Abstract. Anonymous Identity Based Encryption (AIBET) scheme allows a tracer to use the tracing key to reveal the recipient’s identity from the ciphertext while keeping other data anonymous. This special feature makes AIBET a promising solution to distributed IoT data security. In this paper, we construct an efficient quantum-safe Hierarchical Identity-Based cryptosystem with Traceable Identities (AHIBET) with fully anonymous ciphertexts. We prove the security of the AHIBET scheme under the Learning with Errors (LWE) problem in the standard model.

1 Introduction

Internet of Things (IoT) has emerged as a set of interconnected technologies like Wireless Sensors Networks (WSN) and Radio Frequency Identification (RFID), that provide identification, computation, and mutual information exchange among the connected devices all over the world. The key idea of the IoT is to obtain information about our environment to understand and control and act on it [DMR16].

Identity-Based Encryption (IBE) is a type of public-key encryption where the public key is an arbitrary string that uniquely defined the user (for example an email address or a telephone number). The Private-key Generator (PKG) who has knowledge of a master secret key generates the private key for the corresponding identities. This concept was first introduced by Shamir [Sha84] and then in 2001, Boneh and Franklin [BF01] proposed the first practical IBE scheme based on bilinear map. The idea of Hierarchical Identity-Based Encryption (HIBE), which is an extension of IBE where each level can issue private keys for identities of the next level, was first proposed in the work of Gentry and Silverberg [GS02]. Since then, there have been many efficient constructions of HIBE, ranging from classical setting [BB04,BBG05,Wat05] to post-quantum setting [ABB10a,CHKP10,SRB14] just to name a few.

The concept of “Anonymous” IBE offers an additional privacy guarantee to standard IBE schemes where the ciphertexts do not leak the identity of the recipients. AIBE is a promising solution to anonymous communications and it can be applied to many realistic scenarios that provide privacy-preserving and security under cloud environment. It can also bring a secure environment without leaking metadata which has many application scenarios in the aforementioned distributed IoT system [JLL⁺18]. However, the first AIBE construction of Boneh and Frankl in [BF01] is just anonymous in the random oracle model and it was a challenging problem to achieve anonymous IBE in the standard model until [BW06b]. In [BW06a], Boyen and Waters proposed the first secure anonymous HIBE scheme without random oracles. More recently, the HIBE constructions in the post-quantum setting [ABB10a,SRB14] are proven to be anonymous secure in the standard model

in the mean of a ciphertext encrypted for a target identity is indistinguishable from a random element in the ciphertext space which helps hide this identity from any malicious attacker.

Although this strong unconditional privacy seems very attractive from the user’s point of view, it can potentially be a dangerous tool against public safety if there is no way to revoke such privacy when illegal behavior is detected. For example, in the case where the email filtering system has to filter out all encrypted email from members are suspected of illegal activity, standard anonymous IBE and HIBE prevent the system reveal the recipients of those ciphertexts. Traceability can provide a solution to this problem in which an additional traceability function can detect specific identities in ciphertexts and all the others remain anonymous.

In 2019, Blazy et al. [BBP19] first considered the traceability for identity-based encryption and constructed an Anonymous Identity Based Encryption (AIBET) scheme in the standard model but under the matrix Diffie Hellman (MDDH) assumption. Two security notions are formally defined in [4] are *anonymity* and *ciphertext indistinguishability*. Anonymity requires that someone without an associated user secret key or tracing key should not be able to guess the targeted identity. The notion of indistinguishability requires that no one can distinguish between a valid ciphertext and a random string from the ciphertext space even having access to the tracing key of the target identity. Recent, in [LTT⁺21], Liu et al. proposed a lattice-based construction for AIBET which is based on the anonymous IBE by Katsumata and Yamada [KY16]. However, they do not address the notion of indistinguishability which is the main difference between an AIBET and a standard anonymous IBE. Note that the role of the tracer and the Private-key Generator PKG are distinguishable where the tracer has less power than the PKG. For example, it could be a gateway that checks whether an email for a suspected illegal user is passed. Even if the tracers are corrupted, the privacy and the confidentiality of the system will still remain intact.

Our contribution: We propose a concrete construction of an Anonymous Lattice Hierarchical Identity-Based Encryption with Traceable Identities (AHIBET) scheme which is secure in the standard model based on the hardness assumption of lattices. In particular, our AHIBET construction is anonymous across all the levels of hierarchy, i.e., ciphertexts conceal recipients’ identities from everyone which does not know the corresponding keys for decryption or tracing. Traceability cannot be extended down the hierarchy, i.e., knowing the tracing key for identity id doesn’t imply knowing tracing key for any of its descendants. Besides, our construction is ciphertext indistinguishable, i.e., even having the tracing key for identity id , one cannot distinguish the ciphertexts of message \mathbf{m} from the one of random messages for identity id .

An instance of our AHIBET yields a lattice-based construction of AIBET that can be easily converted to a construction over ideal lattices using the techniques in [BFRS18], which outperforms the AIBET by Liu et al. [LTT⁺21]³.

Technical Overview:

The first main idea is that an AHIBET system must be controlled by three levels of trapdoors:

- The master secret key MPK can be used to generate secret key SK_{id} and tracing key Tsk_{id} for each identity id of any level.
- The secret keys SK_{id} enable recipients to decrypt the corresponding ciphertexts. Each secret key SK_{id} can be used to generate the secret keys for identities of the next level and thus control all descendants of id .
- The tracing keys Tsk_{id} enable tracers to detect only the ciphertexts sent to identities id without leaking information of the messages.

³ In fact, the public parameter in Liu et al. [LTT⁺21] will be a factor of dl greater than ours where d is some fixed constant (e.g., $d=2$ or 3) and $l = \lceil n^{1/d} \rceil$ for n the security parameter.

To achieve the identity traceability property, we attach each ciphertext a random tag and its encapsulation whereas tracing keys are the trapdoors for decapsulation.

