = g_\psi(x)\}. \quad (4.4)
\]
A direct calculation gives rise to the following.

**Lemma 4.4.** For any contactomorphism $\psi$, $\Gamma_\psi$ is a Legendrian submanifold of the contact manifold $(M_Q, \ker \mathcal{A})$ with
\[M_Q = Q \times Q \times \mathbb{R}, \quad \mathcal{A} = -e^\eta \pi_1^* \lambda + \pi_2^* \lambda.
\]

The next proposition will be important in the quantitative study of contactomorphisms, in particular for the proof of Theorem 1.13. It is the contact counterpart of the lifted Hamiltonian
\[\tilde{H}(t, x, y) := H(t, y)\]
generating the graph flow of the Hamiltonian path $t \mapsto \phi_t^H$ in symplectic geometry.
Proposition 4.5. Let $H = H_t(q, p, z)$ be the Hamiltonian generating the contact isotopy $\psi_t$ with $\psi_t^* \lambda = e^{g_t \lambda}$, and $\bar{H}_t$ be any contact Hamiltonian generating the Legendrian isotopy $t \mapsto j_{\psi_t}$ on $Q \times Q \times \mathbb{R}$. Then we have
\[ \bar{H}_t(j_{\psi_t}(q, p, z)) = H_t(\psi_t(q, p, z)) \] (4.5)
for each $(q, p, z) \in \text{Fix} \psi_t$. In other words, the values of $\bar{H}$ on the trace of the isotopy $t \mapsto \text{Image} j_{\psi_t}$ are uniquely determined by the contact isotopy $\psi_t$.

Proof. Denote $y = (q, p, z)$. By definition, we have
\[ j_{\psi_t}(x) = (x, \psi_t(x), g_t(x)) \]
for all $x \in Q$. We take the derivative of the isotopy $j_{\psi_t}$ for each given $x \in Q$
\[ \left( X_t(0, \psi_t(y)), 0, -\frac{\partial g_t}{\partial t}(x) \right). \]
Therefore noticing that $\mathcal{A}$ does not have the summand of $d\eta$, we have obtained
\[ \bar{H}_t(j_{\psi_t}(x)) = -\mathcal{A} \left( X_t(\psi_t(x)), 0, -\frac{\partial g_t}{\partial t}(x) \right) \]
\[ = -\left( -e^{g_t} \pi_t^* \lambda + \pi_t^2 \lambda \right) \left( X_t(\psi_t(x)), 0, -\frac{\partial g_t}{\partial t}(x) \right) \]
\[ = -\lambda(X_t(\psi_t(x)) = H_t(\psi_t(x)) \]
which finishes the proof. \qed

Remark 4.6. (1) We would like to attract readers’ attention to the last statement which is quite a contrast against the fact from symplectic geometry: The values of the corresponding Hamiltonian $\bar{H}$ relative to Lagrangian isotopy are determined by the exact Lagrangian isotopy only up to the addition of a function of the type $c = c(t)$ in symplectic geometry.

(2) The above proposition is the reason why we take $\mathcal{A}$ as our contact one-form on $Q \times Q \times \mathbb{R}$ which is the negative of the one $A$ used in [Bhu01]. If we took $A = A := e^{g_t} \pi_t^* \lambda - \pi_t^2 \lambda$ as [Bhu01], then (4.5) would be changed to $\bar{H}_t(j_{\psi_t}(q, p, z)) = -H_t(\psi_t(q, p, z))$, which we would like to avoid.

(3) The contact graph $\Gamma_\psi$ can be also expressed as the set
\[ \left\{ \left( \psi_t^{-1}(y), y, -g_{\psi_t^{-1}}(y) \right) \mid y \in Q \right\} \]
by the identity
\[ -g_{\psi^{-1}} = g_{\psi} \circ \psi^{-1}. \]

Example 4.7. Let $(Q, \xi)$ be any contact manifold let $\lambda$ be a contact form of $\xi$. Equip the product $M = Q \times Q \times \mathbb{R}$ with the contact form (4.2).
\[ \Gamma_{id} = \{ (x, x, 0) \in Q \times Q \times \mathbb{R} \} \subset M. \]
We denote by $\phi_t^{R_\lambda}$ the flow of the Reeb vector field $R_\lambda$. Then we have
\[ R := \Gamma_{id}, \quad Z_{\Gamma_{id}} := \{ (x, \phi_t^{R_\lambda}(x), 0) \mid x \in Q, t \in \mathbb{R} \} \]
(4.6)
since $g_{\phi_t^{R_\lambda}} = 0$ for the Reeb flow $\phi_t^{R_\lambda}$ which are strict contactomorphisms. We remark that $Z_{\Gamma_{id}}$ is an embedded co-Legendrian submanifold
We note that when $\psi = id$, we have 
$$\Gamma_{id} \cap Z_{\Gamma_{id}} = \Gamma_{id}$$
which is of clean intersection in the Bott sense. We would like to highlight the fact that this intersection is degenerate which is but is clean in that 
$$\dim \Gamma_{id} + \dim Z_{\Gamma_{id}} = \dim M, \quad \dim \Gamma_{id} \cap \dim Z_{\Gamma_{id}} = \dim \Gamma_{id}.$$ 
The following corollary provides a link between the intersection set $\psi(R) \cap Z_R$ and Sandon’s notion of translated point of a contactomorphism $\psi$ on $Q$.

**Corollary 4.8.** Let $(Q, \xi)$ be a contact manifold equipped with a contact form $\lambda$. Then

1. $x \in Q$ is a translated point of a contactomorphism $\psi$ if and only if $(x, x, 0) \in \Gamma_{\psi} \cap Z_\Delta$.
2. $\psi$ is nondegenerate if and only if $\Gamma_{\psi} \cap Z_\Delta$.

Proposition 4.5 also implies 
$$\tilde{\psi}(\Gamma_{id}) = \Gamma_{\psi}$$
where $\tilde{\psi} = \psi_1^R$, i.e., $\Gamma_{\psi}$ is contact isotopic to $\Gamma_{id}$ in $Q \times Q \times \mathbb{R}$. Corollary 4.8 and this equality reduce the existence question on the translated points of a contactomorphism $\psi: Q \to Q$ as that of the Reeb chords between the pair $(\psi(R), R)$ of compact Legendrian submanifolds $R$ with $R = \Gamma_{id}$. In this framework, the above nondegeneracy is also equivalent to the standard nondegeneracy of the pair $(\psi(R), R)$ in the sense of Reeb chords.

**5. Tame Contact Manifolds**

In this paper, our analysis of (perturbed) contact instantons will be performed on a general class of contact manifolds which may not be necessarily compact. As in other geometric analysis problems such as that of pseudoholomorphic curves, compactness of the ambient manifolds is not needed as long as relevant $C^0$ confinement results can be achieved.

We first introduces a class of barrier functions which will control the $C^0$ bounds of contact instantons on noncompact contact manifolds.

**Definition 5.1 (Reeb-tame function).** Let $(M, \xi)$ be contact manifold equipped with contact form $\lambda$. A function $\psi: M \to \mathbb{R}$ is called $\lambda$-tame (at infinity) if $L_R \lambda d \psi = 0$ on $M \setminus K$ for a compact subset.

**Definition 5.2 (Contact $J$-convexity).** Let $J$ be a $\lambda$-adapted CR almost complex structure. Let $U \subset M$ be an open subset. We call a function $\psi: U \to \mathbb{R}$ contact $J$-convex if 

$$-d(d\psi \circ J) \geq 0 \quad \text{on } \xi, \quad (5.1)$$

$$R_\lambda d(d\psi \circ J) = 0 \quad \text{on } U.$$ 

Using this, we introduce the following class of contact manifolds for which the $C^0$ estimates for the (perturbed) contact instantons will be available.
Definition 5.3 (Tame contact manifolds). We call a contact form $\lambda$ tame (at infinity) if there exists a compact subset $K \subset M$ such that $\lambda$ admits a contact pseudoconvex pair $(\psi, J)$ on $M \setminus K$ such that $\psi$ is also a $\lambda$-tame exhaustion function of $M \setminus K$. We call $(M, \lambda)$ tame if $\lambda$ is tame, and a contact manifold $(M, \xi)$ tame if it admits a tame contact form.

Example 5.4. (1) Obviously any contact form $\lambda$ on any compact contact manifold is tame.

(2) We will show in Part 2 that the contact form\

$$\mathcal{A} = -e^{\eta} \pi^1 \lambda + \pi^2 \lambda$$

on $Q \times Q \times \mathbb{R}$ is tame for any compact contact manifold $(Q, \lambda)$.

(3) Any one-jet bundle $J^1 B$ with the standard contact form $dz - pdq$ for a compact manifold $M$ is tame. In fact, the coordinate function $z$ is a contact $J$-convex Reeb tame exhaustion function. (See [OY] for its proof and usage in the study of Legendrian spectral invariants.)

6. Hamiltonian-perturbed contact instantons

Consider a time-dependent function $H = H(t, x) : \mathbb{R} \times M \to \mathbb{R}$. Denote by $X_H$ the associated contact vector field. Then we have $\lambda(X_H) = -H$ by definition.

Definition 6.1 (Legendrian dual pair boundary condition). Let $(R_0, R_1)$ be a pair of Legendrian submanifolds in $(M, \xi)$. We call the pair $(R_0, Z_{R_1})$ the Legendrian dual pair associated to $(R_0, R_1)$. We say a Hamiltonian trajectory $\gamma : [0, 1] \to M$ satisfies a Legendrian dual pair boundary condition associated to $(R_0, R_1)$ if it satisfies $$\gamma(0) \in R_0, \quad \gamma(1) \in Z_{R_1}.$$

An upshot of considering the Legendrian dual pair boundary condition $(R_0, Z_{R_1})$ for the contact Hamilton’s equation is that such a curve naturally arises as an asymptotic limit of the perturbed contact instanton $u$ satisfying (6.7). (See the relationship (6.13) between $u$ and $\pi$ and the subsequence limit theorem, Theorem 6.17, below.)

Definition 6.2. Let $(M, \lambda)$ be a contact manifold equipped with a contact form, let $(R_0, R_1)$ be a pair of Legendrian submanifolds in $(M, \xi)$. We say a map $u : \mathbb{R} \times [0, 1] \to M$ is a $X_H$-perturbed contact instanton trajectory with Legendrian boundary condition if it satisfies

$$\begin{cases}
(du - X_H \otimes dt)^{\pi(0, 1)} = 0, \\
d(e^{\eta} u)(u^* \lambda + H \gamma) \circ j = 0
\end{cases} \quad (6.1)$$

together with the boundary condition

$$u(\tau, 0) \in R_0, \quad u(\tau, 1) \in R_1. \quad (6.2)$$

Remark 6.3. Note that it is easy to see that any asymptotic limit $\gamma_\infty$ of a solution $u$ with finite $\pi$-energy $E^\pi_{\pi, H}(u)$ satisfies

$$(\dot{\gamma}(t) - X_H(t, \gamma(t)))^\pi = 0.$$

We refer to [Oh21b, Proposition 3.4] for the general description of such a curve which is consistent with the asymptotic convergence result of the equation (6.7).
6.1. **Gauge transformation.** We first consider two different representations of the trajectory of the ODE $\dot{x} = X_H(x)$, one in terms of the *initial point* and the other in terms of the *final point*. The first one is given by
\[
z^q_H(t) := \psi^t_H(q), \quad q \in M
\]
and the other given by
\[
z^p_H(t) = \psi^t_H((\psi^1_H)^{-1}(p)).
\]
For a given pair $(R_0, R_1)$ of Legendrian submanifolds in $M$ we denote by $\Omega(R_0, R_1)$ the set of smooth paths from $R_0$ to $R_1$.

For a given Hamiltonian $H \mapsto \psi$, the above representations (6.3) and (6.4) provide two different one-to-one correspondences
\[
\Phi_H : \ell(t) \mapsto \psi^t_H((\psi^1_H)^{-1}(\ell(t))
\]
and
\[
\Phi'_H : \hat{\ell}(t) \mapsto \psi^t_H(\hat{\ell}(t)) : \Phi_H
\]
defines a bijective map
\[
\Phi_H : \Omega(\psi^1_H(R_0), R_1) \to \Omega(R_0, R_1)
\]
and $\Phi'_H$ defines
\[
\Phi'_H : \Omega(R_0, (\psi^1_H)^{-1}(R_1)) \to \Omega(\psi^1_H(R_0), R_1).
\]
Obviously the composition
\[
(\Phi_H)^{-1} \circ \Phi'_H : \Omega(R_0, (\psi^1_H)^{-1}(R_1)) \to \Omega(\psi^1_H(R_0), R_1)
\]
is induced by the diffeomorphism $\phi^1_H : M \to M$ in that
\[
(\Phi_H)^{-1} \circ \Phi'_H(\ell)(t) = (\psi^1_H \circ \ell)(t).
\]

**Remark 6.4.** In symplectic geometry, since the Hamiltonian diffeomorphism $\phi^1_H$ satisfies $(\psi^1_H)^*\omega = \omega$ and so induces a filtration preserving transformation between two Floer complexes $CF(\psi^1_H(R_0), R_1)$ and $CF(R_0, (\psi^1_H)^{-1}(R_1))$, one can freely go back and forth between the two without changing the relevant quantitative invariants. (See [Oh99].) However in the current contact context, the transformation changes the overall filtration structure between the two. We would like to emphasize that we will consistently use $\Phi_H$ and its inverse in the study of Shelukhin’s conjecture and never use the transformation $\Phi'_H$ in the present paper. This is because the conformal exponent $e^{q_0}$ would appear if $\Phi'_H$ were used. This appearance of conformal exponent is also responsible for the phenomenon that the Reeb-entangling energy $e^{v_0}(S_0, S_1)$ is not symmetric. (See Subsection 1.7.) To keep the importance of this coordinate change in readers’ minds, we name and call $\Phi_H$ and its inverse *gauge transformation*.

Now let $(M, \lambda, J)$ be a contact triad for the contact manifold $(M, \xi)$, and equip with it the *contact triad metric*
\[
g = d\lambda(\cdot, J \cdot) + \lambda \otimes \lambda.
\]
We also consider the time-dependent contact triads and $H = H(t, x)$ be a time-dependent Hamiltonian, and consider
\[
\begin{cases}
(du - X_H \otimes dt)^{\pi(0,1)} = 0, & d(e^{q_0}(u^* \lambda + H dt)) = 0 \\
u(\tau, 0) \in R, & u(\tau, 1) \in R
\end{cases}
\]
(6.7)
where the function $g_H : \mathbb{R} \times [0,1] \rightarrow \mathbb{R}$ is defined by
\[
g_H(t,x) := g_{\psi^t_H(\psi^1_H)^{-1}(u(t,x))} \tag{6.8}
\]
already introduced in (1.9). Now we take the following coordinate change
\[
\pi(\tau,t) := \Phi_H^{-1}(u(t,x)) = (\psi^t_H(\psi^1_H)^{-1})^{-1}(u(\tau,t)) = \psi^t_H(\psi^1_H)^{-1}(u(\tau,t)) \tag{6.9}
\]
and consider the following particular time-dependent family of $J$'s.

**Choice 6.5** (CR almost complex structures of $J$). Let $J_0 \in \mathcal{J}(\lambda)$. For given contact Hamiltonian $H = H(t,x)$, we fix a time-dependent CR almost complex structures given by
\[
J = \{J_t\}_{0 \leq t \leq 1}, \quad J_t := (\psi^t_H(\psi^1_H)^{-1})_*J_0. \tag{6.10}
\]
of $\lambda$-admissible almost complex structures.

### 6.2. Conversion to the intersection theoretic version.

Now we apply the discussion given in the previous subsection to $w = \pi$ which is defined by
\[
\pi(\tau,t) = (\psi^t_H(\psi^1_H)^{-1})^{-1}(u(\tau,t)). \tag{6.11}
\]

**Choice 6.6** (CR almost complex structures). Let $J_0 \in \mathcal{J}(\lambda)$. For given contact Hamiltonian $H = H(t,x)$, we fix a time-dependent CR almost complex structures given by
\[
J = \{J_t\}_{0 \leq t \leq 1}, \quad J_t := (\psi^t_H(\psi^1_H)^{-1})_*J_0. \tag{6.12}
\]
of $\lambda$-admissible almost complex structures.

The (translated) intersection theoretic version of the contact instanton complex for the pair $(R_0, R_1)$ is generated by the set of Reeb chords
\[
\mathcal{R}_{\text{Reeb}}(R_0, R_1)
\]
between them and its boundary map is constructed by the moduli space of unperturbed contact instanton equation (6.27).

On the other hand, the dynamical version of the complex is generated by some set of solutions of Hamilton’s equation $\dot{x} = X_H(t,x)$ and its boundary map is constructed by the moduli space of (6.7). (See Lemma 6.7 and Proposition 6.9 below for the details of this correspondence.) These two frameworks are related by the bijective map $\Phi_H$ via the correspondence
\[
\ell(t) = \psi^1_H((\psi^1_H)^{-1}(\ell'(t))), \quad u(s,t) = \psi^t_H((\psi^1_H)^{-1}(\pi(s,t))). \tag{6.13}
\]
In particular we have
\[
\pi = \Phi_H^{-1}(u)
\]
when we regard $u$ as a path on $\Omega(R_0, R_1)$ and $\pi$ as one on $\Omega(\psi^1_H(R_0), R_1)$.

For the given pair $(R_0, R_1)$ of compact Legendrian submanifolds and a Hamiltonian $H$, we also consider a family
\[
J = \{J_t\}_{0 \leq t \leq 1}, \quad J_t := (\psi^t_H(\psi^1_H)^{-1})_*J_0 \tag{6.14}
\]
of $\lambda$-admissible almost complex structures.

A straightforward calculation also gives rise to the following.
Lemma 6.7. Let $J_0 \in J(\lambda)$ and $J_t$ defined as in (6.14). We equip $(\Sigma,j)$ a Kähler metric $h$. Let $g_H(u)$ be the function defined in (6.8). Suppose $u$ satisfies

$$\begin{cases}
(du - X_H \otimes dt)^{\pi(0,1)}_J = 0, & d(e^{g_H(u)}(u^*\lambda + H \, dt) \circ j) = 0 \\
u(\tau,0) \in R_0, & u(\tau,1) \in R_1
\end{cases}$$

(6.15)

with respect to $J_t$. Then $\overline{\pi}$ satisfies

$$\begin{cases}
\overline{\partial}_{J_0} \overline{\pi} = 0, & d(\overline{\pi} \circ j) = 0 \\
\overline{\pi}(\tau,0) \in \psi^1_H(R_0), & \overline{\pi}(\tau,1) \in R_1
\end{cases}$$

(6.16)

for $J_0$.

Remark 6.8. We will also consider a variation of (6.16) by replacing $J_0$ by the domain-dependent family $J' = J'(\tau,t)$ such that $J'(\tau,t) \equiv J_0$ for $|\tau|$ sufficiently large. See Choice 9.5.

We apply the above discussion to the case $R_0 = R_1 = R$ and then the subsequence convergence result, Theorem 6.17, to the contact instantons $w = \overline{\pi}$. In the rest of the present paper, we will investigate the simplest dynamical entanglement question for the two-component link $(\psi(R),R)$, which concerns existence of Reeb chords from $\psi(R)$ to $R$.

The following proposition illustrates how the analytical study of the above considered perturbed Cauchy-Riemann equation gives rise to an existence result of Reeb chords between $R$ and $R$. It is the converse of Lemma 6.7 which holds for the case $R_0 = R_1$.

Proposition 6.9. Let $u : [0,\infty) \times [0,1] \to M$ be a smooth map satisfying the boundary condition

$$u(\tau,0), & u(\tau,1) \in R.$$

Denote by $\overline{\pi}$ the map defined in (6.11). Suppose that $\overline{\pi}$ is a contact instanton of finite $\pi$-energy with uniform $C^1$-bound satisfying the boundary condition

$$\overline{\pi}(\tau,0) \in \psi^1_H(R), & \overline{\pi}(\tau,1) \in R.$$

Then the followings hold:

1. There exist a pair of translated points $(\eta_\pm, x_\pm)$ with $x_\pm \in \psi^1_H(R)$ such that the asymptotic Reeb chords of $\overline{\pi}$ have the form

$$t \mapsto \phi^t_{R_1}(x_\pm).$$

2. We have a contact Hamiltonian trajectory $\gamma_\pm$ from $R$ to $\psi^1_H(R)$ given by

$$\gamma_\pm(t) = z^H_{x_\pm}(t) = \psi^t_H((\psi^1_H)^{-1}(x_\pm)).$$

(See (6.16).)

Proof. Statement (1) is the consequence of [Oh21b, Theorem 1.6]. (See Theorem 6.17 below for the precise statement.)

Statement (2) is just a translation of Statement (1) by the definition of translated points $(\eta_\pm, x_\pm)$ associated the asymptotic Reeb chords at $\pm \infty$ respectively. □
The following diagram describes the relationship between translated intersection points and Reeb chords between $R$ and $\psi(R)$ for a Hamiltonian $H \mapsto \psi$:

$$
\begin{array}{c}
R \\
\psi^1_H(R) \\
\phi^\eta_{R\lambda} \\
\psi^1_H(R) \\
\end{array}
\quad \xleftarrow{\phi^\eta_{R\lambda}} \quad \xrightarrow{\psi^1_H(R)}
$$

(6.18)

Figure 1. Translated intersection

Combining Lemma 6.7 and Proposition 6.9, we have the following which shows that nonexistence of intersection $\psi^1_H(R) \cap Z_R = \emptyset$ is an obstruction to the existence of finite energy solution to (6.15). This is the contact analog to a similar obstruction appearing in [Oh97, Lemma 2.2].

The following rephrased form of the last statement will play an important role as an obstruction to compactness of the moduli space of solutions of a suitably cut-off version of Floer trajectory equation.

**Corollary 6.10** (Obstruction to existence). Suppose $\psi^1_H(R) \cap Z_R = \emptyset$. Then the equation (6.15) has no solution of finite $\pi$-energy.

