Abstract

The Hofmann-Mislove theorem says that compact saturated sets of a sober topological space correspond bijectively to open filters of its open set lattice. This paper concerns an analogy of this result for approach spaces. To this end, the notion of compact functions of approach spaces is introduced. Such functions are an analogue of compact subsets in the enriched context. It is shown that for a sober approach space, the inhabited and saturated compact functions correspond bijectively to the proper open \([0, \infty]-\)filters of the metric space of its upper regular functions, which is an analogy of the Hofmann-Mislove theorem for approach spaces.

Keywords Approach space, compact function, sober approach space, metric space, \([0, \infty]-\)ideal, open \([0, \infty]-\)filter

1 Introduction

While metric spaces (not necessarily symmetric and finitary) are ordered sets (or, categories) enriched over Lawvere’s quantale \(([0, \infty], \geq, +, 0)\) \([15]\), approach spaces introduced by Lowen \([22]\) are topological spaces enriched over \(([0, \infty], \geq, +, 0)\). Approach spaces are among the prime examples in Monoidal Topology (see e.g. \([5, 11, 12, 13]\)). For an exposition of these spaces, we refer to the monograph \([24]\) by their inventor.

This paper concerns the connections between metric spaces and approach spaces, such connections are an important ingredient of Quantitative Domain Theory which, roughly speaking, replaces partially ordered sets in Domain Theory \([25, 8]\) by metric spaces and more generally, quasi-uniform spaces (see e.g. \([3, 9, 26, 30]\)). It has become clear that a coherent theory, parallel to that of domains, in the \([0, \infty]-\)enriched context is needed; see \([11, 10, 14, 20, 91]\) for some efforts in this regard. Of course, necessary modifications have to be made in the \([0, \infty]-\)enriched context; these modifications often help us understand the subject better.

An important result in domain theory, known as the Hofmann-Mislove theorem \([15, 8]\), says that the (non-empty) compact saturated sets of a sober topological space \(X\) correspond bijectively to the (proper) open filters of the complete lattice \(\mathcal{O}(X)\) of open subsets of \(X\), hence establishes a connection between objects of a topological nature to objects of an order-theoretic nature. The aim of this paper is to look for an analogy of this theorem in the

\(*\)This work is supported by the National Natural Science Foundation of China (No. 11871358)
In order to achieve this, we have to determine, in the $[0, \infty]$-enriched context, an analogue of compact subset and an analogue of open filter of open-set lattice.

In [1] a notion of open $[0, \infty]$-filter of metric spaces is introduced. There is a natural metric $\rho_X$ on the set $\Upsilon X$ of upper regular functions of an approach space, so, we take open $[0, \infty]$-filters of the metric space $(\Upsilon X, \rho_X)$ for $[0, \infty]$-enriched version of open filters of open-set lattices. It remains to determine an analogue of compact subset in the enriched context. To this end, the notion of compact functions of approach spaces is introduced (Definition 3.9) and some basic properties of such functions are investigated. The results show that such functions behave in a way parallel to that of compact subsets of topological spaces.

With the notions of compact functions and open $[0, \infty]$-filters at hand, we establish an enriched version of the Hofmann-Mislove theorem in the last section, which says that for a sober approach space $(X, \delta)$, the proper open $[0, \infty]$-filters of the metric space $(\Upsilon X, \rho_X)$ of upper regular functions correspond bijectively to the inhabited compact saturated functions of $(X, \delta)$.

2 $[0, \infty]$-ideals and $[0, \infty]$-filters of metric spaces

In this section we recall some basic notions about metric spaces, viewed as categories enriched over Lawvere’s quantale $([0, \infty], \geq, +, 0)$ [18, 4], the aim is to fix terminologies and notations. Only Lemma 2.6, Proposition 2.10 and Proposition 2.11 are new.

A metric space is a pair $(X, d)$ consisting of a set $X$ and a map $d : X \times X \rightarrow [0, \infty]$, called a metric on $X$, such that $d(x, x) = 0$ and $d(x, y) + d(y, z) \geq d(x, z)$ for all $x, y, z \in X$. For each metric $d$ on $X$, $d^{op}(x, y) := d(y, x)$ is also a metric on $X$, called the opposite of $d$. A metric $d$ is

- symmetric, if $d = d^{op}$; that is, $d(x, y) = d(y, x)$ for all $x, y \in X$;
- separated, if $x = y$ whenever $d(x, y) = d(y, x) = 0$;
- finitary, if $d(x, y) < \infty$ for all $x, y \in X$.

A “classical metric” is just a symmetric, separated and finitary one.

A map $f : (X, d_X) \rightarrow (Y, d_Y)$ between metric spaces is non-expansive if for all $x, y \in X$,

$$d_X(x, y) \geq d_Y(f(x), f(y)).$$

A map $f : (X, d_X) \rightarrow (Y, d_Y)$ between metric spaces is isometric if for all $x, y \in X$,

$$d_X(x, y) = d_Y(f(x), f(y)).$$

Non-expansive maps are just $[0, \infty]$-functors when metric spaces are viewed as $[0, \infty]$-categories. Metric spaces and non-expansive maps form a category

$\text{Met}$. 
The **underlying order** \( \sqsubseteq_d \) of a metric space \((X,d)\) is the order relation on \(X\) defined by

\[
x \sqsubseteq_d y \quad \text{if} \quad d(x,y) = 0.
\]

It is clear that a metric space is separated if and only if its underlying order is a partial order and that any non-expansive map preserves the underlying order.

For all \(a, b \in [0, \infty]\), let

\[
d_L(a, b) = b \ominus a := \max\{0, b - a\}.
\]

Then \(d_L\) is a metric on \([0, \infty]\). The opposite of \(d_L\) is denoted by \(d_R\); that is,

\[
d_R(a, b) = a \ominus b.
\]

Both \(([0, \infty], d_L)\) and \(([0, \infty], d_R)\) are separated, non-symmetric, and non-finitary metric spaces.

In general, for each set \(X\), the map

\[
\rho_X : [0, \infty]^X \times [0, \infty]^X \to [0, \infty], \quad \rho_X(\lambda, \mu) = \sup_{x \in X} \mu(x) \ominus \lambda(x)
\]

is a metric on the set \([0, \infty]^X\). If \(X\) is a singleton set then the metric space \(([0, \infty]^X, \rho_X)\) degenerates to \(([0, \infty], d_L)\).

The underlying order \(\sqsubseteq\) of \(([0, \infty]^X, \rho_X)\) is given by

\[
\lambda \sqsubseteq \mu \iff \forall x \in X, \lambda(x) \geq \mu(x).
\]

In particular, the underlying order of \(([0, \infty], d_L)\) is opposite to the usual less-than-or-equal-to relation.

**Convention.** Some conventions and notations.

(a) When talking about a subset \(A\) of \([0, \infty]^X\), we always assume that \(A\) is endowed with the metric inherited from the space \(([0, \infty]^X, \rho_X)\), which will also be denoted by \(\rho_X\).

(b) Though the underlying order of \(([0, \infty]^X, \rho_X)\) is opposite to the usual pointwise order, for each subset \(\{\lambda_i\}_i\) of \([0, \infty]^X\), we still write \(\inf_i \lambda_i\) and \(\sup_i \lambda_i\), respectively, for its greatest lower bound and least upper bound with respect to the usual pointwise order.

(c) For each \(r \in [0, \infty]\) and \(A \subseteq X\), we write \(r_A\) for the map \(X \to [0, \infty]\) given by

\[
r_A(x) = \begin{cases} r, & x \in A, \\ \infty, & x \not\in A. \end{cases}
\]

Assume that \((X, d_X)\), \((Y, d_Y)\) are metric spaces; \(f : X \to Y\) and \(g : Y \to X\) are non-expansive maps. We say that \(f\) is left adjoint to \(g\), or \(g\) is right adjoint to \(f\), and write \(f \dashv g\), if for all \(x \in X\) and \(y \in Y\),

\[
d_Y(f(x), y) = d_X(x, g(y)).
\]

Let \((X, d)\) be a metric space. A **weight** of \((X, d)\) is a map \(\phi : X \to [0, \infty]\) such that for all \(x, y \in X\),

\[
\phi(y) + d(x, y) \geq \phi(x).
\]
Said differently, a weight of $X$ is a non-expansive map $\phi: (X, d) \rightarrow ([0, \infty], d_R)$. We write

$$\mathcal{P}X$$

for the set of all weights of $(X, d)$.

A \textit{coweight} of $(X, d)$ is defined to be a weight of $(X, d^{\text{op}})$. Explicitly, a coweight of $(X, d)$ is a map $\lambda: X \rightarrow [0, \infty]$ such that for all $x, y \in X$,

$$\lambda(x) + d(x, y) \geq \lambda(y).$$

For each element $x$ of a metric space $(X, d)$, the map

$$d(-, x): X \rightarrow [0, \infty]$$

is a weight of $(X, d)$. Weights of this form are said to be \textit{representable}.