We exploit the power of lattice trapdoors in [MP12,CHKP10] combining with the HIBE construction by Agrawal et al. [ABB10a] to achieve our AHIBET.

In [ABB10a], each identity id is assigned a matrix \mathbf{F}_{id} and message \mathbf{m} is encrypted following the dual-Regev scheme:

$$\mathbf{c}^T = \mathbf{s}^T \mathbf{F}_{\text{id}} + \mathbf{e}^T, \quad \mathbf{c}'^T = \mathbf{s}^T \mathbf{U} + \mathbf{e}'^T + \mathbf{m}^T \left\lfloor \frac{q}{2} \right\rfloor.$$

In our scheme, we use one dual-Regev part to encrypt the message and another one to encapsulate the random tag to allow the ciphertext to reveal the recipients' identity from the tracing key holder.

In [MP12], the authors introduced a so-called \mathbf{G} -trapdoor where \mathbf{G} is a gadget matrix in $\mathbb{Z}_q^{n \times \omega}$. A \mathbf{G} -trapdoor for matrix \mathbf{F} is a matrix $\mathbf{R} \in \mathbb{Z}^{(m-\omega) \times \omega}$ such that $\mathbf{F} = [\mathbf{A} | \mathbf{A}\mathbf{R} + \mathbf{H}\mathbf{G}]$ for some invertible matrix $\mathbf{H} \in \mathbb{Z}_q^{n \times n}$ where $\mathbf{A} \in \mathbb{Z}_q^{n \times (m-\omega)}$. The authors called it “strong trapdoor” since a good basis $\mathbf{T}_{\mathbf{F}} \in \mathbb{Z}^{m \times m}$ for $\Lambda_q^\perp(\mathbf{F})$ can be obtained from the knowledge of the matrix \mathbf{R} but the reverse is hard. Moreover, with either \mathbf{R} or $\mathbf{T}_{\mathbf{F}}$, one can easily generate a low norm matrix $\mathbf{D}_{\mathbf{F}} \in \mathbb{Z}_q^{n \times t}$ satisfying $\mathbf{F} \cdot \mathbf{D}_{\mathbf{F}} = \mathbf{U}$ with respect to a given random matrix $\mathbf{U} \in \mathbb{Z}_q^{n \times t}$ using the sampling algorithms from [ABB10a] and [MP12]. Since $\mathbf{D}_{\mathbf{F}}$ is a kind of weaker trapdoor than $\mathbf{T}_{\mathbf{F}}$, we can use such matrices \mathbf{R} , $\mathbf{T}_{\mathbf{F}}$ and $\mathbf{D}_{\mathbf{F}}$ as the three levels of trapdoors MSK , SK_{id} , Tsk_{id} respectively for a traceable identity-based encryption where the matrix \mathbf{F} is associated to an identity $\text{id} = (\text{id}_1, \dots, \text{id}_\ell)$, namely, $\mathbf{F} = \mathbf{F}_{\text{id}} = [\mathbf{A} | \mathbf{A}_1 + \text{FRD}(\text{id}_1)\mathbf{G} | \dots | \mathbf{A}_\ell + \text{FRD}(\text{id}_\ell)\mathbf{G}]$ for the public matrices $\mathbf{A}, \mathbf{A}_1, \dots, \mathbf{A}_\ell$ and the full-rank difference encoding function FRD . However, such trapdoors do not guarantee the anonymity and even the secrecy of messages across the hierarchy of identities. For example, knowing $\mathbf{D}_{\mathbf{F}_{\text{id}_1}}$ and $\mathbf{D}_{\mathbf{F}_{[\text{id}_1 | \text{id}_2]}}$, one can easily find a low norm matrix \mathbf{T} of the same size as $\mathbf{D}_{\mathbf{F}_{[\text{id}_1 | \text{id}_2]}}$ such that $\mathbf{F}_{[\text{id}_1 | \text{id}_2]} \mathbf{T} = \mathbf{0}$, which reveals information of the messages. Therefore, we use a collision resistance hash function H to construct a matrix $\mathbf{F}'_{\text{id}} = [\mathbf{A} | \mathbf{A}_0 + \text{FRD}(\text{H}(\text{id}))\mathbf{G}]$ and use the sampling algorithms to generate the tracing key $\mathbf{D}_{\mathbf{F}'_{\text{id}}}$ of the identity id such that $\mathbf{F}'_{\text{id}} \mathbf{D}_{\mathbf{F}'_{\text{id}}} = \mathbf{U}$. Such tracing keys are determined uniquely by the identities and independent of the secret keys, which ensures the anonymity and secrecy of the messages.

2 Preliminaries

2.1 Anonymous Lattice Hierarchical Identity-Based Encryption with Traceable Identities (AHIBET)

In this section, we describe the model of Anonymous Lattice Hierarchical Identity-Based Encryption with Traceable Identities (AHIBET) based on the Anonymous Lattice Identity-Based Encryption with Traceable Identities (AIBET) from [BBP19] and its security model.

Definition 1 (AHIBET). *An AHIBET scheme consists of the following seven algorithms:*

- $\text{Setup}(\lambda, d)$ takes as input the security parameter λ and the maximal hierarchy depth d of the scheme and outputs the master public key MPK and the master secret key MSK .
- $\text{Extract}(\text{MPK}, \text{MSK}, \text{id})$ uses the master public key MPK and the master secret key MSK to generate the secret key SK_{id} for an identity id at depth 1.
- $\text{Derive}(\text{MPK}, \text{SK}_{\text{id}}, (\text{id} | \text{id}_\ell))$ takes as input the master public key MPK and a secret key SK_{id} corresponding to an identity id at depth $\ell - 1$, outputs the secret key $\text{SK}_{\text{id} | \text{id}_\ell}$ for the identity $(\text{id} | \text{id}_\ell)$ at depth ℓ .

