Convergent and orthogonality preserving schemes for approximating the Kohn-Sham orbitals

Xiaoying Dai · Liwei Zhang · Aihui Zhou

Received: date / Accepted: date

Abstract To obtain convergent numerical approximations without using any orthogonalization operations is of great importance in electronic structure calculations. In this paper, we propose and analyze a class of iteration schemes for the discretized Kohn-Sham Density Functional Theory model, with which the iterative approximations are guaranteed to converge to the Kohn-Sham orbitals exponentially without any orthogonalization as long as the initial orbitals are orthogonal and the time step sizes are given properly. In addition, we present a feasible and efficient approach to get suitable time step sizes.

Keywords gradient flow based model · density functional theory · orthogonality preserving scheme · convergence · temporal discretization

1 Introduction

Electronic structure calculations play an important role in numerous fields such as quantum chemistry, materials science and drug design. Due to the good balance of accuracy and computational cost, the Kohn-Sham Density Functional Theory (DFT) model \[20,22,27,29,30\] becomes one of the most widely used models in electronic structure calculations which is usually treated as either a nonlinear eigenvalue problem (Kohn-Sham equation) or an orthogonality constraint minimization problem (Kohn-Sham total energy direct minimization problem).

In the literature, there are a number of works on the design and analysis of numerical methods for solving the Kohn-Sham equation (see, e.g., \[5,8,7,14,11\]. This work was supported by the National Key R & D Program of China under grants 2019YFA0709600 and 2019YFA0709601, the National Natural Science Foundation of China under grants 12021001.

To obtain the solution of this nonlinear eigenvalue problem, we observe that some self consistent field (SCF) iterations are usually used (see also [27]). Unfortunately, the convergence of SCF iterations is uncertain. We understand that its convergence has indeed been investigated when there is a sufficient large gap between the occupied and unoccupied states and the second-order derivatives of the exchange correlation functional are uniformly bounded from above [3,23,24,38], which is important in the theoretical point of view. It becomes significant to investigate the convergence of SCF iterations when the gap is not large in application.

We see that an alternative approach to obtain the ground states is to solve the Kohn-Sham total energy direct minimization problem, which is an orthogonality constrained minimization problem [30]. The direct minimization approach attracts the attention of many researchers in recent years [6,17,28], and many different kinds of optimization methods are applied to electronic structure calculations and investigated (see, e.g., [10,11,15,19,24,57,41,40]).

For solving either the nonlinear eigenvalue problem or the orthogonality constrained minimization problem, except for few works such as [19], the orthogonalization procedure is usually required, which is very expensive and limits the parallel scalability in numerical implementation.

Recently, Dai et al. proposed a gradient flow based Kohn-Sham DFT model [12] that is a time evolution problem and is completely different from either the nonlinear eigenvalue problem or the orthogonality constrained minimization problem. It is proved in [12] that the flow of the new model is orthogonality preserving and evolves to the ground state. Consequently, the gradient flow based model provides a novel and attractive approach for solving Kohn-Sham DFT apart from the eigenvalue problem model and the direct energy minimization model. Indeed, it has been shown in [12] that the gradient flow based model is quite promising in electronic structure calculations and deserves further investigation.

In this paper, we propose a general framework of orthogonality preserving schemes that produce efficient approximations of the Kohn-Sham orbitals with the help of the gradient flow based model. In addition, we prove the global convergence and local convergence rate of the new schemes under some mild assumptions. We also provide some typical choices for the auxiliary mapping appeared in the framework, and a feasible and efficient approach to obtain the desired time step sizes that satisfy the assumptions required in the analysis, which result in several typical orthogonality preserving schemes that can produce convergent approximations of the Kohn-Sham orbitals.

The rest of the paper is organized as follows: In Section 2, we briefly review the gradient flow based Kohn-Sham DFT model and some notation frequently used throughout this paper. We then propose a framework of orthogonality preserving schemes for solving the discretized Kohn-Sham model in Section 3 and prove its global convergence as well as local convergence rate under some reasonable assumptions and with proper time step size. Then, in Section 4, we provide some specific choices for the auxiliary mapping and the time step size. Finally, we give some concluding remarks in Section 5.
2 Kohn-Sham DFT Model

2.1 Classical Kohn-Sham DFT model

According to Kohn-Sham density functional theory \cite{22}, the ground state of a system can be obtained by solving

\[
\inf_{U \in \left( H^1(\mathbb{R}^3) \right)^N} E_{KS}(U)
\]
\[\text{s.t. } U^T U = I_N, \tag{1}\]

where \( U = (u_1, \ldots, u_N) \in \left( H^1(\mathbb{R}^3) \right)^N, U^T V = \left( \langle u_i, v_j \rangle_{L^2(\mathbb{R}^3)} \right)_{i,j=1}^N, \forall U, V \in \left( H^1(\mathbb{R}^3) \right)^N, \)

and the objective functional \( E_{KS}(U) \) reads as

\[
E_{KS}(U) = \frac{1}{2} \int_{\mathbb{R}^3} \sum_{i=1}^N |\nabla u_i(r)|^2 dr + \frac{1}{2} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \frac{\rho(r)\rho(r')}{|r-r'|} dr dr' + \int_{\mathbb{R}^3} V_{\text{ext}}(r)\rho(r) dr + \int_{\mathbb{R}^3} \varepsilon_{xc}(\rho)(r) \rho(r) dr. \tag{2}\]

Here, \( N \) denotes the number of electrons, \( \{u_i\}_{i=1,2,\ldots,N} \) are usually called the Kohn-Sham orbitals, \( \rho(r) = \sum_{i=1}^N |u_i(r)|^2 \) is the electronic density (we assume each Kohn-Sham orbital is occupied by one electron here), \( V_{\text{ext}}(r) \) is the external potential generated by the nuclei, and \( \varepsilon_{xc}(\rho)(r) \) is the exchange-correlation functional which is not known explicitly. In practice, some approximation such as local density approximation (LDA), generalized gradient approximation (GGA) or some other approximations has to be used \cite{27}.