### 6.3. Maximum principle and $C^0$ estimates on tame contact manifolds

The following theorem is the reason why we introduce the class of tame contact manifolds.

**Theorem 6.11.** Suppose $(M, \lambda)$ is tame and $(\psi, J)$ a pair of $\lambda$-adapted CR almost complex structure and $\psi$ is $\lambda$-tame contact $J$-convex exhaustion function. Let $R \subset M$ be any compact Legendrian submanifold. Then there exists a compact subset $K \subset M$ independent of $\psi, J$ such that for any contact instanton $w : \dot{\Sigma} \to M$ satisfying

$$
\begin{cases}
\begin{align*}
\phi^\eta_{R\lambda} w &= 0, \\
d(w^* \lambda \circ j) &= 0, \\
w(\Sigma_i z_{i+1}) &\subset R_i, \quad i = 0, \ldots, k \\
w(\infty_i) &= \gamma_i, \quad i = 0, \ldots, k
\end{align*}
\end{cases}
$$

(6.19)

we have $\text{Image } w \subset K$.

**Proof.** By definition of tame contact manifolds, there exists a compact subset $K \subset M$ such that on $M \setminus K$ $\psi$ satisfies

$$
\mathcal{L}_{R\lambda} d\psi = 0, 
$$

(6.20)

and

$$
-d(d\psi \circ J) \geq 0 \quad \text{on } \xi
$$

(6.21)

Let $w$ be a solution to (6.19). We decompose

$$
dw = d^\pi w + w^* \lambda \otimes R_{\lambda}
$$

which we often just write $dw = d^\pi w + w^* \lambda R_{\lambda}$ as a $T^* M$-valued one-form on $\dot{\Sigma}$ in the calculation below and henceforth.

We compute

$$
\Delta(\psi \circ w) dA = -d(d(\psi \circ w) \circ j) = -d(d(\psi \circ dw) \circ j)
$$

$$
= -d(d(\psi(d^\pi w + w^* \lambda \otimes R_{\lambda}(w))) \circ j)
$$

$$
= -d(d(\psi(d^\pi w \circ j)) - d(\psi(w^* \lambda \otimes R_{\lambda}(w)) \circ j).
$$

(6.23)
Using the $\lambda$-tameness of $\psi$ and the closedness of $w^*\lambda \circ j$, we compute the second term
\[
\begin{align*}
\quad d(d\psi(w^*\lambda \otimes R_\lambda(w)) \circ j) &= d(w^*(d\psi(R_\lambda)) (w^*\lambda \circ j)) \\
&= w^*(d(d\psi(R_\lambda))) \wedge w^*\lambda \circ j.
\end{align*}
\]
This vanishes by (6.20) since
\[
d(d\psi(R_\lambda)) = \mathcal{L}_{R_\lambda} d\psi.
\]
For the first term of (6.23), using the equation $Jd^\pi w = d^\pi w_j$ and the properties
\[
J(R_\lambda) = 0, \quad \text{Image } J = \xi,
\]
of $CR$ almost complex structure $J$, we compute
\[
\begin{align*}
\quad -d(d^\pi \psi(d^\pi w \circ j))(v, jv) &= -d(d\psi \circ J)(Jd^\pi w)(v, jv) \\
&= d(d\psi \circ J)(d^\pi w(v), d^\pi w(jv)) + d(d\psi \circ J)(d^\pi w(v), w^*\lambda (jv) R_\lambda(w(z_0))) \\
&\quad + d(d\psi \circ J)(w^*\lambda(v) R_\lambda(w(z_0)), d^\pi w(jv)) \\
&\quad + d(d\psi \circ J)(w^*\lambda(v) R_\lambda(w(z_0)), w^*\lambda(jv) R_\lambda(w(z_0))).
\end{align*}
\]
Here the last three terms vanish by (6.22). Combining (6.24)-(6.26), we have derived
\[
\begin{align*}
\quad -d(d\psi \circ J)(dw(v), dw(jv)) &= -d(dl_{\psi \circ J})(d^\pi w(v), d^\pi w(jv)) \\
&= -d(dl_{\psi \circ J})(d^\pi w(v), Jd^\pi w(v)) \geq 0
\end{align*}
\]
for all $v \in T_{z_0} \hat{\Sigma}$, where the last positivity follows by (6.21). This proves
\[
\Delta(\psi \circ w) \geq 0.
\]
Once we have this differential inequality, the classical strong maximum principle applies to get the inequality
\[
\sup_{\Sigma} |\psi \circ w| = \max \left\{ \sup_{\partial \Sigma} |\psi \circ w|, \sup_i \{ |\psi \circ \gamma_i| \}_{i=0}^k \right\}
\]
(See [GT70, Theorem 3.1] for example). Since $w(\partial \Sigma) \subset R$ and $\gamma_i$ are given, this proves
\[
\sup_{\Sigma} |\psi \circ w| \leq \max \left\{ \sup_{\partial \Sigma} |\psi||_R, \sup_i \{ |\psi \circ \gamma_i| \}_{i=0}^k \right\}.
\]
By setting
\[
C = \max \left\{ \sup_{\partial \Sigma} |\psi||_R, \sup_i \{ |\psi \circ \gamma_i| \}_{i=0}^k \right\}, \quad K = \psi^{-1}([-C, C])
\]
we have now finished the proof. \hfill \square
6.4. Coercive elliptic estimates and subsequence convergence. In this section, we fix a contact triad 

\[ (M, \lambda, J) \]

where \( J \in \mathcal{J}(\lambda) \) is a \( \lambda \)-adapted CR-almost complex structure. All relevant estimate is in terms of the associated triad metric \( g = g_{\lambda, J} \) given by

\[ g = d\lambda(J, J) + \lambda \otimes \lambda. \]

Then we consider the equation of (unperturbed) contact instantons

\[
\begin{aligned}
\pi^* w &= 0, & d(w^* \circ j) &= 0, \\
w(\tau, 0) &\in R_0, & w(\tau, 1) &\in R_1,
\end{aligned}
\]

for a general Legendrian pair \((R_0, R_1)\) on general contact manifold \((M, \lambda)\). We will apply the result to the case of \((\psi^1_H(R), R)\) with \( w = \pi \).

We collect some basic results on the analysis of the equation established in [OW18a] or in [Oh21b]. We start with the following local \( W^{2,2} \)-estimates.

**Theorem 6.12** (Theorem 1.3 [Oh21b]). Let \( w : \mathbb{R} \times [0, 1] \to M \) satisfy (6.27). Then for any relatively compact domains \( D_1 \) and \( D_2 \) in \( \Sigma \) such that \( \overline{D_1} \subset D_2 \) with \( w(\partial D_2) \subset R_0 \) or \( w(\partial D_2) \subset R_1 \), we have

\[
\|dw\|_{W^{1,2}(D_1)} \leq C_1\|dw\|_{L^2(D_2)} + C_2\|dw\|_{L^2(D_1)} + C_3\|dw\|_{L^2(\partial D_2)}
\]

where \( C_1, C_2 \) are some constants which depend only on \( D_1, D_2 \) and \((M, \lambda, J)\) and \( C_3 \) is a constant which also depends on \( R_0 \) or \( R_1 \).

Once this \( W^{2,2} \)-estimate is established, we then proceed the following higher regularity estimates.

**Theorem 6.13** (Theorem 1.4 [Oh21b]). Let \( w \) be a contact instanton satisfying (6.27). Then for any pair of domains \( D_1 \subset D_2 \subset \Sigma \) such that \( \overline{D_1} \subset D_2 \) with \( w(\partial D_2) \subset R_0 \) or \( w(\partial D_2) \subset R_1 \), we have

\[
\|dw\|_{C^{k,\alpha}(D_1)} \leq C\|dw\|_{W^{1,2}(D_2)}
\]

for some constant \( C = C(k, \alpha) > 0 \) depending on \( J, \lambda, D_1, D_2, R_0 \) or \( R_1 \), and \((k, \alpha)\) but independent of \( w \).

Let \( w : \mathbb{R} \times [0, 1] \to M \) be any smooth map. As in [OW18a], we define the total \( \pi \)-harmonic energy \( E^\pi(w) \) by

\[
E^\pi(w) = E^\pi_{(\lambda, J)}(w) = \frac{1}{2} \int |d^\pi w|^2
\]

where the norm is taken in terms of the given metric \( h \) on \( \Sigma \) and the triad metric on \( M \).

Next we study the asymptotic behavior of contact instantons \( w \) satisfying the following hypotheses.

**Hypothesis 6.14.** Assume \( w : \mathbb{R} \times [0, 1] \to M \) satisfies the contact instanton equation (6.27) and

1. \( E^\pi_{(\lambda, J, \Sigma, h)}(w) < \infty \) (finite \( \pi \)-energy);
2. \( \|dw\|_{C^{0,0}(\Sigma)} < \infty \).

For any \( w \) satisfying Hypothesis 6.14, we associate two natural asymptotic invariants at \( \tau \pm \infty \).
Definition 6.15. The \textit{asymptotic action} is defined to be
\[
T := \lim_{\tau \to \infty} \int_{\{\tau\} \times [0,1]} (w|_{\{0\} \times [0,1]})^* \lambda \tag{6.29}
\]
and the \textit{asymptotic charge} is by
\[
Q := \lim_{\tau \to \infty} \int_{\{\tau\} \times [0,1]} (w|_{\{0\} \times [0,1]})^* \lambda \circ j. \tag{6.30}
\]
provided they exist. (Here we only look at the positive end. The case of negative end is similar.)

The above finite $\pi$-energy and $C^0$ bound hypotheses imply
\[
\int_{[0,\infty) \times [0,1]} |d^\pi w|^2 d\tau dt < \infty, \quad ||dw||_{C^0([0,\infty) \times [0,1])} < \infty. \tag{6.31}
\]

Remark 6.16. In general there is no reason why these limits exist and even if the limits exist, they may also depend on the choice of subsequences under Hypothesis 6.14. In the closed string case, [OW18a] shows that the asymptotic charge $Q$ may not vanish which is the key obstacle to the compactification and the Fredholm theory of contact instantons for $Q \neq 0$.

As in [OW18a], [Oh21b], we call $T$ the \textit{asymptotic contact action} and $Q$ the \textit{asymptotic contact charge} of the contact instanton $w$ at the given puncture.

Theorem 6.17 (Vanishing asymptotic charge; Theorem 6.7 [Oh21b]). Let $w : [0,\infty) \times [0,1] \to M$ satisfy the contact instanton equations (6.27) and Hypothesis 6.14. Then for any sequence $s_k \to \infty$, there exists a subsequence, still denoted by $s_k$, and a massless instanton $w_\infty(\tau, t)$ (i.e., $E^\pi(w_\infty) = 0$) on the cylinder $\mathbb{R} \times [0,1]$ that satisfies the following:

1. On any given compact subset $K \subset [0,\infty)$, we have
   \[
   \lim_{k \to \infty} w(s_k + \tau, t) = w_\infty(\tau, t)
   \]
   in the $C^l(K \times [0,1], M)$ sense for any $l$.
2. $w_\infty$ has $Q = 0$ and the formula $w_\infty(\tau, t) = \gamma(T t)$, where $\gamma$ is some Reeb chord joining $R_0$ and $R_1$ with action $T$.

We mention that the asymptotic action $T$ could be either positive or negative.

7. The $\pi$-energy identity

Let $H = H(t, x)$ be a given Hamiltonian. It turns out that the correct definition of the $\pi$-energy for the perturbed contact instanton is the following.

Definition 7.1 (The $\pi$-energy of perturbed contact instanton). Let $u : \mathbb{R} \times [0,1] \to M$ be any smooth map. We define
\[
E_{j,H}^\pi(u) := \frac{1}{2} \int e^{g_H(u)} |(du - X_H(u) \otimes dt)^\pi|^2_j
\]
call it the \textit{off-shell $\pi$-energy}. 
Now we apply the gauge transformation $\Phi_H^{-1}$ to $u$ and define $\mathbf{\pi} := \Phi_H^{-1}(u)$ which has the expression
\[
\mathbf{\pi}(\tau, t) = (\psi_H^t(\psi_H^1)^{-1})^{-1}(u(\tau, t)) = \psi_H^1(\psi_H^1)^{-1}(u(\tau, t)).
\] (7.1)
The following identity justifies the presence of weight $e^{\theta_H(u)}$ in this definition. (Also see Remark 7.3 for further justification.)

**Proposition 7.2.** Let $u : \mathbb{R} \times [0, 1] \to M$ be any smooth map and $\mathbf{\pi}$ be as above. Then
\[
E_{J,H}^\mathbf{\pi}(u) = E_{J_0}^\mathbf{\pi}(\mathbf{\pi}).
\] (7.2)

**Proof.** We first note that $u$ satisfies
\[
0 = \frac{\partial}{\partial \tau} \mathbf{\pi}(\partial, \tau) = \left( \frac{\partial \mathbf{\pi}}{\partial \tau} \right)^\mathbf{\pi} + J_0 \left( \frac{\partial \mathbf{\pi}}{\partial t} \right)^\mathbf{\pi}.
\]
We compute $|d^n(\mathbf{\pi}(\partial, \tau))|_J$ and $|d^n(\mathbf{\pi}(\partial))|_J$ separately. By definition, we have
\[
u(\tau, t) = \psi_H^t(\psi_H^1)^{-1}(\mathbf{\pi}(\tau, t)).
\]
Then
\[
du(\partial, \tau) = \frac{\partial u}{\partial \tau} = d(\psi_H^t(\psi_H^1)^{-1}) \left( \frac{\partial \mathbf{\pi}}{\partial \tau} \right) + X_H(u(\tau, t))
\]
and hence we have
\[
\frac{\partial \mathbf{\pi}}{\partial \tau} = 
\frac{\partial(\psi_H^t(\psi_H^1)^{-1})}{\partial \tau} \left( \frac{\partial u}{\partial \tau} - X_H(u(\tau, t)) \right).
\]
And more easily, we compute
\[
\frac{\partial \mathbf{\pi}}{\partial t} = 
\frac{\partial(\psi_H^t(\psi_H^1)^{-1})}{\partial t} \left( \frac{\partial u}{\partial t} \right).
\]

We recall that $J(\xi) \subset \xi$ for any $\lambda$-adapted CR-almost complex structure $J$, and
\[
d(\psi_H^t(\psi_H^1)^{-1})(\xi) = \xi
\]
since $\psi_H^t(\psi_H^1)^{-1}$ is a contactomorphism. For the simplicity of notations, we write
\[
\psi_t := (\psi_H^t(\psi_H^1)^{-1})^{-1} = \psi_H^1(\psi_H^1)^{-1}, \quad g_t := g(\psi_t),
\] (7.3)
for the conformal exponent of the contactomorphism $\psi_t$ in the following calculation. Then we have
\[
\left| \left( \frac{\partial \mathbf{\pi}}{\partial \tau} \right)^\mathbf{\pi} \right|^2 = \left| du_t \left( \frac{\partial u}{\partial \tau} - X_H(u(\tau, t)) \right)^\mathbf{\pi} \right|^2 \bigg|_{J_0}
\]
\[
= d\lambda \left( (du_t \left( \frac{\partial u}{\partial \tau} - X_H(u(\tau, t)) \right)^\mathbf{\pi}, J_0 (du_t \left( \frac{\partial u}{\partial \tau} - X_H(u(\tau, t)) \right)^\mathbf{\pi}) \right)
\]
\[
= \psi_t^*d\lambda \left( \left( \frac{\partial u}{\partial \tau} - X_H(u(\tau, t)) \right)^\mathbf{\pi}, J_t \left( \frac{\partial u}{\partial \tau} - X_H(u(\tau, t)) \right)^\mathbf{\pi} \right)
\]
\[
= d(e^{\theta_H} \lambda) \left( \left( \frac{\partial u}{\partial \tau} - X_H(u(\tau, t)) \right)^\mathbf{\pi}, J_t \left( \frac{\partial u}{\partial \tau} - X_H(u(\tau, t)) \right)^\mathbf{\pi} \right)
\]
\[
= e^{\theta_H} (d\lambda + dg \wedge \lambda) \left( \left( \frac{\partial u}{\partial \tau} - X_H(u(\tau, t)) \right)^\mathbf{\pi}, J_t \left( \frac{\partial u}{\partial \tau} - X_H(u(\tau, t)) \right)^\mathbf{\pi} \right)
\]
\[
= e^{\theta_H} \left| \left( \frac{\partial u}{\partial \tau} - X_H(u(\tau, t)) \right)^\mathbf{\pi} \right|^2 \bigg|_{J_t}.
\]
Here we used the vanishing
\[ \lambda(\cdot)^\pi = 0 \]
for the penultimate equality.

More easily, we also derive
\[ \left| \frac{\partial \pi}{\partial \tau} \right|^2 |_{J_0} = e^{2n} \left| \frac{\partial u}{\partial \tau} \right|^\pi |_{J_t}. \]

By adding the two, we have finished the proof. \( \square \)

**Remark 7.3.**

1. Unless there were aforementioned exponential weight-factor, it would be possible to achieve the kind of a priori estimates neither for the \( \pi \)-energy nor for the \( \lambda \)-energy we are going to define in Part 3. In this regard, the presence of the exponential weight factor in the definition of \( \pi \)-energy is essential.

2. In fact, the most natural explanation of the appearance of this weighting factor can be given in terms of the contact mapping tori construction. See [OS21, Section 2.1]. We will elaborate this point of view when we consider contact fibration elsewhere.

The following proposition is one of the key energy estimates for the solutions \( u \) of (6.7) in terms of the geometry of Legendrian boundary conditions and its asymptotic chords.

**Proposition 7.4.** Let \( \psi_t \) be as in (7.3). Let \( u \) be any finite energy solution of (6.7) with the limits

\[ \gamma_\pm(t) := \lim_{\tau \to \pm \infty} u(\tau, t) \]

and \( \bar{\pi} \) be as above. Consider the paths given by

\[ \gamma_\pm(t) = \psi_t(\gamma_\pm(t)). \]

Then \( \gamma_\pm \) are Reeb chords from \( \psi_1(\mathbb{R}_0) \) to \( \mathbb{R}_1 \) and satisfy

\[ E_{J,H}^\pi(u) = \int_0^1 (\gamma_+)^* \lambda - \int_0^1 (\gamma_-)^* \lambda. \]  \( (7.4) \)

**Proof.** The first statement immediately follows from definition of the gauge transformation \( \Phi_H \) and by the subsequence convergence theorem, Theorem 6.17.

For the energy identity, it is enough to compute \( E_J^\pi(\bar{\pi}) \) by Proposition 7.2. Similarly as in the proof of Proposition 7.2, we compute, this time using the equation \( Jd(\bar{\pi}) = d\bar{\pi}(\partial_t) \),

\[
\begin{align*}
&\int_{-\infty}^{\infty} \int_0^1 |d\bar{\pi}(\partial_\tau)|^2 \, dt \, d\tau \\
&= \int_{-\infty}^{\infty} \int_0^1 d\lambda(\bar{\pi}(\partial_\tau), Jd\bar{\pi}(\partial_\tau)) \, dt \, d\tau \\
&= \int_{-\infty}^{\infty} \int_0^1 d\lambda(\bar{\pi}(\partial_\tau), d\bar{\pi}(\partial_\tau)) \, dt \, d\tau \\
&= \int (\bar{\pi})^* d\lambda \\
&= \left( \int_0^1 (\gamma_+)^* \lambda - \int_0^1 (\gamma_-)^* \lambda \right) + \int_{-\infty}^{\infty} \lambda \left( \frac{\partial \pi}{\partial \tau}(\tau, 0) \right) d\tau - \int_{-\infty}^{\infty} \lambda \left( \frac{\partial \pi}{\partial \tau}(\tau, 1) \right) d\tau \\
&= \int_0^1 (\gamma_+)^* \lambda - \int_0^1 (\gamma_-)^* \lambda.
\end{align*}
\]
Here the last equality follows from the Legendrian boundary condition
\[ \overline{u}(\tau, 0) \in \psi^1_H(R), \quad \overline{u}(\tau, 1) \in R \]
for \( i = 0, 1 \). This finishes the proof. \qed

Part 2. Proof of a conjecture by Sandon and Shelukhin

The discussion given in the previous section applies more generally when the pair \((J, H)\) depends on the domain parameter.

In this part, we set-up the deformation-cobordism framework of parameterized moduli space of perturbed contact instantons by adapting a similar parameterized Floer moduli spaces appearing in the study of the displacement energy of compact Lagrangian submanifolds in [Oh97], and prove a conjecture by Shelukhin [She17].

8. Cut-off Hamiltonian-perturbed contact instanton equation

We will consider the two-parameter family of CR-almost complex structures and Hamiltonian functions:
\[ J = \{J(s, t)\}, \quad H = \{H^s_t\} \quad \text{for} \quad (s, t) \in [0, 1]^2. \]
We write
\[ H^s_t(x) := H(s, t, x) \]
in general for a given two-parameter family of functions \( H = H(s, t, x) \). Note that \([0, 1]^2\) is a compact set and so \( J, H \) are compact families. We always assume the \((s, t)\)-family \( J \) or \( H \) are constant near \( s = 0, 1 \).

We will also consider the family \( J' = J'_s(t) \) defined by
\[ J'_s(t) = (\psi^t_s(\psi^1_H)^{-1})^* J(s, t) = (\psi^t_s(\psi^1_H)^{-1})^* J(s, t) \quad (8.1) \]
for a given \( J = \{J(s, t)\} \). We assume \( J' \) satisfies
\[ J'_s(t) \equiv J_0 \in \mathcal{J}(\xi) \quad (8.2) \]
near \( s = 0, 1 \).