**Lemma 2.1** (Yoneda lemma). \textit{Let $(X, d)$ be a metric space. Then for each point $x$ and each weight $\phi$ of $(X, d)$,}

$$\rho_X(d(-, x), \phi) = \phi(x).$$

The map

$$y: (X, d) \rightarrow (\mathcal{P}X, \rho_X), \quad y(x) = d(-, x)$$

is an isometry by the Yoneda lemma, and is called the \textit{Yoneda embedding}.

Each non-expansive map $f: X \rightarrow Y$ gives rise to an adjunction between $\mathcal{P}X$ and $\mathcal{P}Y$. Precisely, the map

$$f^-: \mathcal{P}X \rightarrow \mathcal{P}Y, \quad f^-(\phi)(y) = \inf_{x \in X} (\phi(x) + d_Y(y, f(x))$$

is left adjoint to

$$f^+: \mathcal{P}Y \rightarrow \mathcal{P}X, \quad f^+(-)(x) = \psi(f(x)).$$

Let $(X, d)$ be a metric space and let $\phi$ be a weight of $(X, d)$. An element $a$ of $X$ is called a \textit{colimit} of $\phi$ if

$$d(a, y) = \rho_X(\phi, d(-, y))$$

for all $y \in X$. Any colimits $a$ and $b$ of the same weight are isomorphic in the sense that $d(a, b) = d(b, a) = 0$. Dually, an element $a$ of $X$ is called a \textit{limit} of a coweight $\psi$ if

$$d(y, a) = \rho_X(\psi, d(y, -))$$

for all $y \in X$.

A metric space $(X, d)$ is \textit{cocomplete} if every weight of $(X, d)$ has a colimit. One readily checks that $(X, d)$ is cocomplete if and only if the Yoneda embedding $y: (X, d) \rightarrow (\mathcal{P}X, \rho_X)$ has a left adjoint. It is known (see e.g. [27]) that $(X, d)$ is cocomplete if and only if $(X, d)$ is \textit{complete} in the sense that every coweight has a limit.

Let $(X, d)$ be a metric space. For each $x \in X$ and $r \in [0, \infty]$, the \textit{tensor of $r$ with $x$}, denoted by $r \otimes x$, is a point of $X$ such that for all $y \in X$,

$$d(r \otimes x, y) = d(x, y) \oplus r.$$
The cotensor of $r$ with $x$, is an element $r \mapsto x$ of $X$ such that for all $y \in X$,
\[
d(y, r \mapsto x) = d(y, x) \ominus r.
\]

A metric space $(X, d)$ is tensored if the tensor $r \otimes x$ exists for all $x \in X$ and $r \in [0, \infty]$. Every cocomplete metric space is tensored: $r \otimes x$ is the colimit of the weight $r + d(-, x)$.

The following characterization of cocomplete (hence complete) metric spaces is a special case of [28, Theorem 2.7], the conditions (ii) and (iii) amount to that $(X, d)$, as an enriched category, is conically cocomplete.

**Proposition 2.2.** A metric space $(X, d)$ is cocomplete if and only if

(i) $(X, d)$ is tensored;

(ii) each subset $A$ of $X$ has a join in $(X, \sqsubseteq_d)$; and

(iii) for each $x \in X$ and each $A \subseteq X$, $d(\bigvee A, x) = \sup_{a \in A} d(a, x)$, where $\bigvee A$ refers to the join of $A$ in $(X, \sqsubseteq_d)$.

**Example 2.3.** For each set $X$, the metric space $([0, \infty]^X, \rho_X)$ is cocomplete, hence complete. In particular, for all $\lambda \in [0, \infty]^X$ and $r \in [0, \infty]$, $r \otimes \lambda = r + \lambda$ and $r \mapsto \lambda = \lambda \ominus r$.

**Proposition 2.4.** If $(X, d_X)$ and $(Y, d_Y)$ are both tensored metric spaces, then a map $f: (X, d_X) \to (Y, d_Y)$ is non-expansive if and only if

(i) $f: (X, \sqsubseteq_{d_X}) \to (Y, \sqsubseteq_{d_Y})$ preserves order; and

(ii) for all $x \in X$ and $r \in [0, \infty]$, $r \otimes f(x) \sqsubseteq_{d_Y} f(r \otimes x)$.

**Proof.** Routine.

For each set $X$, define a function
\[
\triangledown: [0, \infty]^X \times [0, \infty]^X \to [0, \infty]
\]
by
\[
\phi \triangledown \lambda = \inf_{x \in X} (\phi(x) + \lambda(x))
\]
for all $\phi, \lambda \in [0, \infty]^X$. This function is closely related to the metric $\rho_X$ on $[0, \infty]^X$ and plays an important role in this paper.

**Remark 2.5.** Let $(X, d)$ be a metric space; let $\phi$ be a weight and $\lambda$ be a coweight of $(X, d)$. Then, in the terminology of category theory, the value $\phi \triangledown \lambda$ is the $\phi$-weighted colimit of the $[0, \infty]$-functor $\lambda: (X, d) \to ([0, \infty], d_L)$; that is, $\phi \triangledown \lambda = \text{colim} \lambda^\phi$. Furthermore, if we view $\phi$ as a distributor from $(X, d)$ to a singleton metric space and view $\lambda$ as a distributor from a singleton metric space to $(X, d)$ (see. e.g. [27]), then $\phi \triangledown \lambda$ is essentially the composite distributor $\phi \circ \lambda$.

**Lemma 2.6.** Let $X$ be a set and $\phi, \lambda \in [0, \infty]^X$.

(i) $\phi \triangledown \lambda = \sup_{r \in [0, \infty]} (\inf_{x \in X} \{r_X, \phi \triangledown \lambda\})$. 

5
(ii) If $\lambda$ is bounded, then $\rho_X(\phi, b \ominus \lambda) = b \ominus (\lambda \cap \phi)$ for each $b < \infty$ with $\lambda \leq b_X$.

(iii) If $\phi \cap \lambda < \infty$, then $\phi \cap \lambda = b \ominus \rho_X(\phi, b \ominus \lambda)$ for each $b < \infty$ with $\phi \cap \lambda \leq b$.

Proof. Routine calculations.

Let $\lambda \in [0, \infty]^X$. We say that (i) $\lambda$ is inhabited if $\lambda \cap 0_X = 0$; and (ii) $\lambda$ is vacuous if $\lambda \cap \mu = \infty$ for all $\mu \in [0, \infty]^X$. It is clear that $\lambda$ is inhabited if and only if $\inf_{x \in X} \lambda(x) = 0$ and that $\lambda$ is vacuous if and only if $\lambda = \infty_X$.

Let $(X, d)$ be a metric space. A net $\{x_i\}_i$ in $(X, d)$ is forward Cauchy \[26, 3\] if

$$\inf_i \sup_{k \geq j \geq i} d(x_j, x_k) = 0.$$

Definition 2.7. ([6, 1]) A $[0, \infty]$-ideal of a metric space $(X, d)$ is a weight $\phi$ such that

$$\phi = \inf_i \sup_{j \geq i} d(\cdot, x_j)$$

for some forward Cauchy net $\{x_i\}_i$.

The following theorem characterizes $[0, \infty]$-ideals of a metric space $(X, d)$ via their relation to the weights and coweights of $(X, d)$.

Theorem 2.8. Let $\phi$ be a weight of a metric space $(X, d)$. The following are equivalent:

1. $\phi$ is a $[0, \infty]$-ideal.
2. $\phi$ is inhabited and is irreducible in the sense that for all weights $\phi_1, \phi_2$ of $(X, d)$,

   $$\inf \{\phi_1, \phi_2\} \leq \phi \iff \text{either } \phi_1 \leq \phi \text{ or } \phi_2 \leq \phi.$$

3. $\phi$ is inhabited and is flat in the sense that for all coweights $\lambda_1, \lambda_2$ of $(X, d)$,

   $$\phi \cap \sup \{\lambda_1, \lambda_2\} = \max \{\phi \cap \lambda_1, \phi \cap \lambda_2\}.$$

Proof. The equivalence (1) $\iff$ (3) is contained in the proof of [29, Theorem 7.15]; the equivalence (1) $\iff$ (2) is a special case of [17, Theorem 3.13].

Since each ideal $D$ of $(X, \subseteq_d)$ can be viewed as a forward Cauchy net of $(X, d)$, then

$$d(\cdot, D) := \inf_{x \in D} d(\cdot, x)$$

is a $[0, \infty]$-ideal of $(X, \delta)$. For a cocomplete metric space, every $[0, \infty]$-ideal is of this form.

