We show that in van der Waals stacks of twisted hexagonal layers the proximity induced Rashba spin-orbit coupling can be affected by quantum interference. We calculate the quantum phase responsible for this effect in graphene-transition metal dichalcogenide (TMDC) heterostructures[5–7] and discuss its potential effect on spin-to-charge conversion measurements. In twisted trilayer twistsymmetries can be broken as well as restored for certain twist angles. This can be used to deduce the effects of induced spin-orbit coupling on spin-lifetime anisotropy and magnetoconductance measurements.

Multilayer stacks of two-dimensional (2D) materials, commonly referred to as van der Waals (vdW) heterostructures, have become an important platform for exploring a wide range of exciting phenomena, because they offer electronic tunability and a large parameter space. Initially, bilayer structures served as a platform to study e.g., the effects of a moiré potential in graphene/hBN [1–4] the induced spin-orbit coupling (SOC) in graphene/transiiton metal dichalcogenide (TMDC) heterostructures[5–7], or strong electronic correlations in magic-angle twisted bilayer graphene (MATG)[8,9]. A natural next step is to add another layer, which introduces a second twist angle and/or a further layer of different properties and this can enhance the parameter space to tune the properties of the system in several ways. An exciting opportunity is to use MATG and induce SOC into the flatbands by adding a TMDC layer to the stack[10,11]. Further examples include the recent proposal of an engineered topological phase in WS2/bilayer graphene (BLG)/WS2 system[12], the external gate tunability of SOC through changing layer polarization in TMDC/BLG structures[13–16] and imprinting double moiré potential on graphene[17–19]. More generally, vdW multilayers can serve as quantum simulator platform for strongly correlated physics and topological materials[20].

The proximity induced SOC plays a pivotal role in many of the above proposals. A number of recent experimental works based on weak antilocalization (WAL) [5–7, 21–25] spin-lifetime anisotropy measurements[26–29], spin-Hall[30–33] and Rashba-Edelstein effect[32,34–36] proved that SOC is strongly enhanced in graphene/TMDC heterostructures, which also motivated theoretical work to understand these measurements[5,37–45]. Recently, Refs. [46–49] have also discussed the interlayer twist angle dependence of the induced SOC in graphene/TMDC. In particular, it has been noted[47,48] that the most general form of the induced Rashba-SOC in twisted graphene/TMDC heterostructures that obeys time reversal $T$ and three-fold rotation $C_3$ symmetries can be written as

$$H_R = \frac{\lambda_R}{2} e^{i\vartheta_R} (\tau_z \sigma_x s_y - \sigma_y s_x) e^{-i\vartheta_R},$$

where $s_{x,y,z} \ (\sigma_{x,y,z})$ are Pauli matrices acting in the spin (sublattice) space, and $\tau_z$ is a Pauli matrix acting on the valley degree of freedom of graphene. Both $\vartheta_R$ and $\lambda_R$ are functions of the interlayer twist angle $\theta$, which we do not show explicitly in order to ease the notations. $H_R$ differs from the usual Rashba SOC term[50–52]

$$H_R = \frac{\lambda_R}{2} (\tau_z \sigma_x s_y - \sigma_y s_x)$$

by a rotation of angle $\vartheta_R$ in spin-space. The terms containing $\vartheta_R$ appear because for a general interlayer twist angle the symmetry of the heterostructure is lowered from $C_{3v}$ to $C_3$. Thus Eq. (1) is valid not only for graphene/TMDC heterostructures, but for a wide range of twisted heterostructures consisting of hexagonal layers, such as heterostructures of graphene with semiconductor[53,54], ferromagnetic[55], and topological insulator[56,57] structures. This general nature of the effect is one of the main motivations for our work.

However, the physical significance of this spin-space rotation was not previously appreciated and the relation of $\vartheta_R$ to the interlayer twist angle $\theta$ has not been discussed. As we will show, using graphene/TMDC twisted bilayers as an example, $\vartheta_R$ can take finite values and it leads to quantum interference affecting the induced Rashba type SOC in twisted trilayers. While it has been known that $\lambda_R$ is tunable e.g., by pressure[58] in proximity structures, to our knowledge the possibility that quantum interference can affect its value has not been considered yet.

Twisted bilayers In order to obtain the angle $\vartheta_R$ we use the methodology recently developed to calculate the coupling strength $\lambda_R$ for graphene/TMDC bilayers[48]. $\vartheta_R$ is a quantum phase which depends on the interlayer tunneling between the Bloch states of graphene and the TMDC layer and on certain off-diagonal matrix elements of the intrinsic SOC of the TMDC, for details we refer to Ref. [59]. One finds that $\lambda_R$ and $\vartheta_R$ are the absolute value and the phase of the complex Rashba coefficient.
FIG. 1. a) Schematics of a twisted graphene/TMDC bilayer with twist angle $\theta$. b) and c) $\vartheta_R + \theta$ as a function of $\theta$ for MoS$_2$ and WSe$_2$. Blue (red) curves were calculated using DFT (ARPES measurements) parameters, see main text for details. d) Schematics of a twisted TMDC/graphene/TMDC trilayer. The spin-orbit field $s(q)$ for e) $\theta = 0$, f) $\theta = 7^\circ$ and g) $\theta = 15^\circ$, using the $\vartheta_R$ vs $\theta$ dependence shown in Fig. 1(c), calculated for graphene/WSe$_2$. The green circles indicate the Fermi surfaces for the two spin subbands. $s(q)$ lies in the plane if only Rashba SOC is induced in graphene (black arrows), whereas it acquires a non-zero $\langle \hat{s}_x \rangle$ component if the valley-Zeeman type SOC is finite as well (blue and red).

$\lambda_R = \lambda_R e^{i\theta_R}$, which is given by the sum of the contributions from pairs of even ($e$) and odd ($o$) bands of the TMDC: $\lambda_R = \sum_q \lambda_{R,(e,o)} e^{i\theta_{R,(e,o)}} = \sum_q \lambda_{R,q} e^{i\theta_q}$. Here $\lambda_{R,q}$ and $\vartheta_q$ are the magnitude and the phase of the contributions of the pairs of bands. In the calculations of $\lambda_{R,q}$ and $\vartheta_q$ we have used the tight-binding model of Ref. [60]. For the initial steps of the calculations it is convenient to assume that the graphene layer is rotated with respect to the TMDC layer[48]. In the final steps, we change the representation of the Hamiltonian from the coordinate system fixed to the TMDC layer to the system fixed to the graphene layer with a transformation $e^{-i\pi/4} e^{i\theta} H_q e^{i\pi/4} e^{-i\theta}$, see Fig. 1(a). From the explicit form of the transformed Rashba Hamiltonian one finds that the non-zero matrix elements are $\propto e^{i\vartheta_q + \theta_R}$, i.e., the sum of the geometric angle $\theta$ and the quantum phase $\vartheta_R$ plays an important role. Before discussing our numerical calculations, we note that the results depend on i) the position of the Dirac point of graphene within the band gap $E_g$ of the TMDC, and ii) on the value of $E_g$. Theoretical DFT calculations are known to often underestimate $E_g$ and they seem to give[37] different results from experiments[61, 62] for the energy alignment of graphene’s Dirac point with the TMDC bands. Therefore we performed our calculations for two parameter sets, one relying on DFT calculations[63], and one extracted from ARPES measurements[61, 62]. With the exception of Fig. 1(b), the results obtained from two parameter sets qualitatively agree.

The results for the $\vartheta_R + \theta$ vs $\theta$ dependence for two selected TMDCs, MoS$_2$ and WSe$_2$, are shown in Figs. 1(b) and (c), respectively. In the case of MoS$_2$, using the DFT parameter set, one can see that $\vartheta_R + \theta$ remains in a limited range around $\pi$ as $\theta$ varies from 0 to $\pi/3$ (Fig. 1(b)). However, if parameters extracted from ARPES measurements[61] are used then $\vartheta_R + \theta$ covers the entire range [0, 2$\pi$]. For WSe$_2$ one finds that $\vartheta_R + \theta$ covers all of [0, 2$\pi$] (Fig. 1(c)) regardless of which parameters are used. The difference between the results for the two materials can be mainly traced back to the different energy alignment of the Dirac point in the TMDC band gap. One can also note in Figs. 1(b,c) that for $\theta = l\pi/6$, $l = 0, 1, \ldots$ one finds $\vartheta_R + \theta = n\pi$, where $n$ is an integer. We give a detailed discussion of how this result for $\vartheta_R + \theta$ follows from our theoretical method in Ref. [59], but already note at this point that for $\theta = l\pi/6$ the vertical mirror planes of the graphene and the TMDC lattice line up and the system, as a whole, has $C_{3v}$ symmetry. In this case the Hamiltonian of the induced Rashba SOC reads $H_R = (-1)^n \lambda_R(\theta) / 2 (\tau_z \sigma_x s_y - \sigma_y s_x)$, hence $H_R$ simplifies to the form used previously in the literature[37, 50]. We find that $n$ can be, in general, both odd and even (see Figs. 1(b),(c)), which means that $\lambda_R(\theta)$ can acquire a negative sign as $\theta$ is changed. Interestingly, when $\vartheta_R + \theta \neq n\pi$, the spin-orbit field $s(q) = (\langle \hat{s}_x \rangle, \langle \hat{s}_y \rangle, \langle \hat{s}_z \rangle)^T$ is not tangential to the Fermi surface as in the case of usual Rashba SOC (cf. Fig. 1(e) and Figs. 1(f),(g)). Instead, one can show that the in-plane component $(\langle \hat{s}_x \rangle, \langle \hat{s}_y \rangle)^T$ is rotated by an angle $\vartheta_R + \theta$ with respect to the tangential direction. As we will discuss, this might have consequences on the interpretation of experimental results.

Twisted TMDC/graphene/TMDC trilayers Adding another TMDC layer, as shown in Fig. 1(d), introduces...
a second interlayer twist angle and the two twist angles $\theta^{(b)}$ and $\theta^{(t)}$ for the bottom and top TMDC layers allow an even broader control of the induced SOC in graphene. Since the layers are only weakly coupled, the effective graphene Hamiltonian is $H_{\text{orb}} + H_{\text{soc}}^{(t)} + H_{\text{soc}}^{(b)}$, where $H_{\text{soc}}^{(t,b)} = H_{\text{soc}}^{(t)} + H_{\text{soc}}^{(b)}$ and $H_{\text{soc}}^{(t,b)} = H_{\text{soc}}^{(t)} - H_{\text{soc}}^{(b)}$. Note, that the contributions $H_{\text{soc}}^{(b)}$ and $H_{\text{soc}}^{(t)}$ have a different sign. As a simple physical explanation, consider the case when the two TMDC layers are perfectly aligned, e.g., $\theta^{(b)} = \theta^{(t)}$. Then the graphene layer is a horizontal mirror plane of the whole stack, which dictates that the Rashba SOC must vanish. (A more microscopic argument is given in Ref.[59].) One can define the complex Rashba coefficient for the trilayer system (tls) by

$$\lambda^{(tls)}_R = \lambda^{(b)}_R e^{i(\theta^{(b)} + \theta^{(t)})} - \lambda^{(t)}_R e^{i(\theta^{(t)} + \theta^{(b)})},$$