For each \( K \in \mathbb{R}_+ = [0, \infty) \), we define a family of cut-off functions \( \chi_K : \mathbb{R} \to [0, 1] \) so that for \( K \geq 1 \), they satisfy
\[ \chi_K = \begin{cases} 0 & \text{for } |\tau| \geq K + 1 \\ 1 & \text{for } |\tau| \leq K. \end{cases} \quad (8.3) \]
We also require
\[
\begin{align*}
\chi'_K & \geq 0 \quad \text{on } [-K - 1, -K] \\
\chi'_K & \leq 0 \quad \text{on } [K, K + 1].
\end{align*}
\]
(8.4)

For \( 0 \leq K \leq 1 \), define \( \chi_K = K \cdot \chi_1 \). Note that \( \chi_0 \equiv 0 \).
8.1. Setting up the parameterized moduli space. Knowing that $H_K \equiv 0$ when $|\tau|$ is sufficiently large and having Proposition 8.9 in our disposal which we will prove later, we consider a one-parameter family of domains defined as follows.

Consider the following capped semi-infinite cylinders

$$
\Theta_- = \{ z \in \mathbb{C} \mid |z| \leq 1 \} \cup \{ z \in \mathbb{C} \mid \text{Re} z \geq 0, |\text{Im} z| \leq 1 \} \\
\Theta_+ = \{ z \in \mathbb{C} \mid \text{Re} z \leq 0, |\text{Im} z| \leq 1 \} \cup \{ z \in \mathbb{C} \mid |z| \leq 1 \}.
$$

We will fix the $K_0$ once and for all and consider $K$ with $0 \leq K \leq K_0$. (See Proposition 8.9 below for its required condition to satisfy.) For such given $K_0$, we define the spaces

$$
\Theta_{-,K_0+1} := \{ z \in \Theta_- \mid \text{Re} z \leq K_0 + 1 \}, \\
\Theta_{+,K_0+1} := \{ z \in \Theta_- \mid \text{Re} z \geq -K_0 - 1 \}.
$$

We glue the three spaces

$$
\Theta_{-,K_0+1}, \quad [-K_0 + 1, K_0 + 1] \times [0, 1], \quad \Theta_{+,K_0+1}
$$

subdomains of $\mathbb{R} \times [0, 1]$, by making the identification

$$
(0, t) \in \Theta_{-,K_0+1} \leftrightarrow (-K_0 - 1, t) \in [-K_0 - 1, K_0 + 1] \times [0, 1],
$$

$$
(0, t) \in \Theta_{+,K_0+1} \leftrightarrow (K_0 + 1, t) \in [-K_0 - 1, K_0 + 1] \times [0, 1],
$$

respectively. We denote the resulting domain as

$$
\Theta_{K_0+1} := \Theta_- \#_{K_0+1}(\mathbb{R} \times [0, 1]) \#_{K_0+1} \Theta_+ \subset \mathbb{C}
$$

and equip it with the natural complex structure induced from $\mathbb{C}$. (See [FOOO09, Figure 8.1.2] for its visualization of this domain.) We can also decompose $\Theta_{K_0+1}$ into the union

$$
\Theta_{K_0+1} := D^- \cup [-2K_0 - 1, 2K_0 + 1] \cup D^+
$$

where we denote

$$
D^\pm_{K_0} := \{ z \in \mathbb{C} \mid |z| \leq 1, \pm \text{Im}(z) \leq 0 \} \pm (2K_0 + 1)
$$

respectively.

**Remark 8.1** (Domain $\Theta_{K_0+1}$). We highlight the obvious fact that the domain $\Theta_{K_0+1}$ is a compact disk-like domain, where any closed one-form is exact. In particular any contact instanton $w$ on $\Theta_{K_0+1}$ can be lifted to a pseudoholomorphic curve $\bar{u} = (w, f)$ for a uniquely defined function $f : \Theta_{K_0+1} \to \mathbb{R}$ satisfying

$$
df = w^* \lambda \circ j
$$

where $w^* \lambda \circ j$ is closed by the defining equation of contact instantons.

We make the following specific choice of two-parameter Hamiltonians associated to each time-dependent Hamiltonian $H = H(t, x)$ with slight abuse of notations.

**Choice 8.2.** Take the family $H = H(s, t, x)$ given by

$$
H^s(t, x) = sH(t, x)
$$

Then we consider the equation given by

$$
\begin{cases}
(du - X_{H^s}(u))^{[0,1]} = 0, \\
d(\epsilon_0^s(u) (u^* \lambda + u^* H^s dt) \circ j) = 0,
\end{cases}
$$

where

$$
u(\tau, 0) \in R, \quad u(\tau, 1) \in R
$$

and

$$
\begin{cases}
(du - X_{H^s}(u))^{[0,1]} = 0, \\
d(\epsilon_0^s(u) (u^* \lambda + u^* H^s dt) \circ j) = 0,
\end{cases}
$$

where

$$
u(\tau, 0) \in R, \quad u(\tau, 1) \in R
$$
where we write

\[ H_K(\tau, t, x) := H^{\chi_K(\tau)}(t, x) = \chi_K(\tau)H(t, x) \]

and \( g_K(u) \) is the function on \( \Theta_{K_0+1} \) defined by

\[ g_K(u)(\tau, t) := g_{e_{H_K}^{-1}}^{\psi_{H_K}}(u(\tau, t)) \]

for \( 0 \leq K \leq K_0 \). We note that if \( |\tau| \geq K + 1 \), the equation becomes

\[ \overline{\partial}^\pi u = 0, \quad d(u^* \lambda \circ j) = 0. \]

(8.11)

**Definition 8.3.** Let \( K_0 \in \mathbb{R} \cup \{\infty\} \) be given. For \( 0 \leq K \leq K_0 \), we define

\[ \mathcal{M}_K(M, R; J, H) = \{ u : \mathbb{R} \times [0, 1] \to M | u \text{ satisfies (8.9) and } E_{J,K,H}(u) < \infty \} \]

and

\[ \mathcal{M}^{\text{para}}_{[0,K_0]}(M, R; J, H) = \bigcup_{K \in [0,K_0]} \{ K \} \times \mathcal{M}_K(M, R; J, H). \]

(8.12)

The Fredholm theory developed in [Oh21a] provides a natural smooth structure with

\[ \mathcal{M}_K(M, R; J, H), \quad \mathcal{M}^{\text{para}}_{[0,K_0]}(M, R; J, H). \]

[Oh21a] deals with the closed string case which can be easily adapted to the current case with boundary, whose details will be given elsewhere.

**Remark 8.4.**

(1) We would like to attract readers’ attention to the difference in the setting-up of the domain-varying parameterized moduli space: In [Oh97], we fix the domain to be the total strip \( \mathbb{R} \times [0, 1] \) while here we compactify the domain by using the \( K \)-dependent family of capped-strips and vary \( K \to \infty \). The reason for this is because for the pseudoholomorphic curves for the Lagrangian boundary condition the removal singularity theorem automatically compactifies the domain of any finite energy solution defined on \( \mathbb{R} \times [0, 1] \), while such a removable singularity theorem does not apply to the contact instanton equation. Using the fact that the contact instanton equation is still coordinate free, we consider the family of compact domains \( \Theta_{K_0+1} \) and repeat the same kind of proof given in the proof of [Oh97, Lemma 2.2]. Indeed we can also apply the same domain-changing family to the latter case and rewrite the proof of [Oh97, Lemma 2.2] as in the way how the current proof goes.

(2) Because of the aforementioned difference working on the compact domains \( \Theta_{K_0+1} \) instead of the full strip \( \mathbb{R} \times [0, 1] \), strictly speaking, we need to smooth out the seam \( |\tau| = K + 1 \) on a small neighborhood thereof, say on

\[ \{(\tau, t) \in \Theta_{K_0+1} | \tau \in [K + 1 - \delta, K + 1 + \delta]\} \]

for some given \( \delta > 0 \). We replace \( \chi_K \) by \( \chi_{K+\delta} \) so that the equation (8.9) still becomes (8.11) for \( 0 \leq K \leq K_0 \). This being said, we will ignore non-smoothness of the boundary of \( \Theta_{K_0+1} \) at \( |\tau| = K + 1 \) and directly work with it instead of the smoothed one for the simplicity of exposition.
8.2. Obstruction to existence of finite energy solution. We recall the following correspondence
\[ \psi(R) \cap Z_R = \emptyset \iff \psi(R) \cap R = \emptyset \quad \& \quad \text{Reb}(\psi(R), R) = \emptyset \] (8.14)
from Lemma 3.15 applied to \((S_1, S_2) = (R, R)\). We will show that the condition \(\psi(R) \cap Z_R = \emptyset\) will play the role of an obstruction to the existence of finite energy solutions to the contact instanton equation (6.7).

Remark 8.5. This obstruction is the analog to the obstruction employed by in [Che98], [Oh97] for the study of displacement energy of compact Lagrangian submanifolds. Similarly as in the present paper, this kind of non-intersection played the role of an obstruction to compactness of certain parameterized moduli space of Hamiltonian-perturbed Floer trajectories in symplectic geometry. (See [Oh97] for the details.)

In this subsection, we assume the priori energy bound which we will establish in Section 12 for the \(\lambda\)-energy \(E_{\lambda, J, K, H}(u)\) and Section 15. Let
\[ E_{J, K, H}(u) = E_{J, K, H}(u) + E_{J, K, H}(u) \]
be the total energy. We will prove the following propositions in the next section and in Section 13 of Part 3 respectively. We recall the definition of oscillation
\[ \text{osc}(H_t) = \max H_t - \min H_t. \]

Proposition 8.6. Let \(u\) be any finite energy solution of (8.9). Then we have
\[ E_{J, K, H}(u) \leq \int_0^1 \text{osc}(H_t) \, dt =: \|H\| \] (8.15)

Proposition 8.7. Let \(u\) be any finite energy solution of (8.9). Then we have
\[ E_{J, K, H}(u) \leq \|H\|. \] (8.16)

Then using these energy bounds, we will prove the following Gromov-type weak convergence theorem, the details of which we postpone till Section 15 of Part 3. We just mention here that the above explicit upper bound of \(E_{J, K, H}(u)\) plays a fundamental role in our quantitative study while that of \(E_{J, K, H}(u)\), other than the existence of uniform finite upper bound, does not play any role.

We also consider the gauge transformation of \(u\)
\[ \overline{u}_K(\tau, t) := \psi_1^{\chi_K(\tau)H}(\psi_1^{\chi_K(\tau)H})^{-1}(u(\tau, t)) \] (8.17)
and the energy identity
\[ E_{J, K, H}(u) = E_{J, \overline{u}}(\overline{u}); \quad E_{J, K, H}(u) := E_{J, \overline{u}}(\overline{u}). \]

Theorem 8.8. Suppose \(K_\alpha \to K_\infty \leq K_0 \in \mathbb{R}\) and let \(u_\alpha\) be solutions of (8.9) for \(K = K_\alpha\) with uniform energy bound
\[ E_{J, K_\alpha, H}(u_\alpha) < C < \infty \]
for \(C\) independent of \(\alpha\). Let \(\overline{u}\) be as above.

Then, there exist a subsequence again enumerated by \(u_\alpha\) and a cusp-trajectory \((\overline{u}, v, w)\) such that
\[ (1) \ u \text{ is a solution of } (6.15) \text{ for } H_K \text{ with } K = K_\infty, \]
\[ (2) \ v = \{v_i\}_{i=1}^k \text{ where} \]
• each $v_i$ is a contact instanton on the plane $\mathbb{C}$ with end converging to a closed Reeb orbit, and
• each $w_j$ is a contact instanton on the half place $\mathbb{H}$ with its boundary lying on $R$ with end converging to a Reeb chord of the pair $(\psi(R), R)$.

(3) We have
\[
\lim_{\alpha \to \infty} E_{\pi J,K_\alpha}^* (\pi_{\alpha,K_\alpha}) = E_{\pi J,K_\infty}^* (\pi_{K_\infty}) + \sum_i v_i^* d\lambda_{v_i} + \sum_j w_j^* d\lambda_{w_j}.
\]

(4) And $\pi_{\alpha,K_\alpha}$ weakly converges to $(\pi, v, w)$ in the sense of Gromov-Floer-Hofer and converges in compact $C^\infty$ topology away from the nodes. Furthermore, if $v = w = \emptyset$, then $u_\alpha \to u$ smoothly on $\Theta_{K_0+1}$.

With the above energy bound and convergence result in our disposal, we prove the following obstruction result. The following proposition is the analog to [Oh97, Lemma 2.2]: It shows that non-intersection $\psi^*_{\mathbb{H}}(R) \cap Z_R = \emptyset$ is an obstruction to the asymptotic existence of finite energy solutions for the autonomous equation (6.15).

**Proposition 8.9.** Let $H_t$ be the Hamiltonian such that $\psi^*_{\mathbb{H}}(R) \cap Z_R = \emptyset$ is empty and $H = sH_t$ and $J$ as before. Suppose $\|H\| < T_\lambda(\Lambda; R)$. Then there exists $K_0 > 0$ sufficiently large such that $\mathcal{M}_K(M; R; J, H)$ is empty for all $K \geq K_0$.

**Proof.** We give the proof by contradiction by closely following the scheme used in [Oh97].

Suppose to the contrary that there exists a sequence $K_\alpha \to \infty$ and a solution $u_\alpha \in \mathcal{M}_{K_\alpha}(M; R, J, H)$. By the a priori energy bound from Propositions 8.6, 8.7 for $\mathcal{M}_{K_\alpha}(M; R, J, H)$, there exists $(u, v, w)$ such that $u_\alpha \to (u, v, w)$ in the sense of Theorem 8.8. On the other hand, by the hypothesis $\|H\| < T_\lambda(\Lambda; R)$, we derive $v = w = \emptyset$.

In particular, we have produced the $C^1$-limit $u$ of $u_\alpha$ which satisfies the equation (6.7), i.e.,
\[
\begin{cases}
  (du - X_H(u))_{\pi(0,1)} = 0, & d(e^{g_H(u)} (u^* \lambda + u^* H dt) \circ j) = 0, \\
  u(\tau, 0), & u(\tau, 1) \in R
\end{cases}
\]
with $\pi$-energy bound. In particular we also have $\|du\|_{C^0} < \infty$. Furthermore we also have
\[
E_{J,H}^* (u) \leq \limsup_{\alpha \to \infty} E_{J,K_\alpha,H}^* (u_\alpha) \leq \|H\| < \infty.
\]
Then by Theorem 6.17 applied to $w = \pi$, we derive $\Reeb(\psi(R), R) \neq \emptyset$ for $\psi = \psi^*_{\mathbb{H}}$ which in turn implies
\[
\psi(R) \cap Z_R \neq \emptyset.
\]
This contradicts to the standing hypothesis and hence finishes the proof. \qed

9. Deformation-cobordism analysis of parameterized moduli space

With the $\pi$-energy bound (8.15) and the $\lambda$-energy bound (8.16), we are now ready to make a deformation-cobordism analysis of $\mathcal{M}_{[0,K_0+1]}^{\text{para}}(M; \lambda; R, H)$. The logical scheme of this analysis is similar to that of [Oh97].
9.1. **The case** $K = 0$: $J = J_0$ and $H \equiv 0$. In this case, the equation (6.7) becomes

\[
\begin{cases}
\overline{J} u = 0, \\
d(u^*\lambda \circ j) = 0
\end{cases}
\]

with $E_{\rho^*}(u) = E_{\rho^0}(u) + E_{\rho^0}(u) < \infty$.

The following is the open string version of [Abb11, Proposition 1.4], [OW18a, Proposition 3.4]. For the purpose of the present paper, we need this proposition only for the genus zero case but we state it in full generality to manifest the fact that this is the open string version of [Abb11, Proposition 1.4], [OW18a, Proposition 3.4].

**Proposition 9.1.** Assume $w : (\Sigma, \partial \Sigma) \to (M, R)$ is a smooth contact instanton from a compact connected Riemann surface $(\Sigma, j)$ with nonempty boundary $\partial \Sigma$.

Then

1. If $g(\Sigma) = 0$, $w$ is a constant map;
2. If $g(\Sigma) \geq 1$, $w$ is either a constant or the locus of its image is a closed Reeb chord of $R$.

**Proof.** For contact Cauchy–Riemann maps, we have

\[ |d^w w|^2 dA = d(2w^*\lambda). \]

By Stokes’ formula and the Legendrian boundary condition, we derive

\[
\frac{1}{2} \int_\Sigma |d^w w|^2 = \int_\Sigma d^w w = \int_{\partial \Sigma} w^*\lambda = 0
\]

when $\Sigma$ is compact with $w(\partial \Sigma) \subset R$. This implies $|d^w w|^2 = 0$ which in turn implies $dw^*\lambda = 0$ by the above equality. Combining the defining equation $d(w^*\lambda \circ j) = 0$ for contact instantons, this vanishing implies that $w^*\lambda$ (so is $*w^*\lambda$) is a harmonic one-form on the compact Riemann surface $\Sigma$ satisfying

\[ w^*\lambda|_{\partial \Sigma} = 0. \]

If the genus of $\Sigma$ is zero, i.e., when $\Sigma = D^2$. By the reflection argument, we prove $w^*\lambda \equiv 0$ on $\Sigma$. This together with $d^w w = 0$ implies $w$ must be a constant map valued at a point of $R$. This proves statement (1).

Now assume $g(\Sigma) \geq 1$. Suppose $w$ is not a constant map. Since $\Sigma$ is compact and connected, $w(\Sigma)$ is compact and connected. Since

\[ dw = d^w w + w^*\lambda \otimes R_\lambda = w^*\lambda \otimes R_\lambda \]

i.e., $w$ must have its image contained in a single leaf of the (smooth) Reeb foliation with its boundary contained in $R$. Denote this leaf by $\mathcal{L}$ and take a parametrization $\gamma : \mathbb{R} \to \mathcal{L} \subset M$ such that $\dot{\gamma} = R_\lambda(\gamma(t))$. By the classification of compact one dimensional manifolds with nonempty boundary, the image $w(\Sigma)$ must be homeomorphic to the unit closed interval whose boundary points are two distinct points of $R$. Let $I$ denote the unit interval $w(\Sigma)$ which is contained in the leaf $\mathcal{L}$. We slightly extend the interval $I$ to $I' \subset \mathcal{L}$ so that $I'$ still becomes an embedded interval contained in $\mathcal{L}$. The preimage $\gamma^{-1}(I')$ is a disjoint union of a sequence of intervals $[\tau_k', \tau_{k+1}'] \subset \mathbb{R}$ with

\[ \cdots < \tau_{-1}' < \tau_0' < \tau_1' < \cdots \]
for \( k \in \mathbb{Z} \). We fix any single interval, say, \([\tau'_0, \tau'_1]\) \( \subset \mathbb{R} \). We denote by \( \gamma^{-1} : I' \to [\tau'_0, \tau'_1] \subset \mathbb{R} \) the inverse of the parametrisation \( \gamma \) restricted to \([\tau_0, \tau_1]\). Then by construction
\[
\gamma^{-1}(I) \cap [\tau'_0, \tau'_1] \subset (\tau'_0, \tau'_1)
\]
and hence we can write
\[
\gamma^{-1}(I) \cap [\tau'_0, \tau'_1] = [\tau_0, \tau_1]
\]
for some constants \( \tau_0, \tau_1 \) satisfying \( \tau'_0 < \tau_0 < \tau_1 < \tau'_1 \). Furthermore we have
\[
\gamma(\tau_0), \gamma(\tau_1) \in R.
\]
Now we denote by \( t \) the standard coordinate function of \( \mathbb{R} \) and consider the composition \( f := \gamma^{-1} \circ w : \Sigma \to \mathbb{R} \). It follows that \( f \) defines a smooth function on \( \Sigma \) by construction. Then recalling \( \dot{\gamma} = R_\lambda(\gamma) \), we obtain
\[
w^*\lambda = f^*(\gamma^*\lambda) = f^*(dt) = df.
\]
Furthermore we have the equality
\[
w^*\lambda \circ j = -\delta w^*\lambda
\]
which follows from the equality \(*\alpha = -\alpha \circ j\) for any one-form \( \alpha \) on \( \Sigma \). Combining these, we obtain
\[
\Delta f = \delta df = \delta w^*\lambda = 0
\]
from the defining equation \( d(w^*\lambda \circ j) = 0 \) of contact instantons. By the Legendrian boundary condition, (9.3) also implies
\[
df|_{\partial \Sigma} = 0.
\]
Then, by integration by parts, we derive
\[
0 = \int_{\Sigma} f \Delta f \, dA = -\int f \delta df \, dA = -\int (df, df) \, dA.
\]
Therefore \( df \equiv 0 \) and so \( f \) must be a constant function. This in turn implies \( w^*\lambda = 0 \). Combining this with \( d^*w = 0 \), we again conclude \( w \) must be constant. This finishes the proof. \( \square \)

Postponing derivation of the full index formula for the linearization operator \( D\Upsilon(w) \) of the equation (9.1) till [Oh21d], we just prove the following proposition. (See [Oh21a, Section10-11] for the linearization and the full index formula for the closed string case.)

**Proposition 9.2.** Let \( w_p : (D^2, \partial D^2) \to (M, R) \) be the constant map valued at \( p \in R \subset M \) regarded as a constant solution to (9.1). Consider the map
\[
\Upsilon : w \mapsto (\overrightarrow{w}, w^*\lambda \circ j)
\]
and its linearization operator
\[
D\Upsilon(w) : \Omega^0(w^*TM, (\partial w)^*TR) \to \Omega^{(0,1)}(w^*\xi) \oplus \Omega^2(\Sigma, R).
\]
Then we have
\[
\ker D\Upsilon(w_p) = n(= \dim R), \quad \text{Coker } D\Upsilon(w_p) = 0.
\]
In particular, we have
\[
\text{Index } D\Upsilon(w) = n
\]
for any element \( w \in \mathcal{M}_0(M, R; J_0, H_K) \) homotopic to a constant map relative to \( R \) for all \( K \).