Proposition 2.9. ([16, Proposition 4.8]) Let $(X, d)$ be a cocomplete metric space and let $\phi$ be a $[0, \infty]$-ideal of $(X, d)$. Then

1. $\Delta(\phi) := \{x \in X \mid \phi(x) = 0\}$ is an ideal in $(X, \subseteq_d)$ and $\phi = \inf_{x \in \Delta(\phi)} d(\cdot, x)$.
2. Colimits of $\phi$ in $(X, d)$ are precisely joins of $\Delta(\phi)$ in $(X, \subseteq_d)$. 

6
The following characterization of \([0, \infty]\)-ideals of a cocomplete metric space and its dual (Proposition 2.11) are useful in this paper.

**Proposition 2.10.** Let \((X, d)\) be a cocomplete metric space. Then a function \(\phi: X \longrightarrow [0, \infty]\) is a \([0, \infty]\)-ideal if and only if it satisfies:

1. for all \(x \in X\) and \(r \in [0, \infty]\), \(\phi(r \otimes x) = \phi(x) \otimes r\);
2. \(\phi(x \vee y) = \max\{\phi(x), \phi(y)\}\) for all \(x, y \in X\), where \(x \vee y\) is a join of \(x\) and \(y\) in \((X, \subseteq_d)\).

**Proof.** If \(\phi\) is a \([0, \infty]\)-ideal, there is a forward Cauchy net \(\{x_i\}_{i \in I}\) of \((X, d)\) such that

\[
\phi = \inf \sup_{i \geq i} d(-, x_j).
\]

Now we check that it satisfies (i) and (ii).

(i) We calculate:

\[
\phi(r \otimes x) = \inf \sup_{i \geq i} d(r \otimes x, x_j)
= \inf \sup_{i \geq i} (d(x, x_j) \otimes r)
= (\inf \sup_{i \geq i} d(x, x_j)) \otimes r
= \phi(x) \otimes r.
\]

(ii) We calculate:

\[
\phi(x \vee y) = \inf \sup_{i \geq i} d(x \vee y, x_j)
= \inf \sup_{i \geq i} \max\{d(x, x_j), d(y, x_j)\}
= \inf \sup_{i \geq i} \max\{\sup_{j \geq i} d(x, x_j), \sup_{j \geq i} d(y, x_j)\}
= \max\{\inf \sup_{i \geq i} d(x, x_j), \inf \sup_{i \geq i} d(y, x_j)\}
= \max\{\phi(x), \phi(y)\}.
\]

To see the sufficiency, assume that \(\phi: X \longrightarrow [0, \infty]\) satisfies (i) and (ii). First, by (i), (ii) and Proposition 2.4 one sees that \(\phi: (X, d) \longrightarrow ([0, \infty], d_R)\) is non-expansive, hence a weight of \((X, d)\). Next, let

\[
\Delta(\phi) = \{x \in X \mid \phi(x) = 0\}.
\]

By (ii) one sees that \(\Delta(\phi)\) is an ideal of \((X, \subseteq_d)\). Now we show that for each \(x \in X\),

\[
\phi(x) = \inf_{a \in \Delta(\phi)} d(x, a),
\]

which implies that \(\phi\) is a \([0, \infty]\)-ideal since \(\Delta(\phi)\) can be viewed as a forward Cauchy net of \((X, d)\). On one hand, for each \(a \in \Delta(\phi)\), since \(\phi(x) \leq \phi(a) + d(x, a) = d(x, a)\), it follows that

\[
\phi(x) \leq \inf_{a \in \Delta(\phi)} d(x, a).
\]
On the other hand, since \( \phi(\phi(x) \otimes x) = \phi(x) \otimes \phi(x) = 0 \), then \( \phi(x) \otimes x \in \Delta(\phi) \). Since
\[
0 = d(\phi(x) \otimes x, \phi(x) \otimes x) = d(x, \phi(x) \otimes x) \otimes \phi(x),
\]
it follows that \( \phi(x) \geq d(x, \phi(x) \otimes x) \), hence
\[
\phi(x) \geq \inf_{a \in \Delta(\phi)} d(x, a).
\]

Following [1], a map \( \lambda : X \rightarrow [0, \infty] \) is called a \([0, \infty]\)-filter of \((X, d)\) if it is a \([0, \infty]\)-ideal of \((X, d^{\text{op}})\). In other words, a \([0, \infty]\)-filter of \((X, d)\) is a coweight \( \lambda \) such that
\[
\lambda = \inf \sup_{i,j \geq i} d(x_j, -)
\]
for some net \( \{x_i\}_{i \in I} \) that is backward Cauchy in the sense that
\[
\inf_{i} \sup_{k \geq j \geq i} d(x_k, x_j) = 0.
\]

The following proposition is dual to Proposition [2.10]

**Proposition 2.11.** Let \((X, d)\) be a complete metric space. Then a function \( \lambda : X \rightarrow [0, \infty] \) is a \([0, \infty]\)-filter if and only if it satisfies:

(i) for all \( x \in X \) and \( r \in [0, \infty] \), \( \lambda(r \mapsto x) = \lambda(x) \otimes r \);
(ii) \( \lambda(x \wedge y) = \max\{\lambda(x), \lambda(y)\} \) for all \( x, y \in X \), where \( x \wedge y \) is a meet of \( x \) and \( y \) in \((X, \sqsubseteq_d)\).

Let \( f : (X, d_X) \rightarrow (Y, d_Y) \) be a non-expansive map. It is seen readily that if \( \phi \) is a \([0, \infty]\)-ideal of \((X, d_X)\), then \( f^{\rightarrow}(\phi) \) is a \([0, \infty]\)-ideal of \((Y, d_Y)\). We say that \( f \) is \([0, \infty]\)-Scott continuous if \( f \) preserves colimits of \([0, \infty]\)-ideals [1]; that is, for each \([0, \infty]\)-ideal \( \phi \) of \((X, d_X)\), \( f(\text{colim } \phi) = \text{colim } f^{\rightarrow}(\phi) \) whenever \( \text{colim } \phi \) exists.

In the literature, \([0, \infty]\)-Scott continuous maps are also known as Yoneda continuous maps. Here is the reason. An element \( x \) of a metric space \((X, d)\) is called a Yoneda limit of a forward Cauchy net \( \{x_i\} \) if for all \( y \in X \),
\[
d(x, y) = \inf_{i} \sup_{j \geq i} d(x_j, y).
\]

It is known (see e.g. [7]) that \( x \) is a Yoneda limit of a forward Cauchy net \( \{x_i\} \) if and only if \( x \) is a colimit of the \([0, \infty]\)-ideal \( \inf_{i} \sup_{j \geq i} d(-, x_j) \). So, a non-expansive map preserves Yoneda limits (hence Yoneda continuous) if and only if it is \([0, \infty]\)-Scott continuous.

From Proposition [2.9] one immediately derives the following:

**Proposition 2.12.** ([16]) Let \((X, d_X)\) and \((Y, d_Y)\) be cocomplete metric spaces. Then a non-expansive map \( f : (X, d_X) \rightarrow (Y, d_Y) \) is \([0, \infty]\)-Scott continuous if and only if, as an order-preserving map from \((X, \sqsubseteq_{d_X})\) to \((Y, \sqsubseteq_{d_Y})\), \( f \) is Scott continuous.
3 Compact functions of approach spaces

While metric spaces are \([0, \infty]\)-valued ordered sets, approach spaces are \([0, \infty]\)-valued topological spaces.

**Definition 3.1.** ([22][24]) An approach space is a set \(X\) together with a map \(\delta : X \times 2^X \to [0, \infty]\), subject to the following conditions: for all \(x \in X\) and \(A, B \subseteq 2^X\),

1. \(\delta(x, \{x\})=0;\)
2. \(\delta(x, \varnothing) = \infty;\)
3. \(\delta(x, A \cup B) = \min\{\delta(x, A), \delta(x, B)\};\)
4. \(\delta(x, A) \leq \sup_{b \in B} \delta(b, A) + \delta(x, B).\)

The value \(\delta(x, A)\), called the distance from \(x\) to \(A\), measures how far \(x\) is to \(A\).

A contraction (or, a continuous map) \(f : (X, \delta_X) \to (Y, \delta_Y)\) between approach spaces is a map \(f : X \to Y\) such that

\[
\delta_X(x, A) \geq \delta_Y(f(x), f(A))
\]

for all \(A \subseteq X\) and \(x \in X\).

Approach spaces and contractions form a category

\[\text{App}.\]

**Example 3.2.** ([23][24]) For all \(x \in [0, \infty]\) and \(A \subseteq [0, \infty]\), let

\[
\delta_P(x, A) = \begin{cases} 
  x \ominus \sup A, & A \neq \varnothing, \\
  \infty, & A = \varnothing.
\end{cases}
\]

Then \(\delta_P\) is a distance on \([0, \infty]\). The space \(([0, \infty], \delta_P)\) is denoted by \(\mathbb{P}\).