(2)

and its magnitude $|\lambda^{(tls)}_R| = |\lambda^{(tls)}_R|$ and phase $\vartheta^{(tls)} = \text{Arg} \left[\lambda^{(tls)}_R\right]$. In terms of these quantities the induced Rashba type SOC can be written as $H^{(tls)}_R = \frac{\lambda^{(tls)}_R}{2} e^{i\vartheta^{(tls)}} (\tau_x \sigma_x s_y - \sigma_y s_x) e^{-i\vartheta^{(tls)}}$. The importance of this phase $e^{i(\vartheta^{(b,t)})}$ discussed for bilayers becomes now more clear: it follows from Eq. (2) that the strength $\lambda^{(tls)}_R$ of the induced Rashba SOC in trilayer stacks can be affected by quantum interference effects if $\theta^{(b)} + \theta^{(t)}$ and/or $\vartheta^{(t)} + \vartheta^{(b)}$ are non-zero. This can be interpreted as an interference of the virtual hopping processes to the two TMDC layers that give rise to the induced Rashba SOC. Calculations for the twist angle dependence of $\lambda_R$ have already been performed in Refs. [47, 48], therefore we do not show these results here, see Ref. [59] for further details. The results of our numerical calculations for $H^{(tls)}_R$ are summarized in Figs. 2(a)-(d). Firstly, symmetries that are broken in bilayers can be restored in trilayers for certain $\theta^{(b)}$ and $\theta^{(t)}$ angles. If $|\theta^{(b)} - \theta^{(t)}| = l\pi / 3$ with an odd integer $l$, the trilayer stack is inversion symmetric, while for an even $l$, the mirror symmetry of the stack is restored. Therefore the induced Rashba SOC must vanish for any integer $l$, as it can be seen in Figs. 2(a),(b). For WSe$_2$ encapsulation (Fig. 2(a)) the maximum of $\lambda^{(tls)}_R$ is found for $|\theta^{(b)} - \theta^{(t)}| = (2l + 1)\pi / 6$. The maximum value of $\lambda^{(tls)}_R$ is around 70% larger than in the graphene/WSe$_2$ case. Thus, double-sided encapsulation can significantly enhance the induced Rashba SOC. Surprisingly, when using MoS$_2$ for double encapsulation (Fig. 2(b)), we find that $\lambda^{(tls)}_R$ basically cannot be enhanced above the value obtained for one sided proximity effect. This can be understood by considering the explicit dependence of $\lambda^{(b,t)}_R$ on $\theta^{(b,t)}$, see Ref. [59] for details. The origin of the extended regions where $\lambda^{(tls)}_R$ is very small is due to the fact that for those twist angles $\lambda_R$ and $\vartheta_R$ change slowly in both layers and therefore they approximately cancel in Eq. (2). In Figs. 2(c,d) we show the phase $\vartheta^{(tls)}$ of Eq. (2), which determines the winding of the SOC field $s(q)$ in the case of double encapsulation. The apparent diagonal lines correspond to $\lambda^{(tls)}_R = 0$ where $\vartheta^{(tls)}$ is not defined.

For completeness, we also discuss the twist angle dependence of the induced valley Zeeman SOC in TMDC/graphene/TMDC trilayers, see Figs. 2(e,f). The strength of the valley-Zeeman type SOC is simply given by $\lambda^{(vZ)}_R = \lambda^{(b)}_R (\theta^{(b)} + \lambda^{(t)}_R (\theta^{(t)})).$ If the two TMDC layers are (nearly) aligned, they can double the strength of the induced valley Zeeman SOC. When the whole stack has inversion symmetry, the effect of the two layers cancel and $\lambda^{(vZ)}_R = 0$. The valley Zeeman SOC also vanishes along the paths $\theta^{(b)} + \theta^{(t)} = \pi / 3, \pi$, this is a combined effect of time reversal and three-fold rotation symmetry of the TMDC layers. We also note that $\lambda^{(vZ)}_R$ depends sensitively on what kind of TMDC is used in the stacks. The difference between the effects of WSe$_2$ (Fig. 2(e)) and MoS$_2$(Fig. 2(f)) is mainly due to the different alignment of graphene’s Dirac point with the TMDC bands. The calculations shown in Fig. 2, together with Eq. (2) are the main results of this work.

Experimental predictions Several recent works [26, 28, 29] measured an anisotropy of the out-of-plane $\tau_\perp$ and in-

![FIG. 2. a) and b) $\lambda^{(tls)}_R$ for MoS$_2$ and WSe$_2$ two-sided encapsulation. c) and d) the angle $\vartheta^{(tls)}$ for MoS$_2$ and WSe$_2$ two-sided encapsulation. e) and f) $\lambda^{(vZ)}_R$ for MoS$_2$ and WSe$_2$ two-sided encapsulation. plane $\tau_\parallel$ spin lifetimes in graphene/TMDC heterostructures which can be interpreted as direct proof of induced SOC in graphene. Namely, according to the theoretical calculations of Ref.\[39\], if there is a strong intervalley scattering in graphene, then the ratio of the spin lifetimes is given by $\tau_\perp/\tau_\parallel = (\lambda_{vZ}/\lambda_R)^2(\tau_\parallel/\tau_p) + 1/2$, where $\tau_\parallel$ ($\tau_p$) is the intervalley (momentum) scattering time. Let us consider a WSe$_2$/graphene/WSe$_2$ heterostructure and assume that $\theta^{(i)}$ is kept fixed while $\theta^{(t)}$ is changed. Note, that the ratio $\lambda_{vZ}/\lambda_R$ can be tuned in a wider range in trilayer structures than in bilayers. For example, $\lambda_R$ is never zero for graphene/TMDC whereas one can choose $\theta^{(b)}$ and $\theta^{(t)}$ such that $\lambda_{vZ}^{(tls)} \neq 0$ and $\lambda_R^{(tls)} = 0$, see Figs. 2(a),(e). Using $\tau_\parallel/\tau_p \approx 5$ as in Ref.\[39\], we plot $\tau_\perp/\tau_\parallel$ as a function of $\theta^{(t)}$ for $\theta^{(b)} = 0^\circ$ and $\theta^{(b)} = 30^\circ$ in Fig. 3(a). When $\theta^{(b)} \neq 0$ then $\lambda_R^{(tls)} \approx 0$ but $\lambda_{vZ}^{(tls)}$ is finite, therefore $\tau_\perp/\tau_\parallel$ diverges as a function of $\theta^{(t)}$. In contrast, if $\theta^{(b)} = 30^\circ$ then $\tau_\perp/\tau_\parallel$ remains finite for all $\theta^{(t)}$ angles. This dramatic difference in the $\theta^{(t)}$ dependence of $\tau_\perp/\tau_\parallel$ is clearly a consequence of the wider tunability of $\lambda_{vZ}^{(tls)}/\lambda_R^{(tls)}$ in trilayers. One can expect that charge-to-

spin conversion measurements should also be affected by the interlayer twist. Let us consider a graphene/TMDC bilayer and for simplicity assume that i) $\lambda_{vZ} \ll \lambda_R$ and ii) a dc electric field is applied along the $\hat{x}$ direction. In steady state the $\hat{y}$ component of the spin density is given by $\langle S_y \rangle = \frac{1}{2} \int 4\pi \theta \langle s_\parallel(q) \delta f_q \rangle$ where $\delta f_q$ is the deviation of the quasiparticle distribution with respect to equilibrium. Using the semiclassical argument given in Ref.\[41\], for Fermi energies close to the Dirac point $E_D$ such that $|E_F - E_D| < \lambda_R(\theta)$, i.e., when there is a single Fermi surface, one finds that $\langle S_y \rangle \propto \cos(\theta + \theta)$. This suggests that the Rashba-Edelstein effect (REE) may vanish (when $\theta + \theta = (2l + 1)\pi/2$) even though $\lambda_R(\theta)$ is not required to be zero by symmetry for any $\theta$. $\langle S_y \rangle$ can also change sign as a function of the interlayer twist angle, because $\theta + \theta \in [0, 2\pi]$, see Figs. 1(b),(c). Regarding the more realistic situation when there are two spin-polarized Fermi surfaces in graphene for $|E_F - E_D| > \lambda_R$, looking at Figs. 1(e,f,g) one can understand that $\langle S_y \rangle$ can be zero as a function of twist angle in this case as well. Furthermore, in twisted TMDC/graphene/TMDC trilayers, the REE can vanish either because $\lambda_R^{(tls)} = 0$ or because $\theta^{(tls)} = (2l + 1)\pi/2$, which can be expressed compactly as $\text{Re}(\lambda_R^{(tls)}) = 0$. As an example, the region where this condition is fulfilled in the ($\theta^{(t)}, \theta^{(b)}$) space for WSe$_2$/graphene/WSe$_2$ trilayers is shown in Fig. 3(b).

While the spin-lifetime anisotropy measurements require diffuse samples, in Figs. 3 (c)-(d) we show an example of how strong SOC can affect ballistic transport properties. Highly transparent np and nnp junctions in graphene have recently been realized in several experiments\[65–70\] and Fabry-Perrot type interference measurements\[69, 70\]. Assume now that a TMDC/graphene/TMDC trilayer is tuned with interlayer twist angles such that the Rashba SOC is switched off and simultaneously the valley Zeeman SOC enhanced. We calculate the conductance\[59\] through a smooth graphene nnp junction[71] as a function of out-of-plane magnetic field $B_z$ and Fermi energy $E_F$ for $\lambda_{vZ} = 2.6$meV, see Fig. 3(c). One can observe that for $|B_z| > 0.3T$ the high-conductance ridges are split. This is apparent in Fig. 3(d), where we compare the cases when $\lambda_{vZ} = 0$ (blue) and $\lambda_{vZ} = 2.6$meV (orange) for a fixed magnetic field $B_z = 0.436T$. Our calculations also indicate that the Rashba type SOC does not have a similar effect on the conductance ridges (not shown). An additional experimental probe of the twist angle dependent SOC may be the measurement of the reflection of electrons at a planar junction, which is briefly discussed in Ref.\[59\].

Summary We found that the induced Rashba type SOC in twisted hexagonal bilayers can be parameterized by the strength $\lambda_R$ and a spin-rotation angle $\theta_R$. This latter can lead to interference effects for $\lambda_R$ in trilayer heterostructures. We also calculated the valley Zeeman SOC in twisted TMDC/graphene/TMDC trilayers. Finally, we discussed how the interlayer twist angle dependence of the induced SOC can be deduced from spin-lifetime anisotropy, charge-to-spin conversion and magnetotransport measurements.

In this work we have neglected possible lattice relaxation in vdW heterostructures\[72\]. An important future
direction would be to study its effect on the results presented here.

Acknowledgments We acknowledge helpful conversations with Péter Makk and Jaroslav Fabian. I. SYMMETRY PROPERTIES OF THE PHASE $\vartheta_R$

In order to be self-contained and to set the stage, in Sec. IA and IB we carefully re-derive previous results of Ref. [1] for the Hamiltonian $H_R^{gr}$ which describes the proximity induced Rashba SOC in graphene. We then present two short, but important discussions. First, in Sec. IC we argue that the sign of the SOC coupling $\lambda_{bd}$ depends on the layer stacking order and this is important in trilayer stacks. Next, in Sec. ID we discuss the effects of the interlayer twist on $H_R^{gr}$. Our most important results in this section follow in Sec. IE. We prove that the results for the quantum phase $\vartheta_R$ simplify for interlayer twist angles $\theta = 0, \pi/6, \pi/3$, where the bilayer stack has $C_{3v}$ symmetry. Finally, in Sec. IF we give a further discussion of the results obtained in Sec. IE.

A. Preliminaries

1. Lattice vectors

Both graphene and the TMDC layer have hexagonal lattices. We define the lattice vectors $a_1 = \frac{\sqrt{3}}{2} (1, \sqrt{3})^T$, $a_2 = \frac{\sqrt{3}}{2} (1, -\sqrt{3})^T$ (see Fig. 1(a)) and the corresponding primitive reciprocal lattice vectors $b_1 = \frac{2\pi}{a} (1, 1/\sqrt{3})^T$, $b_2 = \frac{2\pi}{a} (1, -1/\sqrt{3})^T$. Here $a = a_{gr}, (a = a_{tmdd})$ is the lattice constant for graphene (TMDC). We will distinguish the reciprocal lattice vectors $b_{1,2}$ of graphene from the TMDC ones by using the notation $b_{1,2}^\tau$ for the latter. The position of the $A$ and $B$ sublattice in the unit cell is given by $t_A = \frac{2\pi}{a} (1, 1/\sqrt{3})^T$, $t_B = \frac{2\pi}{a} (1, -1/\sqrt{3})^T$. The metal (chalcogen) atoms occupy a position corresponding to the $A$ ($B$) sublattice in the unit cell of the TMDC.