- $\text{TskGen}(\text{MPK}, \text{MSK}, \text{id})$ uses the master public key MPK and the master secret key MSK to generate the tracing key Tsk_{id} for a given identity id .
- $\text{Encrypt}(\text{MPK}, \text{id}, \mathbf{m})$ takes as input the master public key MPK , a given identity id and a message \mathbf{m} , outputs the ciphertext CT .
- $\text{Decrypt}(\text{MPK}, \text{CT}, \text{SK}_{\text{id}})$ takes as input the master public key MPK , a ciphertext CT and a secret key SK_{id} . The algorithm outputs the message \mathbf{m} if CT is encrypted for id ; otherwise, it outputs the rejection symbol \perp .
- $\text{TkVer}(\text{MPK}, \text{id}, \text{Tsk}_{\text{id}}, \text{CT})$ takes as input the master public key MPK , an identity id and a ciphertext CT , uses the tracing key Tsk_{id} to check whether a ciphertext CT is encrypted for id . TkVer outputs 1 if CT is for the user with identity id ; otherwise, it outputs 0.

Correctness and soundness.

The *correctness* of AHIBET scheme requires that if for all key pairs (MPK, MSK) output by Setup , all $1 \leq \ell \leq d$, all identities $\text{id} = (\text{id}_1, \dots, \text{id}_\ell)$ where $\text{id}_i \in \mathbb{Z}_q^n \setminus \{\mathbf{0}\}$ and all messages $\mathbf{m} \in \{0, 1\}^\lambda$, it holds that

$$\Pr \left[\begin{array}{l} \text{Decrypt}(\text{MPK}, \text{SK}_{\text{id}}, \text{CT}) = \mathbf{m} \\ (\text{MPK}, \text{MSK}) \leftarrow \text{Setup}(\lambda, d) \\ \text{SK}_{\text{id}} \leftarrow \text{Derive}(\text{MPK}, \text{MSK}, \text{id}) \\ \text{CT} \leftarrow \text{Encrypt}(\text{MPK}, \text{id}, \mathbf{m}) \\ 1 \leftarrow \text{TkVer}(\text{MPK}, \text{id}, \text{Tsk}_{\text{id}}, \text{CT}) \end{array} \right] = 1$$

and the *soundness* of AHIBET requires

$$\Pr \left[\begin{array}{l} \text{Decrypt}(\text{MPK}, \text{SK}_{\text{id}}, \text{CT}) = \perp \\ (\text{MPK}, \text{MSK}) \leftarrow \text{Setup}(\lambda, d) \\ \text{SK}_{\text{id}} \leftarrow \text{Derive}(\text{MPK}, \text{MSK}, \text{id}) \\ \text{CT} \leftarrow \text{Encrypt}(\text{MPK}, \text{id}, \mathbf{m}) \\ 0 \leftarrow \text{TkVer}(\text{MPK}, \text{id}, \text{Tsk}_{\text{id}}, \text{CT}) \end{array} \right] = 1$$

Security models of AHIBET. For the security models, we give the definition of anonymity and ciphertext indistinguishability for the AHIBET scheme.

- **Anonymity** is the property that the adversary can not distinguish the encryption of a chosen message for a first chosen identity from the encryption on the same message for a second chosen identity. Similarly, the adversary can not decide whether a ciphertext it received from the challenger was encrypted for a chosen challenge identity, or for a random identity in the identity space. The anonymity game, denoted **ANON-sID-CPA**, is played between an adversary \mathcal{A} and a challenger \mathcal{C} , provided that the adversary \mathcal{A} does not have the corresponding tracing key of the challenge identity, is defined through the following game:
 - **Init:** The adversary \mathcal{A} is given the maximum depth of the hierarchy d and then \mathcal{A} decides a target pattern $\text{id}^* = (\text{id}_1^*, \dots, \text{id}_\ell^*)$, $\ell \leq d$.
 - **Setup:** At the beginning of the game, the challenger \mathcal{C} runs $\text{Setup}(\lambda, d)$ to obtain (MPK, MSK) and gives the resulting master public key MPK to the adversary \mathcal{A} .
 - **Phase 1:** \mathcal{A} may adaptively make queries polynomial many times to the key derivation oracle $\mathcal{O}_{\text{Derive}}$ and the tracing key oracle $\mathcal{O}_{\text{TskGen}}$ where:
 - * Oracle $\mathcal{O}_{\text{Derive}}(\text{id})$ takes input an identity id different from id^* and its prefixes, returns the output of $\text{Derive}(\text{MPK}, \text{MSK}, \text{id})$.
 - * Oracle $\mathcal{O}_{\text{TskGen}}(\text{id})$ takes input an identity id different from id^* , returns the output of $\text{TskGen}(\text{MPK}, \text{MSK}, \text{id})$.

- **Challenge:** The adversary \mathcal{A} chooses a message $\mathbf{m} \in \{0,1\}^\lambda$ and gives it to the challenger \mathcal{C} . \mathcal{C} then selects a random bit $b \in \{0,1\}$ and a random identity id' in the identity space which has the same depth with the challenge identity id^* . If $b = 0$, \mathcal{C} runs $\text{CT}_0^* \leftarrow \text{Encrypt}(\text{MPK}, \text{id}^*, \mathbf{m})$; otherwise, it runs $\text{CT}_1^* \leftarrow \text{Encrypt}(\text{MPK}, \text{id}', \mathbf{m})$. Finally, \mathcal{C} passes $(\text{MPK}, \text{CT}_b^*)$ through to the adversary \mathcal{A} .
- **Phase 2:** \mathcal{A} continues to issue additional key derivation and tracing key queries and \mathcal{C} responds as in **Phase 1**.
- **Guess:** \mathcal{A} outputs its guess $b' \in \{0,1\}$ and wins if $b' = b$.