Like topological spaces, approach spaces can be described in many equivalent ways. Among them we need the characterizations by lower regular functions and upper regular functions. While the distance function of an approach space \((X, \delta)\) is a \([0, \infty]\]-valued analogy of the closure operator of a topological space, lower regular functions and upper regular functions are respectively analogies of closed sets and open sets in the \([0, \infty]\)-enriched context.

**Definition 3.3.** ([23][24]) A collection \(\mathcal{L} \subseteq [0, \infty]^X\) is called a lower regular function frame if it satisfies:

1. (L1) For each subset \(\{\phi_i\}_{i \in I}\) of \(\mathcal{L}\), \(\sup_{i \in I} \phi_i \in \mathcal{L}\).
2. (L2) For all \(\phi, \psi \in \mathcal{L}\), \(\inf \{\phi, \psi\} \in \mathcal{L}X\).
For all \( \phi \in \mathcal{L} \) and \( r \in [0, \infty] \), both \( \phi + r \) and \( \phi \ominus r \) are in \( \mathcal{L} \).

For each approach space \((X, \delta)\), the set \( \mathcal{L}X \) of all contractions \((X, \delta) \rightarrow \mathbb{P}\) is a lower regular function frame, where \( \mathbb{P} \) is the approach space given in Example 3.2. Elements of \( \mathcal{L}X \) are called lower regular functions of \((X, \delta)\). Conversely, if \( \mathcal{L} \subseteq [0, \infty]^X \) is a lower regular function frame, then \( X \) together with the map
\[
\delta: X \times 2^X \rightarrow [0, \infty], \quad \delta(x, A) = \sup\{\phi(x) \mid \phi \in \mathcal{L}, \forall a \in A, \phi(a) = 0\}
\]
is an approach space with \( \mathcal{L} \) being its set of lower regular functions. Thus, every approach space is determined by its lower regular functions (see e.g. [23, 24]).

Let \((X, \delta)\) be an approach space and \( x \in X \). It is readily verified that \( \delta(\cdot, \{x\}) \) is a lower regular function and
\[
\rho_X(\delta(\cdot, \{x\}), \phi) = \phi(x) \quad (3.i)
\]
for each lower regular function \( \phi \) of \((X, \delta)\).

For each approach space \((X, \delta)\), let
\[
\mathcal{U}X = \{\infty_X\} \cup \left\{ \lambda \in [0, \infty]^X \mid \sup_{x \in X} \lambda(x) < \infty \text{ and } r \ominus \lambda \in \mathcal{L}X \text{ for all } r \in [0, \infty] \right\}.
\]
It is not hard to check that
\[
\mathcal{U}X = \{\infty_X\} \cup \left\{ \lambda \in [0, \infty]^X \mid \sup_{x \in X} \lambda(x) < \infty \text{ and } \left( \sup_{x \in X} \lambda(x) \right) \ominus \lambda \in \mathcal{L}X \right\}
\]
and that \( \mathcal{U}X \) satisfies the following conditions:

(U1) \( \infty_X \in \mathcal{U}X \); and every non-vacuous element (i.e., not equal to \( \infty_X \)) of \( \mathcal{U}X \) is bounded.

(U2) For each subset \( \{\lambda_i\}_{i \in I} \) of \( \mathcal{U}X \), \( \inf_{i \in I} \lambda_i \in \mathcal{U}X \).

(U3) For all \( \lambda, \mu \in \mathcal{U}X \), \( \sup\{\lambda, \mu\} \in \mathcal{U}X \).

(U4) For all \( \lambda \in \mathcal{U}X \) and \( r \in [0, \infty] \), both \( \lambda + r \) and \( \lambda \ominus r \) are in \( \mathcal{U}X \).

Elements of \( \mathcal{U}X \) are called upper regular functions of \((X, \delta)\) [24]. We hasten to note that the definition given here is slightly different from that in [24], the difference is that the function \( \infty_X \), which is an analogy of the empty set, is postulated to be upper regular. It is known (see e.g. [24]) that \( \mathcal{L}X \) is the smallest lower regular function frame that contains
\[
\{r \ominus \lambda \mid r \in [0, \infty], \lambda \in \mathcal{U}X\}.
\]
Thus, every approach space is also characterized by its upper regular functions.

**Proposition 3.4.** ([24 Theorem 1.3.3]) *For a map \( f: (X, \delta_X) \rightarrow (Y, \delta_Y) \) between approach spaces, the following are equivalent:*

1. \( f \) is a contraction.
2. For each lower regular function \( \phi \) of \((Y, \delta_Y)\), \( \phi \circ f \) is a lower regular function of \((X, \delta_X)\).
3. For each upper regular function \( \lambda \) of \((Y, \delta_Y)\), \( \lambda \circ f \) is an upper regular function of \((X, \delta_X)\).
Proposition 3.5. For each approach space \((X, \delta)\), both \((\mathcal{L}X, \rho_X)\) and \((\Omega X, \rho_X)\) are cocomplete metric spaces.

Proof. Actually, \(\mathcal{L}X\) is closed in \(([0, \infty]^X, \rho_X)\) under the formation of limits and \(\Omega X\) is closed in \(([0, \infty]^X, \rho_X)\) under the formation of colimits. In particular, for each \(\phi \in \mathcal{L}X\) and \(r \in [0, \infty]\), \(r + \phi\) and \(\phi \ominus r\) are the tensor and cotensor of \(\phi\) with \(r\) in \((\mathcal{L}X, \rho_X)\), respectively; for each \(\lambda \in \Omega X\) and \(r \in [0, \infty]\), \(\lambda + r\) and \(\lambda \ominus r\) are the tensor and cotensor of \(\lambda\) with \(r\) in \((\Omega X, \rho_X)\), respectively. \(\Box\)

For each approach space \((X, \delta)\), it is clear that

\[
d_\delta(x, y) := \delta(x, \{y\})
\]

is a metric on \(X\), called the specialization metric of \((X, \delta)\). We leave it to the reader to check that every lower regular function of \((X, \delta)\) is a weight and every upper regular function is a coweight of \((X, d_\delta)\).

A function \(\lambda : X \rightarrow [0, \infty]\) is said to be saturated if it is a coweight of the metric space \((X, d_\delta)\); that is, \(d_\delta(x, y) + \lambda(x) \geq \lambda(y)\) for all \(x, y \in X\). All upper regular functions are saturated; we have more.

Proposition 3.6. Let \((X, \delta)\) be an approach space and \(\theta : X \rightarrow [0, \infty]\).

(i) The function \(\uparrow \theta := \sup \{\lambda \in \Omega X \mid \lambda \leq \theta\}\) is saturated.

(ii) \(\theta\) is saturated if and only if \(\theta = \uparrow \theta\).

Thus, \(\uparrow \theta\) is called the saturation of \(\theta\).

Proof. (i) Trivial, since every upper regular function of \((X, \delta)\) is a coweight of \((X, d_\delta)\).

(ii) It suffices to check that if \(\theta\) is saturated then \(\theta \leq \uparrow \theta\). Let \(x \in X\). If \(\theta(x) < \infty\), then \(\theta(x) \ominus \delta(-, \{x\})\) is upper regular and \(\theta(x) \ominus \delta(-, \{x\}) \leq \theta\). So, \(\theta(x) = \theta(x) \ominus \delta(x, \{x\}) \leq \uparrow \theta(x)\).

If \(\theta(x) = \infty\), then for each \(r < \infty\), \(r \ominus \delta(-, \{x\})\) is upper regular and \(r \ominus \delta(-, \{x\}) \leq \theta\). So \(\uparrow \theta(x) = \infty\) by arbitrariness of \(r\). \(\Box\)

Corollary 3.7. Let \((X, \delta)\) be an approach space and \(\theta \in [0, \infty]^X\).

(i) For each upper regular function \(\lambda\) of \(X\), \(\rho_X(\theta, \lambda) = \rho_X(\uparrow \theta, \lambda)\).

(ii) \(\uparrow \theta = \sup \{\lambda \ominus \rho_X(\theta, \lambda) \mid \lambda \in \Omega X\}\).

Definition 3.8. ([11]) A \([0, \infty]\)-filter \(\lambda\) of a metric space \((X, d)\) is open if \(\lambda : (X, d) \rightarrow ([0, \infty], d_L)\) is \([0, \infty]\)-Scott continuous.

Let \((X, \delta)\) be an approach space and let \(\theta \in [0, \infty]^X\). By Proposition 2.11 it is seen readily that \(\rho_X(\theta, -)\) is a \([0, \infty]\)-filter of the cocomplete metric space \((\Omega X, \rho_X)\). Now we introduce the central notion of this paper.