2. Formalism to calculate the induced SOC

As it was shown in Ref[1], an important contribution to the proximity induced Bychkov-Rashba type SOC in graphene comes from virtual interlayer tunneling processes to the TMDC layer. In third order perturbation theory it is given by

$$\langle H_R^{gr} \rangle_{X,b,s,s'} = \sum_{j,b',s'',s'''} \frac{(T(\tau k_j^b))^j_{X,b,s''}(H_{soc})_{bs'',b's'''}(T^\dagger(\tau k_j^b))_{b's''',X',s'}}{[E_{D}^{gr} - E_{bd}^{soc}(\tau k_j^b)][E_{D}^{gr} - E_{bd}^{soc}(\tau k_j^b)]}.$$  \hspace{1cm} (1)

Here $X = \{A, B\}$ runs over sublattice indices of graphene, $s, s'$ are spin indices and $b \neq b'$ are band indices running over the bands of the (isolated) TMDC layer. Spin-flip process can be facilitated by certain off-diagonal elements of the intrinsic SOC matrix of the monolayer TMDC denoted by $(H_{soc})_{bs,b's''}$. The spin-flip off-diagonal matrix elements are allowed between pairs of bands $b, b'$ if one of the bands is symmetric (even) and the other one is antisymmetric (odd) with respect to reflection on the horizontal mirror plane of the TMDC (see, e.g., Ref. [2] for further discussion of the SOC in monolayer TMDCs).

We assume that the TMDC layer is rotated with respect to the TMDC layer by a twist angle $\theta$. Therefore, as indicated in Fig. 1(b), the BZ of graphene is also rotated. For each interlayer twist angle $\theta$ the right-hand side of Eq. (1) needs to be evaluated for wavenumbers $\tau k_j^b$ in the TMDC Brillouin zone (see Fig. 1(b)) that are determined by quasimomentum conservation condition $\tau K^\theta + G^\theta = k' + G'$, such that $|\tau K^\theta + G^\theta| = |K^\theta|$. Here $\tau K^\theta, \tau = \pm 1$ denote the wavevector to the Dirac point of graphene and $G^\theta$ and $(G')$ are reciprocal lattice vectors of graphene (TMDC). As indicated in Fig. 1(b), for each $\tau K^\theta$ there are three wavevectors $\tau k_j^b$ and corresponding reciprocal lattice vectors $G_j^\theta$ and $G_j'^\theta$ that satisfy the quasimomentum conservation condition. These $\tau k_j^b$ vectors are related by $2\pi/3$ rotations. Explicitly, one finds $G_{1,2,3}^\theta = -b_2^\theta, -b_1^\theta, 0$ and $G_{1,2,3}'^\theta = -b_2', -b_1', b_1'$. $E_{bd}^{soc}(\tau k_j^b)$ denote TMDC bands energies and $E_{D}^{gr}$ is the energy of the Dirac point of graphene. $(T(\tau k_j^b))_{X,s,b,s'}$ is the tunneling matrix between Bloch states at $\tau K^\theta$ to states at $\tau k_j^b$. We assume spin-independent tunneling and therefore $(T(\tau k_j^b))_{X,s,b,s'}$ is diagonal in the spin space. $(T(\tau k_j^b))_{X,s,b,s'}$ can be written as

$$\langle H_{orb}\rangle |\Psi^{(b)}_{tmdd}(k_j^b, r)\rangle = e^{i\pi G_j^\theta \cdot t_b(\tau k_j^b)} e^{i\pi G_j'^\theta \cdot t_b(\tau k_j^b)}.$$  \hspace{1cm} (2)
Here $H_{\text{orb}}$ is the orbital part of the Hamiltonian of the system (without the SOC), $\Psi^{(X)}(K_{1}^{\prime},r)$ and $\Psi_{tmdc}(K_{1}^{\prime},r)$ are Bloch wavefunctions of graphene and of band $b$ of the TMDC layer, respectively. A possible lateral shift of the graphene lattice with respect to the TMDC lattice is denoted by $r_0$. We take, for simplicity, $r_0 = 0$ because this choice does not affect our results. The phase $\phi_{j}^{X}$ is defined as $\phi_{j}^{X} = t_{X} \cdot G_{j}$.

The tunneling amplitude $t_{b}(\tau k'_{j})$ to band $b$ of the TMDC can be written as

$$t_{b}(\tau k'_{j}) = e^{-i\tau G_{j} \cdot x_{b}^{(t)}} t_{b}^{p}(\tau k'_{j}) + e^{-i\tau G_{j} \cdot x_{o}^{(t)}} t_{b}^{d}(\tau k'_{j}),$$

(3)

where $t_{b}'$ ($t_{o}'$), $X \neq X'$ is the vector pointing to the chalcogen (metal) atom position in the unit cell of the TMDC layer, and $t_{b}^{p}(\tau k'_{j})$ describes the interlayer tunneling between graphene and the $p$ orbitals of the chalcogen and $d$ orbitals of the metal) atoms. The calculation of the amplitude $t_{b}^{p,d}(\tau k'_{j})$ in terms of materials dependent parameters will be discussed in Sec. II A.

FIG. 1: a) Real space orientation of the hexagonal lattice and the primitive lattice vectors $a_1$, $a_2$. b) The rotated BZ and Dirac points $K^{\theta}$ of graphene, along with the wavenumbers $k_{1}^{\prime}$ in the BZ of the TMDC. As $\theta$ changes in the range $[0, \pi/3]$, the $k_{1}^{\prime}$ trace out the arcs shown by dashed lines. c) Reflection planes of the hexagonal BZ, $R_{x}^{(1,2,3)}$ is relevant for both graphene and the TMDC, $R_{d}^{(1,2,3)}$ only for graphene.

$$(H_{\text{soc}})_{bs,b's'}$$ denote the matrix elements of the spin-orbit coupling operator $\hat{H}_{\text{soc}}$ between Bloch wavefunctions corresponding to bands $b$ and $b'$ of the monolayer TMDC. For our purposes the matrix elements between an even $\Psi_{tmdc}^{(e)}(\tau k'_{j},r)$ and an odd $\Psi_{tmdc}^{(o)}(\tau k'_{j},r)$ Bloch states are important and they can be written as

$$H_{e,o}(\tau k'_{j}) = (\Psi_{tmdc}^{(e)}(\tau k'_{j},r)|\hat{H}_{\text{soc}}|\Psi_{tmdc}^{(o)}(\tau k'_{j},r)) = i\lambda_{soc} \left[ \alpha_{e,o}^{(x)}(\tau k'_{j}) s_{x} + \alpha_{e,o}^{(y)}(\tau k'_{j}) s_{y} \right].$$

(4)

Here $\lambda_{soc}$ characterizes the strength of the intrinsic SOC in the TMDC layer. $\hat{H}_{\text{soc}} \sim \hat{L}_{x} \hat{S}_{x} + \hat{L}_{y} \hat{S}_{y} + \hat{L}_{z} \hat{S}_{z}$ are angular momentum operators, $\hat{L}_{\pm} = \hat{L}_{x} \pm i\hat{L}_{y}$, $\hat{S}_{x,y,z} = \hbar \hat{s}_{x,y,z}$ are spin operators and the Pauli matrices $s_{x,y,z}$ act on the spin degree of freedom. The complex numbers $\alpha_{e,o}^{(x)}(\tau k'_{j})$ are defined as

$$i \alpha_{e,o}^{(x)}(\tau k'_{j}) = (\Psi_{tmdc}^{(e)}(\tau k'_{j},r)|\hat{L}_{z}|\Psi_{tmdc}^{(o)}(\tau k'_{j},r)),$$

(5a)

$$i \alpha_{e,o}^{(y)}(\tau k'_{j}) = (\Psi_{tmdc}^{(e)}(\tau k'_{j},r)|\hat{L}_{y}|\Psi_{tmdc}^{(o)}(\tau k'_{j},r)).$$

(5b)

One can make use of the fact that the $\tau k'_{j}$ vectors are related by $2\pi/3$ rotations, which is also a symmetry of the TMDC lattice. Following Ref. [3] one may write $\Psi_{tmdc}^{(e/o)}(R_{z}^{\pm 2\pi/3}\tau k'_{j},r) = R_{z}^{\pm 2\pi/3}\Psi_{tmdc}^{(e/o)}(\tau k'_{j},r)$ where $R_{z}^{\pm 2\pi/3}$ denotes rotation by $\pm 2\pi/3$. Substituting this into Eq. (4) and taking into account that

$$R_{z}^{2\pi/3} \hat{L}_{z}^{(R_{z}^{2\pi/3})} = e^{i2\pi/3} \hat{L}_{z},$$

one finds

$$H_{e,o}(\tau k'_{j}) = i\lambda_{soc} \begin{pmatrix} 0 & \alpha_{e,o}^{(+)}(\tau k'_{j}) e^{-i(j-1)2\pi/3} \\ \alpha_{e,o}^{(-)}(\tau k'_{j}) e^{-i(j-1)2\pi/3} & 0 \end{pmatrix},$$

(6)

where $\alpha_{e,o}^{(\pm)}(k'_{j}) = \alpha_{e,o}^{(x)}(\tau k'_{j}) \pm i\alpha_{e,o}^{(y)}(\tau k'_{j})$. 
B. Derivation of $\vartheta_R$ and $\lambda_R$

It is instructive to consider the contribution of a single pair of $b = e$ and $b' = o$ bands in Eq. (1). Using Eq. (2), one finds

$$
(H_{R}^{gr})_{e,o} = \sum_j \left( \frac{1}{e^{-i(\phi_j^e - \phi_j^o)}} e^{i\tau(\phi_j^e - \phi_j^o)} \right) \otimes \left[ \frac{[t_{e,o}^x(\tau k'_j) H_{e,o}(\tau k'_j) + t_{o,e}^x(\tau k'_j) H_{o,e}(\tau k'_j)]}{[E_D^{gr} - E_{tmdc}(\tau k'_j)][E_D^{gr} - E_{tmdc}^{tmdc}(\tau k'_j)]} \right] 
$$

$$
= \sum_j M_j(\tau \phi_j^e, \tau \phi_j^o) \otimes \left[ \frac{[t_{e,o}^x(\tau k'_j) H_{e,o}(\tau k'_j) + t_{o,e}^x(\tau k'_j) H_{o,e}(\tau k'_j)]}{[E_D^{gr} - E_{tmdc}(\tau k'_j)][E_D^{gr} - E_{tmdc}^{tmdc}(\tau k'_j)]} \right] 
$$ (7)

As explained in Sec. IA, the phases $\phi_j^{A,B}$ in $M_j(\tau \phi_j^A, \tau \phi_j^B)$ are defined as $\phi_j^{A,B} = t_{A,B} \cdot G_j$. There are a number of possible choices for the vectors $t_{A,B}$ and for the primitive reciprocal lattice vectors $b_{1,2}$ of graphene, and the latter determine $G_j$. For a given $j$ the phase $\phi_j^{A,B}$ depends on these choices, but in general $\phi_j^{A,B} \in \{0, 2\pi/3, -2\pi/3\}$. The different choices lead to unitary equivalent $M_j(\tau \phi_j^A, \tau \phi_j^B) = U(\tau)M_j(\tau \phi_j^A, \tau \phi_j^B)U^\dagger(\tau)$ matrices and hence unitary equivalent $(H_R^{gr})_{e,o}$ Hamiltonians. Importantly, $U(\tau)$ does not depend on the geometric twist angle $\theta$. Using Sec. IA 1, the $M_j$ matrices read

$$
M_j(\tau \phi_j^A, \tau \phi_j^B) = \left( \frac{1}{e^{-i(\pi/2)j}} e^{i\tau \pi j} \right). 
$$ (8)

Furthermore, $H_{e,o}(\tau k'_j) = [H_{e,o}(\tau k'_j)]^\dagger$, $t_{e,o}(\tau k'_j) = t_{e,o}(\tau k'_j) \tau t_{e,o}^*(\tau k'_j)$, and $t_{o,e}(\tau k'_j) = t_{o,e}(\tau k'_j) \tau t_{o,e}^*(\tau k'_j)$. We define $\eta(\tau k'_j) = \text{Arg}[t_{e,o}(\tau k'_j)]$ mod $\pi$ and, as it will be explained in more detail in Sec. IC, the index $\mu = 0, 1$ gives the sign of the induced Rashba SOC which depends on the layer stacking. Because of the $C_3$ symmetry of the system, $t_{e,o}(\tau k'_j)$ does not depend on the index $j$ and from time reversal symmetry follows that $t_{e,o}(-k'_j) = t_{e,o}^*(k'_j)$. Therefore, by taking into account Eq. (6),

$$
t_{e,o}(\tau k'_j) H_{e,o}(\tau k'_j) + t_{e,o}^*(\tau k'_j)[H_{e,o}(\tau k'_j)]^\dagger = 2i\lambda_{soc}[t_{e,o}(\tau k'_j)] \left( \begin{array}{cc} 0 & \Lambda_{e,o}(\tau k'_j) e^{i(j-1)\pi/3} \\ -\Lambda_{e,o}(\tau k'_j)^* e^{i(j-1)\pi/3} & 0 \end{array} \right), 
$$ (9)

where $\Lambda_{e,o}(\tau k'_j) = \text{Im}[e^{i\eta(\tau k'_j)} \alpha_{e,o}(\tau k'_j)] + i\text{Im}[e^{i\eta(\tau k'_j)} \alpha_{o,e}(\tau k'_j)]$. One can show that $\Lambda_{e,o}(\tau k'_j) = \tau \Lambda_{e,o}(k'_j)$ and one may write $\Lambda_{e,o}(k'_j) = |\Lambda_{e,o}(k'_j)| e^{i\hat{\vartheta}_{e,o}(k'_j)}$, where

$$
\hat{\vartheta}_{e,o}(k'_j) = \text{Arg}[\Lambda_{e,o}(k'_j)] = \text{Arctan} \left( \frac{\text{Im}[e^{i\eta(\tau k'_j)} \alpha_{e,o}(\tau k'_j)]}{\text{Im}[e^{i\eta(\tau k'_j)} \alpha_{o,e}(\tau k'_j)]} \right) + m\pi, \quad m = 0, \pm 1, \pm 2 \ldots 
$$ (10)

Here $\text{Im}[\ldots]$ denotes the imaginary part. $\hat{\vartheta}_{e,o}(k'_j)$ is a quantum phase which depends on i) the phase $\eta(k'_j)$ of the interlayer tunneling amplitude between the Bloch states of graphene and the TMD layer and ii) on off-diagonal matrix elements of the induced SOC of the TMD layer defined in Eq. (4).