The advantage of \mathcal{A} is defined as

$$\text{Adv}_{\mathcal{A}, \text{AHIBET}}^{\text{ANON-sID-CPA}} := \left| \Pr[b = b'] - \frac{1}{2} \right|.$$

- In the **ciphertext indistinguishability game**, we use a privacy property called *indistinguishable from random* which means that the challenge ciphertext encrypted for a given message \mathbf{m}^* is computationally indistinguishable from a the challenge ciphertext encrypted for a random message \mathbf{m} on the same challenge identity id^* , even the adversary \mathcal{A} has the corresponding tracing key Tsk_{id^*} of id^* . The IND-sID-CPA security model is defined through the following game, played between an adversary \mathcal{A} and a challenger \mathcal{C} :

- **Init:** The adversary \mathcal{A} is given the maximum depth of the hierarchy d and then \mathcal{A} decides a target pattern $\text{id}^* = (\text{id}_1^*, \dots, \text{id}_\ell^*)$, $\ell \leq d$.
- **Setup:** At the beginning of the game, the challenger \mathcal{C} runs $\text{Setup}(\lambda, d)$ to obtain (MPK, MSK) and gives the resulting master public key MPK to the adversary \mathcal{A} .
- **Phase 1:** \mathcal{A} may adaptively make queries polynomial many times to the key derivation oracle $\mathcal{O}_{\text{Derive}}$ and the tracing key oracle $\mathcal{O}_{\text{TskGen}}$ where:
 - * Oracle $\mathcal{O}_{\text{Derive}}(\text{id})$ takes input an identity id different from id^* and its prefixes, returns the output of $\text{Derive}(\text{MPK}, \text{MSK}, \text{id})$.
 - * Oracle $\mathcal{O}_{\text{TskGen}}(\text{id})$ takes input an identity id different from id^* , returns the output of $\text{TskGen}(\text{MPK}, \text{MSK}, \text{id})$.
- **Challenge:** The adversary \mathcal{A} chooses a message $\mathbf{m}^* \in \{0,1\}^\lambda$ and gives it to the challenger \mathcal{C} . \mathcal{C} sets $\mathbf{m}_0 = \mathbf{m}^*$ and chooses a random message \mathbf{m}_1 in the message space. \mathcal{C} then selects a random bit $b \in \{0,1\}$. If $b = 0$, \mathcal{C} runs $\text{CT}_0^* \leftarrow \text{Encrypt}(\text{MPK}, \text{id}^*, \mathbf{m}_0)$; otherwise, it runs $\text{CT}_1^* \leftarrow \text{Encrypt}(\text{MPK}, \text{id}^*, \mathbf{m}_1)$. Finally, \mathcal{C} passes $(\text{MPK}, \text{CT}_b^*)$ through to the adversary \mathcal{A} .
- **Phase 2:** \mathcal{A} continues to issue additional key derivation and tracing key queries and \mathcal{C} responds as in **Phase 1**.
- **Guess:** \mathcal{A} outputs its guess $b' \in \{0,1\}$ and wins if $b' = b$.

The advantage of \mathcal{A} is defined as

$$\text{Adv}_{\mathcal{A}, \text{AHIBET}}^{\text{IND-sID-CPA}} := \left| \Pr[b = b'] - \frac{1}{2} \right|.$$

2.2 Lattices

A lattice Λ in \mathbb{Z}^m is a set of all integer linear combinations of (linearly independent) basis vectors $\mathbf{B} = \{\mathbf{b}_1, \dots, \mathbf{b}_n\} \in \mathbb{Z}^m$, i.e.,

$$\Lambda := \left\{ \sum_{i=1}^n \mathbf{b}_i x_i \mid x_i \in \mathbb{Z} \ \forall i = 1, \dots, n \right\} \subseteq \mathbb{Z}^m.$$

We call n the rank of Λ and if $n = m$ we say that Λ is a full rank lattice. In this paper, we mainly consider full rank lattices containing $q\mathbb{Z}^m$, called q -ary lattices,

$$\begin{aligned}\Lambda_q(\mathbf{A}) &:= \{\mathbf{e} \in \mathbb{Z}^m \text{ s.t. } \exists \mathbf{s} \in \mathbb{Z}_q^n \text{ where } \mathbf{A}^T \mathbf{s} = \mathbf{e} \pmod{q}\} \\ \Lambda_q^\perp(\mathbf{A}) &:= \{\mathbf{e} \in \mathbb{Z}^m \text{ s.t. } \mathbf{A}\mathbf{e} = \mathbf{0} \pmod{q}\}\end{aligned}$$

and translations of lattice $\Lambda_q^\perp(\mathbf{A})$ defined as follows

$$\Lambda_q^\mathbf{u}(\mathbf{A}) := \{\mathbf{e} \in \mathbb{Z}^m \text{ s.t. } \mathbf{A}\mathbf{e} = \mathbf{u} \pmod{q}\}$$

for given matrices $\mathbf{A} \in \mathbb{Z}^{n \times m}$ and $\mathbf{u} \in \mathbb{Z}_q^n$.

Let $\mathbf{S} = \{\mathbf{s}_1, \dots, \mathbf{s}_k\}$ be a set of vectors in \mathbb{R}^m . We denote by $\|\mathbf{S}\| := \max_{1 \leq i \leq k} \|\mathbf{s}_i\|$ the maximum ℓ_2 length of the vectors in \mathbf{S} . We also denote $\tilde{\mathbf{S}} := \{\tilde{\mathbf{s}}_1, \dots, \tilde{\mathbf{s}}_k\}$ the Gram-Schmidt orthogonalization of the vectors $\mathbf{s}_1, \dots, \mathbf{s}_k$ in that order. We refer to $\|\tilde{\mathbf{S}}\|$ the Gram-Schmidt norm of \mathbf{S} .

Note that for any matrix $\mathbf{B} \in \mathbb{Z}^{n \times m}$, there exists a singular value decomposition $\mathbf{B} = \mathbf{Q}\mathbf{D}\mathbf{P}^T$, where $\mathbf{Q} \in \mathbb{R}^{n \times n}$, $\mathbf{P} \in \mathbb{R}^{m \times m}$ are orthogonal matrices, and $\mathbf{D} \in \mathbb{R}^{n \times m}$ is a diagonal matrix with nonnegative entries $s_i \geq 0$ on the diagonal, in non-increasing order. The s_i are called the *singular values* of \mathbf{B} . Under this convention, \mathbf{D} is uniquely determined and $s_1(\mathbf{B}) = \max_{\mathbf{u}} \|\mathbf{B}\mathbf{u}\| = \max_{\mathbf{u}} \|\mathbf{B}^T \mathbf{u}\| \geq \|\mathbf{B}\|, \|\mathbf{B}^T\|$ where the maxima are taken over all unit vectors $\mathbf{u} \in \mathbb{R}^m$. Note that the singular values of \mathbf{B} and \mathbf{B}^T are the same.