**Proof.** We denote by
\[
D\mathcal{Y}(w) : \Omega^{0}_{k-1,p}(w^*TM, (\partial w)^*TR) \to \Omega^{(0,1)}_{k-1,p}(w^*\xi) \oplus \Omega^{2}_{k-2,p}(\Sigma, \mathbb{R})
\]
the \( W^{(k,p)} \)-completion of \( \Omega(w^*TM, (\partial w)^*TR) \), the set of vector fields over the map \( w \) and similarly for other completions. When \( w_p \) is the constant map valued at \( p \in R \), it is easy to see that we have
\[
D\mathcal{Y}(w_p)(\eta) = (\overline{\partial}\eta^*, -*\Delta f), \quad \eta = \eta^\pi + fR\lambda
\]
where
- \( \eta^\pi \) is a map \( D^2 \to (\xi_p, J_p) \) satisfying the totally real boundary condition \( \eta^\pi_\partial D^2 \subset T_pR \),
- \( f \) is a real-valued function on \( D^2 \) that satisfies the Dirichlet boundary condition, which follows from the Legendrian boundary condition \( R \) along \( \partial D^2 \).
(We refer to [Oh21a, Theorem 10.1] for the precise formula for the linearization operator \( \mathcal{Y}(w) \).)

It is well-known that the Laplacian with Dirichlet boundary condition on the disc has zero kernel and the corresponding index is zero. (For readers’ convenience, we give the proof of this index formula in Appendix B.)

When we identity \( (\xi_p, J_p) \) with \( (\mathbb{C}^n, i) \), \( \overline{\partial} \) is nothing but the standard Cauchy-Riemann operator. Then the first statement of the proposition is a well-known result whose proof can be found in [Oh95]. The second statement follows from the homotopy invariance of the Fredholm index. \( \square \)

An immediate corollary of the above two propositions (with \( g = 0 \)) is the following description of the moduli space \( \mathcal{M}_0(M, R; J_0, H) \cong \mathcal{M}(M, R; J_0, H_0) \).

**Corollary 9.3.** The evaluation map \( ev_{(0,0)} : \mathcal{M}_0(M, R; J_0, H) \to R \) is a diffeomorphism. In particular its \( \mathbb{Z}_2 \)-degree is nonzero.

### 9.2. The case \( K \to K_0 \)

Let \( K_0 > 0 \) be the constant that satisfies Proposition 8.9 so that
\[
\mathcal{M}_{K_0}(M, R; J, H) = \emptyset. \tag{9.4}
\]

The following is the basic structure theorem of \( \mathcal{M}_K(M, R; J, H) \) given in (8.12) whose proof is a variation of the generic transversality theorem and so is omitted. (See [Oh21a] for a proof of similar transversality result proven for the closed string case.)

**Theorem 9.4.**

1. For each fixed \( K > 0 \), there exists a generic choice of \( (J, H) \) such that \( \mathcal{M}_K(M, R; J, H) \) becomes a smooth manifold of dim \( n \) if non-empty. In particular, dim \( \mathcal{M}_K(M, R; J, H) = n \) if non-empty.
2. For the case \( K = 0 \), all solutions are constant and Fredholm regular and hence \( \mathcal{M}_K(M, R; J, H) \cong R \). Furthermore the evaluation map
\[
ev : \mathcal{M}_0(M, R; J, H) \to R : u \mapsto u(0, 0)
\]
is a diffeomorphism.
The parameterized moduli space $M_{[0,K_0]}^\text{para}(M,R;J,H) \to [0,K_0]$ is a smooth manifold of dimension $n + 1$ with boundary
\[
\{0\} \times M_0(M,R;J,H) \bigsqcup_{\{K_0\} \times M_{K_0}(M,R;J,H)} \to \{0\} \times M_0(M,R;J,H) \bigsqcup \{K_0\} \times M_{K_0}(M,R;J,H)
\]

and the evaluation map
\[
Ev : M_{[0,K_0]}^\text{para}(M,R;J,H) \times \mathbb{R} \to L \times \mathbb{R}_+ \times \mathbb{R} : ((K,u),\tau) \mapsto (K,u(\tau),\tau)
\]
is smooth.

$M_K(M,R;J,H) = \emptyset$ for all $K \geq K_0$.

The following upper bound for the bubble energy is a key ingredient in the proof of Shelukhin’s conjecture in which consideration of domain dependent family of contact triads
\[
\{(M,\lambda_z, J_z)\}_{z \in \mathbb{R} \times [0,1]}, \quad z = (\chi_K(\tau), t)
\]
is a crucial ingredient.

**Choice 9.5.** We consider the following two parameter families of $J$ and $\lambda$:
\[
\begin{align*}
J'(s,t) &= ((\psi_H^{-1}(\psi_H^{-1}))^{-1})_* J = (\psi_H^{-1}(\psi_H^{-1}))^* J, \quad (9.5) \\
\lambda'(s,t) &= ((\psi_H^{-1}(\phi_H^{-1}))^{-1})_* \lambda = (\psi_H^{-1}(\phi_H^{-1}))^* \lambda. \quad (9.6)
\end{align*}
\]

See Remark 9.8. Once this set-up is carefully introduced, the proof of the upper bound is an easy consequence of Propositions 8.9 and 8.6.

**Proposition 9.6.** Let $(K_\alpha, u_\alpha)$ be a bubbling-off sequence with
\[
u_\alpha \in M_{K_\alpha}(J,H)
\]
with
\[
u_\alpha \to (u,v,w)
\]
in the sense of Theorem 8.8. Then any bubble must have positive asymptotic action less than $\|H\|$.

**Proof.** By the way how the bubble is constructed, there exists a subsequence, still denoted by $u_\alpha$, we have
\[
\limsup_{\alpha} E^{\pi}_{(\lambda_K,J_K)}(\pi_{\alpha,K_\alpha}) = E^{\pi}_{(\lambda_\infty,J_\infty)}(\pi_{\infty,K_\infty}) + \sum_i E^{\pi}_{(\lambda_{z_i}, J_{z_i})}(v_i) + \sum_j E^{\pi}_{(\lambda_j, J_{z_j})}(w_j)
\]
where each bubble $v_i$ (resp. $w_j$) is a contact instanton for the triad
\[
(M,\lambda_{z_i}, J_{z_i}), \quad z_i = (\tau_i, t_i),
\]
and the norm is taken with respect to the associated triad metrics:
\[
g_{z_i} = d\lambda_{z_i}(\cdot, \cdot) + \lambda_z \otimes \lambda_z.
\]

We first consider the disc bubbles $w_j$. We also assume that the bubble point is contained in $\{t = 0\}$. The other cases with $\{t = 1\}$ is easier and can be treated in the same way.

But by the definition of the triad metric, we have
\[
\frac{1}{2} |d^2 w_j(\lambda_{z_j}, J_{z_j})| dA = w_j^* d\lambda_{z_j} \geq 0
\]
since \( d^\pi w_j \) is \((J_{z_j}, J)\)-complex linear and \( J_{z_j} \) is \( d\lambda_{z_j} \)-adapted. Therefore it follows from Propositions 8.6 that

\[
E^\pi_{J_{z_j}}(w_j) \leq \limsup_{\alpha} E^\pi_{(\lambda_{\pi}, J_{\pi})}(\pi_{\alpha, 0}) \leq \|H\|,
\]

we have derived

\[
\int_{\mathbb{H}} dw_j^* \lambda_{z_j} \leq \|H\|.
\]

Now the proof will be complete once we prove the following key lemma. We recall the definition of the action spectrum \( \text{Spec}(M, \lambda) \) (resp. \( \text{Spec}(M, R; \lambda) \)) and the period gap \( T(M, \lambda) \) (resp. \( T(M, \lambda; R) \)) from Definition 1.6.

**Lemma 9.7.** Let \( \gamma_j \) be the asymptotic \( \lambda_{z_j} \)-Reeb chord of \( w_j \). Then the value

\[
\int_{\mathbb{H}} dw_j^* \lambda_{z_j}
\]

is contained in \( \text{Spec}(M, R; \lambda) \).

**Proof.** By finiteness of the energy \( E^\pi_{J_{z_j}}(w_j) < \infty \) and the Legendrian boundary condition, we derive

\[
\int_{\mathbb{H}} dw_j^* \lambda_{z_j} = \int_{\partial \mathbb{H}} \gamma^* \lambda_{z_j}
\]

with

\[
\gamma(t) = \lim_{\tau \to \infty} w(e^{\pi(\tau + it)})
\]

where \((\tau, t) \in [0, \infty) \times [0, 1] \subset \hat{\Sigma} \setminus \{z_j\}\) is the strip-like coordinate around the bubble point \( z_j = (\tau_j, 0) \in \Sigma := \mathbb{R} \times [0, 1] \).

Recall that \( \gamma \) satisfies the boundary condition

\[
\gamma(0), \gamma(1) \in \psi^1_{H^* \gamma}(R)
\]

for \( s_j = \chi_{K_j}(\tau_j) \), since it is an asymptotic limit of a disc bubble \( w_j \) at \( t = 0 \) where \( w_j \) satisfies

\[
w_j(\{t = 0\}) \subset \psi^1_{H^* \gamma}(R), \quad s_j = \chi_{K_{\infty}}(\tau_j).
\]

On the other hand, we compute

\[
\gamma^* \lambda_{z_j} = \gamma^*(\psi^0_{H^* \gamma}(\psi^1_{H^* \gamma})^{-1})^* \lambda = \gamma^*((\psi^1_{H^* \gamma})^{-1})^* \lambda = ((\psi^1_{H^* \gamma})^{-1} \circ \gamma)^* \lambda.
\]

If we set

\[
\tilde{\gamma}(y) := (\psi^1_{H^* \gamma})^{-1}(\gamma(y)),
\]

(9.7) implies

\[
\tilde{\gamma}(0), \tilde{\gamma}(1) \in R.
\]

Furthermore \( \tilde{\gamma} \) is a \( \lambda \)-Reeb chord, since \( \gamma \) is a \( \lambda(s_j, 0) \)-Reeb chord and

\[
\lambda(s_j, 0) = (\psi^1_{H^* \gamma})^* \lambda.
\]

Therefore we have proved

\[
\int_{\partial \mathbb{H}} \gamma^* \lambda_{z_j} = \int_{\partial \mathbb{H}} \tilde{\gamma}^* \lambda \in T(M, \lambda; R).
\]

This finishes the proof. \( \square \)

Easier proof also applies to the sphere bubble \( v_i \), which now finishes the proof of the proposition. \( \square \)
Remark 9.8. For the above action bound to hold for the bubbles, it is essential to vary the contact triads depending on the domain parameters by simultaneously varying the pairs \((\lambda, J)\).

For example, if one fixed \(\lambda\) while \(J\) varies, one would not be able to prove this bound of the asymptotic period for the given contact form \(\lambda\) in terms of the oscillation norm \(\|H\|\): The only thing one could get is the kind of statement that there is a \(s_1 \in [0, 1]\) and a bubble whose \((\psi_{s_1}^*)^\lambda\)-period is less than or equal to \(\|H\|\). Since general contactomorphism does not preserve \(\lambda\) and hence \((\psi_{s_1}^*)^\lambda \neq \lambda\), the two periods are generally different. This is a fundamental difference from the symplectic case where the symplectic form can be fixed while the almost complex structure varies since symplectomorphism preserves the symplectic form.

10. Existence of Reeb chords and translated intersections

We start with the following definition.

Definition 10.1. We say the pair \((\lambda, (R_0, R_1))\) is nondegenerate if all closed \(\lambda\)-Reeb orbits of \(M\) and \(\lambda\)-Reeb chords from \(R_0\) to \(R_1\) are nondegenerate.

Note that the latter nondegeneracy is equivalent to the transversality of the intersection \(R_0 \pitchfork Z_{R_1}\).

The following is a standard lemma in contact geometry, which is an easy consequence of nondegeneracy.

Lemma 10.2. Let \((M, \xi)\) be a closed contact manifold. Then we have the following:

1. \(\text{Spec}(M, \lambda)\) (resp. \(\text{Spec}(M, \lambda; R_0, R_1)\)) is either empty or countable nowhere dense in \(\mathbb{R}_+\).
2. \(T(M, \lambda) > 0\) (resp. \(T_\lambda(R_0, R_1)\)).
3. When the pair \((\lambda, (R_0, R_1))\) is nondegenerate, then each of the sets

\[
\text{Spec}^K(M, \lambda) = \text{Spec}(M, \lambda) \cap (0, K]
\]

and

\[
\text{Spec}^K(M, \lambda; R_0, R_1) = \text{Spec}(M, \lambda; R_0, R_1) \cap (0, K]
\]

are finite for each \(K > 0\).

Definition 10.3 (Relative period gap). For given Legendrian submanifold \(R \subset M\), we define the constant \(T_\lambda(M; R) > 0\) by

\[
T_\lambda(M, R) = \min \{T(M, \lambda), T(M, \lambda; R)\}
\]

and call it the period gap of the pair \((M, R)\).

We now introduce the notion of Reeb-untangling energy of one Legendrian submanifold from the Reeb trace of another Legendrian submanifold.

Definition 10.4 (Reeb-untangling energy). Let \((M, \xi)\) be a contact manifold, and let \(R_0, R_1\) of compact Legendrian submanifolds \((M, \xi)\).
(1) We define
\[ e^{\text{trn}}_{\lambda}(R_0, R_1) := \inf\{ \|H\| \mid \psi_H^1(R_0) \cap Z_{R_1} = \emptyset \}. \] (10.1)

We put \( e^{\text{trn}}_{\lambda}(R_0, R_1) = \infty \) if \( \psi_H^1(R_0) \cap Z_{R_1} \neq \emptyset \) for all \( H \). We call \( e^{\text{trn}}_{\lambda}(R_0, R_1) \) the \( \lambda \)-untangling energy between them.

(2) We put
\[ e^{\text{trn}}(R_0, R_1) = \inf_{\lambda \in \mathcal{E}(\xi)} e^{\text{trn}}_{\lambda}(R_0, R_1). \] (10.2)
We call \( e^{\text{trn}}(R_0, R_1) \) the Reeb-untangling energy between \((R_0, R_1)\) on \((M, \xi)\).

10.1. **Without nondegeneracy assumption.** The following proof is the contact analog to [Oh97, Theorem]. (See also [Che98].)

**Theorem 10.5.** Let \( R \subset (M, \lambda) \) be a compact Legendrian submanifold. Then we have
\[ e^{\text{trn}}_{\lambda}(R, R) \geq T_{\lambda}(M, R) \]

*Proof.* If \( R \) is not displaceable from \( Z_R \), by definition, we have \( e^{\text{trn}}_{\lambda}(R, R) = \infty \). Then there is nothing to prove.

Now suppose there exists a Hamiltonian \( H \) with \( \mathcal{R}eeb(\psi_H^1(R), R) = \emptyset \). Let \( H \) be any such Hamiltonian. We consider the parameterized moduli space
\[ \mathcal{M}_{\text{para}}^{[0, K_0]}(M, R; J, H) = \bigcup_{K \in [0, K_0]} \{ K \} \times \mathcal{M}_K(M, R; J, H) \] (10.3)
which is fibered over \([0, K_0]\), and consider the evaluation map
\[ \mathcal{E}v : \mathcal{M}_{\text{para}}^{[0, K_0]}(M, R; J, H) \to L \times [0, K_0]; \quad u \mapsto (u(0, 0), K). \]
The transversality theorem (see [Oh21a, Section 12]) implies that for generic choice of \( J \), \( \mathcal{M}_{\text{para}}^{[0, K_0]}(M, R; J, H) \) is a smooth manifold of dimension \((\dim R + 1)\) with boundary
\[ \mathcal{M}_0(M, R; J, H) \bigsqcup \mathcal{M}_{K_0}(M, R; J, H). \]
We also know that
\[ ev_0 : \mathcal{M}_0(M, R; J, H) \to R \] is a diffeomorphism.

In particular, its \( \mathbb{Z}_2 \)-degree of \( ev_0 \) is 1. On the other hand we have
\[ \mathcal{M}_{K_0}(M, R; J, H) = \emptyset \]
by Proposition 8.9, hence the \( \mathbb{Z}_2 \)-degree of the map \( ev_{K_0} \) is zero. But the \( \mathbb{Z}_2 \)-degree is invariant under a compact cobordism. Therefore \( \mathcal{M}_{[0, K_0]}(M, R; J, H) \) cannot be compact. By Theorem 8.8, a bubble must develop, i.e., there exists subsequences of \( K_\alpha \) \( u_\alpha \) again denoted by the same such that
\[ K_\alpha \to K_\infty \in [0, K_0], \]
and \( u_\alpha \in \mathcal{M}_{K_\alpha}(M, R; J, H) \) converging to some cusp-curve \((u, v, w)\) in the sense of Theorem 8.8 with either \( v \neq \emptyset, w \neq \emptyset \). Recall Corollary 9.6 implies that the \( \pi \)-energy of the bubble is always less than \( \|H\| \), and hence
\[ T_{\lambda}(M, R) \leq \|H\|. \]
Now taking the infimum of \( \|H\| \) over all \( H \) with \( Z_R \cap \psi_H^1(R) = \emptyset \), we obtain
\[ 0 < T_{\lambda}(M, R) \leq \inf_{H \in \mathcal{E}(\xi)} \{ \|H\| \mid Z_R \cap \psi_H^1(R) = \emptyset \}. \]
But the quantity in the right hand side of this inequality is nothing but the Reeb-untangling energy $e_{\lambda}^{\text{trn}}(R, R)$ of $R$ and finishes the proof. \hfill \Box

10.2. **With nondegeneracy assumption: the lower bound of $\text{Fix}_{\lambda}^{\text{trn}}(\psi)$.** In this subsection, we assume that $(\lambda, (\psi(R), R))$ is nondegenerate in the sense of Definition 10.1.

We will prove the following lower bound adapting the argument used by Chekanov [Che98] in the context of Lagrangian Floer theory. (See [FOOO13] for the relevant energy estimates and the proof of lower bound.) The algebraic arguments leading to the lower bound is based on a purely algebraic homological machinery equally applies to the current context, as long as bubbling does not occur which is ensured by the inequality

$$\|H\| < T_{\lambda}(M, R).$$

Therefore we will be brief in the details of the proof leaving full details for the relevant algebraic argument to [Che98] or [FOOO13].

**Theorem 10.6.** Suppose $\psi$ is nondegenerate and let $H \mapsto \psi$ with $\|H\| < T_{\lambda}(M, R)$.

Then

$$\text{dim} H_{*}(R; \mathbb{Z}_{2}) \geq \text{Fix}_{\lambda}^{\text{trn}}(\psi).$$

**Proof.** Under the nondegeneracy assumption, we consider the $\mathbb{Z}_{2}$-vector space

$$CI^{*}_{\lambda}(\psi(R), R) := \mathbb{Z}_{2}\langle \text{Reeb}(\psi(R), R) \rangle.$$

(Here $CI_{\lambda}^{*}$ stands for contact instanton for $\lambda$ as well as the letter $C$ also stands for complex at the same time.)

We define a $\mathbb{Z}_{2}$-linear map

$$\delta_{(\psi(R), R; H)} : CI^{*}_{\lambda}(\psi(R), R) \to CI^{*}_{\lambda}(\psi(R), R)$$

by its matrix element

$$\langle \delta_{(\psi(R), R; H)}(\gamma^{-}), \gamma^{+} \rangle := \#_{\mathbb{Z}_{2}}(M(\gamma^{-}, \gamma^{+})).$$

Here $M(\gamma^{-}, \gamma^{+})$ is the moduli space

$$M(\gamma^{-}, \gamma^{+}) = M(M, \lambda; R; \gamma^{-}, \gamma^{+})$$

of contact instanton Floer trajectories $u$ satisfying $u(\pm \infty) = \gamma_{\pm}$.

Similarly we define the maps

$$\delta_{(R, R; 0)} : CI^{*}_{\lambda}(R, R) \to CI^{*}_{\lambda}(R, R).$$

We denote by $\overline{H}$ the inverse Hamiltonian of $H$ given by the formula (2.5) and consider the maps

$$\Psi_{H} = (\Phi_{H})_{*} : CI^{*}_{\lambda}(R, R) \to CI^{*}_{\lambda}(\psi(R), R)$$

and

$$\Psi_{\overline{H}} = (\Psi_{R})^{-1}_{*} : CI^{*}_{\lambda}(\psi(R), R) \to CI^{*}_{\lambda}(R, R)$$

where $\Phi_{H}$ is the gauge transformation defined in Subsection 6.1. Recall $\psi_{R} = \psi^{-1}$. Then we consider the composition

$$\Psi_{\overline{H}} \circ \Psi_{H} : CI^{*}_{\lambda}(R, R) \to CI^{*}_{\lambda}(R, R).$$

By considering the one-parameter family of Hamiltonians $H_{K}$ defined in (1.14), we define a family of homomorphisms

$$\Psi_{H_{K}} : CI^{*}_{\lambda}(R, R) \to CI^{*}_{\lambda}(R, R).$$
with \(0 \leq K \leq K_0\) which defines a chain homotopy map
\[
\mathcal{H} : CI^*_\lambda(R, R) \to CI^{*-1}_\lambda(R, R)
\]
between \(\Psi_{\mathcal{H}} \circ \Psi_H\) and \(id\) on \(CI^*_\lambda(R, R)\), i.e., it satisfies
\[
\Psi_{\mathcal{H}} \circ \Psi_H - id = \delta H + H \delta
\]
on \(CI^*_\lambda(R, R)\) provided the relevant parameterized moduli space
\[
\mathcal{M}_{\text{para}}^{[0, K]}(M, R; J, H)
\]
that we considered in the previous section does not bubble-off. A standard algebraic argument then shows that the latter homotopy identity follows as long as no bubbling occurs which is ensured by the inequality \(\|H\| < T_\lambda(M, R)\). Therefore we have shown that
\[
HI^*_\lambda(\psi(R), R) \cong H^*_\lambda(R, R).
\]
It remains to show that \(HI^*_\lambda(R, R) \cong H^*(R)\). This can be shown by a couple of ways either by the Morse-Bott argument (or the PSS-type argument) or by the direct comparison argument with the Morse complex of the generating function as done in [FO97, Mil00] in a Darboux-Weinstein neighborhood after localizing the cohomology as in [Oh96]. (See also [OY] for the details in the case of one-jet bundle in the current contact context.) This finishes the proof. \(\square\)

**Remark 10.7.** We note that the virtual dimension of the moduli space of holomorphic half plane
\[
\mathcal{M}((\mathbb{H}, \partial \mathbb{H}), (M, R); \gamma)
\]
for a given asymptotic Reeb chord of \(R\) will have at least 2 thanks to the action of automorphism of \((D^2 \setminus \{1\}, \partial D^2 \setminus \{1\}) \cong (\mathbb{H}, \partial \mathbb{H})\) preserving the infinity. Therefore if the starting pair of Reeb chords \(\gamma_{\pm} \in \mathcal{R}_{\text{Reeb}}(\psi(R), R)\) is the one with the virtual dimension of the associated moduli space \(\tilde{\mathcal{M}}(\psi(R), R; \gamma_+, \gamma_-)\) is one, the moduli space cannot produce such a bubble. This implies compactness of the quotient
\[
\tilde{\mathcal{M}}(\psi(R), R; \gamma_+, \gamma_-)/\mathbb{R}
\]
when \(\text{vir.dim.} \tilde{\mathcal{M}}(\psi(R), R; \gamma_+, \gamma_-) = 1\). Combining the fact that \(\psi\) is contact isotopic to the identity, we can also prove that this counting of moduli space of dimension one gives rise to the boundary map \(\partial\) satisfying \(\partial^2 = 0\) by the arguments similar to the one used in [Oh93] in the Lagrangian Floer theory. Therefore the cohomology group \(HI^*_\lambda(\psi(R), R)\) is defined. This is implicitly used in the proof of Theorem 10.6 above.