Due to $C_3$ symmetry, the denominator of Eq. (7) is the same for all $j$ and because of time reversal symmetry it does not depend on $\tau$. Therefore the denominator can be pulled out of the summation. Substituting Eqs. (8) and (9) into Eq. (7) and performing the summation over $j$ one finds

$$
(H_{R}^{gr})_{e,o} = \lambda_{R,(e,o)}(k'_j) e^{i\frac{\pi}{2} \vartheta_{e,o}(k'_j)} \left( \begin{array}{ccc} 0 & 0 & 0 \\ 0 & 0 & i\frac{\pi+1}{2} \\ -i\frac{\pi+1}{2} & 0 & 0 \end{array} \right) e^{-i\frac{\pi}{2} \vartheta_{e,o}(k'_j)}. 
$$ (11)

Here we defined

$$
\vartheta_{e,o}(k'_j) = \hat{\vartheta}_{e,o}(k'_j) + 2\pi/3, 
$$ (12)
and $\lambda_{R,(e,o)}(\mathbf{k}'_1)$ is given by[1]

$$
\lambda_{R,(e,o)}(\mathbf{k}'_1) = (-1)^\mu 6\lambda_{soc}|t_{e,o}(\mathbf{k}'_1)||\Lambda_{e,o}(\mathbf{k}'_1)|\left[\frac{E_D^e - E_{tmdc}(\mathbf{k}'_1)}{E_D^o - E_{tmdc}(\mathbf{k}'_1)}\right].
$$

(13)

Using the $\tau_z$ Pauli matrix, one may rewrite Eq. (11) in a more compact form:

$$
(H^g_R)_{e,o} = -\frac{\lambda_{R,(e,o)}(\mathbf{k}'_1)}{2} e^{i\theta_{e,o}(\mathbf{k}'_1)} (\tau_z\sigma_x s_y + \sigma_y s_z) e^{-i\frac{\pi}{2}\theta_{e,o}(\mathbf{k}'_1)}.
$$

(14)

Note, that in the derivation of Eqs. (12)-(14) we only made use of time reversal symmetry and that the $\mathbf{k}'_j$ vectors are related by $2\pi/3$ rotations. Therefore these results are valid for arbitrary interlayer twist angle $\theta$. On the other hand, we considered the contribution of a single pair of $e$ and $o$ bands of the TMDC to the induced Rashba type SOC. As Eq. (1) shows, one needs to sum over all $q$ pairs of $(e,o)$ bands and one may define the complex Rashba SOC coupling by

$$
\bar{\lambda}_R = \sum_q \lambda_{R,(e,o)_q} e^{i\theta_{(e,o)_q}}.
$$

(15)

In terms of its magnitude $\lambda_R(\mathbf{k}'_1) = |\bar{\lambda}_R(\mathbf{k}'_1)|$ and phase $\vartheta_R(\mathbf{k}'_1) = \text{Arg}[\bar{\lambda}_R(\mathbf{k}'_1)]$, the Hamiltonian of the induced Rashba SOC can be written as

$$
H^g_R = -\frac{\lambda_R(\mathbf{k}'_1)}{2} e^{i\vartheta_R(\mathbf{k}'_1)} (\tau_z\sigma_x s_y + \sigma_y s_z) e^{-i\frac{\pi}{2}\vartheta_R(\mathbf{k}'_1)}.
$$

(16)

Note, that both $\lambda_R(\mathbf{k}'_1)$ and $\vartheta_R(\mathbf{k}'_1)$ depend implicitly on $\theta$ through $\mathbf{k}'_1$, as shown in Fig. 1. We will discuss the $\theta$ dependence of $\vartheta_R$ in more detail in Sec. 1E.

C. Staking order dependent sign of $\lambda_R$

In our theory the sign of $\lambda_R$ depends on the stacking order of the graphene and the TMDC layers, i.e., whether is graphene below or above the TMDC layer. Such a sign has no physical significance in TMDC/graphene bilayer stacks, but it is important in TMDC/graphene/TMDC trilayers, because it means that the contributions of the two TMDC layers to the induced Rashba SOC add up with an opposite sign.

As explained below Eq. (8), the induced Rashba SOC is a second order process in interlayer tunneling. The tunneling amplitude is given by $t_{e,o}(\tau\mathbf{k}'_j) = t_e(\tau\mathbf{k}'_j)t_o(\tau\mathbf{k}'_j)$, i.e., it depends on the product of the tunneling amplitudes to an $e$ and to an $o$ band of the TMDC. $\Psi^{(e)}_{tmdc}(\mathbf{r})$ of an $e$ band of the TMDC is even with respect to the mirror plane that contains the metal atoms of the TMDC layer. However, the graphene $p_z$ orbitals have a different sign above and below the graphene layer. Therefore one can expect that the matrix element given in Eq. (2) between the graphene Bloch wavefunction $\Psi^{gr}_{e}(\mathbf{r})$ and $\Psi^{(e)}_{tmdc}(\mathbf{r})$ should have a global sign difference depending on the stacking order of the two layers, i.e., whether the graphene layer is above or below the TMDC layer. This sign difference is described by the index $\mu = 0, \pm 1$ introduced below Eq. (8). On the other hand, similar consideration suggests that the sign of the amplitude $t_o(\tau\mathbf{k}'_j)$ between $\Psi^{gr}(\mathbf{r})$ and $\Psi^{(o)}_{tmdc}(\mathbf{r})$ does not depend on the stacking order. The stacking order dependence of $t_e(\tau\mathbf{k}'_j)$ and $t_o(\tau\mathbf{k}'_j)$ can be explicitly seen if they are calculated using the two-center Slater-Koster parametrization of the corresponding transfer integrals, see Refs.[1, 4] for details.

D. Effects of the interlayer twist

$H^g_R$ in Eq. (16) was obtained in the $x'-y'$ coordinate system of the TMDC layer (see Fig. 2), where the matrix elements of $\tilde{H}_{soc}$ were evaluated. Our choice of reciprocal lattice vectors leads to $H^g_{orb} = v_F(\tau_z\sigma_x\delta k_x - \sigma_y\delta k_y)$ for the orbital Hamiltonian of graphene in the $x-y$ coordinate system, where $\delta k = (\delta k_x, \delta k_y)$ is a small wavevector measured from the $\tau\mathbf{K}$ point. In the $x'-y'$ system $H^g_{orb}$ is given by $H^g_{orb,\theta} = e^{-i\tau_z\frac{\pi}{2}\theta} H^g_{orb} e^{i\tau_z\frac{\pi}{2}\theta}$. The total effective Hamiltonian of graphene is therefore

$$
H^g_{eff,\theta} = e^{-i\tau_z\frac{\pi}{2}\theta} H^g_{orb} e^{i\tau_z\frac{\pi}{2}\theta} + H^g_{R} + H^g_{vZ},
$$

(17)
FIG. 2: Schematics of a twisted graphene/TMDC bilayer with twist angle θ and the coordinate systems $x - y$ and $x' - y'$.

where we have also taken into account the valley-Zeeman induced SOC, which is described by

$$H_{vZ}^{gr} = \lambda_{vZ} \tau_z s_z.$$  \hspace{1cm} (18)

One may perform a unitary transformation $e^{i\tau_z \sigma_z \theta / 2} H_{eff}^{gr} e^{-i\tau_z \sigma_z \theta / 2}$. This transformation leaves $H_{vZ}$ unchanged and one finds

$$H_{eff}^{gr} = H_{orb}^{gr} + e^{i\tau_z \sigma_z \theta / 2} H_R^{gr} e^{-i\tau_z \sigma_z \theta / 2} + H_{vZ}^{gr}.$$  \hspace{1cm} (19)

It is convenient to perform another unitary transformation $H_{eff}^{gr} \rightarrow \sigma_x H_{eff}^{gr} \sigma_x$. This changes the orbital Hamiltonian $v_F(\tau_z \sigma_x \delta k_x - \sigma_y \delta k_y) \rightarrow v_F(\tau_z \sigma_x \delta k_x + \sigma_y \delta k_y)$, leaves $H_{vZ}^{gr}$ unchanged, and transforms the Rashba Hamiltonian to

$$\sigma_x e^{i\tau_z \sigma_z \theta / 2} H_R^{gr} e^{-i\tau_z \sigma_z \theta / 2} \sigma_x = -\frac{\lambda_R(k'_1)}{2} e^{-i\tau_z \sigma_z \theta / 2} e^{i\tau_z \sigma_z \theta / 2} (\tau_z \sigma_x s_y - \sigma_y s_x) e^{-i\tau_z \sigma_z \theta / 2} \sigma_x e^{i\tau_z \sigma_z \theta / 2}.$$  \hspace{1cm} (20)

Eq. (20) shows more explicitly the effects of interlayer rotation on the graphene Rashba Hamiltonian $\tilde{H}_R^{gr} = \frac{\lambda_R}{2} (\tau_z \sigma_x s_y - \sigma_y s_x)$ derived previously in Refs. [5, 6]: i) $\tilde{H}_R^{gr}$ is rotated in real space by $\theta$, an ii) if $\theta_R \neq 2m\pi$, $m$ integer, then a rotation in spin-space appears.

E. Calculation of $\vartheta_R$ for $\theta = 0$, $\theta = \pi/6$ and $\theta = \pi/3$ twist angles

The calculations of Sec. 1B are valid for arbitrary interlayer twist angle $\theta$. For $\theta_l = l\pi/6$, $l = 0, 1, 2 \ldots$, the graphene/TMDC bilayer has a higher, $C_{3v}$ symmetry, which implies further constraints on the form of $H_R^{gr}$. By calculating $\vartheta_{e,o}(k'_1)$ defined in Eq. (12) for $\theta = 0, \pi/6, \pi/3$ explicitly, we show how the results of Sec. 1B are simplified in this case.