Gaussian distribution. We will use the following definitions of the discrete Gaussian distributions.

Definition 2. Let $\Lambda \subseteq \mathbb{Z}^m$ be a lattice. For a vector $\mathbf{c} \in \mathbb{R}^m$ and a positive parameter $\sigma \in \mathbb{R}$, define:

$$\rho_{\sigma, \mathbf{c}}(\mathbf{x}) = \exp\left(-\pi \frac{\|\mathbf{x} - \mathbf{c}\|^2}{\sigma^2}\right) \quad \text{and} \quad \rho_{\sigma, \mathbf{c}}(\Lambda) = \sum_{\mathbf{x} \in \Lambda} \rho_{\sigma, \mathbf{c}}(\mathbf{x}).$$

The discrete Gaussian distribution over Λ with center \mathbf{c} and parameter σ is

$$\forall \mathbf{y} \in \Lambda, \quad \mathcal{D}_{\Lambda, \sigma, \mathbf{c}}(\mathbf{y}) = \frac{\rho_{\sigma, \mathbf{c}}(\mathbf{y})}{\rho_{\sigma, \mathbf{c}}(\Lambda)}.$$

For convenience, we will denote by ρ_σ and $\mathcal{D}_{\Lambda, \sigma}$ for $\rho_{\sigma, \mathbf{0}}$ and $\mathcal{D}_{\Lambda, \sigma, \mathbf{0}}$ respectively. When $\sigma = 1$ we will write ρ instead of ρ_1 .

It is well-known that for a vector \mathbf{x} sampled from $\mathcal{D}_{\mathbb{Z}, \sigma}^m$, one has that $\|\mathbf{x}\| \leq \sigma\sqrt{m}$ with overwhelming probability.

Lemma 3. For $\mathbf{x} \leftarrow \mathcal{D}_{\Lambda_q^\mathbf{u}(\mathbf{A}), \sigma}$, $\Pr[\|\mathbf{x}\| > \sigma\sqrt{m}] \leq \text{negl}(n)$.

Lemma 4. For a prime q and a positive integer n , let $m \geq n \lceil \log q \rceil$. For $\mathbf{A} \leftarrow \mathbb{Z}_q^{n \times m}$, $\mathbf{r} \leftarrow \mathcal{D}_{\mathbb{Z}, \sigma}^m$ with $\sigma \geq \omega(\sqrt{\log n})$, the distribution of $\mathbf{u} = \mathbf{A}\mathbf{r} \in \mathbb{Z}_q^n$ is statistically close to the uniform distribution over \mathbb{Z}_q^n .

Furthermore, fix $\mathbf{u} \in \mathbb{Z}_q^n$, the distribution of \mathbf{r} conditioned on $\mathbf{A}\mathbf{r} = \mathbf{u}$ is $\mathcal{D}_{\Lambda_q^\mathbf{u}(\mathbf{A}), \sigma}$.

The security of our construction reduces to the LWE (Learning With Errors) problem introduced by Regev [Reg09].

Definition 5 (Learning With Errors - LWE problem). Consider a prime q , a positive integer n , and a distribution χ over \mathbb{Z}_q . An $\text{LWE}_{n, m, q, \chi}$ problem instance consists of access to an unspecified challenge oracle \mathcal{O} , being either a noisy pseudorandom sampler \mathcal{O}_s associated with a secret $\mathbf{s} \in \mathbb{Z}_q^n$, or a truly random sampler $\mathcal{O}_\$$ whose behaviors are as follows:

\mathcal{O}_s : samples of the form $(\mathbf{a}_i, b_i) = (\mathbf{a}_i, \mathbf{s}^T \mathbf{a}_i + e_i) \in \mathbb{Z}_q^n \times \mathbb{Z}_q$ where $\mathbf{s} \in \mathbb{Z}_q^n$ is a uniform secret key, $\mathbf{a}_i \in \mathbb{Z}_q^n$ is uniform and $e_i \in \mathbb{Z}_q$ is a noise withdrawn from χ .
 \mathcal{O}_\S : samples are uniform pairs in $\mathbb{Z}_q^n \times \mathbb{Z}_q$.

The $\text{LWE}_{n,m,q,\chi}$ problem allows respond queries to the challenge oracle \mathcal{O} . We say that an algorithm \mathcal{A} decides the $\text{LWE}_{n,m,q,\chi}$ problem if

$$\text{Adv}_{\mathcal{A}}^{\text{LWE}_{n,m,q,\chi}} := |\Pr[\mathcal{A}^{\mathcal{O}_s} = 1] - \Pr[\mathcal{A}^{\mathcal{O}_\S} = 1]|$$

is non-negligible for a random $\mathbf{s} \in \mathbb{Z}_q^n$.

Regev [Reg09] showed that (see Theorem 6 below) when χ is a distribution $\bar{\Psi}_\alpha$ with $\alpha \in (0, 1)$, the LWE problem is hard.

Theorem 6. *If there exists an efficient, possibly quantum, algorithm for deciding the $\text{LWE}_{n,m,q,\bar{\Psi}_\alpha}$ problem for $q > 2\sqrt{n}/\alpha$ then there is an efficient quantum algorithm for approximating the SIVP and GapSVP problems, to within $\tilde{O}(n/\alpha)$ factors in the ℓ_2 norm, in the worst case.*

The theorem implies, for n/α is a polynomial in n , the LWE problem is as hard as approximating the SIVP and GapSVP problems in lattices of dimension n to within polynomial (in n) factors.