Definition 3.9. Let \((X, \delta)\) be an approach space. A function \(\theta : X \rightarrow [0, \infty]\) is compact if \(\rho_X(\theta, -)\) is an open \([0, \infty]\)-filter of the metric space \((\Omega X, \rho_X)\) of upper regular functions.

11
This definition is a direct extension of the characterization of compact subsets in \[15\] Corollary 2.14 to the \([0,\infty]\)-enriched context.

The following property of compact functions follows immediately from Corollary 3.7.

**Proposition 3.10.** Let \((X,\delta)\) be an approach space and \(\theta: X \to [0,\infty]\) be a function. Then \(\theta\) is compact if and only if so is its saturation \(\uparrow \theta\).

Since \((\Omega X, \rho X)\) is a cocomplete metric space and its underlying order is opposite to the usual pointwise order, from Proposition 2.12 we immediately derive the following characterization of compact functions.

**Proposition 3.11.** Let \((X,\delta)\) be a metric space and \(\theta: X \to [0,\infty]\). Then \(\theta\) is a compact function of \((X,\delta)\) if and only if for each filtered family \(\{\lambda_i\}_{i \in I}\) of upper regular functions,

\[
\rho_X(\theta, \inf_{i \in I} \lambda_i) = \inf_{i \in I} \rho_X(\theta, \lambda_i).
\]

The following proposition is an analogy of the fact that continuous images of compact sets are compact.

**Proposition 3.12.** Let \(f: (X,\delta X) \to (Y,\delta Y)\) be a contraction between approach spaces. Then for each compact function \(\theta\) of \((X,\delta X)\), the function

\[
f(\theta): Y \to [0,\infty], \quad f(\theta)(y) = \inf\{\theta(x) | f(x) = y\}
\]

is compact in \((Y,\delta Y)\).

**Proof.** This follows directly from the above proposition and the fact that

\[
\rho_Y(f(\theta), \lambda) = \rho_X(\theta, \lambda \circ f)
\]

for every upper regular function \(\lambda\) of \((Y,\delta Y)\). \(\square\)

In a topological space \(X\), a subset \(K\) is compact if and only if for each filtered family of closed sets \(\{F_i\}_{i \in I}\) such that \(K\) meets each \(F_i\), \(K\) meets the intersection \(\bigcap_{i \in I} F_i\). The following proposition is an analogy of this fact in the enriched context.

**Proposition 3.13.** Let \((X,\delta)\) be an approach space. For each function \(\theta: X \to [0,\infty]\), the following are equivalent:

1. \(\theta\) is compact.
2. For each directed family \(\{\phi_j\}_{j \in J}\) of lower regular functions,

\[
(\sup_{j \in J} \phi_j) \cap \theta = \sup_{j \in J} (\phi_j \cap \theta).
\]

3. The map

\[- \cap \theta: (\mathcal{L} X, \rho X) \to ([0,\infty], d_L)\]

preserves limits of \([0,\infty]\)-filters.
Proof. (1) ⇒ (2) It suffices to check that \((\sup_{j \in J} \phi_j) \cap \theta \leq \sup_{j \in J} (\phi_j \cap \theta)\) for each directed family \(\{\phi_j\}_{j \in J}\) of lower regular functions. We proceed with two cases.

If \(\sup_{j \in J} \phi_j\) is bounded by \(b < \infty\), then \(\{b \ominus \phi_j\}_{j \in J}\) is a filtered family of upper regular functions of \((X, \delta)\). Appealing to Lemma 2.6 we have

\[
\rho_X(\theta, b \ominus (\sup_{j \in J} \phi_j)) = b \ominus \rho_X(\theta, \inf_{j \in J} (b \ominus \phi_j))
\]

\[
= \inf_{j \in J} b \ominus (\phi_j \cap \theta)
\]

\[
= b \ominus \sup_{j \in J} (\phi_j \cap \theta).
\]

From the arbitrariness of \(b\) it follows that \((\sup_{j \in J} \phi_j) \cap \theta = \sup_{j \in J} (\phi_j \cap \theta)\).

If \(\sup_{j \in I} \phi_j\) is not bounded, then

\[
(\sup_{j \in J} \phi_j) \cap \theta = (\sup_{r \in [0, \infty)} \inf_{j \in J} (r X, \sup_{j \in J} \phi_j) \cap \theta)
\]

\[
= (\sup_{r \in [0, \infty)} (\inf_{j \in J} (r X, \phi_j) \cap \theta))
\]

\[
= \sup_{r \in [0, \infty)} \sup_{j \in J} (\inf_{r \in [0, \infty)} (r X, \phi_j) \cap \theta)
\]

\[
= \sup_{j \in J} \inf_{r \in [0, \infty)} (r X, \phi_j) \cap \theta = \sup_{j \in J} \phi_j \cap \theta.
\]

(2) ⇒ (1) Let \(\{\lambda_i\}_{i \in I}\) be a filtered family of upper regular functions. Without loss of generality, we may suppose that all \(\lambda_i\) are bounded by \(b < \infty\). Then \(\{b \ominus \lambda_i\}_{i \in I}\) is a directed family of lower regular functions. Hence by Lemma 2.6 we have

\[
\rho_X(\theta, \inf_{i \in I} \lambda_i) = b \ominus (\inf_{i \in I} (b \ominus \lambda_i) \cap \theta)
\]

\[
= b \ominus ((\sup_{i \in I} (b \ominus \lambda_i)) \cap \theta)
\]

\[
= b \ominus \sup_{i \in I} ((b \ominus \lambda_i) \cap \theta)
\]

\[
= \inf_{i \in I} b \ominus ((b \ominus \lambda_i) \cap \theta)
\]

\[
= \inf_{i \in I} \rho_X(\theta, \lambda_i),
\]

which shows that \(\theta\) is compact.

(2) ⇔ (3) This follows from the dual of Proposition 2.9.
Proposition 3.14. Let \((X, \delta)\) be an approach space and \(A \subseteq X\). Then a function \(\theta: A \to [0, \infty]\) is compact in the subspace \((A, \delta|A)\) if and only if
\[
\theta^\ast: X \to [0, \infty], \quad \theta^\ast(x) = \begin{cases} 
\theta(x), & x \in A \\
\infty, & x \notin A
\end{cases}
\]
is compact in \((X, \delta)\).

Proof. This follows from Proposition 3.13 and the fact that \(\lambda: A \to [0, \infty]\) is a lower regular function of \((A, \delta|A)\) if and only if there is some lower regular function \(\tilde{\lambda}\) of \((X, \delta)\) such that \(\lambda\) is the restriction of \(\tilde{\lambda}\) on \(A\).

Proposition 3.15. Let \((X, \delta)\) be an approach space. If both \(\theta_1\) and \(\theta_2\) are compact functions of \((X, \delta)\), then so is \(\inf\{\theta_1, \theta_2\}\).

Proof. Use the fact that for any upper regular function \(\lambda\) of \((X, \delta)\),
\[
\rho_X(\inf_{x \in X} \theta(x), \lambda) = \max\{\rho_X(\theta_1, \lambda), \rho_X(\theta_2, \lambda)\}.
\]

The following proposition implies that the family of compact functions is determined by the inhabited ones. We note that for each approach space \((X, \delta)\), the function \(\infty_X\) is compact.

Proposition 3.16. Let \((X, \delta)\) be an approach space and \(\theta: X \to [0, \infty]\) be a function.

(i) If \(\theta\) is compact then so is \(\theta + r\) for each \(r \in [0, \infty]\).

(ii) If \(\theta\) is compact and \(\theta \neq \infty_X\), then for each \(r \leq \inf_{x \in X} \theta(x)\), \(\theta + r\) is compact.

Hence for each \(\theta \neq \infty_X\), \(\theta\) is compact if and only if \(\theta + \inf_{x \in X} \theta(x)\) is compact.

Proof. (i) Since for each directed family \(\{\phi_i\}_{i \in I}\) of lower regular functions,
\[
(\sup_{i \in I} \phi_i) \cap (\theta + r) = \inf_{x \in X} (\sup_{i \in I} \phi_i(x) + \theta(x) + r) = (\sup_{i \in I} \phi_i) \cap \theta + r = \sup_{i \in I} (\phi_i \cap \theta) + r = \sup_{i \in I} (\phi_i \cap (\theta + r)),
\]
hence \(\theta + r\) is compact.

(ii) Similar.