1. $\theta = 0$ twist angle

In Fig. 3 we show the wavevectors $k'_{1,2,3}$ that satisfy the quasimomentum conservation as well as the three reflection planes $R_{1,2,3}$ that the system possess in addition to the $C_3$ symmetry. First, we will derive a useful relation for the tunneling amplitude $t_{e,o}(k'_1) = t_e(k'_1)t_o(k'_1)$, defined below Eq. (8).
Using the definition $t_{e,o}(k'_1)$ given in Eq. (2) and denoting $K^{θ=0}_1 = K^{(0)}_1$, consider the following:

$$t_{e,o}(K'_1)e^{-iφ^X} = \langle \Psi^{(X)}_{gr}(K^{(0)}_1, r)|H_{orb}|\Psi^{(e,o)}_{tmdc}(K'_1, r)\rangle = \langle (H_{orb}\Psi^{(e,o)}_{tmdc}(K'_1, r))^{*}|(\Psi^{(X)}_{gr}(K^{(0)}_1, r))^{*}\rangle$$

$$= \langle H_{orb}\Psi^{(e,o)}_{tmdc}(K'_1, r)\rangle^{*}\Psi^{(X)}_{gr}(K^{(0)}_1, r)\rangle^{*} = \langle H_{orb}\Psi^{(e,o)}_{tmdc}(-K'_1, r)|\Psi^{(X)}_{gr}(-K^{(0)}_1, r)\rangle$$

$$= \langle H_{orb}\Psi^{(e,o)}_{tmdc}(K'_1 - b'_1, r)|\Psi^{(X)}_{gr}(R^{(1)}_v K^{(0)}_1, r)\rangle$$

$$= \langle R^{(2)}_v H_{orb}\Psi^{(e,o)}_{tmdc}(K'_1 - b'_1, r)|\Psi^{(X)}_{gr}(R^{(1)}_v K^{(0)}_1, r)\rangle$$

$$= \langle H_{orb}\Psi^{(e,o)}_{tmdc}(K'_1 - b'_1, r)|\Psi^{(X)}_{gr}(R^{(1)}_v K^{(0)}_1, r)\rangle$$

$$\langle \Psi^{(X)}_{gr}(K^{(0)}_1, r)|H_{orb}|\Psi^{(e,o)}_{tmdc}(K'_1, r)\rangle e^{iω^X} = t^{*}_{e,o}(K'_1)e^{iφ^X}e^{iω^X}e^{-iω^{(e,o)}}. \quad (21)$$

Here we have made use of i) time reversal symmetry when assuming $H_{orb}^{*} = H_{orb}$, ii) $R^{(2)}_v = (R^{(2)}_v)^{-1}$, and iii) $R^{(2)}_v$ is a symmetry of the system therefore $R^{(2)}_v H_{orb} = H_{orb} R^{(2)}_v$. Moreover, Bloch wavefunctions at equivalent wavenumbers can differ at most by a phase factor, i.e., $|\Psi^{(X)}_{gr}(K^{(0)}_1 - b^{(0)}_1, r)\rangle = |\Psi^{(X)}_{gr}(K^{(0)}_1, r)\rangle e^{iω^X}$ and $|\Psi^{(e,o)}_{tmdc}(K'_1 - b'_1, r)\rangle = |\Psi^{(e,o)}_{tmdc}(K'_1, r)\rangle e^{iω^{(e,o)}}$. From Eq. (21) one finds that

$$t_{e,o}(K'_1) = t_{e}(K'_1)t^{*}_{o}(K'_1) = t^{*}_{e,o}(K'_1)e^{-iω^{(e)}} e^{iω^{(o)}}. \quad (22)$$

A similar relation can be derived for the matrix elements of $\tilde{H}_{soc}$, namely, for $\langle \Psi^{(e)}(K'_1, r)|L_{±}|\Psi^{(o)}(K'_1, r)\rangle$:

$$\langle \Psi^{(e)}(K'_1, r)|L_{±}|\Psi^{(o)}(K'_1, r)\rangle = \langle (L_{±}\Psi^{(o)}(K'_1, r))^{*}|(\Psi^{(e)}(K'_1, r))^{*}\rangle = -\langle L_{±}\Psi^{(o)}(-K'_1, r)|\Psi^{(e)}(-K'_1, r)\rangle$$

$$= -\langle L_{±}\Psi^{(o)}(R^{(2)}_v K'_1 - b'_1, r)|\Psi^{(e)}(R^{(2)}_v K'_1 - b'_1, r)\rangle$$

$$= -\langle L_{±}\Psi^{(o)}(R^{(2)}_v K'_1 - b'_1, r)|\Psi^{(e)}(R^{(2)}_v K'_1 - b'_1, r)\rangle$$

$$= e^{±iφ^X} e^{iω^{(e)}} \langle L_{±}\Psi^{(o)}(K'_1 - b'_1, r)|\Psi^{(e)}(K'_1 - b'_1, r)\rangle$$

$$= e^{±iφ^X} \langle L_{±}\Psi^{(o)}(K'_1 - b'_1, r)|\Psi^{(e)}(K'_1 - b'_1, r)\rangle e^{iω^{(e)}} e^{-iω^{(o)}}. \quad (23)$$

FIG. 3: The BZ of graphene (purple) and of the TMDC (orange), along with $k'_1,2,3$ vectors and the reflection planes $R^{1,2,3}_v$ for $θ = 0$. 

[Text continues on page 7]
In terms of $\alpha_{e,o}^{(\pm)}(k'_1)$, introduced after Eq. (6), Eq. (23) means that

$$\alpha_{e,o}^{(\pm)}(k'_1) = -e^{\mp i2\pi} [\alpha_{e,o}^{(\pm)}(k'_1)] e^{i\omega_{k'_1}^{(e)}} e^{-i\omega_{k'_1}^{(o)}}. $$

Therefore,

$$\alpha^{(x)}_{e,o}(k_1) = \frac{1}{2} \left( \alpha^{(+)}_{e,o}(k'_1) + \alpha^{(-)}_{e,o}(k'_1) \right) = -\frac{1}{2} \left( e^{-i2\pi} [\alpha^{(+)}_{e,o}(k'_1)]^* + e^{i2\pi} [\alpha^{(-)}_{e,o}(k'_1)]^* \right) e^{i\omega_{k_1}^{(e)}} e^{-i\omega_{k_1}^{(o)}}$$

$$= -\frac{1}{2} \left( \frac{1}{\sqrt{3}} \right) \left( \left( \alpha^{(+)}_{e,o}(k'_1) \right)^* - i\frac{\sqrt{3}}{2} \left( \left( \alpha^{(-)}_{e,o}(k'_1) \right)^* - \left( \alpha^{+}(k'_1) \right)^* \right) \right) e^{i\omega_{k_1}^{(e)}} e^{-i\omega_{k_1}^{(o)}},$$

(24a)

$$\alpha^{(y)}_{e,o}(k_1) = \frac{1}{2i} \left( \alpha^{(+)}_{e,o}(k'_1) - \alpha^{(-)}_{e,o}(k'_1) \right) = -\frac{1}{2i} \left( e^{-i2\pi} [\alpha^{(+)}_{e,o}(k'_1)]^* - e^{i2\pi} [\alpha^{(-)}_{e,o}(k'_1)]^* \right) e^{i\omega_{k_1}^{(e)}} e^{-i\omega_{k_1}^{(o)}}$$

$$= -\frac{1}{2i} \left( \frac{1}{\sqrt{3}} \right) \left( \left( \alpha^{(+)}_{e,o}(k'_1) \right)^* - \left( \alpha^{(-)}_{e,o}(k'_1) \right)^* \right) - i\frac{\sqrt{3}}{2} \left( \left( \alpha^{+}(k'_1) \right)^* + \left( \alpha^{-}(k'_1) \right)^* \right) e^{i\omega_{k_1}^{(e)}} e^{-i\omega_{k_1}^{(o)}}.$$  (24b)

Eqs. (24) can be written as

$$\begin{pmatrix} \alpha^{(x)}_{e,o}(k'_1) \\ \alpha^{(y)}_{e,o}(k'_1) \end{pmatrix} = \frac{1}{2} \begin{pmatrix} 1 & \sqrt{3} \\ 1 & -1 \end{pmatrix} \begin{pmatrix} \alpha^{(x)}_{e,o}(k'_1) \\ \alpha^{(y)}_{e,o}(k'_1) \end{pmatrix} e^{i\omega_{k_1}^{(e)}} e^{-i\omega_{k_1}^{(o)}},$$

(25)

One now calculate $\theta_{e,o}(k'_1)$ for $\theta = 0$. First, combining Eq. (22) and Eq. (25) one arrives at

$$t_{e,o}(k'_1) \begin{pmatrix} \alpha^{(x)}_{e,o}(k'_1) \\ \alpha^{(y)}_{e,o}(k'_1) \end{pmatrix} = -\frac{1}{2} \begin{pmatrix} 1 & \sqrt{3} \\ 1 & -1 \end{pmatrix} \begin{pmatrix} \alpha^{(x)}_{e,o}(k'_1) \\ \alpha^{(y)}_{e,o}(k'_1) \end{pmatrix} R^2_{\theta}.$$  (26)

This means that $\text{Im} \left[ t_{e,o}(k'_1) \alpha^{(x)}_{e,o}(k'_1) \right] = -\frac{1}{2} \text{Im} \left[ t_{e,o}(k'_1) \alpha^{(y)}_{e,o}(k'_1) \right]$ for $\theta = 0$. Regarding Eq. (12), one finds from Eq. (20) that for $\theta = 0$

$$H^\theta_{R} = (-1)^m \frac{\lambda_3(k'_1)}{2} (\tau_2 s_x s_y - s_y s_x).$$

2. $\theta = \pi/6$ twist angle

Graphene has two, inequivalent sets of vertical reflection planes, see Fig. 1. For $\theta = \pi/6$, the $R^{(1,2,3)}_{\theta}$ set aligns with the TMDC's $R^{(1,2,3)}_\nu$ reflection planes, therefore the stack again has $C_{3v}$ symmetry.

We denote the three wavevectors in the BZ of the TMDC that satisfy the quasimomentum conservation by $k'_{1,2,3}$, see Fig. 4. As one can see, the $k'_j$ vectors now lie on the $\Gamma-M$ lines of the BZ of the TMDC. Let us consider the matrix element $\langle \Psi^{(e)}(k'_1, r) | L_{\pm} | \Psi^{(o)}(k'_1, r) \rangle$.

$$\langle \Psi^{(e)}(k'_1, r) | L_{\pm} | \Psi^{(o)}(k'_1, r) \rangle = \langle \Psi^{(e)}(k'_1, r) | (R^{(3)}_\nu)^{\dagger} R^{(3)}_\nu L_{\pm} (R^{(3)}_\nu)^{\dagger} | \Psi^{(o)}(k'_1, r) \rangle$$

$$= \langle \Psi^{(e)}(k'_1, r) | R^{(3)}_\nu R^{(3)}_\nu L_{\pm} (R^{(3)}_\nu)^{\dagger} | \Psi^{(o)}(k'_1, r) \rangle$$

$$= \langle \Psi^{(e)}(k'_1, r) | R^{(3)}_\nu L_{\pm} (R^{(3)}_\nu)^{\dagger} | \Psi^{(o)}(k'_1, r) \rangle$$

$$= e^{\pm i\frac{\pi}{6}} \langle \Psi^{(e)}(k'_1, r) | L_{\pm} | \Psi^{(o)}(k'_1, r) \rangle,$$  (28)

where we made use of $R^{(3)}_{\nu} L_{\pm} (R^{(3)}_{\nu})^\dagger = e^{\pm i\frac{\pi}{3}} L_{\mp}$ and that $R^{(3)}_{\nu} k'_1 = k'_1$. In terms of $\alpha^{(\pm)}_{e,o}(k'_1)$, Eq. (28) can be rewritten as $\alpha^{(\pm)}_{e,o}(k'_1) = e^{-i\frac{\pi}{6}} \alpha^{(\mp)}_{e,o}(k'_1)$. Therefore,

$$\alpha^{(x)}_{e,o}(k'_1) = \frac{1}{2} \left( \alpha^{(+)}_{e,o}(k'_1) + \alpha^{(-)}_{e,o}(k'_1) \right) = \frac{1}{2} \left( 1 + e^{-i\frac{\pi}{3}} \right) \alpha^{(+)}_{e,o}(k'_1),$$

(29a)

$$\alpha^{(y)}_{e,o}(k'_1) = \frac{1}{2i} \left( \alpha^{(+)}_{e,o}(k'_1) - \alpha^{(-)}_{e,o}(k'_1) \right) = \frac{1}{2i} \left( 1 - e^{-i\frac{\pi}{3}} \right) \alpha^{(+)}_{e,o}(k'_1).$$  (29b)
FIG. 4: The BZ of graphene (purple) and of the TMDC (orange), along with \( \tilde{k}_{1,2,3}' \) vectors and the reflection planes \( R_{v}^{1,2,3} \) for \( \theta = \pi/6 \).