### 11. Wrap-up of the proof of Sandon-Shelukhin’s conjecture

In this section, we wrap-up the proof of Shelukhin’s conjecture by explaining how Theorem 1.13 implies Theorem 1.17. We introduce the following definition from [She17].

**Definition 11.1** (Definition 24 [She17]). For given \(\psi \in \text{Cont}_0(M, \xi)\), we define
\[
\|\psi\|^{\text{osc}}_{\lambda} = \inf_{\mathcal{H} \mapsto \psi} \|\mathcal{H}\|.
\]

Using this, we introduce the following analogs of \(\lambda\)-untangling energy \(e^{\text{trn}}_{\lambda}(R_0, R_1)\) for contact form \(\lambda\).
Definition 11.2 (λ-untangling energy). Let \((M, \xi)\) be a contact manifold. For each contact form \(\lambda\) of \(\xi\), we define
\[
e_{\lambda}^{\text{trn}}(M, \xi) := \inf_{\psi \in \text{Cont}_0(M, \xi)} \{\|\psi\|_{\text{osc}} | \text{Fix}_{\lambda}^{\text{trn}}(\psi) = \emptyset\} \tag{11.1}
\]
and
\[
e^{\text{trn}}(M, \xi) := \inf_{\lambda \in C(\xi)} e_{\lambda}^{\text{trn}}(M, \xi). \tag{11.2}
\]
We call \(e_{\lambda}^{\text{trn}}(M, \xi)\) (resp. \(e^{\text{trn}}(M, \xi)\)) the \(\lambda\)-untangling energy of the contact form \(\lambda\) (resp. the Reeb-untangling energy of contact structure \(\xi\)).

We observe the equality
\[
e_{\lambda}^{\text{trn}}(M, \xi) = \inf_{H \mapsto \psi} \{\|H\| | \text{Fix}_{\lambda}^{\text{trn}}(\psi_H) = \emptyset\}.
\]
Therefore Sandon’s observation in [San12] implies \(e_{\lambda}^{\text{trn}}(M, \xi) > 0\).

11.1. Reduction to a chord entanglement problem. We consider the contact manifold \((M_Q, \mathscr{A})\) given by
\[
M_Q = Q \times Q \times \mathbb{R}, \quad \mathscr{A} = -\eta^1 \pi_1^* \lambda + \pi_2^* \lambda.
\]
We also have one-to-one correspondence between \(\text{Fix}^{\text{trn}}(\psi)\) and the intersection set \(\Gamma_{\psi} \cap Z_{\Gamma_{id}}\).

Lemma 11.3. Let \((M_Q, \mathscr{A})\) be as above. Then we have
\[
T(Q, \lambda) = T(M_Q, \mathscr{A}; \Gamma_{id}).
\]

Proof. We recall from Section 4 that the Reeb vector field of \(\mathscr{A}\) is given by \((0, R_\lambda, 0)\) (see Lemma 4.2). The lemma immediately follows therefrom.

We also recall
\[
\Gamma_{\psi} = \psi^1_H(\Gamma_{id})
\]
for any lifted Hamiltonian \(\tilde{H}\) generating the isotopy
\[
t \mapsto \Gamma_{\psi_H},
\]
which is a consequence of Proposition 4.5. We derive the following inequality from this.

Proposition 11.4. Let \((Q, \xi)\) and \((M_Q, \mathscr{A})\) be as above. Then
\[
e_{\mathscr{A}}^{\text{trn}}(\Gamma_{id}, \Gamma_{id}) \leq e_{\lambda}^{\text{trn}}(Q, \xi).
\]

Proof. Let \(\epsilon > 0\) be given. By definition, there exists a Hamiltonian \(H : \mathbb{R} \times Q \to \mathbb{R}\) such that
\[
\|H\| \leq e_{\lambda}^{\text{trn}}(Q, \xi) + \frac{\epsilon}{2} \tag{11.3}
\]
and \(\text{Fix}_{\lambda}^{\text{trn}}(\psi_H^1) = \emptyset\). Then we have
\[
\emptyset = Z_{\Gamma_{id}} \cap \psi_H^1 = Z_{\Gamma_{id}} \cap \psi_H^1(\Gamma_{id}).
\]
By compactness of \(\Gamma_{id}\) and \(\Gamma_{\psi_H}\), is an isotopy of embedded Legendrian submanifolds, we can choose a lifted Hamiltonian \(\tilde{H}\) of \(H\) that satisfies (4.5). Then we can take a cut-off Hamiltonian \(\tilde{H}'\) of \(\tilde{H}\) given by
\[
\tilde{H}'(t, x) = \chi_\epsilon(x)\tilde{H}(t, x)
\]
such that $\chi_t(x) \equiv 1$ on $\psi^t(H, \Gamma_{id})$ and is supported in a small neighborhood thereof and

$$\|\tilde{H}'\| \leq \|H\| + \frac{\epsilon}{2}.$$  \hspace{1cm} (11.4)

By adding (11.3) and (11.4), we have

$$\|\tilde{H}'\| \leq e^{\text{trn}}(Q, \xi) + \epsilon.$$ 

Furthermore by the support condition of the cut-off functions $\chi_t$, we also have

$$\psi^1(H, \Gamma_{id}) = \Gamma_{\psi}$$

and hence $\psi^1(H, \Gamma_{id}) \cap Z_{\Gamma_{id}} = \emptyset$. This implies

$$e^{\text{trn}}(\Gamma_{id}, \Gamma_{id}) \leq e^{\text{trn}}(Q, \xi) + \epsilon.$$ 

Since $\epsilon > 0$ is arbitrary, we have finished the proof of the proposition. \hfill \Box

Now the following corollary of Lemma 11.3 and Proposition 11.4 reduce Shelukhin’s conjecture to the existence problem of the Reeb chords for the pair $(\psi(R), R)$.

**Corollary 11.5.** We have the following implication:

$$e^{\text{trn}}(\Gamma_{id}, \Gamma_{id}) \geq T(M_Q, \mathcal{A}; \Gamma_{id}) \implies e^{\text{trn}}(Q, \xi) \geq T(Q, \lambda).$$

Therefore we have reduced Shelukhin’s conjecture to the existence problem of the Reeb chords for the pair $(\psi(R), R)$ for any compact Legendrian submanifold $R$ in tame contact manifold $M$, not necessarily compact. Once the latter is proved, then we have only to apply the result to the pair

$$(M, \lambda; R) = (M_Q, \mathcal{A}; \Gamma_{id}).$$

This being said, we will solve this general chord problem between the pair $(\psi(R), R)$ given on general tame contact manifold $(M, \lambda)$ in Part 3.

11.2. **Tameness of contact manifold** $(Q \times Q \times \mathbb{R}, \mathcal{A})$. We introduce a family of $\mathcal{A}$-adapted almost complex structures on $M_Q = Q \times Q \times \mathbb{R}$.

**Lemma 11.6.** Let $J$ be any $\lambda$-adapted almost complex structure on $(Q, \lambda)$. Then the CR almost complex structure $\tilde{J}$ on $TM_Q$ defined by

$$\tilde{J} \left( X + aR_{\lambda}, Y + bR_{\lambda}, c \frac{\partial}{\partial \eta} \right) = \left( JX, JY + cR_{\lambda}, -b \frac{\partial}{\partial \eta} \right)$$

is $\mathcal{A}$-admissible. We call $\tilde{J}$ a lifted CR almost complex structure from $Q$.

**Proof.** A straightforward calculation shows that this definition satisfies the defining conditions of $\mathcal{A}$-adaptedness given in Definition 1.18. \hfill \Box

More explicitly saying, this definition of $\tilde{J}$ is equivalent to

$$\tilde{J}(R_{\lambda}, 0, 0) = (0, 0, 0), \quad \tilde{J}(X, 0, 0) = (JX, 0, 0),$$

and

$$J(0, R_{\lambda}, 0) = -\frac{\partial}{\partial \eta}, \quad \tilde{J} \frac{\partial}{\partial \eta} = (0, R_{\lambda}, 0),$$

$$\tilde{J}(0, Y, 0) = (0, JY, 0)$$ \hspace{1cm} (11.5)
for $X, Y \in \ker \lambda$.

We first prove the following

**Proposition 11.7.** The contact manifold $(M_Q, \mathcal{A})$ is tame in the sense of Definition 1.12.

**Proof.** Let $\tilde{J}$ be defined as in Lemma 11.6. We will show that the coordinate function $\eta : M_Q \to \mathbb{R}$ is indeed a Reeb-tame, contact $\tilde{J}$-convex exhaustion function on $M_Q$.

Clearly $\eta$ is an exhaustion function since $\eta^{-1}([-N,N])$ is compact and

$$M_Q = \bigcup_{N=0}^{\infty} \eta^{-1}([-N,N]).$$

It is also $\mathcal{A}$-tame since $d\eta(R_{\mathcal{A}}) = 0$ since $R_{\mathcal{A}} = (0, R_{\lambda}, 0)$.

We now prove the following.

**Lemma 11.8.** Let $\tilde{J}$ be any lifted CR almost complex structure on $M_Q$ and $\eta : M_Q \to \mathbb{R}$ be the projection i.e., the coordinate function of the $\mathbb{R}$-factor. Then $\eta$ satisfies the equality

$$-d\eta \circ \tilde{J} = \pi_2^* \lambda.$$ \hspace{1cm} (11.7)

**Proof.** Using Lemma 11.6 or (11.5)-(11.6), it is straightforward to check $-d\eta \circ \tilde{J} = \pi_2^* \lambda$. \hfill $\square$

By taking the differential, we get

$$-d(d\eta \circ \tilde{J}) = \pi_2^* d\lambda.$$ \hspace{1cm} (11.8)

Therefore we obtain

$$R_{\mathcal{A}}|d(d\eta \circ \tilde{J}) = R_{\mathcal{A}}|\pi_2^* d\lambda = \pi_2^* (R_{\lambda}|d\lambda) = 0$$

which proves the first defining condition of tameness of $\lambda$.

**Lemma 11.9.** The two-form

$$\pi_2^* d\lambda$$

is a positive $(1,1)$-current on $\ker \mathcal{A}$ with respect to $\tilde{J}$

**Proof.** We will show $\pi_2^* d\lambda$ satisfies

$$\pi_2^* d\lambda(W, \tilde{J}W) \geq 0$$

for any tangent vector $W \in \ker \mathcal{A} \subset TM_Q$. From the decomposition

$$W = \left( X + aR_{\lambda}, Y + bR_{\lambda}, c \frac{\partial}{\partial \eta} \right), \quad X, Y \in \xi_Q = \ker \lambda$$

it follows that $W \in \ker \mathcal{A}|_{(x,y,\eta)}$ if and only if $X, Y \in \xi_Q$ are arbitrary and $a$ and $b$ satisfy

$$c^0 a = b.$$

By definition of $\tilde{J}$, we obtain

$$\tilde{J}(W) = \left( JX, JY + cR_{\lambda}, -b \frac{\partial}{\partial \eta} \right).$$
Then we compute
\[
\pi_2^*d\lambda(W, \tilde{J}W) = d\lambda(\pi_2(W), \pi_2(\tilde{J}W)) = d\lambda(Y + bR_\lambda, JY + dR_\lambda) = d\lambda(Y, JY) \geq 0
\]
where the penultimate equality follows since \( R_\lambda d\lambda = 0 \) and the positivity follows since \( J \) is \( \lambda \)-adapted.

Therefore combining this with (11.8), we have derived
\[
-d(d\eta \circ \tilde{J}) = \pi_2^*d\lambda \geq 0 \quad \text{on ker } \mathcal{A}.
\]
This proves that the function \( \psi := \eta \) is an \( \mathcal{A} \)-tame \( \tilde{J} \)-convex exhaustion function. We have now finished the proof of Proposition 11.7. □

11.3. **Solving the entanglement problem for \( \Gamma_{id} \).** We now establish this \( C^0 \)-bound for any contact instantons \( U \) for any contact instantons for the triad
\[(M_Q, \mathcal{A}, \tilde{J})\]
with Legendrian boundary conditions
\[U(\tau, 0) \in \Gamma_\psi, \quad U(\tau, 1) \in \Gamma_{id}\]
utilizing the maximum principle in the rest of the present subsection.

**Proposition 11.10.** Let \( U \) be any contact instantons with Legendrian pair boundary \((\Gamma_\psi, \Gamma_{id})\). Then we have
\[
\|\eta \circ U\|_{C^0} \leq \|g_\psi\|_{C^0}.
\]
In particular, Image\( U \) is precompact in \( M_Q = Q \times Q \times \mathbb{R} \).

**Proof.** Since \( U \) is a contact instanton for the contact triad \((M_Q, \mathcal{A}, \tilde{J})\) and \( \eta \) is an \( \mathcal{A} \)-tame CR \( \tilde{J} \)-convex function \( \eta \circ U \) is a subharmonic function by Proposition 11.7.

By the maximum principle applied to the function \( \eta \circ u \), we obtain
\[
\sup_{z \in \Sigma} |\eta \circ U(z)| \leq \max \left\{ \sup_{z \in \partial \Sigma} |\eta \circ U(z)|, \max \{ |\eta(\gamma_\pm)| \} \right\}.
\]
(Note that \( \eta \circ U(\tau, 1) \equiv 0 \) and so max \( \eta \circ U \geq 0 \) and min \( \eta \circ U \leq 0 \.)

Now we examine the values of \( \eta \circ U \) on the boundary and at infinity of \( \Sigma = \mathbb{R} \times [0, 1] \). We focus on the boundary component \( \{ t = 0 \} \) since \( \eta \circ U \equiv 0 \) on \( \{ t = 1 \} \) because \( U(\{ t = 1 \}) \subset \Gamma_{id} \). By definition, we have
\[\Gamma_\psi = \{(x, \psi(x), g_\psi(x)) \mid x \in Q\} .\]
This implies
\[
\sup_{z \in \partial \Sigma} |\eta \circ U(z)| \leq \|g_\psi\|_{C^0}.
\]
Furthermore since \( R_\psi = (0, R_\lambda, 0) \) is tangent to the level sets of \( \eta \), we also have
\[
\max_{t \in [0, 1]} |\eta \circ U(\pm \infty, t)| = |\eta \circ U(\pm \infty, 1)| = |g_\psi(u_1(\pm \infty, 1))| \leq \|g_\psi\|_{C^0}
\]
for \( u_1 = \pi_1 \circ U \), where we use the observation that \( t \mapsto U(\pm, t) \) are Reeb chords from \( \Gamma_\psi \) to \( \Gamma_{id} \) and hence we can write
\[
u(\pm \infty, t) = \left( x_\pm, \phi_{R_\lambda}^{t\psi}(x_\pm), g_\psi(x_\pm) \right) .
\]
for some \( \eta \pm > 0 \) and \( x \pm \in Q \) with \( \phi_{\lambda}^{\eta \pm}(x \pm) = \psi(x \pm) \). (Recall we assume \( \psi(R) \cap R = \emptyset \).) Combining the above, we have proved
\[
\sup_{z \in \Sigma} |\eta \circ U(z)| \leq \|g\eta\|_{C^0}
\]
which finishes the proof. \( \square \)

Once this \( C^0 \)-bound in our disposal, we can apply the whole package we develop in the present work to the case of \( M_Q = Q \times Q \times \mathbb{R} \), and hence Theorem 1.13 implies Theorem 1.17. This finishes the proof of Theorem 1.17.

**Part 3. Energy bounds, bubbling analysis and weak convergence**

In this part, we assume that \((M, \lambda)\) is a tame contact manifold. Then we consider \( J_K \) is the two-parameter family of \( \lambda \)-adapted CR almost complex structures defined by
\[
J_K(\tau, t) = (\psi_H^t(\tau)^{\dagger}(\psi_{H^K(\tau)}^{\dagger})^{-1})^*J'_K(\tau, t)
\]
which is associated to the family given in (8.1), and the two-parameter family of Hamiltonians \( H_K = H^K \) given in (1.14). By the boundary-flatness assumed in (8.2), \( J'_K \equiv J_0 \) for all \( \tau \) with \(|\tau| \) sufficiently large.

Then we study the equation (8.9) which we recall here:
\[
\begin{align*}
&\left\{ 
\begin{array}{l}
(du - X_{H^K(\tau)}(u))\pi^{(0,1)} = 0, \\
d(e^{g_K(u)}(u^*\lambda + u^*H_K dt) \circ j) = 0,
\end{array}
\right.
\quad u(\tau, 0) \in \mathbb{R}, u(\tau, 1) \in \mathbb{R}
\end{align*}
\]
(11.10)
where \( g_K \) is the function on \( \Theta_{K_0+1} \) given in (8.10) for \( 0 \leq K \leq K_0 \).

We will develop the necessary analytic package which provides the definition of relevant off-shell energy and the bubbling argument and construct the compactification of the moduli space
\[
\mathcal{M}(M, R; J, H), \quad \mathcal{M}_{para}(M, R; J, H)
\]
of solutions of (11.10), and other relevant moduli space of (perturbed) contact instantons.

For the purpose of compactification of the moduli space of contact instantons, identifying a suitable notion of the \( \lambda \)-energy that controls the \( C^1 \)-estimate is the key element in the compactness study of moduli space of contact instantons. The framework we will use is the one from [Oh21a] where the closed string case is studied. In the closed string case, the asymptotic charge \( Q \) may not be zero which is the key obstacle to the compactification and the Fredholm theory. Since in our current case, the asymptotic charge vanishes by Theorem 6.17, which is proved in [Oh21b], this bubbling-off analysis applies to general Legendrian boundary condition.

**12. A priori uniform \( \pi \)-energy bound**

The following a priori \( \pi \)-energy identity is a key ingredient in relation to the lower bound of the Reeb-untangling energy. The proof will be carried out by the calculation similar to the one which we extract from the calculation made in [Oh97] in the context of Lagrangian Floer theory. However the current calculation is significantly much more complex than and varies from that of [Oh97] because of the presence of the new conformal exponent factor \( e^{g_K(u)} \) which makes the calculation much more involved that of [Oh97].
Remark 12.1. We would like to emphasize that the calculation leading to the proof of the energy identity is the heart of the matter that relates the \( \pi \)-energy and the oscillation norm similarly as in [Oh97]. This is one of the key ingredients in the quantitative symplectic and contact topology.

Proposition 12.2. Let \( u \) be any finite energy solution of (8.9). Then we have

\[
E_{(J_K,H_K)}^\pi(u) = \int_{-2K-1}^{-2K} -\chi_K(\tau) \left( \int_0^1 H(r, \phi_{x_K(\tau)}^r H(u(\tau,0))) \, dr \right) \, d\tau \\
+ \int_{2K}^{2K+1} -\chi_K(\tau) \left( \int_0^1 H(r, \phi_{x_K(\tau)}^r H(u(\tau,0))) \, dr \right) \, d\tau.
\]

(12.1)

Proof. By the energy identity given in Proposition 7.2, we have

\[
E_{(J_K,H_K)}^\pi(u) = E_{J_0}^\pi(\bar{\pi}) = \int_{\Theta_{K+1}} \bar{\pi}^* d\lambda = \int_{\partial \Theta_{K+1}} \bar{\pi}^* \lambda.
\]

We note

\[
\Theta_{K+1} \setminus [-2K_0 - 1, 2K_0 + 1] \times [0,1] = D^- \cup D^+
\]

where \( D^\pm \) are two semi-discs given by

\[
D_{K_0}^\pm = \{ z \in \mathbb{C} \mid |z| \leq 1, \pm \text{Re} \, z > 0 \} \pm (2K_0 + 1,0)
\]

with their boundaries given by

\[
\partial D_{K_0}^\pm = \{ z \in \mathbb{C} \mid |z| = 1, \pm \text{Re} \, z > 0 \} \pm (2K_0 + 1,0).
\]

We decompose the integral into

\[
\int_{\partial \Theta_{K+1}} \bar{\pi}^* d\lambda = \int_{[-2K-1,2K+1]} \bar{\pi}^* \lambda|_{t=0} - \int_{[-2K-1,2K+1]} \bar{\pi}^* \lambda|_{t=1} + \int_{\partial D_{K_0}^+} \bar{\pi}^* \lambda - \int_{\partial D_{K_0}^-} \bar{\pi}^* \lambda.
\]

(12.3)

We now examine the four summands of the right hand side separately.

The last two terms vanish by the Legendrian boundary condition on \( u \), since \( H_K \equiv 0 \) and so \( \bar{\pi} = u \) on the relevant integration domains. It remains to estimate the first two terms.