In [21], Lowen introduced the notion of index of compactness for approach spaces. In order to discuss the relationship between compact functions and the compactness-indices of approach spaces, we introduce the following:

Definition 3.17. Let \((X, \delta)\) be an approach space and \(\theta \in [0, \infty]^X\). The value
\[
\chi(\theta) := \sup_I \left( (\sup_{\phi \in I} \phi \cap \theta) \sup_{\phi \in I} \phi \cap \theta \right)
\]
is called the index of compactness of \(\theta\), where \(I\) ranges over all ideals of the complete lattice \(\mathcal{L}X\) of lower regular functions of \((X, \delta)\).
We leave it to the reader to check that
\[
\chi(\theta) = \sup_F \left( \left( \inf_{\lambda \in F} \rho_X(\theta, \lambda) \right) \ominus \rho_X(\theta, \inf_{\lambda \in F} \lambda) \right),
\]
where \( F \) ranges over all filters of the complete lattice \( \mathcal{U}X \) of upper regular functions of \( (X, \delta) \).

It is clear that \( \theta \) is a compact function if and only if \( \chi(\theta) = 0 \); that is, \( \theta \) has 0 as index of compactness.

**Proposition 3.18.** Let \( (X, \delta) \) be an approach space.

(i) The index of compactness of the constant function \( 0_X \) is given by
\[
\chi(0_X) = \sup_{J} \inf_{x \in X} \sup_{\phi \in J} \phi(x),
\]
where \( J \) ranges over all ideals composed of inhabited lower regular functions.

(ii) \( \chi(0_X) \) is equal to the index of compactness of \( (X, \delta) \) in the sense of Lowen [21, 22].

(iii) \( \chi(0_X) = 0 \) if and only if \( (X, \delta) \) is 0-compact in the sense of Lowen [24].

**Proof.** (i) By definition,
\[
\chi(0_X) = \sup_{I} \left( \inf_{x \in X} \sup_{\phi \in I} \phi(x) \ominus \inf_{x \in X} \sup_{\phi \in I} \phi(x) \right),
\]
where \( I \) ranges over all ideals of the complete lattice \( \mathcal{L}X \). Since \( \sup_{\phi \in I} \inf_{x \in X} \phi(x) = 0 \) for each ideal \( J \) composed of inhabited lower regular functions, it suffices to check that for each ideal \( I \) of \( \mathcal{L}X \), there is an ideal \( J \) composed of inhabited lower regular functions such that
\[
\inf_{x \in X} \sup_{\phi \in I} \phi(x) \ominus \inf_{x \in X} \sup_{\phi \in I} \phi(x) \leq \inf_{x \in X} \sup_{\psi \in J} \psi(x).
\]

If \( \sup_{\phi \in I} \inf_{x \in X} \phi(x) = \infty \), any ideal composed of inhabited lower regular functions meets the requirement. If \( \sup_{\phi \in I} \inf_{x \in X} \phi(x) = b < \infty \), then \( \{ \phi \ominus b \}_{\phi \in I} \) is a directed family consisting of inhabited lower regular functions. Let \( J \) be the ideal generated by this family. Then \( J \) is composed of inhabited lower regular functions and
\[
\inf_{x \in X} \sup_{\psi \in J} \psi(x) = \inf_{x \in X} \sup_{\phi \in I} (\phi(x) \ominus b) = \inf_{x \in X} \sup_{\phi \in I} \phi(x) \ominus b,
\]
which shows that \( J \) satisfies the requirement.

(ii) Follows from (i) and [24, Theorem 4.3.9].

(iii) A special case of (ii).

The above proposition shows that Definition 3.17 provides an extension of the notion of index of compactness for approach spaces in the sense of Lowen; and it also leads to the following:

**Definition 3.19.** We say that an approach space \( (X, \delta) \) is compact if its index of compactness is 0; or equivalently, \( 0_X \) is a compact function.
Compact approach spaces are just the 0-compact ones in the sense of Lowen [24]. It follows from Lemma 3.16 that an approach space \((X, \delta)\) is compact if and only if for all \(r \in [0, \infty]\), the constant function \(r_X\) is compact.

In the following we show that compact functions in approach spaces are an extension of compact subsets in topological spaces and precompact subsets in metric spaces.

For each topological space \(X\), the map
\[
\delta_X: X \times 2^X \rightarrow [0, \infty], \quad \delta_X(x, A) = \begin{cases} 
0, & \text{if } x \text{ is in the closure of } A, \\
\infty, & \text{otherwise}
\end{cases}
\]
is an approach structure on the set \(X\). The correspondence \(X \mapsto \omega(X) := (X, \delta_X)\) defines a full and faithful functor
\[
\omega: \text{Top} \rightarrow \text{App}.
\]
Approach spaces of the form \(\omega(X)\) are said to be topologically generated [23, 24]. It is clear that a function \(\phi: X \rightarrow [0, \infty]\) is a lower regular function of \(\omega(X)\) if and only if \(\phi\) is lower semicontinuous; and that \(\lambda: X \rightarrow [0, \infty]\) is an upper regular function of \(\omega(X)\) if and only if either \(\lambda = \infty_X\) or \(\lambda\) is bounded and upper semicontinuous.

For a topological space \(X\), it is shown in [24, Proposition 4.3.11] that the approach space \(\omega(X)\) is compact if and only if the topological space \(X\) is compact. This fact together with Proposition 3.14 yields the following proposition, which shows that the notion of compact functions of approach spaces extends that of compact subsets of topological spaces.

**Proposition 3.20.** Let \(X\) be a topological space and \(A\) a subset of \(X\). Then \(0_A\) is a compact function of \(\omega(X)\) if and only if \(A\) is a compact subset of \(X\).

**Proposition 3.21.** Let \(X\) be a topological space and let \(\theta: X \rightarrow [0, \infty]\) be a lower semicontinuous function. Then \(\theta\) is a compact function of \(\omega(X)\) if and only if \(\theta^{-1}([0, r])\) is a compact subset of \(X\) for each \(r \in [0, \infty]\).

**Proof.** We check the necessity first. Let \(A = \theta^{-1}[0, r]\). Since \(\theta\) is lower semicontinuous, \(A\) is a closed set in \(X\). Let \(\{F_i\}_{i \in I}\) be a filtered family of non-empty closed sets of \(A\). Since \(A\) is closed, it follows that \(\{0_{F_i}\}_{i \in I}\) is a directed family of lower regular functions of \(\omega(X)\), hence
\[
\left(\sup_{i \in I} 0_{F_i}\right) \cap \theta = \sup_{i \in I} (0_{F_i} \cap \theta) \leq r,
\]
which shows that \(\{F_i\}_{i \in I}\) has a nonempty intersection and consequently, \(A\) is compact.

As for sufficiency, it suffices to prove that, for each directed family of lower semicontinuous functions \(\{\phi_i: X \rightarrow [0, \infty]\}_{i \in I}\),
\[
\left(\sup_{i \in I} \phi_i\right) \cap \theta \leq \sup_{i \in I} (\phi_i \cap \theta).
\]
If \(\sup_{i \in I} (\phi_i \cap \theta) < r < \infty\), then for each \(i \in I\),
\[
\inf_{x \in X} (\phi_i(x) + \theta(x)) < r.
\]
Let $F_i = (\phi_i + \theta)^{-1}[0,r]$ for each $i \in I$. By lower semicontinuity of $\theta$ and $\phi_i$, one sees that \{F_i\}_{i \in I} is a filtered family of non-empty closed sets contained in the closed set $A := \theta^{-1}[0,r]$. Since $A$ is compact, then
\[
(\sup_{i \in I} \phi_i) \cap \theta = \inf_{x \in X} (\sup_{i \in I} \phi_i(x) + \theta(x)) \leq r
\]
and consequently,
\[
(\sup_{i \in I} \phi_i) \cap \theta \leq \sup_{i \in I} (\phi_i \cap \theta)
\]
as desired. \[\square\]

**Corollary 3.22.** If $X$ is a compact topological space, then every lower semicontinuous function from $X$ to $[0, \infty]$ is compact in $\omega(X)$.

Given a metric space $(X,d)$, the map
\[
\Gamma(d): X \times 2^X \to [0, \infty], \quad \Gamma(d)(x,A) = \begin{cases} 
\infty, & A = \emptyset, \\
\inf_{y \in A} d(x,y), & A \neq \emptyset
\end{cases}
\]
is an approach structure on the set $X$. Spaces of the form $(X,\Gamma(d))$ are called **metric approach spaces** [23][24].

It is not hard to check that $\phi: X \to [0, \infty]$ is a lower regular function of the metric approach space $(X,\Gamma(d))$ if and only if $\phi$ is a weight of $(X,d)$; and $\lambda: X \to [0, \infty]$ is an upper regular function of $(X,\Gamma(d))$ if and only if either $\lambda = \infty_X$ or $\lambda$ is a bounded coweight of $(X,d)$. Then, by the dual statement of the Yoneda lemma (Lemma 2.1) one sees that for each $x \in X$, $d(x,-): X \to [0, \infty]$ is a compact function of $(X,\Gamma(d))$. So, by Proposition 3.15 for each finite subset $F$ of $X$,
\[
d(F,-) := \inf_{a \in F} d(a,-)
\]
is a compact function of $(X,\Gamma(d))$.