It follows that \( \alpha_{e,o}^{(y)}(\tilde{k}_1') = \sqrt{3} \alpha_{e,o}^{(x)}(\tilde{k}_1') \). Regarding Eq. (10), one finds Arctan \( \frac{\text{Im}[e^{i\eta(\tilde{k}_1')}]}{\text{Im}[e^{i\eta(\tilde{k}_1')}] + \text{Re}[e^{i\eta(\tilde{k}_1')}] + 1} = \frac{\pi}{6} \), and from Eq. (12) \( \vartheta_{e,o}(\tilde{k}_1') = \frac{\pi}{6} + m'\pi = (m' + 1)\pi - \pi/6 \).

3. \( \theta = \pi/3 \) twist angle

We again denote the three wavevectors in the BZ of the TMDC that satisfy the quasimomentum conservation by \( \tilde{k}_{1,2,3}' \), see Fig. 5. Note, that \( \tilde{k}_1' \) is related to \( \tilde{k}_1 \) in the \( \theta = 0 \) case by \( \tilde{k}_1' = R_{v}(3)\tilde{k}_1 \) and the \( K^{(\pi/3)} \) point of graphene is given by \( -K^{(0)} + b_1 \). This can be used to calculate the amplitude \( t_{e,o}(\tilde{k}_1') \) and \( \alpha_{e,o}^{(\pm)}(\tilde{k}_1') \). Similarly to Eq. (21), one may write

\[
\begin{align*}
t_{e,o}(\tilde{k}_1')e^{-i\phi_X} & = \langle \Psi_{gr}^{(X)}(K^{(\pi/3)}, r) | H_{\text{orb}} | \Psi_{\text{tmcd}}^{(e,o)}(\tilde{k}_1', r) \rangle \\
& = \langle \Psi_{gr}^{(X)}(-K^{(0)} + b_1, r) | H_{\text{orb}} | \Psi_{\text{tmcd}}^{(e,o)}(R_{v}(3)\tilde{k}_1', r) \rangle \\
& = \langle \Psi_{gr}^{(X)}(-K^{(0)} + b_1, r) | H_{\text{orb}} | \Psi_{\text{tmcd}}^{(e,o)}(R_{v}(3)\tilde{k}_1', r) \rangle \\
& = \langle \Psi_{gr}^{(X)}(-K^{(0)} + b_1, r) | H_{\text{orb}} | \Psi_{\text{tmcd}}^{(e,o)}(\tilde{k}_1', r) \rangle \\
& = \langle \Psi_{gr}^{(X)}(R_{v}(3)^{-1}(K^{(0)} + b_1), r) | H_{\text{orb}} | \Psi_{\text{tmcd}}^{(e,o)}(\tilde{k}_1', r) \rangle \\
& = \langle \Psi_{gr}^{(X)}(K^{(0)} - b_1, r) | H_{\text{orb}} | \Psi_{\text{tmcd}}^{(e,o)}(\tilde{k}_1', r) \rangle \\
& = t_{e,o}(\tilde{k}_1')e^{-i\phi_X} e^{-i\omega_X}. \quad (30)
\end{align*}
\]
This means that \( t_{e,o}(\tilde{k}_1) = t_e(\tilde{k}_1)t_o(\tilde{k}_1) = t_e(k_1)t_o(k_1) = t_{e,o}(k_1) \). Regarding the matrix elements of \( \hat{H}_{soc} \), one finds

\[
\langle \psi^{(e)}(\tilde{k}_1, r)|L_\pm|\psi^{(o)}(\tilde{k}_1, r)\rangle = \langle \psi^{(e)}(R_v^{(3)}k_1, r)|L_\pm|\psi^{(o)}(R_v^{(3)}k_1, r)\rangle = e^{\pm i\frac{2\pi}{3}} \langle \psi^{(e)}(k_1, r)|L_\pm|\psi^{(o)}(k_1, r)\rangle = e^{\pm i\frac{2\pi}{3}} \langle \psi^{(e)}(k_1, r)|L_\pm|\psi^{(o)}(k_1, r)\rangle
\]

(31)

Here we have used \([R_v^{(3)}]|L_\pm R_v^{(3)} = e^{\pm i\frac{2\pi}{3}} L_\mp\). Performing analogous calculations as in Eqs. (24), one finds

\[
t_{e,o}(\tilde{k}_1) \left( \begin{array}{c} \alpha^{(x)}_{e,o}(\tilde{k}_1) \\ \alpha^{(y)}_{e,o}(\tilde{k}_1) \end{array} \right) = \frac{1}{2} \left( \begin{array}{cc} -1 & \sqrt{3} \\ \sqrt{3} & 1 \end{array} \right) \left( \begin{array}{c} \alpha^{(x)}_{e,o}(k_1) \\ \alpha^{(y)}_{e,o}(k_1) \end{array} \right) t_{e,o}(k_1).
\]

(32)

One can now easily calculate \( \vartheta_{e,o}(\tilde{k}_1) \). Using Eq. (32)

\[
\text{Im}[t_{e,o}(\tilde{k}_1)\alpha^{(x)}_{e,o}(\tilde{k}_1)] = -\frac{1}{2} \text{Im}[t_{e,o}(k_1)\alpha^{(x)}_{e,o}(k_1)] + \frac{\sqrt{3}}{2} \text{Im}[t_{e,o}(k_1)\alpha^{(y)}_{e,o}(k_1)].
\]

(33)

However, in Sec. IE1 we found that \( \text{Im}[t_{e,o}(k_1)\alpha^{(x)}_{e,o}(k_1)] = \sqrt{3} \text{Im}[t_{e,o}(k_1)\alpha^{(y)}_{e,o}(k_1)] \), which means that \( \text{Im}[t_{e,o}(\tilde{k}_1)\alpha^{(y)}_{e,o}(\tilde{k}_1)] = 0 \) and from Eq. (12) \( \vartheta_{e,o}(\tilde{k}_1) = 2\pi/3 + m''\pi = (m'' + 1)\pi - \pi/3 \).

**F. Discussion of the results of Sec. IE**

Similar calculations to those in Sec. IE1-IE3 can be performed for all interlayer twist angles \( \theta_l = l\pi/6 \), \( l = 0, 1, 2, \ldots \). We now summarize the most important findings.

- One finds that \( \vartheta_{e,o}(\theta_l) \) can be expressed as \( \vartheta_{e,o}(\theta_l) = m(\theta_l)\pi - \theta_l \), where \( m(\theta_l) \) is an integer.

- The results of Sec. IE1-IE3 were obtained for an arbitrary pair of \( e \) and \( o \) bands. This means, that using Eq. (15) one finds \( \vartheta_R(\theta_l) = m(\theta_l)\pi - \theta_l \).

- According to Eq. (20), the non-zero matrix elements of \( H^{gr}_R \) are \( \propto \lambda_R(\theta) e^{\pm i(\theta + \vartheta_R)} \). For \( \theta = \theta_l \) one finds that these matrix elements are \( \lambda_R(\theta_l)(-1)^m(\theta_l) \). This means that for interlayer twist angles where the \( C_{3v} \) symmetry of the stack is restored, the Hamiltonian of the induced Rashba SOC simplifies to

\[
H^{gr}_R = (-1)^{m(\theta_l)} \frac{\lambda_R(\theta_l)}{2} (\tau_z \sigma_x s_y - \sigma_y s_x),
\]

(34)

which is, apart from the sign \((-1)^{m(\theta_l)}\), the well-known result of Refs. [5, 6]. This shows our results are in agreement with general expectations based on the symmetry of the system.

- For twist angles \( \theta \in (\theta_l, \theta_{l+1}) \), i.e., when the stack has only \( C_3 \) symmetry, \( \vartheta_R \) is a continuous function of \( \theta \) (through the wavenumbers \( k'_1 \)). Therefore the matrix elements \( \lambda_R(\theta) e^{\pm i(\theta + \vartheta_R)} \) of \( H^{gr}_R \) are complex numbers.

- One would expect that \( \lambda_R(\theta) = \lambda_R(\theta + 2\pi/3) \). As shown in Figs. 7(b) and 8(b) below, we find that \( \lambda_R(\theta) = \lambda_R(\theta + \pi/3) \). Note, that Eq. (1) gives the lowest order non-vanishing contribution. We expect that higher order contributions in the perturbation series, albeit small in magnitude, would lead to \( 2\pi/3 \) periodicity.

**II. DETAILS OF THE NUMERICAL CALCULATIONS FOR \( \vartheta_R, \lambda_R \) AND \( \lambda_{xZ} \)**

In this section we discuss questions related to the choice of material and other parameters in our numerical calculations and compare some of our results to corresponding results in Ref. [1].
A. Interlayer tunneling parameters

In Ref. [1] it was argued that for the description of the tunneling between the monolayer graphene (MLG) sheet and the MoS$_2$ layer it is sufficient to consider only the $p$ orbitals of the metal atoms. Namely, the $d$ orbitals are farther away from the carbon atoms of MLG and therefore their overlap with the carbon $p_z$ orbitals should be small. We have extended the calculations of Ref. [1] by taking into account contributions from tunneling processes involving the $d$ orbitals of the metal atoms as well. The results shown in the main text have been obtained in this way.

As already mentioned in Sec. I A, the tunneling matrix $(T(\tau k'_j))_b$ can be written as

$$ (T(\tau k'_j))_b = t_b(\tau k'_j)e^{i\tau \phi^b_\alpha} \begin{pmatrix} e^{i\tau \phi^A_\alpha} \\ e^{i\tau \phi^B_\alpha} \end{pmatrix}. $$

When only the $p$ orbitals are considered in the interlayer tunneling, then the interlayer tunneling amplitude $t^b_p(\tau K^0, \tau k'_j) \equiv t^b_p(\tau k'_j)$ between the $K^0$ point of graphene and electronic states at wavenumber $k'_j$ in band $b$ of the TMDC is given by

$$ t^b_p(\tau k'_j) = i\tau [c_{bz}(\tau k'_j) \cos \theta + c_{by}(\tau k'_j) \sin \theta] t^b_\parallel + c_{bz}(\tau k'_j) t^b_\perp. \quad (35) $$

Here $c_{bz}(\tau k'_j)$, $c_{by}(\tau k'_j)$ and $c_{bz}(\tau k'_j)$ are the complex amplitudes of the $p_x$, $p_y$ and $p_z$ orbitals of the chalcogen atoms at the BZ point $k'_j$ in band $b$ of the TMDC. As it was shown in Ref. [1], $t^b_p(\tau k'_{2,3}) = t^b_p(\tau k'_1)$. According to Eq. (35), two independent tunneling coefficients are needed: $t^b_\parallel$ and $t^b_\perp$, and Ref. [1] obtained them from a fitting procedure using previous results [7] of DFT band structures calculations for MLG/TMDC heterostructures. The values of these parameters were estimated to be $t^b_\parallel \approx 70 \approx 100$ meV.

Considering now the $d$ orbitals of the TMDC metal atoms one can derive a similar expression for the tunneling amplitude $t^d_b(\tau k'_j)$ between MLG and the $d$ orbitals:

$$ t^d_b(\tau k'_{2,3}) = t^d_b(\tau k'_1) = (c_{b,x^2-y^2}(\tau k'_1) \cos(2\theta) + c_{b,xy}(\tau k'_1) \sin(2\theta)) t^d_\parallel + i\tau (c_{b,xz}(\tau k'_1) \cos(\theta) + c_{b,yz}(\tau k'_1) \sin(\theta)) t^d_\perp + c_{b,z^2-r^2}(\tau k'_1) t^d_\perp. \quad (36) $$

Here $c_{b,d}(\tau k'_1)$ ($d = \{x^2-y^2, xy, xz, yz, 3z^2-r^2\}$) are the complex amplitudes of the $d$ orbitals of the TMDC metal atoms at the BZ point $k'_1$ in band $b$. The derivation of Eq (36) involves the same steps as that of Eq. (35) and therefore we do not give further details here. As one can see, $t^d_b(\tau k'_1)$ involves three more overlap parameters: $t^d_\perp$, $t^d_\parallel$, and $t^d_\perp$. Therefore there are altogether five transfer integrals parameters that describe the overlap between graphene’s $p_z$ orbitals and the $p$, $d$ orbitals of the TMDC layer. The approach used in Ref. [1] to estimate $t^d_\parallel$ and $t^d_\perp$ is not applicable to estimate all five transfer integrals parameters.