We see that the feasible set of \eqref{eq:1} is a Stiefel manifold which is defined as

\[
\mathcal{M}^N = \{ U \in \left( H^1(\mathbb{R}^3) \right)^N : U^T U = I_N \}. \tag{3}\]

To get rid of the uniqueness of the minimizer caused by the invariance of the energy functional under orthogonal transformations to the Kohn-Sham orbitals (i.e., \( E(U) = E(UP), \forall P \in O^N \) with \( O^N \) being the set of orthogonal matrices of order \( N \)), we, following \cite{10,12,13}, consider \eqref{eq:1} on the Grassmann manifold \( \mathcal{G}^N \) which is a quotient manifold of Stiefel manifold, that is

\[
\mathcal{G}^N = \mathcal{M}^N / \sim.
\]

Here, \( \sim \) denotes the equivalence relation which is defined as: \( \hat{U} \sim U \), if and only if there exists \( P \in O^N \), such that \( \hat{U} = UP \). For any \( U \in \mathcal{M}^N \), we denote

\[
[U] = \{ UP : P \in O^N \},
\]

then the Grassmann manifold \( \mathcal{G}^N \) can be formulated as

\[
\mathcal{G}^N = \{ [U] : U \in \mathcal{M}^N \}.
\]

For \([U] \in \mathcal{G}^N\), the tangent space of \([U]\) on \( \mathcal{G}^N \) is the following set

\[
\mathcal{T}_{[U]} \mathcal{G}^N = \{ W \in V^N : W^T U = 0 \in \mathbb{R}^{N \times N} \}. \tag{4}
\]
In this paper, we assume that (1) achieves its minimum in $G^N$, which implies that (1) is equivalent to
\[
\min_{[U] \in G^N} E(U). \tag{5}
\]
In addition, we see from [1] that the Grassmann gradient of $E_{KS}(U)$ is
\[
\nabla_G E_{KS}(U) = \nabla E_{KS}(U) - UU^T \nabla E_{KS}(U),
\]
where
\[
\nabla E_{KS}(U) = \mathcal{H}(\rho)U, \quad \forall U \in (H^1(\mathbb{R}^3))^N
\]
is the Euclidean gradient of $E_{KS}(U)$, and
\[
\mathcal{H}(\rho) = -\frac{1}{2} \Delta + V_{ext} + \int_{\mathbb{R}^3} \rho(r') \frac{1}{|r - r'|} dr' + v_{xc}(\rho),
\]
is symmetric and
\[
v_{xc}(\rho) = \frac{\partial \varepsilon_{xc}(\rho)}{\partial \rho}.
\]
For any $U \in M^N$, we see from [12] that $\nabla_G E_{KS}(U) = A_U U$, where
\[
A_U = \nabla E_{KS}(U)U^T - U \nabla E_{KS}(U)^T
\]
is anti-symmetric. Furthermore, the Hessian of $E_{KS}(U)$ on $G^N$ has the form
\[
\nabla^2 G E_{KS}(U) = \tr(D_1^T \mathcal{H}(\rho) D_2) - \tr(D_1^T D_2 U^T \mathcal{H}(\rho) U) + 2 \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \frac{\delta^2 (\varepsilon_{xc}(\rho))}{\partial \rho^2} (r) \left( \sum_i u_i(r) d_{i,i}(r) \right) \left( \sum_j u_j(r') d_{i,j}(r') \right) dr dr'
\]
provided that the total energy functional is of second order differentiable, or more specifically, the approximated exchange-correlation functional is of second order differentiable. Here, $D_i = (d_{i,1}, d_{i,2}, \ldots, d_{i,N})(i = 1, 2)$ belong to $T[U]G^N$.

The ground state of a system can also be obtained by considering the Euler-Lagrange equation of (1), which reads as
\[
\begin{cases}
\mathcal{H}(\rho)U = U\Lambda, \\
U \in M^N.
\end{cases} \tag{6}
\]
The nonlinear eigenvalue problem (6) is indeed the so-called Kohn-Sham equation. For decades, the Kohn-Sham DFT models are investigated as either a minimization problem (5) or an eigenvalue problem (6).

In practice, we may discrete the Kohn-Sham energy minimization model (5) as well as the nonlinear eigenvalue model (6) by, e.g., the plane wave method, the local basis set method, or real space methods. More details about the discretization methods can be found in, for instance, the review paper [33]. If we choose a $N_g$-dimension space $V_{N_g} \subset H^1(\mathbb{R}^3)$ to approximate $H^1(\mathbb{R}^3)$, then the associated discretized Kohn-Sham model can be formulated as
\[
\min_{[U] \in G^N_{N_g}} E_{KS}(U). \tag{7}
\]
or

\[
\begin{aligned}
\mathcal{H}(\rho)U &= U\Lambda, \\
U &\in \mathcal{M}_{N_g}^N,
\end{aligned}
\]  
(8)

where \(\mathcal{G}_{N_g}^N\) is the discretized Grassmann manifold defined by

\[
\mathcal{G}_{N_g}^N = \mathcal{M}_{N_g}^N / \sim,
\]

and

\[
\mathcal{M}_{N_g}^N = \{U \in (V_{N_g})^N : U^TU = I_N\}
\]
is the discretized Stiefel manifold with the equivalent relation \(\sim\) having the similar meaning to what we have mentioned. Usually, \(N_g \gg N\). We should point out that the operators on the discretized manifold, such as the Grassmann gradient and the Grassmann Hessian, have exactly the same forms as those on the continuous manifold.

\[2.2\] Gradient flow based Kohn-Sham DFT model

Different from the minimization model (7) and the eigenvalue model (8), the gradient flow based Kohn-Sham DFT model proposed in [12] has the following form:

\[
\begin{aligned}
\frac{d}{dt} U(t) &= -\nabla_G E(U(t)), \forall t \in \mathbb{R}, \\
U(0) &= U_0 \in \mathcal{M}_{N_g}^N.
\end{aligned}
\]  
(9)

It is shown in [12] that for the gradient flow based model (9), there hold

\[
U(t) \in \mathcal{M}_{N_g}^N, \forall t \geq 0,
\]  
(10)

and

\[
\frac{d}{dt} E(U(t)) = -\|\nabla_G E(U(t))\|^2 \leq 0, \forall t \geq 0,
\]  
(11)

which mean that the flow of the gradient flow based model (9) is orthogonality preserving and the corresponding energy functional is strictly non-increasing. Besides, it is proved in [12] that the norm of the extended gradient of energy functional exponentially decays to zero over time \(t\), and the flow will evolve to the ground state under some mild assumptions.