A metric space $(X,d)$ is **precompact** if for each $r > 0$, there exists a finite subset $A$ of $X$, such that $X = \bigcup_{x \in A} B(x,r)$, where $B(x,r) = \{y \in X \mid d(x,y) < r\}$. A subset $K$ is called a precompact subset if $(K,d)$ is a precompact metric space.

**Proposition 3.23.** Let $(X,d)$ be a metric space and $K$ a subset of $X$. The following are equivalent:

1. $K$ is a precompact subset of $(X,d)$.
2. $d(K,-)$ is a compact function of $(X,\Gamma(d))$.
3. $0_K$ is a compact function of $(X,\Gamma(d))$.

**Lemma 3.24.** Let $(X,\delta)$ be an approach space and $\theta: X \to [0, \infty]$ be a function. If for each $r > 0$, there exists a compact function $\xi$ such that $\theta \leq \xi \leq \theta + r$, then $\theta$ is compact.
Proof. Let \( \{ \phi_i \}_{i \in I} \) be a directed family of lower regular functions and let \( r > 0 \). Pick a compact function \( \xi \) such that \( \theta \leq \xi \leq \theta + r \). Then

\[
(\sup_{i \in I} \phi_i) \cap \theta \leq (\sup_{i \in I} \phi_i) \cap \xi
= \sup_{i \in I} (\phi_i \cap \xi)
\leq \sup_{i \in I} (\phi_i \cap (\theta + r))
= \sup_{i \in I} (\phi_i \cap \theta) + r,
\]

hence \( \theta \) is compact by arbitrariness of \( r \).

Proof of Proposition 3.23. First, it is shown in [21, Theorem 4.4] that for a metric space \( (X, d) \), the approach space \( (X, \Gamma(d)) \) is compact if and only if \( (X, d) \) is precompact. The equivalence \( (1) \Leftrightarrow (3) \) follows immediately from this fact and Proposition 3.14. Here we present a proof of the proposition by help of Lemma 3.24.

(1) \( \Rightarrow \) (2) Since \( K \) is a precompact subset of \( X \), for each \( r > 0 \), there exists a finite subset \( F \) of \( K \) such that,

\[
K \subseteq \bigcup_{x \in F} B(x, r).
\]

It follows that

\[
d(K, y) \leq d(F, y) < d(K, y) + r
\]

for each \( y \in X \). Since \( F \) is finite, \( d(F, -) \) is a compact function, so, \( d(K, -) \) is compact by Lemma 3.24.

(2) \( \Rightarrow \) (3) This follows from that for each weight \( \phi \) of \( (X, d) \),

\[
\phi \cap d(K, -) = \inf_{x \in X} (\phi(x) + d(K, x))
= \inf_{x \in K} \phi(x)
= \phi \cap 0_K.
\]

(3) \( \Rightarrow \) (1) Suppose on the contrary that \( K \) is not precompact. Then there exists \( r > 0 \) such that \( K \not\subseteq \bigcup_{x \in F} B(x, r) \) for any finite subset \( F \) of \( K \). For each \( x \in K \), let

\[
\phi_x = d(\_, X \setminus B(x, r)).
\]

Since \( \phi_x(x) \geq r \) for all \( x \in K \), it follows that

\[
(\sup_{x \in K} \phi_x) \cap 0_K = \inf_{y \in K} \sup_{x \in K} \phi_x(y) \geq r.
\]

For each finite subset \( F \) of \( K \), there is some \( z \in K \) such that \( d(x, z) \geq r \) for all \( x \in F \). Thus,

\[
(\sup_{x \in F} \phi_x) \cap 0_K = \inf_{y \in K} \sup_{x \in F} \phi_x(y) \leq \sup_{x \in F} \phi_x(z) = 0,
\]

which contradicts the compactness of \( 0_K \). \( \blacksquare \)
4 Hofmann-Mislove theorem

Definition 4.1. Let \((X, \delta)\) be an approach space and let \(\Lambda\) be a \([0, \infty]\)-filter of the metric space \((\Upsilon X, \rho_X)\) of upper regular functions of \((X, \delta)\). We say that \(\Lambda\) is

(i) decent if \(\Lambda(\lambda) \neq 0\) for some \(\lambda \neq \infty_X\);
(ii) proper if \(\Lambda(r_X) = r\) for each \(r \in [0, \infty]\).

For each approach space \((X, \delta)\) with \(X\) being non-empty, the metric space \((\Upsilon X, \rho_X)\) has exactly two \([0, \infty]\)-filters that are not decent, both of them are open. The first is \(\rho_X(\infty_X, -)\) and the second is given by

\[
\Lambda(\lambda) = \begin{cases} 
0, & \lambda \neq \infty_X, \\
\infty, & \lambda = \infty_X.
\end{cases}
\]

The following proposition is obvious.

Proposition 4.2. Let \(\theta\) be a compact saturated function of an approach space \((X, \delta)\).

(i) If \(\theta\) is inhabited then \(\rho_X(\theta, -)\) is a proper open \([0, \infty]\)-filter of \((\Upsilon X, \rho_X)\).
(ii) If \(\theta\) is non-vacuous then \(\rho_X(\theta, -)\) is a decent open \([0, \infty]\)-filter of \((\Upsilon X, \rho_X)\).

Our aim is to show that for a sober approach space \((X, \delta)\), every proper open \([0, \infty]\)-filter of \((\Upsilon X, \rho_X)\) is of the form \(\rho_X(\theta, -)\) for a unique inhabited and saturated compact function.

A lower regular function \(\phi\) of an approach space \((X, \delta)\) is said to be irreducible if for all lower regular functions \(\phi_1\) and \(\phi_2\),

\[
\inf\{\phi_1, \phi_2\} \leq \phi \implies \text{either } \phi_1 \leq \phi \text{ or } \phi_2 \leq \phi.
\]

Definition 4.3. \([2]\) An approach space \((X, \delta)\) is sober if for each inhabited and irreducible lower regular function \(\phi\) of \((X, \delta)\), there is a unique \(x \in X\) such that \(\phi = \delta(-, \{x\})\).

Example 4.4. (a) \([2]\) For each topological space \(X\), the approach space \(\omega(X)\) is sober if and only if \(X\), as a topological space, is sober.

(b) \([19]\) For each metric space \((X, d)\), the metric approach space \((X, \Gamma(d))\) is sober if and only if \((X, d)\) is Smyth complete; that is, \((X, d)\) is separated and all of its forward Cauchy nets converge in its symmetrization (defined in an obvious way). In the case that the metric \(d\) is symmetric, this conclusion was first proved in \([2]\).

Proposition 4.5. An approach space \((X, \delta)\) is sober if and only if for each non-vacuous irreducible lower regular function \(\phi\) of \((X, \delta)\), there exist a unique \(x \in X\) and a unique \(s \in [0, \infty)\) such that \(\phi = s + \delta(-, \{x\})\).

Proof. Consider the lower regular function \(\phi \ominus \inf_{x \in X} \phi(x)\).

Now we state the main result of this paper.

Theorem 4.6. Let \((X, \delta)\) be a sober approach space.

(i) For each proper open \([0, \infty]\)-filter \(\Lambda\) of \((\Upsilon X, \rho_X)\), there is a unique inhabited compact saturated function \(\nu\) of \((X, \delta)\) such that \(\Lambda = \rho_X(\nu, -)\).
(ii) For each decent open \([0, \infty]\)-filter \(\Lambda\) of \((\Omega X, \rho X)\), there is a unique non-vacuous compact saturated function \(\mu\) of \((X, \delta)\) such that \(\Lambda = \rho X(\mu, -)\).

Therefore, for a sober approach space \((X, \delta)\), the proper (decent, resp.) open \([0, \infty]\)-filters of the metric space \((\Omega X, \rho X)\) of upper regular functions correspond bijectively to the inhabited (non-vacuous, resp.) compact saturated functions of \((X, \delta)\).

A lemma first.

**Lemma 4.7.** Let \((X, \delta)\) be an approach space. If \(\lambda\) is a compact saturated function of \((X, \delta)\), then the map

\[\Phi: \mathcal{L}X \rightarrow [0, \infty], \quad \Phi(\phi) = \phi \cap \lambda\]

satisfies the following conditions:

(C1) For each directed subset \(\{\phi_i\}_{i \in I}\) of \(\mathcal{L}X\), \(\Phi(\sup_{i \in I} \phi_i) = \sup_{i \in I} \Phi(\phi_i)\).

(C2) For all \(\phi_1, \phi_2 \in \mathcal{L}X\), \(\Phi(\inf \{\phi_1, \phi_2\}) = \min \{\Phi(\phi_1), \Phi(\phi_2)\}\).

(C3) For all \(\phi \in \mathcal{L}X\) and \(r \in [0, \infty]\), \(\Phi(\phi + r) = \Phi(\phi) + r\).