Therefore we used the Slater–Koster method to re-calculate the tunneling coefficients both for the chalcogen $p$ orbitals and the $d$ orbitals of the metal atoms. The steps needed to calculate $t^d_\parallel$, $t^d_\perp$, $t^d_\parallel$, and $t^d_\perp$ in terms of the set of parameters of the Slater–Koster method are explained in Refs. [1, 4]. We only note that the parametrization of the transfer integrals is based on the Harrison’s model [8] and the numerical values of the necessary parameters, with the exception of $\eta_{C-Se}$, are listed in Refs. [4], see Eqs(4), (5) therein. All our calculations for MLG/MoS$_2$ are based on the parameters given in Ref. [4].

However, for the calculations for MLG/WSe$_2$ we also needed the Harrison’s model parameter $\eta_{C-Se}$. We have fixed its value in the following way. We took the values $\lambda_{\nu Z}$ and $\lambda_R$ of the induced valley Zeeman and Rashba SOC from Ref. [7], where they were obtained by fitting band structure calculations of graphene/WSe$_2$ heterostructures at $\theta = 0$ twist angle. Using the methodology of Ref. [1] to calculate $\lambda_{\nu Z}$ and $\lambda_R$, we adjusted the value of $\eta_{C-Se}$ such that we obtain a reasonable agreement with Ref. [7], for $\theta = 0$. We found that $\eta_{C-Se} = 0.748$ minimizes the deviation to $\approx \pm 20\%$ between our results for $\lambda_{\nu Z}$, $\lambda_R$ and those of Ref. [7].

TABLE I: Tunneling coefficients
To summarize, we used tunneling coefficients shown in Table I. Regarding the $t^p$ coefficients for MoS$_2$, they are indeed not very different from those estimated in Ref. [1] ($\approx 100$ meV) using a different method, but the sign of $t^p_t$ is opposite to the one given in Ref. [1]. This can be traced back to the fact that the TB model of Ref.[9] uses a different orientation of the TMDC lattice with respect to Ref. [1]. This gave rise to an overlooked $\mathbf{k} \rightarrow -\mathbf{k}$ transformation in reciprocal space, which resulted in a sign change in the estimation of the tunneling parameter. One can also see that the values of the $t^d$ coefficients are indeed much smaller than $t^p$ and $t^p_L$. On the other hand, the complex amplitude factors $c_{b,xz-y^2}$, $c_{b,xy}$, $c_{b,xz}$, $c_{b,yz}$, and $c_{b,3z^2-r^2}$ turn out to be significantly larger than $c_{b,x}$, $c_{b,y}$ and $c_{b,z}$ in large regions of the BZ. Therefore $t^d_b(\tau \mathbf{k}_f')$ is found to be small, but non-negligible with respect to $t^p_b(\tau \mathbf{k}_f')$.

B. Further parameters

In addition to $t_b(\tau \mathbf{k}_f')$, there are a couple of further parameters that enter the numerical calculations. We will briefly discuss them here.

- The value of the band gap $E_g$ of the TMDC.
  As briefly discussed in the main text, one can take its value either from experiments (when available) or from previous theoretical works. Regarding the latter, since we use the TMDC TB model of Ref. [9] to calculate the band structure, the spin-orbit coupling Hamiltonian matrix elements and the interlayer tunneling amplitude, we also used the $E_g$ of this model. (We implemented the TB model in the Kwant code[10]). Although the model of Ref. [9] itself is based on DFT calculations, the value of $E_g$ is different from what one can extract from the calculations of Ref. [7] that were performed for MLG/TMDC supercells at $\theta = 0$. For example, in the case of MoS$_2$ the model of Ref. [9] has a band gap that is 17% larger than the corresponding $E_g$ given in Ref. [7]. See Table II for the $E_g$ values used in this work.

- The position of the Dirac point of graphene within the the band gap of the TMDC.
  We describe the energy of the Dirac point of graphene in the band gap of the TMDC by a number $f_G \in [0,1]$. Its value is a linear function of the position of the Dirac point in the TMDC band gap. When $f_G = 0$, the Dirac point is aligned with the TMDC valence band edge, for $f_G = 1$ the Dirac point has the same energy as the TMDC conduction band edge. When available, the value of $f_G$ can also be taken from experiments[11, 12]. See Table II for the $f_g$ values used in this work.

- The number of bands in the model for the TMDC layer.
  The explicit expression to calculate $\lambda_{\nu Z}$ involve a sum over contributions of individual bands. Similarly, in order to calculate $\vartheta_R$ and $\lambda_R$, one needs to sum over pairs of even (e) and odd (o) bands. Ref. [1] used the approximation that the conduction band (CB) and the valence band (VB) were taken into account for $\lambda_{\nu Z}$, and three pairs of e-o bands for $\lambda_R$. As it will be shown below, this already leads to qualitatively good results in most cases, see Sec. II C below. An exception is the value of $\lambda_R$ for $\theta \approx \pi/6$, where, due to band crossings and near-degeneracies of certain e bands, more pairs of e and o bands need to be taken into account. The TB model that we use involves 11 bands of the TMDC layer. Unless otherwise indicated, we use the contributions of all 11 bands to calculate $\lambda_{\nu Z}$, and 30 pairs of e and o bands for the $\vartheta_R$ and $\lambda_R$ calculations.

TABLE II: Band gap and MLG Dirac point energy position parameters from DFT calculation and experiments.

- The TB model of the TMDC
  We also note that the TB model of the TMDC appears to be less accurate for the bands above the band gap[9]. This can add further uncertainty to the results, especially in the case graphene/MoS$_2$, where
$f_G = 0.974$, i.e., the relative contributions of $e$-$o$ band pairs above $E_g$ is larger than the contribution coming from the valence bands.

These details, in addition to those already discussed in Sec. II A, also need to be considered when comparing our results to related previous works[1, 4, 7, 13].

C. Numerical calculations of the induced SOC in MLG/TMDC twisted bilayers

We now show our results for the twist angle dependence of $\lambda_{vZ}$ and $\lambda_R$ for graphene/MoS$_2$ and graphene/WSe$_2$. In the former case we also compare our results to those of Ref. [1]. For the numerical calculations of $\lambda_R$ we evaluated Eqs. (13) and (15). To calculate $\lambda_{vZ}$ we used the result of Ref. [1]:

$$\lambda_{vZ} = 3 \sum_b \left| t_b(k'_1) \right|^2 \frac{\Delta_{0,b}(k'_1)}{E^Z_b(k'_1) - \Delta^2_{0,b}(k'_1)}, \quad (37)$$

where $t_b(k'_1)$ is defined in Eq. (3) and the summation runs over all bands $b$ of the tight-binding model.

1. Comparison to the results of Ref. [1]

First, we briefly discuss how the tunneling parameters shown in Table I modify the results for tunneling amplitude $t_b$ compared to the corresponding results in Ref. [1]. In Fig. 6 we plot the tunneling strength $|t_c|^2$ and $|t_v|^2$ to the CB and VB of MoS$_2$ as a function of the twist angle $\theta$ using the parameters from Table I (solid lines). We also show the corresponding results of Ref. [1], where only $t^p \parallel \approx t^p \perp$ were non-zero.

![FIG. 6: Tunneling strength $|t_c|^2$ to the conduction band (light green) and to the valence band $|t_v|^2$ (blue) of monolayer MoS$_2$. The solid curves are the results of this work, the dashed curves are reproduced from Ref. [1].]

As one can see in Fig. 6, the present calculations tend to yield larger tunneling strengths. However, the twist angle dependence of $|t_c|^2$ and $|t_v|^2$ remain qualitatively the same.

In Fig. 7(a) we show calculations for $\lambda_{vZ}$ vs $\theta$ for graphene/MoS$_2$ using the DFT parameters for $E_g$ and $f_G$, see Table II. The dashed curve in Fig. 7(a) again corresponds to the result of Ref. [1], which uses the contributions of the CB and the VB only. The thin solid line is obtained using the tunneling amplitudes from Table I and only tunneling to the VB and the CB is taken into account. One can see a pronounced increase of $\lambda_{vZ}$ around $\theta = 18^\circ$ with respect to Ref. [1], which is mainly due to the larger tunneling strengths, as shown in Fig. 6. Nevertheless, the curves remain qualitatively very similar. The thick solid line shows the result that we obtain by using the tunneling amplitudes from Table I and taking into account tunneling to all 11 bands of the TB model. It is again qualitatively similar to the other two results, the most important change is the two new zero crossings close to $\theta = 30^\circ$. 
In Fig. 7(b) we show similar calculations for $\lambda_R$ vs $\theta$. The larger tunneling strength $t_b$ used in this work leads again to an enhancement of $\lambda_R$ (thin solid line) compared to Ref. [1] (dashed line), but the $\theta$ dependence of the two results otherwise agree, including the deep minimum at $\theta = 30^\circ$. However, if all possible $e$-$o$ pairs of bands are included in the calculation (thick solid line), then this minimum becomes a small dip and the value of $\lambda_R$ is significantly enhanced. As already mentioned, this is because of band crossings and near-degeneracies of certain $e$ bands which means that more pairs of $e$ and $o$ bands need to be taken into account than it was done in Ref. [1]. For comparison, in Fig. 7 we also indicate by red marks the results of the DFT calculations of Ref. [7] for $\theta = 0$. As one can see, all our curves take values close to these reference values. As we explained in Sec. IIB, the exact results depend on a number of details, including potentially fine-tuned Slater–Koster parameters. This leaves us with much freedom to adjust our parameters and fit previously published results, but this goes beyond the scope of this paper.

We found a qualitatively similar $\lambda_{vZ}$ and $\lambda_R$ vs $\theta$ dependence using the experimental parameters of $E_g$ and $f_G$ from Table II, but the maximum values of the induced SOC are significantly smaller.

2. Calculations for MLG/WSe$_2$

Our calculations for the twist angle dependence of $\lambda_{vZ}$ and $\lambda_R$ are shown in Fig. 8. We used the tunneling parameters given in Tables I and the DFT parameters in Table II. Contributions from all bands or pairs of bands of the TB model are taken into account. Red marks denote the results of Ref. [7] for $\theta = 0$, they differ $\approx 20\%$ from our results.
Importantly, one can see that both $\lambda_{vZ}(\theta)$ and $\lambda_R(\theta)$ are different from the MLG/MoS$_2$ heterostructures in Fig. 7. This is mainly due to the fact that the Dirac point of graphene is closer to the VB (we used $f_G = 0.161$ in these calculations versus $f_G = 0.976$ in Fig. 7, i.e., here the valence bands give larger contributions. Similarly to MLG/MoS$_2$, $\lambda_{vZ}$ and $\lambda_R$ vs $\theta$ dependence using the experimental parameters for $E_g$ and $f_G$ from Table II are qualitatively similar, but the maximum values of the induced SOC are significantly smaller.

**Comparison of MLG/MoS$_2$ and MLG/WSe$_2$**

The different $\theta$ dependence of the induced SOC for MLG/MoS$_2$ (Fig. 7) and MLG/WSe$_2$ (Fig. 8) explain the differences in the results for the corresponding twisted trilayer systems shown in Fig. 3 of the main text. We point out, in particular, that $\lambda_R$ has a single maximum for MLG/MoS$_2$, while it has two maxima for MLG/WSe$_2$. Together with the $\theta$ dependence of $\theta_R$ given in Fig. 1 of the main text, this can explain the finding that $\lambda_{R}^{(\text{tls})}$ can be enhanced for WSe$_2$/MLG/WSe$_2$, but not for MoS$_2$/MLG/MoS$_2$.

3. Comparison to the results of Refs. [14] and [13]

During the preparation of this manuscript, a preprint by Naimer et al. [14] has appeared discussing the twist angle dependence of the proximity-induced SOC in graphene/TMDC bilayers. Their methodology is based on DFT calculations. The incommensurate graphene/TMDC heterostructures were approximated by periodic supercells, which required several approximations, e.g., straining the graphene sheet.

In agreement with our results, the calculations of Ref. [14] indicate that the strength of the proximity induced SOC in graphene/TMDC heterostructures is tunable by interlayer twist. The twist angle dependence of $\lambda_{vZ}$ for graphene/MoS$_2$ and graphene/WSe$_2$ are qualitatively similar: in the former case there is a maximum at $\theta \approx 20^\circ$, in the latter case $\lambda_{vZ}$ monotonically decreases as $\theta$ is changed from 0$^\circ$ to 30$^\circ$. They also find that the phase factor $\theta_R$ in $H_R$ is in general non-zero and depends on the twist angle $\theta$. Regarding the $\theta$ dependence of $\lambda_{R}$ for graphene/MoS$_2$, their results seem to be qualitatively similar to ours, while for graphene/WSe$_2$ the results show differences. On a more quantitative level, however, our results for $\lambda_{vZ}$ and $\lambda_R$ display a much stronger enhancement as a function of $\theta$ than in Ref. [14]. The reasons for this discrepancy remains to be investigated in future works.