3 A general framework of orthogonality preserving schemes

With the help of the gradient flow based model (2.9), we design a general framework that enables us to obtain a class of orthogonality preserving schemes for getting convergent approximations of Kohn-Sham orbitals. To propose our numerical schemes, we first introduce the partition of the time interval

\[
0 = t_0 < t_1 < \cdots < t_n < \cdots.
\]

In addition, we denote \(\Delta t_n = t_{n+1} - t_n\) and use \(U_n\) to symbolize the approximation of \(U(t_n)\) for \(n \in \mathbb{N}_0\) where \(\mathbb{N}_0\) is the set of nonnegative integers.
3.1 Scheme framework

Given $U_0 \in \mathcal{M}_{N_g}^N$, we consider the following recursive scheme on the interval $[t_n, t_{n+1})$:

$$
\begin{aligned}
U(t) - U_n &= -(t - t_n)A_{U^{\text{Aux}}(t)} \frac{U_n + \tilde{U}(t)}{2}, \quad t \in [t_n, t_{n+1}), \\
U_{n+1} &= \tilde{U}(t_{n+1}).
\end{aligned}
$$

(12)

Here $U^{\text{Aux}} : \mathbb{R} \to (V_{N_g})^N$ is a piecewise smooth auxiliary mapping which satisfies $U^{\text{Aux}}(t_n) = U_n$ for all $n$. We hence name our schemes as interpolation based schemes.

In general, we are not able to determine $U^{\text{Aux}}(t)$ over the whole time interval in advance since $\{U_k\}_{k \geq n+1}$ are unknown at the $n$-th time interval $[t_n, t_{n+1})$. We may instead define $U^{\text{Aux}}(t)$ over each time subinterval successively. As a result, we obtain the following interpolation based scheme (Algorithm 1) for solving (9).

Algorithm 1: A framework for interpolation based scheme

1. Given $\epsilon > 0$, initial orbitals $U_0 \in \mathcal{M}_{N_g}^N$, calculate the gradient $\nabla G E(U_0)$ and let $n = 0$.
2. while $\|\nabla G E(U_n)\|_F > \epsilon$ do
3.     Choose a suitable $\Delta t_n > 0$ and let $t_{n+1} = t_n + \Delta t_n$;
4.     Define $U^{\text{Aux}}(t), t \in [t_n, t_{n+1})$ such that $U^{\text{Aux}}(t_n) = U_n$;
5.     Update $U_{n+1} = \lim_{t \to t_{n+1}} \tilde{U}(t)$ with $\tilde{U}(t)$ satisfying
6. \[ \tilde{U}(t) - U_n = -(t - t_n)A_{U^{\text{Aux}}(t)} \frac{U_n + \tilde{U}(t)}{2}, \quad t \in [t_n, t_{n+1}); \]
7.     Let $n = n + 1$, calculate the gradient $\nabla G E(U_n)$;
8. end while

We see from Algorithm 1 that the time step sizes in our scheme can be provided step by step and adaptively, i.e., we may make a full use of the information obtained during the iteration to determine a suitable time step size at each step. Besides, we point out here that if the definition of $U^{\text{Aux}}(t), t \in [t_n, t_{n+1})$ is independent of $\tilde{U}(t), t \in [t_n, t_{n+1})$ at the $n$-th iteration, then the problem (9) is said to be linear, and the corresponding scheme is called an explicit scheme. Otherwise, it is an implicit scheme. The following Theorem 1 shows that the proposed scheme preserves the orthogonality of iterations no matter whether it is explicit or not.

Theorem 1 If $\{U_n\}_{n \in \mathbb{N}_0}$ is produced by Algorithm 1 then $\{U_n\}_{n \in \mathbb{N}_0} \subset \mathcal{M}_{N_g}^N$.

Proof By rearranging (12), we have that

$$
U_{n+1} = (I + \Delta t_n A_{U^{\text{Aux}}(t_{n+1}^-)})^{-1} (I - \frac{\Delta t_n}{2} A_{U^{\text{Aux}}(t_{n+1}^-)}) U_n.
$$

(14)

Since $A_{U^{\text{Aux}}(t_{n+1}^-)}$ is anti-symmetric, we see that

$$
(I + \frac{\Delta t_n}{2} A_{U^{\text{Aux}}(t_{n+1}^-)})^{-1} (I - \frac{\Delta t_n}{2} A_{U^{\text{Aux}}(t_{n+1}^-)})
$$

is symmetric.
forms a Cayley transformation. Hence, $U_{n+1} \in \mathcal{M}^N_{Ng}$ as long as $U_n \in \mathcal{M}^N_{Ng}$. Note that $U_0 \in \mathcal{M}^N_{Ng}$, we complete the proof by conduction.

In fact, we see from the proof of Theorem 1 that $\tilde{U}(t)$ is orthogonal for all $t$, namely, $\tilde{U}(t) \in \mathcal{M}^N_{Ng}$. In addition, we see that for any explicit scheme, the orbitals $U_{n+1}$ can be updated simply by (14). Therefore, to update $U_{n+1}$ at each iteration of an explicit scheme, the main cost is to compute the inverse of

$$I + \frac{\Delta t_n}{2} \mathcal{A}_{U_{aux}(t_n^{n+1})},$$

which is a $Ng$-dimensional matrix inverse problem and is very expensive to be obtained. Even though we can deal with it by solving the corresponding linear system using some iterative methods, it is still not cheap, especially when $Ng$ is large.

Fortunately, we observe that $\mathcal{A}_U$ $(\forall U \in V^N)$ is anti-symmetry and has the following factorization

$$\mathcal{A}_U = (\nabla E(U) U) \left( \begin{array}{cc} U^T & -\nabla E(U)^T \end{array} \right).$$

Hence, by applying the Sherman-Morrison-Woodbury (SMW) formulae [15], we have [12]

$$\left(I + \frac{\Delta t_n}{2} \mathcal{A}_U \right)^{-1} = I - \frac{\Delta t_n}{2} (\nabla E(U) U)$$

$$[I_{2N} + \frac{\Delta t_n}{2} \left( \begin{array}{cc} U^T \nabla E(U) & U^T U \\ -\nabla E(U)^T \nabla E(U) - \nabla E(U)^T U \end{array} \right)]^{-1} \left( \begin{array}{c} U^T \\ -\nabla E(U)^T \end{array} \right),$$

which reduces the dimension of the matrix inverse problem significantly from $Ng$ to $2N$. Therefore, we only need to deal with linear system of dimension $2N$.