We recall the definition

\[
\bar{\pi}_K(\tau,t) := \psi_{H_K(\tau)}^1 (\psi_{H_K(\tau)}^t)^{-1}(u(\tau,t))
\]

from (8.17) for the \( (\tau,t) \)-family of Hamiltonians

\[
\text{Dev} (\tau \mapsto \psi_{H_K(\tau)}^t) (\tau,t) = \chi_K(\tau) H_K(\tau)(t,x)
\]

where we recall \( H_K(\tau,t) = \text{Dev} (s \mapsto \psi_{H_K}^s) (s,t) \) by definition for \( H_K(\tau,t) = sH(t,x) \).

We denote by \( \nu_{(\tau,t)}^K \) the \( \tau \)-path associated to the two-parameter family

\[
\tau \mapsto \nu_{(\tau,t)}^K := \psi_{x_K(\tau)}^1 H_K(\tau)(t,x)
\]

(12.4)

and let \( X_\tau \) be the vector field generating the contact Hamiltonian path. Then by definition we have

\[
\text{Dev} (\tau \mapsto \nu_{(\tau,t)}^K) = -\lambda(X_\tau).
\]

We denote

\[
G_K(\tau,t,x) = \text{Dev} (\tau \mapsto \nu_{(\tau,t)}^K)(\tau,x).
\]

(12.5)
Then we compute
\[ \frac{\partial \overline{\pi}_K}{\partial \tau} \]
at \( t = 0, 1 \) respectively.

At \( t = 1 \), \( \nu^K_\tau (\tau, 1) = id \) and hence \( X_\tau (1, x) \equiv 0 \). Then we have
\[ \overline{\pi}_K \lambda \left( \frac{\partial}{\partial \tau} \right)(\tau, 1) = \lambda \left( \frac{\partial \overline{\pi}_K}{\partial \tau}(\tau, 1) \right) = 0 \]
by the Legendrian boundary condition put on \( u \). This proves that the first integral of (12.3) vanishes.

On the other hand, at \( t = 0 \), we have
\[ \nu^K_\tau (\tau, 0) = \psi^1_{\chi_K(\tau)H}, \]
and so
\[ \overline{\pi}_K (\tau, 0) = \psi^1_{\chi_K(\tau)}(u(\tau, 0)) \]  \hspace{1cm} (12.6)
from (8.17). We compute
\[ \frac{\partial \overline{\pi}_K}{\partial \tau}(\tau, 0) = d\psi^1_{\chi_K(\tau)H} \left( \frac{\partial u}{\partial \tau}(\tau, 0) \right) + \chi^1_K(\tau)X_{G_K}(\chi_K(\tau), 0, \overline{\pi}_K(\tau, 0)) \]
keeping the moving boundary condition we required at \( t = 0 \) in mind. Therefore
\[ \overline{\pi}_K \lambda |_{t=1} \left( \frac{\partial}{\partial \tau} \right) = \lambda \left( \frac{\partial \overline{\pi}_K}{\partial \tau}(\tau, 0) \right) = \lambda \left( d\psi^1_{\chi_K(\tau)H} \left( \frac{\partial u}{\partial \tau}(\tau, 0) \right) \right) + \chi^1_K(\tau)X_{G_K}(\chi_K(\tau), 0, \overline{\pi}_K(\tau, 0)) = -\chi^1_K(\tau)G_K(\tau, 0, \overline{\pi}_K(\tau, 0)) \]
The first term in the second line of the equation vanishes by the Legendrian boundary condition imposed on \( u \) at \( t = 0 \) since \( \nu^K_\tau (\tau, 0) = \psi^1_{\chi_K(\tau)H} \) are contact diffeomorphisms which preserve contact distribution.

We note
\[ \nu^K_\tau (\tau, 0) = \mu(\chi_K(\tau), 1) \]  \hspace{1cm} (12.7)
where \( \mu(s, t) = \phi^t_{sH} \) that already appeared in Lemma 2.7. Therefore we can compute
\[ G_K(\tau, 0, \overline{\pi}_K(\tau, 0)) \]
in terms of the \( s \)-Hamiltonian
\[ L(s, t, x) := \text{Dev}(s \mapsto \psi^t_{sH})(s, x) \]
which was already computed in Lemma 2.7
\[ L(s, 1, \psi^1_{sH}(x)) = \int_0^1 H(r, \psi^r_{sH}(s, x)) \, dr. \]
Using (12.7), we have the equality
\[ G_K(\tau, 0, \overline{\pi}_K(\tau, 0)) = \chi^1_K(\tau)L(\chi_K(\tau), 1, \overline{\pi}_K(\tau, 0)) \]
\[ = \chi^1_K(\tau)L(\chi_K(\tau), 1, \psi^1_{\chi_K(\tau)H}(u(\tau, 0))) \]
\[ = \chi^1_K(\tau)\int_0^1 H(r, \psi^r_{\chi_K(\tau)H}(u(\tau, 0))) \, dr \]
from Lemma 2.7.
Since $\chi'_K$ is supported in $[-2K - 1, -2K] \cup [2K, 2K + 1]$, the second integral of (12.3) is reduced to
\[
\left( \int_{-2K}^{-2K-1} + \int_{2K}^{2K+1} \right) (\pi'_K)^* \lambda|_{t=0} \, dt
\]
\[
= \int_{-2K}^{-2K-1} -\chi'_K(\tau) \left( \int_0^1 H \left( r, \psi^{r}_{\chi,K}(\tau) H(u(\tau,0)) \right) \, dr \right) \, d\tau
\]
\[
- \int_{2K}^{2K+1} -\chi'_K(\tau) \left( \int_0^1 H \left( r, \psi^{r}_{\chi,K}(\tau) H(u(\tau,0)) \right) \, dr \right) \, d\tau
\]
Combining the above calculations, we have finished the proof of (12.1). □

Once we have (12.1), we immediately obtain
\[
E^{\pi}_{J,K,H}(u) \leq \int_0^1 (\max H_t - \min H_t) \, dt = ||H||
\]
since
\[
\chi'_K(\tau) \begin{cases} 
\geq 0 & \text{on } [-2K - 1, -2K], \\
\leq 0 & \text{on } [2K, 2K + 1].
\end{cases}
\]
This then finishes the proof of the inequality (12.1).

13. Off-shell $\lambda$-energy of contact instantons

Let $w : \tilde{\Sigma} \to M$ be a smooth map for a punctured Riemann surface $(\tilde{\Sigma}, j)$. In this section and henceforth, we simplify the notation $E_{J,K,H}$ to $E$ since the pair $(J,K,H)$ will not be changed. And we will also highlight the domain almost complex structure dependence thereof by considering the pair $(j,w)$ instead of $w$.

Defining the horizontal part of energy is easy and the same as that of [Hof93].

Definition 13.1. For a smooth map $\tilde{\Sigma} \to M$, we define the $\pi$-energy of $w$ by
\[
E^{\pi}(j,w) = \frac{1}{2} \int_{\tilde{\Sigma}} |d^{\pi} w|^2.
\]  

Hofer’s definition of the so called $\lambda$-energy $E^{\lambda}(j,w)$, which we denote by $E^{\perp}(j,w)$ instead, strongly relies on the presence of the additional symplectization factor and the associated radial coordinates $s$, and the associated pseudoholomorphic curve equation requires the form $w^*\lambda \circ j = d(w^*s)$ which in particular implies that the form $w^*\lambda \circ j$ is always a (globally) exact one-form.

Defining the vertical part of the energy is not as straightforward as in the symplectization case introduced by Hofer [Hof93], because the form $w^*\lambda \circ j$ is only required to be closed but not exact in general and we do not have the presence of the background radial function $s$ for the case of contact instanton equation.

Luckily, the Riemann surfaces that are relevant to the purposes of the present paper are of the following three types:

Situation 13.2 (Charge vanishing). (1) First, we mention that the starting Riemann surface will be an open Riemann surface of genus zero with a finite number of boundary punctures, and mostly
\[
\tilde{\Sigma} \cong \mathbb{R} \times [0, 1] \]
together with a contact instanton with Legendrian pair boundary condition \((R_0, R_1)\), or
\[ \hat{\Sigma} \cong D^2 \]
with moving Legendrian boundary condition.

(2) \(\mathbb{C}\) which will appear in the bubbling analysis at an interior point of \(\hat{\Sigma}\),
(3) \(\mathbb{H} = \{ z \in \mathbb{C} \mid \text{Im} \, z \geq 0 \}\) which will appear in the bubbling analysis at an boundary point of \(\hat{\Sigma}\).

An upshot is that the asymptotic charges vanish in all these three cases. Therefore in the present paper, it will be enough to consider the punctures (both interior or boundary) where the asymptotic charges vanish, which we will assume from now on.

This being said, we follow the procedure exercised in [Oh21a] for the closed string case. We introduce the following class of test functions following the modification made in [BEHZ03] of Hofer’s original definition [Hof93].

**Definition 13.3.** We define
\[ \mathcal{C} = \left\{ \varphi : \mathbb{R} \to \mathbb{R}_\geq 0 \mid \text{supp } \varphi \text{ is compact, } \int_\mathbb{R} \varphi = 1 \right\} \quad (13.2) \]

Then on the given cylindrical neighborhood \(D_\delta(p) \setminus \{p\}\), we can write
\[ w^* \lambda \circ j = df \]
for some function \(f : [0, \infty) \times S^1 \to \mathbb{R}\).

**Definition 13.4** (Contact instanton potential). We call the above function \(f\) the **contact instanton potential** of the contact instanton charge form \(w^* \lambda \circ j\).

We denote by \(\psi\) the function determined by
\[ \psi' = \varphi, \quad \psi(-\infty) = 0, \quad \psi(\infty) = 1. \quad (13.3) \]

**Definition 13.5.** Let \(w\) satisfy \(d(w^* \lambda \circ j) = 0\). Then we define
\[ E_C(j, w; p) = \sup_{\varphi \in \mathcal{C}} \int_{D_\delta(p) \setminus \{p\}} df \circ j \wedge d(\psi(f)) = \sup_{\varphi \in \mathcal{C}} \int_{D_\delta(p) \setminus \{p\}} (-w^* \lambda) \wedge d(\psi(f)). \]

We note that
\[ df \circ j \wedge d(\psi(f)) = \psi'(f) df \circ j \wedge df = \varphi(f) df \circ j \wedge df \geq 0 \]
since
\[ df \circ j \wedge df = |df|^2 \, d\tau \wedge dt. \]
Therefore we can rewrite \(E_C(j, w)\) into
\[ E_C(j, w; p) = \sup_{\varphi \in \mathcal{C}} \int_{D_\delta(p) \setminus \{p\}} \varphi(f) df \circ j \wedge df. \]
We remark that when \(w\) is given, the function \(f\) on \(D_\delta(p) \setminus \{p\}\) is uniquely determined modulo the shift by a constant. However the following proposition shows that the definition of \(E_C(j, w)\) does not depend on the constant shift in the choice of \(f\).
Proposition 13.6. For a given smooth map \( w \) satisfying \( d(w^*\lambda \circ j) = 0 \), we have \( E_{c,f}(w) = E_{c,g}(w) \) for any pair \((f,g)\) with
\[
df = w^*\lambda \circ j = dg
\]
on \( D^2_{\delta}(p) \setminus \{p\} \).

Proof. Certainly \( df \) or \( df \circ j \) are independent of the addition by constant \( c \). On the other hand, we have
\[
\varphi(g) = \varphi(f + c)
\]
and the function \( a \mapsto \varphi(a + c) \) still lie in \( \mathcal{C} \). Therefore after taking the supremum over \( \mathcal{C} \), we have derived
\[
E_{c,f}(j,w;p) = E_{c,g}(j,w;p).
\]
This finishes the proof. \( \square \)

This proposition enables us to introduce the following

Definition 13.7 (Vertical energy). (1) We denote the common value of \( E_{c,f}(j,w;p) \)
by \( E_{\lambda}^p(w) \), and call the \( \lambda \)-energy at \( p \).
(2) We define the vertical energy, denoted by \( E^\perp(j,w) \), to be the sum
\[
E^\perp(j,w) = \sum_{l=1}^{k} E_{\lambda}^{p_l}(w).
\]

Now we define the final form of the off-shell energy.

Definition 13.8 (Total energy). Let \( w : \hat{\Sigma} \to Q \) be any smooth map. We define the total energy to be the sum
\[
E(j,w) = E^\pi(j,w) + E^\perp(j,w).
\] (13.4)

In the rest of the paper, we suppress \( j \) from the arguments of the energy \( E(j,w) \)
and just write \( E(w) = E^\pi(w) + E^\perp(w) \).

14. Bubbling analysis for the contact instantons

As in Hofer’s bubbling-off analysis in pseudo-holomorphic curves on symplectization [Hof93], it turns out that the study of contact instantons on the plane for the closed string case, and on the half plane in addition for the open string case, plays a crucial role in the bubbling-off analysis of contact instantons. Overall bubbling arguments is by now standard which we apply to the new case of conformally invariant elliptic boundary value problem, the contact instanton equation with Legendrian boundary condition. We refer readers to [Oh15a, Section 8.4] for the full details of this bubbling argument, especially for the process of disc bubblings for pseudoholomorphic curves with Lagrangian boundary condition in symplectic geometry.

However there are two marked differences between the current blowing-up argument and that of pseudoholomorphic curves:

Remark 14.1. (1) We need to replace the standard harmonic energy by the \( \pi \)-harmonic energy for the blowing-up argument in the proofs of the \( \epsilon \)-regularity or of the period-gap theorem. Of course, we also need the uniform bound for the \( \lambda \)-energy which itself, however, does not enter in this proof other than the presence of uniform bound.
Because of the presence of the equation 
\[ d(w^* \lambda \circ j) = 0 \]
in the defining equation of the contact instanton map which is of the second order, not of the first order, the local \( C^{k,\alpha} \) a priori estimate for \( k = 2 \) given in [Oh21b] is the minimum regularity needed to apply the bubbling argument to establish that the limit map of a subsequence obtained via application of Ascoli-Arzela theorem still satisfies the equation 
\[ \overrightarrow{\omega} w = 0, \quad d(w^* \lambda \circ j) = 0. \]
The upshot is that the \( C^{1,\alpha} \) bound is not enough to carry out the bubbling process and produce a limit for the contact instanton map, unlike the case of pseudoholomorphic curves.

We recall the following useful lemma from [HV92] whose proof we refer thereto.

**Lemma 14.2.** Let \( (X, d) \) be a complete metric space, \( f : X \to \mathbb{R} \) be a nonnegative continuous function, \( x \in X \) and \( \delta > 0 \). Then there exists \( y \in X \) and a positive number \( \epsilon \leq \delta \) such that
\[
d(x, y) < 2\delta, \quad \max_{B_y(\epsilon)} f \leq 2f(y), \quad \epsilon f(y) \geq \delta f(x).
\]

We start with the case of \( \mathbb{C} \).

### 14.1. Contact instantons on the plane.

We start with a proposition which is an analog to [Hof93, Theorem 31]. We refer to [Oh21a] or [OS21] for its proof. We also refer the proof of the corresponding statement of Proposition 14.8 for the case of contact instantons on the half place, which is harder to prove than the case of the plane.

**Proposition 14.3.** Let \( w : \mathbb{C} \to Q \) be a contact instanton. Regard \( \infty \) as a puncture of \( \mathbb{C} = \mathbb{C}P^1 \setminus \{ \infty \} \). Suppose
\[
E^\pi (w) = 0, \quad E^\perp_{\infty} (w) < \infty.
\]
Then \( w \) is a constant map.

Using the above proposition, we prove the following fundamental result.

**Theorem 14.4.** Let \( w : \mathbb{C} \to Q \) be a contact instanton. Suppose
\[
E(w) = E^\pi (w) + E^\perp_{\infty} (w) < \infty.
\]
Then \( \|dw\|_{C^0} < \infty \).

**Proof.** Suppose to the contrary that \( \|dw\|_{C^0} = \infty \) and let \( z_\alpha \) be a blowing-up sequence. We denote \( R_\alpha = |dw(z_\alpha)| \to \infty \). Then by applying Lemma 14.2, we can choose another such sequence \( z'_\alpha \) and \( \epsilon_\alpha \to 0 \) such that
\[
|dw(z'_\alpha)| \to \infty, \quad \max_{z \in D_{\alpha}(z'_\alpha)} |dw(z)| \leq 2R_\alpha, \quad \epsilon_\alpha R_\alpha \to 0.
\]
We consider the re-scaling maps \( v_\alpha : D^2_{\epsilon_\alpha R_\alpha}(0) \to Q \) defined by
\[
v_\alpha(z) = w \left( z'_\alpha + \frac{z}{R_\alpha} \right).
\]
Then we have
\[
\|dv_\alpha\|_{C^0; \epsilon_\alpha R_\alpha} \leq 2, \quad |dv_\alpha(0)| = 1.
\]
Applying Ascoli-Arzela theorem, there exists a continuous map \( v_\infty : \mathbb{C} \to Q \) such that \( v_\alpha \to v_\infty \) uniformly on compact subsets. Then by the a priori \( C^{k,\alpha} \)-estimates, [Oh21b, Section 5], the convergence is in compact \( C^\infty \) topology and \( v_\infty \) is smooth. Furthermore \( v_\infty \) satisfies
\[
\partial \pi v_\infty = 0 = d(v_\infty^* \lambda \circ j) = 0, \quad E^\pi(v_\infty) \leq E(w) < \infty \quad \text{and} \quad \|dv_\infty\|_{C^{0,\infty}} \leq 2, \quad |dv_\infty(0)| = 1.
\] (14.4)

On the other hand, by the finite \( \pi \)-energy hypothesis and density identity
\[
\frac{1}{2} |d^\pi w|^2 dA = d(w^* \lambda),
\]
we derive
\[
0 = \lim_{\alpha \to \infty} \int_{D_{\alpha}(z_\alpha')} d(v^* \lambda) = \lim_{\alpha \to \infty} \int_{D_{\alpha}(z_\alpha')} d(v_\alpha^* \lambda)
\]
\[
= \lim_{\alpha \to \infty} \int_{D_{\alpha}(z_\alpha')} |d^\pi v_\alpha|^2 = \int_Q |d^\pi v_\infty|^2.
\]
Therefore we derive
\[
E^\pi(v_\infty) = 0.
\]
Then Proposition 14.3 implies \( w_\infty \) is a constant map which contradicts to
\[
|dv_\infty(0)| = 1
\]
in (14.4). This finishes the proof. \( \square \)

An immediate corollary of this theorem and Proposition 14.3 is the following

**Corollary 14.5.** For any non-constant contact instanton \( w : \mathbb{C} \to Q \) with the energy bound \( E(w) < \infty \), we obtain
\[
E^\pi(w) = \int z^* \lambda > 0
\]
for \( \gamma_w = \lim_{R \to \infty} w(RE^{2\pi it}) \). In particular \( E^\pi(w) \geq T(M, \lambda) > 0 \).

Now we have the following refinement of the asymptotic convergence result from [Hof93] and [OW14]. It is a refinement of [OW14, Theorem 6.3] in that the derivative bound \( \|dw\|_{C^0} < \infty \) imposed therein is replaced by the more natural energy bound \( E(w) < \infty \).

Combining Theorem 6.17 and Theorem 14.4, we immediately derive

**Corollary 14.6.** Let \( w \) be a non-constant contact instanton on \( \mathbb{C} \) with
\[
E(w) < \infty.
\] (14.5)
Then there exists a sequence \( R_j \to \infty \) and a Reeb orbit \( \gamma \) such that \( z_{R_j} \to \gamma(T(\cdot)) \) with \( T \neq 0 \) and
\[
T = E^\pi(w), \quad Q = \int z^* \lambda \circ j = 0.
\]

**Proof.** If \( T = 0 \), the above theorem shows that there exists a sequence \( \tau_i \to \infty \) such that \( w(\tau_i, \cdot) \) converges to a constant in \( C^\infty \) topology and so
\[
\int_{\{\tau = \tau_i\}} w^* \lambda \to 0
\]
as $i \to \infty$. By Stokes’ formula, we derive
\[
\int_{D_{\tau_i}(0)} w^* d\lambda = \int_{\tau=\tau_i} w^* \lambda \to 0.
\]
On the other hand, we have
\[
E^\pi(w) = \lim_{i \to \infty} \frac{1}{2} \int_{D_{\tau_i}(0)} |d^F w|^2 = \lim_{i \to \infty} \int_{D_{\tau_i}} w^* d\lambda = 0.
\]
This contradicts to Corollary 14.5, which finishes the proof. \qed

The following is the analog to [Hof93, Proposition 30].

**Corollary 14.7.** Let $w$ be a contact instanton on $\mathbb{R} \times S^1$ with $E(\pi) < \infty$. Then $\|dw\|_{C^0} < \infty$.

**Proof.** As in Hofer’s proof of [Hof93, Proposition 30], we apply the same kind of bubbling-off argument as that of Theorem 14.4 and derive the same conclusion. Since the arguments are essentially the same, we omit the details by referring readers to the proof of [Hof93, Proposition 30]. \qed

Now we consider the case $w : \mathbb{H} \to M$ with $w(\partial \mathbb{H}) \subset R$ (resp. $w(\partial \mathbb{H}) \subset Z$) with Legendrian boundary condition (resp. with co-Legendrian boundary condition).

14.2. **Contact instantons on $\mathbb{H}$ with Legendrian boundary condition.** Let $R$ be a compact Legendrian submanifold on general contact manifold $(M, \lambda)$.

**Proposition 14.8.** Let $w : (\mathbb{H}, \partial \mathbb{H}) \to (M, R)$ be a contact instanton
\[
\begin{cases}
\nabla^\pi w = 0, \\
\pi(w(\partial \mathbb{H})) \subset R.
\end{cases}
\]

Regard $\infty$ as a puncture of $D^2 \setminus \{1\} \cong \mathbb{H}$. Suppose $\|dw\|_{C^0} < \infty$ and
\[
E^\pi(w) = 0, \quad E^\pi_\infty(w) < \infty.
\]

Then $w$ is a constant map valued in $R$.