In this paper, we will use the discrete Gaussian distribution $\mathcal{D}_{\mathbb{Z},\sigma}^m$ and denote $\text{LWE}_{n,m,q,\sigma}$ instead of $\text{LWE}_{n,m,q,\mathcal{D}_{\mathbb{Z},\sigma}^m}$ for convenience.

We use the following lemma which was introduced by Katsumata and Yamada in [KY16] to rerandomize LWE instances:

Lemma 7. *Let ℓ, q, m be positive integers and let r be a positive real number satisfying $r \geq \max\{\omega(\sqrt{\log m}), \omega(\sqrt{\log \ell})\}$. Let $\mathbf{b} \in \mathbb{Z}_q^m$ be arbitrary and $\mathbf{z} \leftarrow \mathcal{D}_{\mathbb{Z},r}^m$. Then there exists an efficient algorithm ReRand such that for any $\mathbf{D} \in \mathbb{Z}^{m \times \ell}$ and positive real $\sigma \geq s_1(\mathbf{D})$, the output of $\text{ReRand}(\mathbf{D}, \mathbf{b}^T + \mathbf{z}^T, r, \sigma)$ is distributed as $\mathbf{b}'^T = \mathbf{b}^T \mathbf{D} + \mathbf{z}^T \in \mathbb{Z}_q^\ell$ where the distribution of \mathbf{z}' is close to $\mathcal{D}_{\mathbb{Z},2r\sigma}^\ell$.*

Lattice trapdoors

Our work heavily bases on the notion \mathbf{G} -trapdoor introduced in [MP12]. In the following, we recap this notion as well as some usefull algorithms.

As in [MP12], let $n \geq 1$, $q \geq 2$ and let $\omega = n \lceil \log q \rceil = nk$, we will use the vector $\mathbf{g}^T = (1, 2, 4, \dots, 2^{k-1})$ and extend it to get the gadget matrix $\mathbf{G} = \mathbf{I}_n \otimes \mathbf{g}^T \in \mathbb{Z}_q^{n \times \omega}$ such that the lattice $\Lambda_q^\perp(\mathbf{G})$ has a public known matrix $\mathbf{T}_\mathbf{G} \in \mathbb{Z}^{\omega \times \omega}$ with $\|\widetilde{\mathbf{T}_\mathbf{G}}\| \leq \sqrt{5}$ and $\|\mathbf{T}_\mathbf{G}\| \leq \max(\sqrt{5}, \sqrt{k})$.

Definition 8. (\mathbf{G} -trapdoor) *Let $n \geq 1$, $q \geq 2$ and $\omega = n \lceil \log q \rceil$, $m \geq \omega$. Let $\mathbf{A} \in \mathbb{Z}_q^{n \times m}$, $\mathbf{G} \in \mathbb{Z}_q^{n \times \omega}$. Let $\mathbf{H} \in \mathbb{Z}_q^{n \times n}$ be some invertible matrix. A matrix $\mathbf{R} \in \mathbb{Z}^{(m-\omega) \times \omega}$ is called a \mathbf{G} -trapdoor for \mathbf{A} with tag \mathbf{H} if it holds that $\mathbf{A} \begin{bmatrix} -\mathbf{R} \\ \mathbf{I}_\omega \end{bmatrix} = \mathbf{H}\mathbf{G} \pmod{q}$. The quality of the trapdoor is measured by its largest singular value $s_1(\mathbf{R})$.*

[MP12] also presented an algorithm to generate a pseudorandom matrix $\mathbf{F} \in \mathbb{Z}_q^{n \times (m+\omega)}$ together with a “strong” \mathbf{G} -trapdoor for the lattice $\Lambda_q^\perp(\mathbf{F})$:

1. Sample $\mathbf{A} \leftarrow \mathbb{Z}_q^{n \times m}$, $\mathbf{R} \leftarrow \mathcal{D}_{\mathbb{Z},\omega(\sqrt{\log n})}^{m \times \omega}$ and an invertible matrix $\mathbf{H} \leftarrow \mathbb{Z}_q^{n \times n}$
2. Return $\mathbf{F} = [\mathbf{A} | \mathbf{A}\mathbf{R} + \mathbf{H}\mathbf{G}]$ and the \mathbf{G} -trapdoor \mathbf{R} .

The matrix $\mathbf{R} \leftarrow \mathcal{D}_{\mathbb{Z}, \omega(\sqrt{\log n})}^{m \times \omega}$ can do everything that a low-norm basis of $\Lambda_q^\perp(\mathbf{F})$ does. Moreover, \mathbf{R} can be used to efficiently generate low-norm basis $\mathbf{T}_{\mathbf{F}} \in \mathbb{Z}^{(m+\omega) \times (m+\omega)}$ for $\Lambda_q^\perp(\mathbf{F})$.

Next, we recall the following lemma from [GPV08]:

Lemma 9. *Let q, k, n, m be integers with $q > 2, k > 1, m > n$ and let $\mathbf{A} \in \mathbb{Z}_q^{n \times m}, \mathbf{U} \in \mathbb{Z}_q^{n \times k}$. Let $\mathbf{T}_{\mathbf{A}}$ be a basis for $\Lambda_q^\perp(\mathbf{A})$. For $\sigma \geq \|\widetilde{\mathbf{T}_{\mathbf{A}}}\| \cdot \omega(\sqrt{\log m})$, there is a PPT algorithm $\text{SamplePre}(\mathbf{A}, \mathbf{T}_{\mathbf{A}}, \mathbf{U}, \sigma)$ that returns a matrix $\mathbf{D} \in \mathbb{Z}_q^{n \times k}$ sampled from a distribution statistically close to $\mathcal{D}_{\Lambda_q^\perp(\mathbf{A}), \sigma}$, whenever $\Lambda_q^\perp(\mathbf{A})$ is not empty such that $\mathbf{AD} = \mathbf{U}$.*

The following lemma consists of algorithms for generating bases for lattices collected from the sampling technique in the work of Agrawal et al. [ABB10a] and the SamplePre algorithm from the work of Micciancio et al. [MP12, Theorem 5.1] which will be used in our construction. Note that the SamplePre algorithm in [MP12] is different from the SamplePre algorithm from [ABB10a] in Lemma 9 above.