3.2 Numerical analysis

Note that [11] indicates the energy functional is non-increasing with respect to $t$, we may impose the following assumption on the time step sizes to maintain the similar property. We will show the existence of the desired time partition and introduce an efficient strategy to obtain such time step sizes in the next section.

**Assumption 2** The sequence $\{t_n\}_{n=0}^\infty$ satisfies

$$\sum_{n=0}^\infty \Delta t_n = +\infty, \text{ i.e., } \lim_{n \to \infty} t_n = +\infty$$

and

$$E(U_{n+1}) - E(U_n) = E(\tilde{U}(t_n^{n+1})) - E(U_n) \leq -\eta \Delta t_n \|\nabla G E(U_n)\|^2, n \in \mathbb{N}_0$$

(17)
with $\eta > 0$ being a given parameter.

The condition (16) on Assumption 2 is simple and reasonable, as we are discretizing an infinite time period. Meanwhile, the condition (17) follows from (11), which indicates that the finite difference approximation of the temporal derivative stated in the left hand side of (11) is somewhat comparable to $\|\nabla G E(U(t))\|^2$.

Under Assumption 2, we obtain the following asymptotic behaviour for approximate solution of (9) produced by Algorithm 1.

**Theorem 3** If the sequence $\{t_n\}_{n \in \mathbb{N}_0}$ satisfies Assumption 2, then for the sequence $\{U_n\}_{n \in \mathbb{N}_0}$ produced by Algorithm 1 with initial guess $U_0 \in \mathcal{M}_{N_g}$, there holds

$$\liminf_{n \to \infty} \|\nabla G E(U_n)\| = 0.$$  

**Proof** We see from Assumption 2 that

$$E(U_n) - E(U_{n+1}) \geq \eta \Delta t_n \|\nabla G E(U_n)\|^2.$$  

Hence,

$$E(U_0) - E_{\text{min}} \geq \sum_{n=0}^{\infty} \left( E(U_n) - E(U_{n+1}) \right) \geq \eta \sum_{n=0}^{\infty} \Delta t_n \|\nabla G E(U_n)\|^2,$$

where $E_{\text{min}}$ is the minimum of the energy functional $E(U)$. Thus,

$$\sum_{n=0}^{\infty} \Delta t_n \|\nabla G E(U_n)\|^2 < \infty. \quad (18)$$

If $\liminf_{n \to \infty} \|\nabla G E(U_n)\| > 0$, then there exists $\epsilon_0 > 0$ such that

$$\|\nabla G E(U_n)\| \geq \epsilon_0, \forall n \in \mathbb{N}_0.$$  

Hence, we obtain from (16) that

$$\sum_{n=0}^{\infty} \Delta t_n \|\nabla G E(U_n)\|^2 \geq \epsilon_0^2 \sum_{n=0}^{\infty} \Delta t_n = \infty,$$

which is contradict to (18). As a result,

$$\liminf_{n \to \infty} \|\nabla G E(U_n)\| = 0.$$  

We see that a sufficient condition for (16) is $\Delta t_n > \tau, \forall n \in \mathbb{N}_0$ for some $\tau > 0$. Under this setting, Theorem 3 indicates that the sequence $\{U_n\}_{n=0}^{\infty}$ produced by Algorithm 1 will converge to an equilibrium point of (10) (at least for a subsequence). If the equilibrium point, says $U^*$, is a local minimizer of the Kohn-Sham energy functional $E(U)$, we assume in addition that the Hessian of the Kohn-Sham energy functional is bounded from both above and below in a neighborhood of $U^*$, that is to say, the following assumption holds.
Assumption 4 There exists $\delta_1 > 0$, such that for all $[U] \in B([U^*], \delta_1)$,
\[ \nabla^2_{G_E} E(U)[D,D] \geq \underline{c} \| D \|^2, \forall D \in T_{[U]}G^N_{N_g}, \]
and
\[ \nabla^2_{G_E} E(U)[D] \leq \bar{c} \| D \|, \forall D \in T_{[U]}G^N_{N_g}, \tag{19} \]
where $U^*$ is the local minimizer of $E(U)$ and $\underline{c} \geq \bar{c} > 0$ are some constants. Here, $B([U], \delta)$ is defined as
\[ B([U], \delta) := \{ [V] \in G^N_{N_g} : \min_{P \in O_N \times N} \| U - VP \| \leq \delta \}. \]

Remark 1 Under Assumption 4 there exists a positive constant $C$ such that
\[ \| \nabla_{G_E} E(U) \| \leq C, \forall U \in M^N_{N_g}, \]
where $C$ can be chosen as $\sqrt{2\bar{c}N}$.

Besides, we review some preliminaries on the Grassmann manifold which will be used in the following analysis.

Let $[U], [W] \in G^N_{N_g}$, with $U, W \in M^N_{N_g}$. We obtain from Lemma A.1 in [10] that there exists a geodesic
\[ \Gamma(t) = [UA \cos(\Theta t) A^T + A_2 \sin(\Theta t) A^T], t \in [0, 1], \tag{20} \]
such that
\[ \Gamma(0) = [U], \Gamma(1) = [W]. \]
Here, $U^T W = A \cos \Theta B^T$ and $W - U(U^T W) = A_2 \sin \Theta B^T$ is the SVD of $U^T W$ and $W - U(U^T W)$, respectively,
\[ \Theta = \text{diag}(\theta_1, \theta_2, \ldots, \theta_N) \]
is a diagonal matrix with $\theta_i \in [0, \pi/2]$ and
\[ \sin(\Theta t) = \text{diag}(\sin(\theta_1 t), \sin(\theta_2 t), \ldots, \sin(\theta_N t)) \]
with a similar notation for $\cos(\Theta t)$. Note that $A_2 \in M^N_{N_g}$.