**Proof.** By the same argument used in the beginning of the proof of Proposition 9.1 using the vanishing $E^\pi(w) = 0$, we derive
\[
dw = w^* \lambda \otimes R_{\lambda}(w)
\]
with $w^* \lambda$ a bounded harmonic one-form. Since $\mathbb{H}$ is connected, the image of $w$ must be contained in a single leaf of Reeb foliation.

Then there is a smooth function $b = b(z)$ such that
\[
w(z) = \gamma(b(z))
\]
for a Reeb trajectory $\gamma = \gamma(t)$ as before but this time, $w$ satisfies the boundary condition
\[
w(\partial \Theta) = \gamma(b(\partial \Theta)) \subset R.
\]
In particular, we have $(w|_{\partial \mathbb{H}})^* \lambda = 0$. We compute
\[
w^* \lambda = b^* \gamma^* \lambda = b^* (dt) = db
\]
which is bounded on $\mathbb{H}$. We also have
\[
db|_{\partial \mathbb{H}} \equiv 0
\]
and so \( b|_{\partial \mathbb{H}} \) is a constant function. Let \( b|_{\partial \mathbb{H}} \equiv b_0 \). Since we also have \( d(w^* \lambda \circ j) = 0 \),
\[
d(db \circ j) = 0
\]
i.e., \( b: \mathbb{H} \to \mathbb{R} \) is a harmonic function hence \( b \) is the imaginary part of a holomorphic function, say \( f \), with \( f(z) = a(z) + ib(z) \) whose gradient is bounded as before. Furthermore \( b \) satisfies
\[
b|_{\partial \mathbb{H}} \equiv b_0.
\]
this time. By applying the reflection principle, we obtain a holomorphic function \( \tilde{f}: \mathbb{C} \to \mathbb{C} \) which has bounded gradient on \( \mathbb{C} \). Therefore \( \tilde{f}(z) = \alpha z + \beta \) for some constants \( \alpha, \beta \in \mathbb{C} \) as before. Then \( b(z) \equiv b_0 \) on \( \partial \mathbb{H} \) implies \( \text{Im} \tilde{f}|_{\partial \mathbb{H}} \equiv b_0 \). By the unique continuation applied to holomorphic functions, we conclude \( \tilde{f} \) must be constant on \( \mathbb{C} \). This in turn implies \( b(z) \equiv b_0 \) on \( \mathbb{H} \) in particular. Thanks to the Legendrian boundary condition \( w(\partial \mathbb{H}) \subset \mathbb{R} \), \( w \) must be a constant map valued in \( \mathbb{R} \). This finishes the proof. \( \square \)

Again using the above proposition, we prove the following fundamental \( C^1 \)-bound.

**Theorem 14.9.** Let \( w: (\mathbb{H}, \partial \mathbb{H}) \to (M, R) \) be a solution of (14.6) with
\[
E(w) = E^\pi(w) + E^\perp_\infty(w) < \infty.
\]
Then \( \|dw\|_{C^0} < \infty \).

*Proof.* Suppose to the contrary that \( \|dw\|_{C^0} = \infty \) and let \( z_\alpha \) be a blowing-up sequence. We denote \( R_\alpha = |dw(z_\alpha)| \to \infty \). Again by applying Lemma 14.2, we can choose another such sequence \( z'_\alpha \) and \( \epsilon_\alpha \to 0 \) such that
\[
|dw(y_\alpha)| \to \infty, \quad \max_{z \in D_{R_\alpha}(y_\alpha)} |dw(z)| \leq 2R_\alpha, \quad \epsilon_\alpha R_\alpha \to 0.
\]
We consider the re-scaling maps \( v_\alpha: D_{\epsilon_\alpha R_\alpha}(0) \to M \) defined by
\[
v_\alpha(z) = w \left( y_\alpha + \frac{z}{R_\alpha} \right).
\]
Then we have
\[
|dv_\alpha|_{C^\infty_{\epsilon_\alpha R_\alpha}} \leq 2, \quad |dv_\alpha(0)| = 1
\]
as before. *Up until now, the proof is the same as that of Theorem 14.9.*

Due to the presence of the boundary \( \partial \mathbb{H} \), we consider two cases separately:

1. The case \( y_\alpha \to y_\infty \in \text{Int} \mathbb{H} \),
2. The case \( y_\alpha \to y_\infty \in \partial \mathbb{H} \).

We denote
\[
d_\alpha := \text{dist}(y_\alpha, \partial \mathbb{H}).
\]
The case (1) can be treated in the same way as in Theorem 14.9 to produce a non-constant contact instanton defined on \( \mathbb{C} \).

Therefore we will focus on the case (2) from now on. In this case, the map \( v_\alpha \) is defined at least for those \( z \)'s satisfying
\[
\text{Im} \left( y_\alpha + \frac{z}{R_\alpha} \right) \geq 0.
\]
In particular, \( v_\alpha(z) \) is defined at least on the domain
\[
\Theta_\alpha := \{ z \in \mathbb{C} \mid |z| \leq \epsilon_\alpha R_\alpha, \ \text{Im} \ y_\alpha \geq \min \{ \epsilon_\alpha R_\alpha, R_\alpha (d_\alpha - \text{Im} \ y_\alpha) \} \}.
\]

At this stage, after applying Ascoli-Arzelà theorem, there are two cases to consider:
- there exists a continuous map \( v_\infty : \mathbb{C} \to M \) or,
- there exists a continuous map \( v_\infty : (\mathbb{H}, \partial \mathbb{H}) \to (M, R) \)

such that \( v_\alpha \to v_\infty \) uniformly on compact subsets.

Since the first case can be studied as before to produce a sphere-bubble, we now focus on the latter case. By the a priori \( C^{k,\alpha} \)-estimates, Theorem 6.13, the convergence is in compact \( C^\infty \) topology and \( v_\infty \) is smooth. Furthermore \( v_\infty \) satisfies
\[
\mathcal{D} v_\infty = 0 = d(v_\infty^* \lambda \circ j) = 0, \quad E^\pi(v_\infty) \leq E(w) < \infty
\]
and
\[
\|dv_\infty\|_{C^0;\mathcal{C}} \leq 2, \quad |dv_\infty(0)| = 1
\]
and \( v_\infty \) also satisfies the boundary condition \( v_\infty(\partial \mathbb{H}) \subset R \).

On the other hand, Combining the finite \( \pi \)-energy hypothesis, Legendrian boundary condition, and the density identity
\[
\frac{1}{2} |d^\pi w|^2 dA = d(w^* \lambda),
\]
we again derive
\[
0 = \lim_{\alpha \to \infty} \int_{D_{\alpha R_\alpha}(y_\alpha)} d(w^* \lambda) = \lim_{\alpha \to \infty} \int_{D_{\alpha R_\alpha}(y_\alpha)} d(v_\alpha^* \lambda)
\]
\[
= \lim_{\alpha \to \infty} \int_{D_{\alpha R_\alpha}(y_\alpha)} |d^\pi v_\alpha|^2 = \int_{\mathcal{C}} |d^\pi v_\infty|^2
\]
and hence \( E^\pi(v_\infty) = 0 \). Then Proposition 14.8 implies \( w_\infty \) is a constant map which contradicts to \( |dw_\infty(0)| = 1 \). This finishes the proof. \( \square \)

An immediate corollary of this theorem and Proposition 14.8 is the following

**Corollary 14.10.** For any non-constant contact instanton \( w : (\mathbb{H}, \partial \mathbb{H}) \to (M, R) \) with the energy bound \( E(w) < \infty \), we obtain
\[
E^\pi(w) = \int z^* \lambda > 0
\]
for \( z = \lim_{R \to \infty} w(Re^{\pi it}) \). In particular \( E^\pi(w) \geq T_\lambda(M, R) > 0 \).

Combining Theorem 6.17 and Theorem 14.9, we immediately derive

**Corollary 14.11.** Let \( w : (\mathbb{H}, \partial \mathbb{H}) \to (M, R) \) be a non-constant contact instanton with
\[
E(w) < \infty.
\]
Then there exists a sequence \( R_j \to \infty \) and a Reeb orbit \( \gamma \) such that \( z_{R_j} \to \gamma(T(\cdot)) \) with \( T \neq 0 \) and
\[
T = E^\pi(w), \quad Q = \int z w^* \lambda \circ j = 0.
\]
Proof. By considering the coordinates \((\tau, t) \in [0, \infty) \times [0, 1]\) with \(e^{\tau+it} \in \mathbb{H}\) which is a strip-like coordinate of \(\mathbb{H} \cong D^2 \setminus \{1\}\) near \(\infty\) of \(\mathbb{H}\), the charge vanishing theorem 6.17 implies \(Q = 0\).

We then prove \(T \neq 0\) by contradiction. If \(T = 0\), the above theorem shows that there exists a sequence \(\tau_i \to \infty\) such that \(w(\tau_i, \cdot)\) converges to a constant in \(C^\infty\) topology and so

\[
\int_{\{\tau = \tau_i\}} w^* \lambda \to 0
\]
as \(i \to \infty\). By Stokes’ formula and the Legendrian boundary condition, we derive

\[
\int_{D_{\tau_i}(0)} w^* d\lambda = \int_{\partial D_{\tau_i}(0)} w^* \lambda \to 0.
\]

On the other hand, this implies

\[
E^\pi(w) = \lim_{i \to \infty} \int_{D_{\tau_i}(0)} |d^\pi w|^2 = \lim_{i \to \infty} \int_{D_{\tau_i}(0)} w^* d\lambda = 0.
\]

This contradicts to Corollary 14.5, which finishes the proof. \(\square\)

We also have the following.

**Corollary 14.12.** Let \(w\) be a contact instanton on \(\mathbb{R} \times [0, 1]\) with \(E(w) < \infty\). Then \(\|dw\|_{C^0} < \infty\).

**Proof.** We apply the same kind of bubbling-off argument as that of Theorem 14.9 and derive the same conclusion. \(\square\)

**Remark 14.13.** A priori we cannot rule out the possibility \(\text{Spec}(M, \lambda) = \emptyset\) or \(\text{Spec}(M, R; \lambda) = \emptyset\). Nonemptiness of this set is precisely the content of Weinstein’s conjecture or of the Arnold chord conjecture: The conjecture has been proved by Taubes [Tau07] (resp. by Hutchings-Taubes [HT13] respectively in the three dimensional cases after other scattered results obtained earlier.

15. **A PRIORI UNIFORM VERTICAL ENERGY BOUND**

In this section, we establish the \(C^1\)-estimates and weak convergence result for the parameterized moduli space

\[
\mathcal{M}^{\text{para}}(M, R; J, H)
\]
defined in (10.3) for \(K_0 = \infty\).

For this purpose, we need to establish the fundamental a priori energy bound for the energy

\[
E(\pi_K) = E^\pi(\pi_K) + E^\perp(\pi_K)
\]
where \(\pi_K(\tau, t) = \psi^J_H(\psi^H_H)^{-1}(u(\tau, t))\).

We have already shown \(E^\pi_J(u) = E^\pi(\pi)\) in Proposition 7.2, and already proved the \(\pi\)-energy bound

\[
E^\pi(\pi_K) \leq \|H\|
\]
in Proposition 8.6.

In this section, we complete the study of energy bounds by proving the bound for the \(\lambda\)-energy as well.

**Proposition 15.1.** Let \(u\) be any finite energy solution of (8.9). Then we have

\[
E^\perp(\pi_K) \leq \|H\|.
\]

(15.1)
Proof. For the simplicity and to highlight that $\pi_K$ is an unperturbed contact instanton, we denote

$$\pi_K =: w$$

unless the original notation $\pi_K$ needs to be used for clarity.

By the defining equation $d(w^*\lambda \circ j) = 0$ of contact instantons, there exists a global function $f : \Theta_{K_0+1} \to \mathbb{R}$ such that

$$w^*\lambda \circ j = df$$

since $\Theta_{K_0+1}$ is simply connected. By definition of $E^\perp$, we need to get a uniform bound for the integral

$$\int_{\Theta_{K_0+1}} (-w^*\lambda) \wedge d(\psi(f)) \geq 0. \quad (\text{See Definition 13.5.})$$

By integration by parts, we rewrite

$$\int_{\Theta_{K_0+1}} (-w^*\lambda) \wedge d(\psi(f)) = d(\psi(f)w^*\lambda) - \psi(f)dw^*\lambda.$$

Recall that $dw^*\lambda = \frac{1}{2} |d\pi w|^2$ for any $w$ satisfying $\overline{\nabla} w = 0$. Then similarly as we proved Proposition 8.6, we derive

$$0 \leq \int_{\Theta_{K_0+1}} (-w^*\lambda) \wedge d(\psi(f)) \leq \int_{\Theta_{K_0+1}} d(\psi(f)w^*\lambda)
\leq \int_{\partial D_{K_0}^+} \psi(f(\infty,t))(\overline{\gamma}_+)^*\lambda - \int_{D_{K_0}^-} \psi(f(\gamma_-)^*\lambda)
+ \int_{-2K_0-1}^{2K_0+1} \psi(f(\tau,0))\lambda \left( \frac{\partial\pi_K}{\partial \tau}(\tau,0) \right) d\tau - \int_{-2K_0-1}^{2K_0+1} \psi(f(\tau,1))\lambda \left( \frac{\partial\pi_K}{\partial \tau}(\tau,1) \right) d\tau
\leq \int_{0}^{1} - \min \psi(f(\cdot,t))H_t \ dt + \int_{0}^{1} \max \psi(f(\cdot,t))H_t \ dt
\leq \int_{0}^{1} (\max H_t - \min H_t) \ dt = \|H\|.$$

Here for the penultimate inequality, we employ the following:

- We use the same calculations as the ones performed after Lemma ?? in the course of evaluation of the integral (II) therein, and apply Proposition 12.2.
- Moreover, we also have used the inequality

$$\chi_K' \begin{cases} 0 & \text{for } \tau \in [-2K_0-1,-2K_0] \\ \leq 0 & \text{for } \tau \in [2K_0,2K_0+1]. \end{cases}$$

Then for the last equality, we use the fact $0 \leq \psi(f) \leq 1$. Combining all the above discussion, we have finished the proof of

$$\int_{\Theta_{K_0+1}} (-w^*\lambda) \wedge d(\psi(f)) \leq \|H\|$$

for any $\psi \in \mathcal{E}$ and hence the proof of the proposition by definition of $E^\perp$. \qed
16. \(C^1\)-estimates and weak convergence of contact instantons

Combining all the results established in the previous sections of Parts 2 and 3, we prove the following alternatives. This will be also the key step towards a full compactification of the moduli space of contact instantons similarly as in the case of pseudoholomorphic curves.

**Theorem 16.1.** Consider the parameterized moduli space

\[ M_{\text{para}}(M, R; J, H) = \bigcup_{K \in [0, \infty)} \{K\} \times M_K(M, R; J, H). \]

As before we consider the gauge-transformed map \( \overline{\pi} : \Theta_{K+1} \to M \) given by \( \overline{\pi} = \Phi_H^{-1}(u) \). Then one of the following alternative holds:

1. There exists some \( C > 0 \) such that
   \[ \|d\overline{\pi}\|_{C^0, \Theta_{K+1}} \leq C \]
   for all \( u \in M_K(M, R; J, H) \) for all \( K \geq 0 \).

2. There exists a sequence \( u_\alpha \in M_K(M, R; J, H) \) such that \( \|d\overline{\pi}_\alpha\| \to \infty \) that gives rise to a non-constant finite \( \pi \)-energy contact instanton of the following two types:

   \[ v : \mathbb{C} \to M, \quad v : (\mathbb{H}, \partial \mathbb{H}) \to (M, R) \]

   as a bubble.

**Proof.** We denote \( u = \overline{\pi} \) for the simplicity of notation.

Then we have established

\[ E^\pi(w), E^\perp(w) \leq \|H\| \]

in Proposition 8.6 and Proposition 8.7, respectively.

This being said, suppose that the case (1) fails to hold so that there exist a sequence of pairs \((K_\alpha, x_\alpha)\) with \( K_\alpha \) and \( x_\alpha \in \Theta_{K_\alpha} \) such that

\[ |dw_\alpha(x_\alpha)| \to \infty, \quad x_\alpha = (r_\alpha, t_\alpha). \]

We divide our proof into the two cases, after choosing a subsequence if necessary, one with \( K_\alpha \to K_0 \) for some \( K_0 > 0 \). In this case, we have \( |r_\alpha| \leq K_0 + 1 \) by definition of the domain \( \Theta_{K_0+1} \). We denote

\[ d_\alpha := \text{dist}(x_\alpha, \partial \Theta_{K_0+1}). \]

Similarly as in the proof of Theorem 14.9, the first case will gives rise to a non-constant contact instanton on \( \mathbb{C} \).

Again we will focus on the second case where \( d_\alpha \to 0 \). In this case, regarding \( \Theta_{K_0+1} \) as a subset of \( \mathbb{C} \), we can find a pair of nested discs in \( \mathbb{C} \)

\[ D' \subset D \subset \mathbb{C} \]

centered at \( x_\infty \) with \( \overline{D'} \subset \partial \overline{D} \) and a sequence \( \{w_\alpha\} \) such that the map \( w_\alpha \) is defined on

\[ \Theta_{K_0+1} \cap D \]

and

\[ \overline{\partial} w_\alpha = 0, \quad d(w_\alpha \circ j) = 0 \]
thereon. It also satisfies
\[ E^\pm_{\tilde{\lambda},y,D}(w_\alpha) \leq \|H\|, \quad E^\pm(w_\alpha) \leq \|H\|, \quad \|dw_\alpha\|_{C^0,D^+\cap \Theta_{K_\alpha+1}} \to \infty \quad (16.4) \]
as \( \alpha \to \infty \). Obviously we have \( d(x_\alpha - x_\infty) = |x_\alpha - x_\infty| \to 0 \).
We choose sufficiently small constants \( \delta_\alpha \to 0 \) so that
\[ \delta_\alpha |dw_\alpha(x_\alpha)| \to \infty \).
We adjust the sequence \( x_\alpha \) to \( y_\alpha \) by applying Lemma 14.2, so that \( d(y_\alpha, x_\infty) \to 0 \) and
\[ \max_{x \in B_{y_\alpha}(\epsilon_\alpha)} |dw_\alpha| \leq 2|dw_\alpha(y_\alpha)|, \quad \delta_\alpha |dw_\alpha(y_\alpha)| \to \infty. \quad (16.5) \]
We denote \( R_\alpha = |dw_\alpha(y_\alpha)| \) and consider the re-scaled map
\[ \tilde{w}_\alpha(z) = w_\alpha \left( y_\alpha + \frac{z}{R_\alpha} \right). \]
Then the domain of \( w_\alpha \) at least includes \( z \in \Theta_{K_\alpha+1} \subset \mathbb{C} \) such that
\[ y_\alpha + \frac{z}{R_\alpha} \in D^2(\delta) \cap \Theta_{K_\alpha+1}. \]
In particular, \( \tilde{w}_\alpha(z) \) is defined at least on the domain
\[ \Theta_\alpha := \{ z \in \mathbb{C} \mid |z| \leq \epsilon_\alpha R_\alpha, \Im y_\alpha \geq \min\{ \epsilon_\alpha R_\alpha, R_\alpha(d_\alpha - d(y_\alpha, x_\infty)) \} \}
The case where
\[ \epsilon_\alpha R_\alpha \leq R_\alpha(d_\alpha - d(y_\alpha, x_\infty)) \]
(with \( \Im y_\alpha \to 0 \)) corresponds to a ‘sphere bubble’ which is easier to handle than the rest. Therefore we will focus on the remaining cases henceforth. We divide our discussion on the remaining cases into three after choosing a subsequence if necessary:

1. The case \( \text{dist}(y_\alpha, \{ t = 1 \}) \to 0 \) and so \( \text{dist}(y_\alpha, \{ t = 1 \}) < \text{dist}(y_\alpha, \{ t = 0 \}) \)
2. The case \( \text{dist}(y_\alpha, \{ t = 0 \}) \to 0 \) and so \( \text{dist}(y_\alpha, \{ t = 1 \}) > \text{dist}(y_\alpha, \{ t = 0 \}) \).
3. The case \( \text{dist}(y_\alpha, \partial D_{K_\alpha+1}^+) \to 0 \).

The arguments needed to study these cases have little difference and so we focus on the Case (1).

Note that \( \delta_\alpha R_\alpha \to \infty \) by (16.5) for any given \( R > 0 \), \( \tilde{w}_\alpha(z) \) is defined eventually on
\[ \Theta_{R+1}(0) := \{ z \in B_{R+1}(0) \mid \Im z \geq I_0 \} \]
for some \( \{ -\infty \} \cup I_0 \in \mathbb{R} \). Furthermore, we may assume,
\[ \Theta_{R+1}(0) \subset \left\{ z \in \mathbb{C} \mid \eta_\alpha z + y_\alpha \in \overline{D} \right\} \]
Therefore, the maps \( \tilde{w}_\alpha : \Theta_{R+1}(0) \subset \mathbb{C} \to M \)
satisfy the following properties:

(i) \( E^\pm(\tilde{w}_\alpha) \leq \|H\|, \quad \overline{\partial} \tilde{w}_\alpha = 0, \quad E^\pm_{\tilde{\lambda}}(\tilde{w}_\alpha) \leq \|H\| \), (from the scale invariance)
(ii) \( |d\tilde{w}_\alpha(0)| = 1 \) by definition of \( \tilde{w}_\alpha \) and \( R_\alpha \),
(iii) \( \|d\tilde{w}_\alpha\|_{C^0,B_1(x)} \leq 2 \) for all \( x \in B_R(0) \subset D^2(\epsilon_\alpha R_\alpha) \),
(iv) \( \widehat{\partial} \tilde{w}_\alpha = 0 \) and \( d(\tilde{w}_\alpha^* \Lambda \circ j) = 0 \),
(v) \( \tilde{w}_\alpha(\partial \Theta_{R+1}) \subset R \).
For each fixed $R$, we take the limit of $\tilde{w}_\alpha|_{B_R}$, which we denote by $w_R$. Applying (iii) and then the local $C^{2,\alpha}$ estimates, Theorem 6.13, we obtain

$$\|d\tilde{w}_\alpha\|_{2,\alpha:B^*_{\tilde{B}}(x)} \leq C$$

for some $C = C(R)$. Therefore we have a subsequence that converges in $C^2$ in each $B^*_{\tilde{B}}(x)$, $x \in \tilde{D}$. Then we derive that the convergence is in $C^2$-topology on $B^*_{\tilde{B}}(x)$ for all $x \in \tilde{D}$ and in turn on $\Theta_R(0)$.