Lemma 10. *Let $n \geq 1, q \geq 2, \omega = n \lceil \log q \rceil, m \geq \omega$. Let $\mathbf{A} \leftarrow \mathbb{Z}_q^{n \times m}$.*

- *Let $\mathbf{T}_{\mathbf{A}}$ be a basis for $\Lambda_q^\perp(\mathbf{A})$, $\mathbf{M} \leftarrow \mathbb{Z}_q^{n \times m_1}$ and $\sigma \geq \|\widetilde{\mathbf{T}_{\mathbf{A}}}\| \cdot \omega(\sqrt{\log(m + m_1)})$. Then there exists a PPT algorithm $\text{SampleBasisLeft}(\mathbf{A}, \mathbf{M}, \mathbf{T}_{\mathbf{A}}, \sigma)$ that outputs a basis of $\Lambda_q^\perp([\mathbf{A}|\mathbf{M}])$.*
- *Let $\mathbf{R} \leftarrow \mathcal{D}_{\mathbb{Z}, \omega(\sqrt{\log n})}^{m \times \omega}$, $\mathbf{U} \leftarrow \mathbb{Z}_q^{n \times \omega}$, and let $\mathbf{H} \leftarrow \mathbb{Z}_q^{n \times n}$ be an invertible matrix. Let $\mathbf{F} = [\mathbf{A}|\mathbf{AR} + \mathbf{HG}]$. Then for $\sigma \geq 5 \cdot s_1(\mathbf{R}) \cdot \omega(\sqrt{\log n})$, there exists a PPT algorithm $\text{SampleRight}(\mathbf{R}, \mathbf{F}, \mathbf{H}, \mathbf{U}, \sigma)$ that outputs a matrix $\mathbf{D} \in \mathbb{Z}^{(m+\omega) \times \omega}$ distributed statistically close to $\mathcal{D}_{\Lambda_q^\perp(\mathbf{F}), \sigma}$ s.t. $\mathbf{FD} = \mathbf{U}$. In particular, there exists a PPT algorithm $\text{SampleBasisRight}(\mathbf{R}, \mathbf{F}, \mathbf{H}, \mathbf{U}, \sigma)$ that outputs a basis $\mathbf{T} \in \mathbb{Z}^{(m+\omega) \times (m+\omega)}$ of $\Lambda_q^\perp(\mathbf{F})$ which distributes statistically close to $\mathcal{D}_{\Lambda_q^\perp(\mathbf{F}), \sigma}$, i.e., $\mathbf{FT} = \mathbf{0}$.*

Here, we note that the algorithm SampleBasisRight basically runs $\text{SampleRight}(\mathbf{R}, \mathbf{F}, \mathbf{H}, \mathbf{0}, \sigma)$ many times until there are enough linearly independent output vectors to form a basis of $\Lambda_q^\perp(\mathbf{F})$. According to [ABB10b], $2(m + \omega)$ samples are needed in expectation to get the basis \mathbf{T} for $\Lambda_q^\perp(\mathbf{F})$.

Peikert [Pei09] shows how to construct a basis for $\Lambda_q^\perp(\mathbf{A}_1|\mathbf{A}_2|\mathbf{A}_3)$ from a basis for $\Lambda_q^\perp(\mathbf{A}_2)$.

Theorem 11. *For $i = 1, 2, 3$, let \mathbf{A}_i be a matrix in $\mathbb{Z}^{n \times m_i}$ and let $\mathbf{A} = (\mathbf{A}_1|\mathbf{A}_2|\mathbf{A}_3)$. Let \mathbf{T}_2 be a basis of $\Lambda_q^\perp(\mathbf{A}_2)$. There is a deterministic polynomial time algorithm ExtendBasis that outputs a basis \mathbf{T} for $\Lambda_q^\perp(\mathbf{A})$ such that $\|\widetilde{\mathbf{T}}\| = \|\widetilde{\mathbf{T}_2}\|$.*

We will also use the following lemma in the decryption algorithm to recover the message.

Lemma 12. *Let \mathbf{A} be a uniformly random matrix in $\mathbb{Z}_q^{n \times m}$ where $m > 2n$. Let $\mathbf{T} \in \mathbb{Z}^{m \times m}$ be a basis of $\Lambda_q^\perp(\mathbf{A})$. Given $\mathbf{y} = \mathbf{s}^T \mathbf{A} + \mathbf{e}^T$ where $\mathbf{s} \in \mathbb{Z}_q^n, \mathbf{e} \in \mathbb{Z}^m$ with $\|\mathbf{e}^T \mathbf{T}\|_\infty < q/4$, there exists an algorithm $\text{Invert}(\mathbf{A}, \mathbf{T}, \mathbf{y})$ that outputs \mathbf{s} and \mathbf{e} with overwhelming probability.*

It can be easily seen that the lemma is true since the algorithm works by computing $\mathbf{y}^T \mathbf{T} \bmod q = \mathbf{e}^T \mathbf{T} \bmod q$. We have $\|\mathbf{e}^T \mathbf{T}\|_\infty < q/4$, so $\mathbf{e}^T \mathbf{T} \bmod q = \mathbf{e}^T \in \mathbb{Z}^m$. Since $\mathbf{T} \in \mathbb{Z}^{m \times m}$ is a basis of lattice $\Lambda_q^\perp(\mathbf{A})$, \mathbf{T} has linearly independent columns, one can simply use the Gaussian elimination to recover \mathbf{e} and then get $\mathbf{s}^T \mathbf{A}$. Finally, \mathbf{s} can be recovered by Gaussian elimination because $\mathbf{A} \in \mathbb{Z}^{n \times m}$ has at least n linearly independent column vectors.