Remark 2 For any $U \in M^N, D \in T_{[U]}G^N$, let $D = ASB^T$ be the SVD of $D$ where $A \in T_{[U]}G^N_{N_g}, S, B \in \mathbb{R}^{N \times N}$, then there exists an unique geodesic
\[ \Gamma(t) = [UB \cos(S t) B^T + A \sin(S t) B^T], \tag{21} \]
which start from $[U]$ and with direction $D \in T_{[U]}G^N_{N_g}$. The above expression (20) is just a special case with direction $D = A_2 \Theta A^T$.

More specifically, we use macro $[\exp_{[U]}(tD)]$ to denote the geodesic on $G^N_{N_g}$ which starting from $[U]$ and with the initial direction $D \in T_{[U]}G^N_{N_g}$. We now define the parallel mapping which maps a tangent vector along the geodesic [16].
Definition 1 The parallel mapping $\tau_{(U,D,t)}: \mathcal{T}_[U]\mathcal{G}_{N_y}^N \rightarrow \mathcal{T}_{[\exp_U(tD)]}\mathcal{G}_{N_y}^N$ along the geodesic $[\exp_U(tD)]$ is defined as
\[
\tau_{(U,D,t)} \tilde{D} = \left((-U \sin (St) + A \cos (St)A^T + (I_N - AA^T))\tilde{D},
\right)
\]
where $D = ASB^T$ is the SVD of $D$.

It can be verified that
\[
\|\tau_{(U,D,t)} \tilde{D}\| = \|\tilde{D}\|, \forall \tilde{D} \in \mathcal{T}_[U]\mathcal{G}_{N_y}^N.
\] (22)

To state our theory, we introduce two distances on the Grassmann manifold $\mathcal{G}_{N_y}^N$:
\[
\text{dist}_{cF}([U],[W]) = \min_{P \in O_{N \times N}} \|U - WP\|,
\]
\[
\text{dist}_{geo}([U],[W]) = \|A_2 \Theta A^T\|.
\] (23)

Remark 3 It can be calculated that
\[
\text{dist}_{cF}([U],[W]) = \|2 \sin \frac{\Theta}{2}\|, \\
\text{dist}_{geo}([U],[W]) = \|\Theta\|,
\]
which indicate that these two kinds of distance are equivalent. More specifically,
\[
\text{dist}_{cF}([U],[W]) \leq \text{dist}_{geo}([U],[W]) \leq 2\text{dist}_{cF}([U],[W]).
\]

In addition, we see that
\[
\|D\| = \|A_2 \Theta A^T\| = \|\Theta\|_{cF} = \text{dist}_{geo}([U],[W]),
\] (24)
where $D$ is the initial direction of the geodesic (20).

Furthermore, we need the following conclusion, which can be obtained from Remark 3.2 and Remark 4.2 of [35].

Proposition 1 Suppose $E(U)$ is of second order differentiable, then for all $U \in \mathcal{M}_{N_y}^N$, $D \in \mathcal{T}_[U]G_{N_y}^N$, there exists a $\xi \in (0,t)$ such that
\[
E(\exp_U(tD)) = E(U) + t(\nabla_GE(\exp_U(\xi D)), \tau_{(U,D,t)} D),
\]
\[
= E(U) + t(\nabla_GE(U), D) + \frac{t^2}{2} \nabla^2_G E(U)[D,D] + o(t^2\|D\|^2).
\]

and
\[
\tau_{(U,D,t)}^{-1} \nabla_G E(\exp_U(tD)) = \nabla_G E(U) + t\tau_{(U,D,t)}^{-1} \nabla^2_G E(\exp_U(\xi D))[\tau_{(U,D,t)} D].
\]

Now we are ready to have the local convergence rate of the numerical approximations $\{U_n\}_{n=0}^\infty$ as stated in the following theorem.
Theorem 5 Let Assumptions $3$ and $4$ hold true and there exists a $\tau > 0$ such that $\Delta t_n > \tau, \forall n \in \mathbb{N}_0$. Then for the sequence $\{U_n\}_{n \in \mathbb{N}_0}$ produced by Algorithm $4$ with initial guess $[U_0] \in B([U^*], \delta_1) \subset \mathcal{G}^N_{\mathcal{S}_g}$, there exists a constant $\nu \in (0, 1)$ such that

$$E(U_{n+1}) - E(U^*) \leq \nu (E(U_n) - E(U^*)),$$

and hence, there exist $C_1, C_2 > 0$, such that

$$E(U_n) - E(U^*) \leq C_1 \nu^n \text{dist}_{geo}([U_0], [U^*])^2,$$

and

$$\text{dist}_{geo}([U_n], [U^*]) \leq C_2 (\sqrt{\nu})^n \text{dist}_{geo}([U_0], [U^*]).$$

Proof For simplicity, we denote $d_n = \text{dist}_{geo}([U_n], [U^*])$. We see that

$$E(U_{n+1}) - E(U^*) = E(U_{n+1}) - E(U_n) + E(U_n) - E(U^*)$$

$$\leq -\eta \Delta t_n \|\nabla_G E(U_n)\|^2 + E(U_n) - E(U^*).$$

For $U_n$ and $U^* \in \mathcal{M}^N_{\mathcal{S}_g}$, there exists an unique geodesic $\exp_{U^*}(t D_n)$ such that

$$\exp_{U^*}(0) = [U^*]$$

and

$$\exp_{U^*}(D_n) = [U_n],$$

where $0$ is the zero element on the tangent space $T_{[U^*]} \mathcal{G}^N_{\mathcal{S}_g}$. Furthermore, there holds $\|D_n\| = d_n$.