Therefore the limit $w_R: B_R(0) \to M$ of $\tilde{w}_\alpha|_{B_R(0)}$ satisfies

1. $\tilde{\mathcal{T}}w_R = 0$, $d(w^*_R \lambda \circ j) = 0$ and
2. $E^\pi(w_R) \leq \limsup_\alpha E^\pi(\tilde{w}_\alpha) \leq \|H\|$,
3. Since $\tilde{w}_\alpha \to w_R$ converges in $C^2$, we have

$$\|dw_R\|^2_{p,B_1(0)} = \lim_{\alpha \to \infty} \|d\tilde{w}_\alpha\|^2_{p,B_1(0)} \geq \frac{1}{2}.$$ 

By letting $R \to \infty$ and taking a diagonal subsequence argument, we have derived nonconstant contact instanton map $w_\infty: (\mathbb{H}, \partial \mathbb{H}) \to (M, Z)$.

On the other hand, the bound $E^\pi(w_R) \leq \|H\|$ for all $R$ and again by Fatou’s lemma implies

$$E^\pi(w_\infty) \leq \|H\|.$$ (By definition of $T_\lambda$, we must have $E^\pi(w_\infty) \geq T_\lambda$.) Now we examine the effect of the equation

$$d(w^*_\infty \lambda \circ j) = 0$$

on $E^\pi(w_\infty)$.

Using the identity $d(w^*_\infty \lambda) = \frac{1}{2} |d^*w_\infty|^2$ and Fatou’s lemma, we have

$$E^\pi(w_\infty) = \int_{\mathbb{H}} d(w^*_\infty \lambda) = \lim_{R \to \infty} \int_{\mathbb{H}_R} d(w^*_R \lambda)$$

$$= \lim_{r \to \infty} \int_{|z| \leq r, y=0 \cup \mathbb{H} \cap \{|z|=r\}} w^*_\infty \lambda.$$ 

On the other hand, since Image $w_\infty|_{\partial \mathbb{H}} \subset R$, a Legendrian submanifold,

$$(w_\infty|_{\partial \mathbb{H}})^* \lambda = 0.$$ 

Therefore we have shown that

$$E^\pi(w_\infty) = \lim_{r \to \infty} \int_{|z| = r, y \geq 0} \frac{w^* \lambda}{\alpha^* \lambda > 0}$$

where $\alpha$ is the asymptotic self Reeb chord of $R$ given by

$$\alpha(t) := \lim_{r \to \infty} w(e^{\pi(\tau+it)}), \quad x + iy = e^{\pi(\tau+it)} \in \mathbb{H}$$

Hence we have produced a bubble map $w_\infty: (\mathbb{H}, \partial \mathbb{H}) \to (M, R)$ with its asymptotic chord given by $\alpha$.

An examination of the above proof in fact shows that the whole argument can be repeated equally applies to the case of $K_\alpha \to \infty$ and $x_\alpha \to \infty$, except that $J_{K_\alpha}$ is replaced by $J_\infty = J_0$ Hence we have established the two alternatives of the statement of the theorem.
By applying the standard procedure based on Theorem 16.1, we have finally finished the proof of Theorem 1.25.

APPENDIX A. RELATIONSHIP WITH THE HAMILTONIAN FLOER TRAJECTORIES IN SYMPLECTIZATION

In this appendix, we explain the relationship between the Hamiltonian perturbed contact instanton equation (6.15) and the Hamiltonian Floer trajectory equation

$$\frac{\partial u}{d\tau} + J\left(\frac{\partial u}{dt} - X_{\tilde{H}}(u)\right) = 0$$

on the symplectization $\tilde{M} \cong M \times \mathbb{R}$ associated the homogeneous Hamiltonian $\tilde{H}$ defined by

$$\tilde{H}(x, a) = e^a \pi^* H(x)$$

for the projection $\pi : \tilde{M} \to M$.

A.1. Canonical symplectization of contact manifolds. Denote by $(\tilde{M}, \omega)$ the symplectization of $(M, \xi)$. It canonically depends on $(M, \xi)$ and independently of the contact form $\lambda$. Concretely, $\tilde{M}$ is a $(2n + 2)$-dimensional submanifold of the cotangent bundle $T^*M$ defined as

$$\tilde{M} := \{(x, \alpha_x) \in T^*M| \ker \alpha_x = \xi_x\} = \tilde{M}^+ \cup \tilde{M}^-,$$

with

$$\tilde{M}^\pm := \{(x, \alpha_x) \in \tilde{M}| \alpha_x(R_\lambda) \gtrless 0\}.$$ (Here we use a contact form $\lambda$ to define, but the definition is independent of coorientation-compatible contact forms. )

We equip $T^*M$ with the canonical symplectic form

$$\omega_0 = -d\theta = d(-\theta)$$

for the canonical Liouville one-form $\theta = p \, dq$ which is characterized by the property $\tilde{\alpha}^* \theta = \alpha$ for any smooth one-form $\alpha$ and the associated section map $\tilde{\alpha} : M \to T^*M$.

The exact two-form $\omega$ on $\tilde{M} \subset T^*M$ is the restriction of the form $\omega_0 = d(-\theta)$, i.e., $\omega = d(e^a \pi^* (R_\lambda))$. In other words, when we consider $(T^*M, \omega_0)$ as a Liouville manifold, the associated Liouville form is $\lambda = -\theta$ and its associated Liouville vector field is the Euler vector field

$$\frac{\partial}{\partial p}.$$ 

In particular, the nondegeneracy of $\omega$ follows from the maximal nonintegrability of the contact distributions $\xi$ on $M$. Clearly, the restriction of the fibration $\pi_M : T^*M \to M$ to $\tilde{M}$ (resp $\tilde{M}^\pm$), which we still denote by $\pi_M$, has fibers isomorphic to $\mathbb{R}^*$ (resp $\mathbb{R}^\pm$). Since these two components are similar, we consider $\tilde{M}^+$ only for the simplicity of the following discussion.

A choice of contact form $\lambda$ provides a global trivialization of the $\tilde{M}^+$ with $\mathbb{R}$-fibers as

$$\Psi_\lambda : M \times \mathbb{R} \to \tilde{M}^+, \quad (x, a) \mapsto (x, e^a \lambda_x).$$

(A.2)

The symplectic form is pulled back as

$$\Psi_\lambda^* \omega = d(e^a \lambda) = e^a(da \wedge \lambda + d\lambda).$$

on $M \times \mathbb{R}$. 

A contactomorphism $\phi$ is a diffeomorphism of $M$ to itself whose tangent map preserves $\xi$, i.e., $d\phi(\xi_x) = \xi_{\phi(x)}$. Denote by $\text{Aut}(M, \xi)$ the Lie group of contactomorphisms of $(M, \xi)$. Its Lie algebra, which we denote by $\text{aut}(M, \xi)$, is the contact vector fields, i.e.,

$$\text{aut}(M, \xi) = \{ X \in \Gamma(TM) | L_X(\xi) \subset \xi \}.$$  

Given a contact form $\lambda$, there is a bijective map between $\text{aut}(M, \xi)$ and $C^\infty(M, \mathbb{R})$ given by the contact Hamiltonian, i.e.,

$$\text{aut}(M, \xi) \rightarrow C^\infty(M, \mathbb{R}), \quad X \rightarrow -\lambda(X).$$

Moreover, $L_X \lambda = -R_\lambda(X)\lambda$. As a special case, the constant $-1$ function corresponds to the Reeb vector field $R_\lambda$.

Another way to see the correspondence is via symplectization (c.f. [Arn89, Appendix 4. Section G]). Concretely, given a contact vector field, there is a canonical symplectization to obtain a vector field over the symplectization, which becomes a Hamiltonian vector field with a homogeneous Hamiltonian. Then the restriction of the Hamiltonian function on the image of embedding $\iota_\lambda : M \rightarrow T^*M$

recovers the contact Hamiltonian of the contact vector field. We now describe this construction, express it in terms of the symplectization coordinate, and generalize a little bit by including time-dependent contact vector fields. In particular, we would like to discuss the relation between the contact Hamiltonian and the lifted Hamiltonian on the symplectization.

Consider a time-dependent contact vector field $X_t$ whose time-dependent contact Hamiltonian is given by $H_t = -\lambda(X_t)$. Let $\psi^t_H$ be its flow. Then we have

$$(\psi^t_H)^* \lambda = e^{g_{\psi^t_H}} \lambda;$$

We adopt the notation $g_{\psi^t_H} = g_{\psi^t_H}(t, x)$ given by

$$g_{\psi^t_H}(t, x) := g_{\psi^t_H}(x)$$

for the contact Hamiltonian path $\psi^t_H : t \mapsto \psi^t_H$ as before.

Then we have

$$\frac{\partial g_{\psi^t_H}}{\partial t} = -R_\lambda[H](t, \psi^t_H(x)) = -R_\lambda[H](\psi^t_H(x)).$$

Denote $\tilde{\psi}_t := \psi^t_H$ for the simplicity of notation. We can naturally lift each $\tilde{\psi}_t : M \rightarrow M$ to a diffeomorphism $\tilde{\psi}_t$ on the cotangent bundle $T^*M$ by considering the dual map of the inverse of the derivative, i.e.,

$$\tilde{\psi}_t(x, \alpha) = (\psi_t(x), (d(\psi_t(x))^{-1})^* \alpha).$$

In particular, the property of contactomorphism guarantees that $\tilde{\psi}_t$ maps $\tilde{M}$ to $\tilde{M}$. Moreover, it is a symplectomorphism and its vector field $\tilde{X}_t$, which is the lifting of $X_t$ to $T^*M$, is given by the Hamiltonian vector field generated by the Hamiltonian function defined by

$$\tilde{H}_t(x, \alpha) = -\alpha(X_t(x)).$$
Note in particular for $\alpha = \lambda(x)$, we have the relationship

$$i_\lambda^* \tilde{H}(x) = \tilde{H}_t(x, \lambda(x)) = -\lambda(X_t(x)) = H(t, x)$$

i.e., $i_\lambda^* \tilde{H} = H$, the contact Hamiltonian on $\tilde{M}$.

It is straightforward to check the following whose proofs are omitted.

**Lemma A.1.** In terms of the radial coordinates $(x, a)$ with $\tilde{M} \cong M \times \mathbb{R}_+$, $\tilde{\psi}_t$ is given by

$$\tilde{\psi}_t(x, \alpha) = (\psi_t(x), e^{g_t(x)} \alpha)$$

and

$$\tilde{X}_t = X_t \oplus (-R_\lambda[H_t](\psi_t(x)) \frac{\partial}{\partial a}).$$

In terms of the coordinate $y = (x, a)$ for $\tilde{M} \cong M \times \mathbb{R}$ associated to $\lambda$, we have

$$\tilde{\psi}(x, a) = (\psi_t(x), a + g_t(x)),$$

for the conformal exponent $g_t$ of $\psi_t$. If we write

$$h_t(x) := -R_\lambda[H_t](\psi_t(x)).$$

it then follows from $dH_t = X_t|d\lambda + R_\lambda[H_t]\lambda$ that

$$\tilde{X}_t|d(e^a\lambda)) = \tilde{X}_t|d(e^a\lambda)) + (X_t \oplus (h_t(\psi_t(x)) \frac{\partial}{\partial a}))|d(e^a(da \wedge \lambda + d\lambda))$$

$$= -\lambda(X_t)de^a + h_t e^a \lambda + e^a(X_t|d\lambda)$$

$$= H_t de^a + h_t e^a \lambda + e^a(dH_t - h_t \lambda)$$

$$= H_t de^a + e^a dH_t = d(e^2 H_t)$$

i.e., we have the Hamiltonian of the vector field $\tilde{X}_t$ is given by

$$\tilde{H}_t = e^a H_t$$

in the coordinate of $\tilde{M} \cong M \times \mathbb{R}$. When restricted to the image, i.e., the level set $a = 0$, the Hamiltonian is exactly the contact Hamiltonian $H_t$.

Similarly we can lift any Legendrian submanifold $R$ of the contact manifold $(M, \xi)$ to a homogeneous Lagrangian submanifold given by

$$L = \tilde{R} := \pi^{-1}_M(R)$$

in the symplectization $\tilde{M}$.

**A.2. Contact reduction of Hamiltonian Floer trajectories of homogeneous Hamiltonian.** Let $(M, \lambda, J)$ be a contact triad and $H = H(t, x)$ be a contact Hamiltonian.

Take an almost Kähler structure on the symplectization

$$(\tilde{M}, \omega, \tilde{J})$$

which respect the given contact triad $(M, \lambda, J)$ in the following sense: We write a point of $\tilde{M}$ as $y = (x, a)$ in terms of the isomorphism

$$(\tilde{M}, \omega) \cong (M \times \mathbb{R}, d(e^a \pi^* \lambda)),$$
In the $\lambda$ trivialization, we have the splitting
\[ T\tilde{M} = \tilde{\xi} \oplus \mathbb{R}\langle \tilde{R}_\lambda \rangle \oplus \mathbb{R} \langle \frac{\partial}{\partial a} \rangle \]
where $\tilde{R}_\lambda = (0, R_\lambda, 0)$ and
\[ \tilde{\xi} = \left( \text{span}_\mathbb{R} \left\{ \tilde{R}_\lambda, \frac{\partial}{\partial a} \right\} \right)^\omega, \quad \omega = d\lambda. \]

Then we require $\tilde{J}|_{\tilde{\xi}}$ to satisfy
- $\tilde{J}(\tilde{\xi}) \subset \tilde{\xi}$ and $\tilde{J}|_{\tilde{\xi}} = (J \oplus 0)|_{\tilde{\xi}}$, and
- On the summand $\mathbb{R}\langle \tilde{R}_\lambda \rangle \oplus \mathbb{R} \langle \frac{\partial}{\partial a} \rangle \cong \mathbb{C}$, we require
  \[ \tilde{J}R_\lambda = \frac{\partial}{\partial a}, \quad \tilde{J} \frac{\partial}{\partial a} = -R_\lambda. \]

It also satisfies the boundary condition
\[ u(\partial D) \subset L = (\pi_M)^{-1}(R). \]

It is straightforward to check that the Hamiltonian perturbed Cauchy–Riemann equation in coordinates $(\tau, t)$ of $\mathbb{R} \times [0, 1]$, is equivalent to the following system of equations
\[ \left( \frac{\partial u}{\partial \tau} + J \left( \frac{\partial u}{\partial t} - X_H(u) \right) \right)^\pi = 0 \]  
(A.5)
\[ \begin{cases} \frac{\partial u}{\partial \tau} - \lambda \left( \frac{\partial u}{\partial t} \right) + H_t(u) = 0 \\ \frac{\partial u}{\partial \tau} + \lambda \left( \frac{\partial u}{\partial t} \right) + R_\lambda(H_t(u)) = 0 \end{cases} \]  
(A.6)

In particular, equations (A.6) can be rewritten as
\[ (u^*\lambda - u^* R_\lambda(H_t) d\tau + u^* H_t dt) \circ j = da. \]

Extending the scope of the equation by replacing the exactness by the closedness, which eliminates the primitive function entirely, we obtain the following system of equation for
\[ u : \mathbb{R} \times [0, 1] \to M \]
\[ \begin{cases} \pi \frac{\partial u}{\partial \tau} + J\pi \left( \frac{\partial u}{\partial t} - X_H(u) \right) = 0 \\ d((u^*\lambda - u^* R_\lambda(H_t) d\tau + u^* H_t dt) \circ j) = 0 \end{cases} \]  
(A.7)

which is written purely in terms of the contact manifold $(M, \xi)$ with respect to the given contact form $\lambda$.

Next for the construction of Floer-type complex, we equip the equation with Legendrian boundary condition
\[ u(\tau, 0) \in R_0, \ u(\tau, 1) \in R_1. \]

Here $J$ forms a contact triad as introduced in [OW14]. Clearly, the definition of this system doesn’t need to involve the notion of symplectization but only contact triad is enough. For a simply connected domain, as the disk for now, the equation can be lifted to the symplectization one by choosing the primitive $g : \Sigma \to \mathbb{R}$ satisfying
\[ (u^*\lambda - u^* R_\lambda(H_t) d\tau + u^* H_t dt) \circ j = dg \]
and a base point $a_0 \in \mathbb{R}$ and considering
\[ \tilde{u}(\tau, t) = (u(\tau, t), a_0 + g(\tau, t)). \]
However, when \( H^1(\Sigma, \partial \Sigma) \neq 0 \), the map \( u \) may not lift to the symplectization.

### A.3. Comparison.

Now we compare with the equation (A.7) and (6.15). Let \( \Psi_\lambda \) be the symplectization map (A.2) and equip \( \tilde{M} \times \mathbb{R} \) with the symplectic form

\[
\Psi_\lambda^* \omega = d(e^\alpha \pi^* \lambda) = e^\alpha (d\lambda + da \wedge \lambda).
\]

Equip \( (\tilde{M}, \omega) \) with the \( \lambda \)-adapted almost complex structure such that

\[
\tilde{J}|_\xi = J, \quad \tilde{J} \frac{\partial}{\partial a} = R_\lambda, \quad \tilde{J} R_\lambda = - \frac{\partial}{\partial a}.
\]

The equivalence of the first equation is standard and so its proof is omitted.

For the comparison of the second equation, we first prove the following.

**Lemma A.2.** Let \( (M, \lambda, J) \) be a contact triad and \( H = H(t, y) \) be a contact Hamiltonian of \( (M, \lambda) \). Then we have

\[
d(u^* \lambda + u^* H dt) \circ j = -d(g_H(u)) \wedge (u^* \lambda + u^* H dt) \circ j). \tag{A.8}
\]

**Proof.** By expanding the equation \( d(e^{g_H(u)}(u^* \lambda + u^* H dt) \circ j) = 0 \), we obtain

\[
d(g_H(u)) \wedge (u^* \lambda + u^* H \gamma) \circ j) + d(u^* \lambda \circ j + u^* H \gamma \circ j) = 0.
\]

In particular, we obtain

\[
d(u^* \lambda \circ j + u^* H \gamma \circ j) = -d(g_H(u)) \wedge (u^* \lambda + u^* H \gamma) \circ j).
\]

This finishes the proof. \( \square \)

Therefore the Reeb component of the perturbed contact instanton equation becomes

\[
d(u^* \lambda + u^* H dt) \circ j = -d(g_H(u)) \wedge (u^* \lambda + u^* H dt) \circ j).
\]

On the other hand, the second equation of (A.7)

\[
d((u^* \lambda - u^* R_\lambda(H_t) dt + u^* H dt) \circ j) = 0
\]

can be rewritten as

\[
d((u^* \lambda + u^* H dt) \circ j) = -d(u^* R_\lambda(H_t) dt).
\]

We denote

\[
\begin{align*}
P_1(H, w) &= -d(g_H(u)) \wedge (u^* \lambda + u^* H dt) \circ j), \\
P_2(H, w) &= -d(u^* R_\lambda(H_t) dt)
\end{align*}
\]

and then both equations form elliptic systems of the form

\[
\begin{cases}
(du - X_H(u))^\pi(0,1) = 0 \\
d((u^* \lambda + u^* H dt) \circ j) = P_i(H, w),
\end{cases} \tag{A.9}
\]

for each \( i = 1, 2 \) and are shown to satisfy the a priori coercive estimates in [Oh21d].
Appendix B. Proof of the index formula for the Laplacian

In this section, we give the proof of the index formula for the following Dirichlet problem for the harmonic equation on the unit disc $D^2$:

$$\Delta f = 0, \quad f|_{\partial D^2} = 0.$$  

The index problem is about the operator

$$(\Delta, \Tr) : C^\infty(D^2) \to C^\infty(D^2) \times C^\infty(\partial D^2)$$

where $\Tr$ is the restriction map of a function on $D^2$ to its boundary. We denote by $dA = dx dy$ the Lebesgue measure on the unit disc $D^2$. Then the $L^2$-cokernel equation for

$$(g, \eta) \in C^\infty(D^2) \times C^\infty(\partial D^2)$$

is given by the equation

$$\int_{D^2} \Delta g \, dA + \int_{\partial D^2} (f|_{\partial D^2}) \eta \, d\theta = 0 \quad (B.1)$$

for all $f \in C^\infty(D^2)$. Applying Green’s formula,

$$\int_{D^2} (g \Delta f - f \Delta g) \, dA = \int_{\partial D^2} \left( \frac{\partial g}{\partial \nu} - f \frac{\partial g}{\partial \nu} \right) \, d\theta,$$

we convert the equation (B.1) into

$$\int_{D^2} f \Delta g \, dA - g \int_{\partial D^2} \frac{\partial f}{\partial \nu} \, d\theta + \int_{\partial D^2} \left( \frac{\partial g}{\partial \nu} + \eta \right) f \, d\theta = 0$$

for all $f \in C^\infty(D^2)$. Therefore we have obtained the $L^2$-adjoint equation

$$\Delta g = 0, \quad g|_{\partial D^2} = 0, \quad \eta + \frac{\partial g}{\partial \nu} = 0.$$  

This proves that the only solution $(g, \eta)$ for the equation becomes $g = 0, \eta = 0$, which concludes that the cokernel of the operator $(\Delta, \Tr)$ is zero. This finishes the proof of the index formula.