Conversely, if \((X, \delta)\) is a sober approach space, then for each map \(\Phi: \mathcal{L}X \rightarrow [0, \infty]\) that satisfies (C1)-(C3), there is a compact saturated function \(\lambda\) of \((X, \delta)\) such that \(\Phi(\phi) = \phi \cap \lambda\).

**Proof.** We leave it to the reader to check that for each compact saturated function \(\lambda\) of \((X, \delta)\), the map \(\Phi(\phi) = \phi \cap \lambda\) satisfies (C1)-(C3).

For the converse part, suppose that \(\Phi: \mathcal{L}X \rightarrow [0, \infty]\) satisfies (C1)-(C3).

First of all, by (C2), (C3) and Proposition 2.4 one sees that \(\Phi: (\mathcal{L}X, \rho X) \rightarrow ([0, \infty], d_L)\) is a non-expansive map. We claim that the function

\[\lambda: X \rightarrow [0, \infty], \quad \lambda(x) = \Phi(\delta(-, \{x\}))\]

satisfies the requirement; that is, \(\lambda\) is a compact saturated function of \((X, \delta)\) and \(\Phi(\phi) = \phi \cap \lambda\).

Since

\[\lambda(x) + \delta(x, \{y\}) = \Phi(\delta(-, \{x\})) + \rho X(\delta(-, \{x\}), \delta(-, \{y\})) \geq \Phi(\delta(-, \{y\})) = \lambda(y),\]

it follows that \(\lambda\) is saturated.

Next we show that for each \(\phi \in \mathcal{L}X\), \(\Phi(\phi) = \phi \cap \lambda\). Note that this equality together with (C1) imply that \(\lambda\) is compact. On one hand,

\[\phi \cap \lambda = \inf_{x \in X} (\phi(x) + \Phi(\delta(-, \{x\}))\]

\[= \inf_{x \in X} (\rho X(\delta(-, \{x\}), \phi) + \Phi(\delta(-, \{x\}))) \quad \text{(Equation 3.1)}\]

\[\geq \Phi(\phi).\]

On the other hand, for each \(r \in [0, \infty)\) with \(\Phi(\phi) \leq r\), let

\[\mathcal{A}_r = \{\xi \in \mathcal{L}X \mid \phi \leq \xi, \Phi(\xi) \leq r\}.\]
By (C1) and Zorn’s lemma, $A_r$ has a maximal element, say $\psi$. By (C2) one sees that $\psi$ is an irreducible lower regular function; by (C3) one sees that $\psi$ is non-vacuous. Since $(X, \delta)$ is sober, there exist a unique $x$ and a unique $s \in [0, \infty)$ such that $\psi = s + \delta(-, \{x\})$. Since $\psi \in A_r$, it follows that

$$\phi \upharpoonright \lambda \leq \psi \upharpoonright \lambda \leq \phi \upharpoonright \lambda$$

$$= \inf_{z \in X} (s + \delta(z, \{x\}) + \Phi(\delta(-, \{z\})))$$

$$= s + \inf_{z \in X} \left( \rho_X(\delta(-, \{z\}), \delta(-, \{x\})) + \Phi(\delta(-, \{z\})) \right)$$

$$= s + \Phi(\delta(-, \{x\}))$$  \hspace{1cm} (C3)

$$\leq r.$$  \hspace{1cm}  

Therefore, $\phi \upharpoonright \lambda \leq \Phi(\phi)$ by arbitrariness of $r$.  

\begin{proof}[Proof of Theorem 4.6] (i) Suppose that $\Lambda: \mathfrak{U}X \rightarrow [0, \infty]$ is a proper open $[0, \infty]$-filter of $(\mathfrak{U}X, \rho_X)$. First of all, we assert that $\Lambda$ satisfies that

$$\Lambda(\lambda + r) = \Lambda(\lambda) + r$$

for all $\lambda \in \mathfrak{U}X$ and $r \in [0, \infty]$. If $\lambda = \infty_X$, the equality is obvious; if $\lambda$ is bounded, then by Proposition 2.11 we have that $\Lambda(\lambda + r) \geq r$ and

$$\Lambda(\lambda) = \Lambda((\lambda + r) \uplus r) = \Lambda(\lambda + r) - r,$$

hence $\Lambda(\lambda + r) = \Lambda(\lambda) + r$.

We turn to the proof of the conclusion. Uniqueness of $\nu$ follows from Corollary 3.7 as for existence, define a map $\Phi: \mathfrak{L}X \rightarrow [0, \infty]$ as follows: for each lower regular function $\phi$ of $(X, \delta)$, let

$$\Phi(\phi) = \sup_{x \in X} \phi(x) \uplus \Lambda \left( \sup_{x \in X} \phi(x) \uplus \phi \right)$$

if $\phi$ is bounded; and let

$$\Phi(\phi) = \sup_{r \in [0, \infty)} \Phi(\inf_{r \in [0, \infty)} \phi, r_X)$$

if $\phi$ is not bounded.

Before proceeding, we notice that, as a consequence of the equality $\Lambda(\lambda + r) = \Lambda(\lambda) + r$, for each bounded $\phi$ and each bound $b$ of $\phi$, it holds that

$$\Phi(\phi) = b - \Lambda(b - \phi).$$

We claim that $\Phi: \mathfrak{L}X \rightarrow [0, \infty]$ satisfies the conditions (C1)-(C3) in Lemma 4.7. Here we check (C1) for example. Let $\{\phi_i\}_{i \in I}$ be a directed family of lower regular functions. If
\[\Phi(\sup_{i \in I} \phi_i) = b \ominus \Lambda(b \ominus \sup \phi_i) = b \ominus \Lambda(\inf b \ominus \phi_i) = b \ominus \inf \Lambda(b \ominus \phi_i) = \sup b \ominus \Lambda(b \ominus \phi_i) = \sup \Phi(\phi_i).\]

If \(\sup_{i \in I} \phi_i\) is not bounded, we have
\[
\Phi(\sup_{i \in I} \phi_i) = \sup r \in [0, \infty) \Phi(\inf \{\sup_{i \in I} \phi_i, r\}) = \sup \Phi(\inf \{\phi_i, r\}) = \sup r \in [0, \infty) \sup_{i \in I} \Phi(\inf \{\phi_i, r\}) = \sup_{i \in I} \Phi(\phi_i).
\]

Since \((X, \delta)\) is sober, by Lemma 4.7 there is a compact saturated function \(\nu\) of \((X, \delta)\) such that \(\Phi(\phi) = \phi \pitchfork \nu\). We show that \(\nu\) satisfies the requirement. First, it follows from \(0_X \pitchfork \nu = \Phi(0_X) = 0\) that \(\nu\) is inhabited. Second, we show that \(\rho_X(\nu, \lambda) = \Lambda(\lambda)\) for all \(\lambda \in \mathfrak{M}X\). The equality is trivial if \(\lambda = \infty_X\); if \(\lambda\) is bounded, pick a bound \(b\) of \(\lambda\), then
\[
\rho_X(\nu, \lambda) = \rho_X(\nu, b \ominus (b \ominus \lambda)) = b \ominus ((b \ominus \lambda) \pitchfork \nu) = b \ominus \Phi(b \ominus \lambda)
\]
\[= b \ominus (b - \Lambda(b - (b - \lambda))) = b - (b - \Lambda(\lambda)) = \Lambda(\lambda).\]

(ii) Suppose \(\Lambda: \mathfrak{M}X \rightarrow [0, \infty]\) is a decent open \([0, \infty]-\)filter of \((\mathfrak{M}X, \rho_X)\). Let
\[s = \sup \{r \in [0, \infty) \mid \Lambda(r_X) = 0\}.
\]
Since \(\Lambda\) is decent, \(s < \infty\). Then for each \(r \in [0, \infty)\), \(\Lambda(r_X + s) = r\). Hence the map
\[\Lambda': \mathfrak{M}X \rightarrow [0, \infty], \quad \Lambda'(\lambda) = \Lambda(\lambda + s)
\]
is a proper open \([0, \infty]-\)filter of \((\mathfrak{M}X, \rho_X)\). By (i), there exists a unique inhabited compact
saturated function $\nu$ of $(X, \delta)$ such that $\Lambda' = \rho_X(\nu, -)$. Since for each $\lambda \in \mathcal{U}X$ we have

$$
\Lambda(\lambda) = \Lambda((\lambda + s) \ominus s)
= \Lambda(\lambda + s) \ominus s
= \Lambda'(\lambda) \ominus s
= \rho_X(\nu, \lambda) \ominus s
= \rho_X(\nu + s, \lambda),
$$

then $\mu := \nu + s$ is a compact saturated function of $(X, \delta)$ such that $\Lambda = \rho_X(\mu, -)$. \qed