We obtain from (25) that there exists $\xi_{n,1} \in (0, 1), x_{n,2} \in (0, 1)$ such that

$$\mathcal{G}_n^2 \leq E(U_n) - E(U^*) = \nabla_G^2 E(\exp_{U^*}(\xi_{n,1} D_n)) \|\tau_{\xi_{n,1}} D_n, \tau_{\xi_{n,1}} D_n\| \leq \xi d_n. \quad (25)$$

and

$$\|\nabla_G E(U_n)\| = \|\tau_{\xi_{n,2}}^{-1} \nabla_G^2 E(\exp_{U^*}(\xi_{n,2} D_n)) \| \|\tau_{\xi_{n,2}} D_n\|$$

$$\geq \|\nabla_G^2 E(\exp_{U^*}(\xi_{n,2} D_n)) \| \|\tau_{\xi_{n,2}} D_n\| \geq \mathcal{G}_n. \quad (26)$$

Combining (25) and (26), we see that

$$\|\nabla_G^2 E(U_n)\|^2 \geq \frac{2}{\mathcal{G}_n} (E(U_n) - E(U^*)). \quad (27)$$

Hence, we obtain from the fact that $\{\Delta t_n\}_{n=0}^\infty$ is bounded from below that

$$E(U_{n+1}) - E(U^*) \leq -\eta \Delta t_n \|\nabla_G E(U_n)\|^2 + E(U_n) - E(U^*)$$

$$\leq (1 - \eta \mathcal{G}_n^2) (E(U_n) - E(U^*)).$$

Finally, we complete the proof by using (25) again, and choosing

$$\nu = 1 - \eta \mathcal{G}_n^2, \quad C_1 = \bar{c}, \quad C_2 = \sqrt{\frac{\bar{c}}{\mathcal{G}_n}}.$$
4 Some typical orthogonality preserving schemes

In the previous section, we propose and analyze a general framework of interpolation based orthogonality preserving schemes to discretize the gradient flow based Kohn-Sham DFT model (9). In that framework, how to determine the specific form of the auxiliary mapping $U_{\text{Aux}}$ and the time step size $\Delta t_n$ are not given. The specific form and the efficiency of Algorithm 1 depend strongly on the definition of the auxiliary mapping $U_{\text{Aux}}$ and the choice of the time step size. For example, if the time step size $\Delta t_n$ is chosen to be too large, Assumption 2 may not hold, which may lead to divergence. On the contrary, Theorem 5 indicates that tiny step sizes will cause slow convergence. In this section, we will provide some choices for the auxiliary mapping $U_{\text{Aux}}$, and propose an adaptive approach for determining the time step sizes. We will prove that our approach can produce time step sizes which can not only satisfy Assumption 2 but also avoid slow convergence.

4.1 Auxiliary mapping $U_{\text{Aux}}$

We see from the previous discussion that Algorithm 1 gives a general framework of orthogonality preserving numerical schemes for solving (12), which provides at least a subsequence that converges to the equilibrium point under some mild assumptions. All our analysis is independent of the specific form of $U_{\text{Aux}}$ at each interval $[t_n, t_{n+1})$. However, the choice of the auxiliary mapping is one of the keys when we carry out Algorithm 1. Here, we provide some potential choices for auxiliary mapping $U_{\text{Aux}}$ in this subsection.

- **Choice 1** $U_{\text{Aux}}(t) = (1 - \alpha_n)U_n + \alpha_n \tilde{U}(t)$, $\alpha_n \in [0, 1], t \in [t_n, t_{n+1})$.

If we use Crank-Nicolson’s strategy [9], which is a widely used second order scheme in time, to discretize (9), then we have

$$U_{n+1} = (I_N + \frac{\Delta t}{2} A_{U_{n+1}})^{-1} (I_N - \frac{\Delta t}{2} A_{U_n}) U_n. \quad (28)$$

However, it will not preserve the orthogonality of orbitals unless $U_{n+1} = U_n$. Notice that if we choose $\alpha_n = 0$ in Example 1 then the orbitals can be updated as

$$U_{n+1} = (I_N + \frac{\Delta t}{2} A_{U_{n+1}})^{-1} (I_N - \frac{\Delta t}{2} A_{U_n}) U_n, \quad (29)$$

which preserves the orthogonality automatically and is an approximation of Crank-Nicolson scheme (28) simply by substituting $A_{U_{n+1}}$ with $A_{U_n}$ in (28).

Hence, we may denote the auxiliary mapping in this case as $U_{\text{Aux}}^\text{CN}(t) = U_n$. Besides, if $\alpha_n$ is chosen to be 1/2, then we have $U_{\text{Aux}}(t) = (\tilde{U}(t) + U_n)/2$. We can see that in this case, the updating formula is the same as the midpoint scheme studied in [12]. Hence, we denote

$$U_{\text{Aux}}^\text{Mid}(t) = (\tilde{U}(t) + U_n)/2.$$

Therefore, the framework that we proposed (Algorithm 1) contains both the Crank-Nicolson like scheme (29) and the midpoint scheme [12]. Under the classification mentioned in this paper, we see that the midpoint scheme is implicit and is not easy to be carried out. Instead, Dai et al. also
proposed an explicit approximation to midpoint scheme based on Picard iteration [12], more precisely, the midpoint scheme can be replaced approximately by the iterative formulae

\[ U_{n+1/2}^m(t) = (I + \frac{t - t_n}{2} A_{t_{n+1/2}^m}^{-1}(\Delta t_n))^{-1} U_n, \ m = 1, 2, \ldots, \]

where \( U_{n+1/2}^0 = U_n \). This gives us the following example.

- **Choice 2** \( U_{n+1/2}^{\text{Aux}}(t) = U_{n+1/2}^m(t) := U_{\text{Mid-m}}^m(t), \ t \in [t_n, t_{n+1}], \forall m \in \mathbb{N}_0. \)

It is easy to check that \( U_{\text{Mid-m}}^m(t_n) = U_n \). Replacing the midpoint \( \frac{U_n + U_{n+1}}{2} \) by approximated midpoints \( U_{\text{Aux}}^m(t) \) in the midpoint scheme, we obtain a set of explicit scheme and name them as approximated midpoint schemes. They are also included in our interpolation based schemes.

We can of course construct some simpler explicit schemes, e.g., the following one.

- **Choice 3** Let

\[ U_{\text{Aux}}(t) = U_n - m_n(t - t_n) \nabla G E(U_n), \ t \in [t_n, t_{n+1}], \]

or

\[ U_{\text{Aux}}(t) = 2(I + m_n(t - t_n) A_{t_n}^{-1}) U_n - U_n, \ t \in [t_n, t_{n+1}] \]

where \( m_n \) can be arbitrary real number.