Another relevant recent work is by Pezo et al. [13], who performed supercell based DFT calculations for graphene/MoTe$_2$ bilayers for three different interlayer twist angles ($\theta = 0, \pi/12, \pi/6$). It was noted in Ref. [13] that the position of graphene’s Dirac point is closer to the valence band of MoTe$_2$. Therefore one would expect that the $\theta$ dependence of the induced SOC should be similar to the one in graphene/WSe$_2$, meaning, e.g., that magnitude of both $\lambda_{vZ}$ and $\lambda_R$ should decrease for $\theta = \pi/6$ compared to their $\theta = 0$ value. This seems to be in agreement with results of Ref. [13].

Finally, we note that both Refs. [14] and [13] emphasize the effect of the strain that is always present in their supercell based DFT calculations.

### III. MAGNETOTRANSPORT CALCULATIONS FOR GRAPHENE npn JUNCTIONS

In this section we briefly explain the theoretical model that was used in the magnetotransport calculations through a npn graphene junction with proximity induced SOC shown in Fig. 4 of the main text. We assume that the graphene flake is perfectly ballistic and due to external gates it is doped such that it hosts an npn junction, see Fig. 9. We numerically calculate the transmission through the junction as a function of perpendicular magnetic field magnetic field $B_z$ and Fermi energy $E_F$ using the in-house code EQuUs[15].

We use the nearest-neighbor tight-binding (TB) model of graphene:

$$\hat{H}_{\text{orb}} = \sum_{i,s} U_i \left( a_{i,s}^\dagger a_{i,s} + b_{i,s}^\dagger b_{i,s} - \gamma \sum_{\langle ij \rangle} e^{i\phi_{ij}} a_{i,s}^\dagger b_{j,s} + \text{h.c.} \right)$$  \hspace{1cm} (38)

where $a_{i,s}^\dagger$ ($a_{i,s}$) and $b_{i,s}^\dagger$ ($b_{i,s}$) are creation (annihilation) operators for electrons of spin $s$ on the A and B sublattice site, respectively. $\gamma = 2.97$ eV is the hopping amplitude between the nearest-neighbor atomic sites $\langle ij \rangle$ in the graphene lattice, $\phi_{ij}$ encodes the effect of perpendicular magnetic field through Peierls
FIG. 9: Schematics of an npn junction in graphene. The Dirac point of graphene is shifted in energy due to the doping potential $U(x)$ in the $n$ and $p$ doped regions. The length of the $n$ ($p$) doped region is $L_n$ ($L_p$). $E_F$ denotes the Fermi energy.

substitution, and $U_i$ is the on-site energy on the atomic site $i$. Following Ref. [16], we used

$$U(x) = U_n + \frac{U_p - U_n}{2} \left( \tanh \left[ \frac{x - L_n}{l_1} \right] - \tanh \left[ \frac{x - L_n - L_p}{l_2} \right] \right).$$

(39)

Here $L_n = 50$ nm gives the length of the $n$-doped regions and we used $U_n = -240$ meV. The $p$-doped middle region was $L_p = 150$ nm long and the doping was $U_p = 40$ meV. The parameters $l_1 = l_2 = 25$ nm set the smoothness of the transition between the $n$ and $p$-doped regions.

In the TB formalism the Bychkov-Rashba SOC can be written as[5, 17]:

$$H_R = i \frac{\lambda_R(\theta)}{3} e^{i \frac{\beta}{2} \varphi_R} \sum_{(i,j),s,s'} \left[ a^\dagger_{i,s} \left( s \times \hat{d}_{(i,j)} \right)_z b_{j,s'} - h.c. \right] e^{-i \frac{\varphi}{2} \varphi_R}.$$  

(40)

where $s = (s_x, s_y, s_z)$ are the Pauli matrices representing the electron spin operator. Moreover, $\hat{d}_{(i,j)} = d_{(i,j)}/d$ are unit vectors, where $d_{(i,j)}$ points from atom $j$ to its nearest neighbors $i$ and $d = |d_{(i,j)}|$. The corresponding continuum SOC Hamiltonian, that can be obtained by Fourier transforming Eq.(40) and expanding it at the $\pm K$ points of the Brillouin zone, reads $H_R = \frac{\lambda_R(\theta)}{2} e^{i \frac{\beta}{2} \varphi_R} (\tau_z \sigma_x s_y - \sigma_y s_x) e^{-i \frac{\varphi}{2} \varphi_R}$. As long as only a perpendicular magnetic field is applied, the phase $\varphi_R$ will not affect the results, because the corresponding terms in Eq. (40) can be removed by a unitary transformation.

The valley-Zeeman SOC can be written as[17]:

$$H_{vZ} = \frac{i}{3 \sqrt{3}} \sum_{(i,j),s,s'} \left[ \lambda_{vZ}^{(A)} \nu_{ij} [s_z |s_z] a^\dagger_{i,s} a_{j,s'} + \lambda_{vZ}^{(B)} \nu_{ij} [s_z |s_z] b^\dagger_{i,s} b_{j,s'} \right].$$  

(41)

It couples same spins and depends on clockwise ($\nu_{ij} = 1$) or counterclockwise ($\nu_{ij} = -1$) paths along a hexagonal ring from site $j$ to $i$. In the case of valley-Zeeman SOC $\lambda_{vZ}^{(A)} = -\lambda_{vZ}^{(B)}$. The term Eq.(41) can also describe the intrinsic SOC if the SOC strength $\lambda_I$ is the same on the two sublattices, i.e., $\lambda_I^{(A)} = -\lambda_I^{(B)}$. The corresponding continuum SOC Hamiltonian reads $H_{vZ} = \tau_z s_z \lambda_{vZ}$.

We used periodic boundary conditions perpendicular to the transport direction ($\hat{x}$ in Fig.9). Thus, the transverse momentum $q_n$ is a good quantum number and the total transmission can be calculated as a sum over all $q_n$:

$$T(E_F, B_z) = \sum_{n} t(q_n, E_F, B_z),$$  

(42)

where $t(q_n, E_F, B_z)$ is the transmission coefficient for mode $n$. When there are many transverse momenta the exact form of the boundary conditions is not important and therefore we used the infinite mass boundary condition[18] to obtain $q_n$: $q_n = (n + \frac{1}{2}) \frac{\pi}{W}$, where $n = 0, 1, 2, \ldots$ and $W$ is the width of the junction.
IV. ELECTRON SCATTERING AT A PLANAR JUNCTION IN A GRAPHENE-WSE$_2$ SYSTEM

We will discuss a further setup to investigate twist-angle dependent transport in a graphene-TMDC system. It is motivated by recent electron optics experiment of Ref.[19, 20] where collimated electron beams were created in monolayer graphene. By making use of such collimated electron beams one can test the twist-angle dependence of the induced SOC through spin-dependent scattering.

To demonstrate this, we consider the TMDC/MLG/TMDC stack shown in Fig. 10. It consists of a MLG/WSe$_2$ bilayer of a fixed twist angle $\theta(b)$ (purple region). Part of this bilayer is covered by a top WSe$_2$ layer (orange region) of twist angle $\theta(t)$. Thus the induced SOC in graphene changes at the bilayer-trilayer boundary and in the trilayer region it is assumed to be tunable by $\theta(t)$. The left edge of the top layer defines a junction along the $y$ axis, where ballistic electrons scatter into various forward-propagating and back-propagating modes, as indicated in Fig. 10. We calculate below the reflection coefficient of this junction for a collimated beam of electrons.

The general form of the Hamiltonian is $H^\text{gr eff} = H^\text{gr orb} + H^\text{gr R} + H^\text{gr vZ}$, see Sec. ID for the definition of each term. On the left-hand side of the junction $H^\text{gr R}$ is given in Eq. (20), with $\theta = \theta(b)$ and $\lambda_{vZ} = \lambda_v^{(b)}(\theta(b))$ in $H^\text{gr vZ}$. On the right hand side, as shown in the main text, the Rashba Hamiltonian is $H^\text{rash}(tls) = \frac{\lambda_R^{(tls)}}{\sqrt{2}} e^{-i \frac{\phi^{(tls)}}{2}} (\tau_z \sigma_y s_y - \sigma_y s_z) e^{-i \frac{\phi^{(tls)}}{2}}$, while $\lambda_{vZ} = \lambda_v^{(b)}(\theta(b)) + \lambda_v^{(t)}(\theta(t))$ in $H^\text{gr vZ}$. One can easily show that the reflection coefficient is the same for electrons in both valleys, for concreteness, we perform the calculation for the $K$ valley. We express the electronic states as plane waves multiplied by spinors in the basis $\{|A \uparrow\rangle, |B \uparrow\rangle, |A \downarrow\rangle, |B \downarrow\rangle\}$ and we assume that their energy is $E = 20 \text{meV}$. Due to translational symmetry along the $\hat{y}$ axis, the $\delta k_y$ component of the wavevector of the electronic states is conserved. The SOC leads to the splitting of the bands, therefore (at the $E_F$ given above) for each direction of propagation one can find two modes for the incoming electrons with slightly different wave vectors and opposite pointing spins. We assume a net zero spin polarization with an equal mixture of the two incoming modes, and for each incoming mode, one can find two reflected and two refracted solutions. In total this gives four back-scattered and four forward-scattered modes within one valley. Depending on the exact parameters and the angle of incidence, some of these modes can be decaying waves carrying no current. The particle current operator can be calculated as $J_x = \frac{i}{\hbar}[H, x] = \tau v_F s_0 \otimes \sigma_x$, and in a similar fashion, $J_y = v_F s_0 \otimes \sigma_y$. The ratio of the current carried by all the back-scattered waves and that of all the incoming modes give us the reflection.
coefficient:

\[
R = - \sum_{i=1}^{4} \langle J_{x,i}^{(\text{back})} \rangle \left/ \sum_{i=1}^{2} \langle J_{x,i}^{(\text{in})} \rangle \right.
\]  

(43)

In an experimental scenario one can never create a beam of electrons with an exact direction of propagation. Nevertheless, as shown in Refs.\[19, 20\] there are experimental techniques to collimate electrons in graphene from a source. In Ref \[19\] absorptive pinhole collimators were devised to collimate ballistic electrons into a triangular shaped angular distribution with a half width at half maximum (HWHM) of just below 10°; while in Ref \[20\] a cosine-shaped distribution was achieved with a similar HWHM of 9° using zigzag contacts to absorb stray electrons. Therefore we consider the effective reflection index \( R \) that is obtained by averaging \( R \) with a certain normalized distribution \( d \) centered around an angle of incidence \( \alpha \):

\[
\overline{R}(\alpha) = \int d(\alpha' - \alpha) R(\alpha')d\alpha'.
\]  

(44)

In Fig 11, \( \overline{R} \) is plotted as function of the rotation angle \( \theta^{(t)} \) of the top TMDC layer for fixed twist angle \( \theta^{(b)} = \pi/4 \) of the bottom layer. As shown in Fig.2 of the main text, by changing \( \theta^{(t)} \) all three SOC parameters \( \lambda^{(tls)}_R, \hat{g}^{(tls)} \) and \( \lambda^{(tls)}_{\nu Z} \) discussed for the trilayer case are changing and they all affect \( \overline{R} \). As one can see, the main features in \( \overline{R} \) do not seem to depend much on the specific angular distribution of the incoming plane waves or on the exact value of the central angle of incidence.

![FIG. 11: The effective reflection \( \overline{R} \) as a function of \( \theta^{(t)} \). Angular distribution of incoming electrons taken from Ref \[19\] (blue) and from Ref \[20\] (red) centered at \( \alpha = 70^\circ \). The green curve shows the result for \( \alpha = 75^\circ \) using the angular distribution from Ref \[20\].](image)

Experimentally, in order to check the predictions in Fig. 11, a straightforward approach would be to prepare a few different samples with different \( \theta^{(t)} \). Alternatively, a setup similar to Ref. \[21\] could also be feasible, whereby the top layer is rotated \textit{in situ}.