There are also many other explicit schemes and we will not go further into them. With regard to implicit schemes, we can also propose the following example motivated by the Verlet algorithm [35]. Consider the first order Taylor expansion of \( U(t) \) at \( t_{n+\frac{1}{2}} = \frac{t_n + t_{n+1}}{2} \), that is,

\[ U_{n+1} \approx U(t_{n+1/2} + \Delta t_n/2) \approx U(t_{n+1/2}) + \frac{\Delta t_n}{2} \dot{U}(t_{n+1/2}), \]

\[ U_n \approx U(t_{n+1/2} - \Delta t_n/2) \approx U(t_{n+1/2}) - \frac{\Delta t_n}{2} \dot{U}(t_{n+1/2}). \]

It can be observed that the midpoint scheme uses \( \frac{U_n + U_{n+1}}{2} \) to approximate \( U_{n+1/2} \) with linear accuracy. We may further consider the second order Taylor expansion of \( U(t) \), which is formulated as

\[ U_{n+1} \approx U(t_{n+1/2} + \Delta t_n/2) \approx U(t_{n+1/2}) + \frac{\Delta t_n}{2} \dot{U}(t_{n+1/2}) + \frac{\Delta t_n^2}{8} \ddot{U}(t_{n+1/2}), \]

\[ U_n \approx U(t_{n+1/2} - \Delta t_n/2) \approx U(t_{n+1/2}) - \frac{\Delta t_n}{2} \dot{U}(t_{n+1/2}) + \frac{\Delta t_n^2}{8} \ddot{U}(t_{n+1/2}), \]

where

\[ \ddot{U}(t) = -\frac{d}{dt} \nabla G E(U(t)) \]

\[ = (I - U(t) U(t)^T) \nabla^2 E(U(t)) \nabla G E(U(t)) \]

\[ + (\nabla G E(U(t)) U(t)^T + U(t) \nabla G E(U(t))^T) \nabla E(U(t)) \]

\[ := G(U(t)), \]

based on which a higher order approximation of the midpoint can be obtained.
The corresponding interpolation based scheme is read as the following Algorithm 2.

Inspired by the adaptive step size strategy proposed in [13], we provide an adaptive strategy to get the time step sizes that satisfy Assumption 2, with which the efficiency, which will be further studied in our future work.

4.2 Time step sizes

In Algorithm 2, \( \delta t_{\text{min}} \) and \( \delta t_{\text{max}} \) are the preset bound of the initial step sizes. One of the significant advantages of Algorithm 2 is that the step size is given explicitly without any trial or test process, i.e., we only need to update \( U_{n+1} \) once at each iteration of Algorithm 2.

For Algorithm 2, we have the following theorem, which shows the convergence of our interpolation based scheme with adaptive step sizes.

**Theorem 6** If Assumption 4 holds and the initial guess \( [U_0] \in B([U^*]_{\delta_{1}}) \subset G^N \), then there exist \( \{\theta_n\}_{n \in N_0} \), such that for the sequence \( \{U_n\}_{n \in N_0} \) generated by Algorithm 2, there holds either \( \nabla G E(U_n) = 0 \) for some \( n \in N_0 \) or

\[
\liminf_{n \to \infty} \|\nabla G E(U_n)\| = 0. \tag{31}
\]

Furthermore, there also holds that

\[
\liminf_{n \to \infty} \text{dist}_{\text{geo}}(U_n, U^*) = 0.
\]
Orthogonality preserving schemes for approximating the KS orbitals 15

Proof To simplify the notation, we denote $D_n = -\nabla G E(U_n)$. We see that the time step size $\Delta t_n$ given by Algorithm 2 should satisfy $\Delta t_n \|D_n\| \leq \theta_n$ and

$$\Delta t_n \|D_n\|^2 + \frac{\Delta t_n^2}{2} \nabla^2 G E(U_n)[D_n, D_n] \leq \eta \Delta t_n \|D_n\|^2, \forall n \in \mathbb{N}_0.$$  

Define

$$\theta_n = \sup \left\{ \tilde{\theta}_n : E(\tilde{U}(t_n + \Delta t)) - E(U_n) - \Delta t \|D_n\|^2 - \frac{\Delta t^2}{2} \nabla^2 G E(U_n)[D_n, D_n] \leq \frac{\eta \Delta t \|D_n\|^2}{2}, \forall \Delta t \leq \frac{\tilde{\theta}_n}{\|D_n\|} \right\} \geq 0.$$

Then, we obtain from the definition of $E(U_{n+1})$ and $\theta_n$ that

$$E(U_{n+1}) - E(U_n) \leq \frac{\eta}{2} \Delta t_n \|D_n\|^2, \forall n \in \mathbb{N}_0,$$

i.e., (19) holds.

As for the condition (18), we see that $\Delta t_n$ has only three possible values, that is,

$$\Delta t_n = \max (t_{n_{\text{initial}}}, t_{\text{tmin}}),$$

$$\Delta t_n = -\|D_n\|^2 / \nabla^2 G E(U_n)[D_n, D_n],$$

or

$$\Delta t_n = \frac{\theta_n}{\|D_n\|}.$$

So there is at least one infinite subsequence of $\{n_j\}_{j=0}^\infty$, which is, with out loss of generality, also denoted by $\{n\}_{n=0}^\infty$, such that

Case 1. $\Delta t_n = \max (t_{n_{\text{initial}}}, t_{\text{tmin}})$. We have immediately that

$$\sum_{n=0}^\infty \Delta t_n \geq \sum_{j=0}^\infty \Delta t_{n_j} = +\infty.$$

Case 2. $\Delta t_n = -\|D_n\|^2 / \nabla^2 G E(U_n)[D_n, D_n]$. We obtain from Assumption 4 that $\Delta t_n \geq \frac{1}{\eta}$ and hence

$$\sum_{n=0}^\infty \Delta t_n = +\infty.$$

Case 3. $\Delta t_n = \frac{\theta_n}{\|D_n\|}$. If

$$\lim_{n \to \infty} \Delta t_n > 0,$$

then (18) is satisfied and we complete the proof. Assume otherwise, i.e., there exists a subsequence of $\{\Delta t_n\}_{n \in \mathbb{N}_0}$, which is also denoted by $\{\Delta t_n\}_{n=0}^\infty$ such that $\lim_{n \to \infty} \Delta t_n = 0$. This simply leads to $\lim_{n \to \infty} \theta_n = 0$ since $\|D_n\|$ is bounded from above.

We have that for all $n \in \mathbb{N}_0$, there hold

$$E(\tilde{U}(t_n + \Delta t)) - E(U_n) - \Delta t \|D_n\|^2 - \frac{\Delta t^2}{2} \nabla^2 G E(U_n)[D_n, D_n]$$

$$= E(\tilde{U}(t_n + \Delta t)) - E(\exp[U_n](\Delta t D_n)) + E(\exp[U_n](\Delta t D_n)) - E(U_n)$$

$$+ \Delta t \|D_n\|^2 - \frac{\Delta t^2}{2} \nabla^2 G E(U_n)[D_n, D_n] := T_n^{(1)} + T_n^{(2)},$$

$$T_n^{(1)} = E(\tilde{U}(t_n + \Delta t)) - E(\exp[U_n](\Delta t D_n)),$$
where
\[ T_n^{(1)} = E(\tilde{U}(t_n + \Delta t)) - E(\exp_{[U_n]}(\Delta t D_n)) \]
and
\[ T_n^{(2)} = E(\exp_{[U_n]}(\Delta t D_n)) - E(U_n) + \Delta t \| D_n \|^2 - \frac{\Delta t^2}{2} \nabla_G^2 E(U_n)[D_n, D_n]. \]

We see from Remark 2 that there exists a geodesic \([\exp(\tilde{U}(t_n + \Delta t))](\tilde{D})\) such that
\[ \exp(\tilde{U}(t_n + \Delta t))(0) = \tilde{U}(t_n + \Delta t), \quad \exp(\tilde{U}(t_n + \Delta t))'(\tilde{D}) = [\exp_{[U_n]}(\Delta t D_n)]. \]

and obtain from (25) that
\[ |T_n^{(1)}| = |E(\exp(\tilde{U}(t_n + \Delta t))(0\tilde{D})) - E(\exp(\tilde{U}(t_n + \Delta t))'(\tilde{D}))| \]
\[ \leq \| \nabla_G E(\exp(\tilde{U}(t_n + \Delta t))'(\tilde{D})) \| \| \tilde{U}(t_n + \Delta t) - \tilde{U}(t_n) \| \]
\[ \leq C \| \tilde{D} \|, \]

where Assumption 3 and (22) are used in the last inequality.

From (24), we have that
\[ \| \tilde{D} \| = \text{dist}_{\text{geo}}([\tilde{U}(t_n + \Delta t)], [\exp_{[U_n]}(\Delta t D_n)]) \]
\[ \leq 2 \text{dist}_{\text{F}}([\tilde{U}(t_n + \Delta t)], [\exp_{[U_n]}(\Delta t D_n)]) \]
\[ \leq 2 \| \tilde{U}(t_n + \Delta t) - \exp_{[U_n]}(\Delta t D_n) \| \]
\[ \leq 2 \| \tilde{U}(t_n + \Delta t) - U_n - \Delta t D_n \| \]
\[ + \| \exp_{[U_n]}(\Delta t D_n) - U_n - \Delta t D_n \|. \]

Notice that \( \tilde{U}(t) \) and \( \exp_{[U_n]}(tD_n) \) satisfy
\[ \tilde{U}(t_n) = 0, \quad \tilde{U}'(t_n) = D_n \]
and
\[ \exp_{[U_n]}(0) = U_n, \quad \exp_{[U_n]}'(0) = D_n, \]
we have \( \| \tilde{D} \| = o(\Delta t) \). If the sequence \( \{ \| D_n \| \}_{n \in N_0} \) is not bound from below, then we complete the proof. Otherwise, we obtain
\[ T_n^{(1)} = o(\Delta t \| D_n \|) \] (32)
since \( \| D_n \| \) is bounded from both above and below. As for \( T_n^{(2)} \), (25) gives that
\[ T_n^{(2)} = o(\Delta t^2 \| D_n \|^2). \] (33)

Combining (32) and (33), we arrive at
\[ E(\tilde{U}(t_n + \Delta t)) - E(U_n) + \Delta t \| D_n \|^2 - \frac{\Delta t^2}{2} \nabla_G^2 E(U_n)[D_n, D_n] \]
\[ = T_n^{(1)} + T_n^{(2)} = o(\Delta t \| D_n \|), \quad \forall n \in N_0. \]
Note that the definition of $\theta_n$ implies that for all $n$, there exists a
\[
\Delta t_n^* \in (\frac{\theta_n}{\|D_n\|}, \frac{\theta_n + 1}{n}),
\]
such that
\[
o(\Delta t_n^* \|D_n\|) = E(\tilde{U}(t_n + \Delta t_n^*)) - E(U_n)
\]
\[
+ \Delta t_n^* \|D_n\|^2 - \frac{\Delta t_n^*}{2} \nabla G E(U_n)[D_n, D_n]
\]
\[
> \frac{\eta \Delta t_n^* \|D_n\|^2}{2}.
\]
(34)

Hence, it is easy to see that
\[
0 \leq \lim_{n \to \infty} t_n^* \|D_n\| \leq \lim_{n \to \infty} \left(\theta_n + \frac{1}{n}\right) = 0.
\]
Finally, we obtain by letting $n \to \infty$ in (34) that
\[
0 \geq \lim_{n \to \infty} \frac{\eta}{2} \|D_n\|,
\]
which together with (26) completes the proof.

5 Concluding remarks

In this paper, we proposed and analyzed a general framework of orthogonality preserving schemes for approximating the Kohn-Sham orbitals, from which we can obtain many orthogonality preserving schemes. We proved the convergence and derived the local exponentially convergence rate of the framework under some mild and reasonable assumptions. In addition, we provided some typical choices for the auxiliary mapping which lead to several orthogonality preserving schemes. We then presented an efficient approach to obtain the desired time step sizes that satisfy all the assumptions required in our analysis. We will address the implementation details and report numerical experiments on electronic structure calculations of some typical systems elsewhere.