3 AHIBET Construction over Integer Lattices

- Let λ be the security parameter, d be the hierarchy depth and identities are vector $\text{id} = (\text{id}_1, \dots, \text{id}_\ell)$ ($1 \leq \ell \leq d$) where all components id_i are in $\mathbb{Z}^n \setminus \{\mathbf{0}\}$.

- Let $\text{FRD} : \mathbb{Z}_q^n \rightarrow \mathbb{Z}_q^{n \times n}$ be a full-rank difference encoding (FRD) from [ABB10a] s.t. for all distinct $\mathbf{u}, \mathbf{v} \in \mathbb{Z}_q^n$, $\text{FRD}(\mathbf{u}) - \text{FRD}(\mathbf{v}) \in \mathbb{Z}_q^{n \times n}$ is an invertible matrix.
- Let $\text{H} : (\mathbb{Z}_q^n)^* \rightarrow \mathbb{Z}_q^n$ be a collision resistant hash function.
- For an integer $q > 2$, $x \in \mathbb{Z}_q$, the algorithm $\text{Round}(x)$ returns 0 if x is closer to 0 than to $\lfloor \frac{q}{2} \rfloor$ modulo q ; otherwise, it returns 1.

In the construction of the AHIBET scheme, we assume each identity id can only be given exactly one tracing key Tsk_{id} .

Setup(λ, d)

On input security parameter λ and a maximum hierarchy depth d , set the parameters $(n, m, q, \omega, \bar{\sigma}, \tau, \alpha, r)$ as in section 3.1, the algorithm does:

1. Sample uniformly random matrices $\mathbf{A} \leftarrow \mathbb{Z}_q^{n \times m}$, $\mathbf{A}_2, \dots, \mathbf{A}_d \leftarrow \mathbb{Z}_q^{n \times \omega}$ and $\mathbf{R}_0, \mathbf{R}_1 \leftarrow \mathcal{D}_{\mathbb{Z}, \omega(\sqrt{\log n})}^{m \times \omega}$.
2. Set $\mathbf{A}_0 \leftarrow \mathbf{A}\mathbf{R}_0 \in \mathbb{Z}_q^{n \times \omega}$, $\mathbf{A}_1 \leftarrow \mathbf{A}\mathbf{R}_1 \in \mathbb{Z}_q^{n \times \omega}$ and choose $\mathbf{U}_1, \mathbf{U}_2 \leftarrow \mathbb{Z}_q^{n \times \lambda}$ uniformly at random.
3. Output the master public key and the master secret key

$$\text{MPK} = (\mathbf{A}, \mathbf{A}_0, \mathbf{A}_1, \dots, \mathbf{A}_d, \mathbf{U}_1, \mathbf{U}_2), \text{MSK} = (\mathbf{R}_0, \mathbf{R}_1).$$

Extract(MPK, MSK, id)

On input the master public key MPK, the master secret key MSK and an identity id of level 1, the algorithm generates secret key for id as follows:

1. Compute $\mathbf{F}_{\text{id}} = [\mathbf{A} | \mathbf{A}_1 + \text{FRD}(\text{id})\mathbf{G}] \in \mathbb{Z}_q^{n \times (m+\omega)}$.
2. Sample $\mathbf{T}_{\text{id}} \leftarrow \text{SampleBasisRight}(\mathbf{F}_{\text{id}}, \mathbf{R}_1, \text{FRD}(\text{id}), \sigma_1) \in \mathbb{Z}_q^{(m+\omega) \times (m+\omega)}$ s.t. $\mathbf{F}_{\text{id}}\mathbf{T}_{\text{id}} = 0$.
3. Output $\text{SK}_{\text{id}} \leftarrow \mathbf{T}_{\text{id}}$.

Derive(MPK, SK_{id}, (id|id_ℓ))

On input the master public key MPK, a secret key SK_{id} corresponding to an identity $\text{id} = (\text{id}_1, \dots, \text{id}_{\ell-1})$ at depth $\ell - 1$ and an identity $\text{id}|_{\text{id}_\ell} = (\text{id}_1, \dots, \text{id}_{\ell-1}, \text{id}_\ell)$ of level $\ell > 1$, the algorithm generates secret key for id as follows:

1. Set $\mathbf{F}_{\text{id}|_{\text{id}_\ell}} = [\mathbf{F}_{\text{id}} | \mathbf{A}_\ell + \text{FRD}(\text{id}_\ell)\mathbf{G}] \in \mathbb{Z}_q^{n \times (m+\ell\omega)}$ with $\mathbf{F}_{\text{id}} = [\mathbf{A} | \mathbf{A}_1 + \text{FRD}(\text{id}_1)\mathbf{G}] \dots [\mathbf{A}_{\ell-1} + \text{FRD}(\text{id}_{\ell-1})\mathbf{G}]$.
2. Sample $\mathbf{T}_{\text{id}|_{\text{id}_\ell}} \leftarrow \text{SampleBasisLeft}(\mathbf{F}_{\text{id}}, \mathbf{A}_\ell + \text{FRD}(\text{id}_\ell)\mathbf{G}, \text{SK}_{\text{id}}, \sigma_\ell)$ s.t. $\mathbf{F}_{\text{id}|_{\text{id}_\ell}}\mathbf{T}_{\text{id}|_{\text{id}_\ell}} = 0$.
3. Output $\text{SK}_{\text{id}|_{\text{id}_\ell}} \leftarrow \mathbf{T}_{\text{id}|_{\text{id}_\ell}}$.

TskGen(MPK, MSK, id)

On input the master public key MPK, the master secret key MSK and an identity $\text{id} = (\text{id}_1, \dots, \text{id}_\ell)$, the algorithm generates the tracing key for id as follows:

1. Compute $\mathbf{F}'_{\text{id}} = [\mathbf{A} | \mathbf{A}_0 + \text{FRD}(\text{H}(\text{id}))\mathbf{G}] \in \mathbb{Z}_q^{n \times (m+\omega)}$.
2. Sample $\mathbf{D}'_{\text{id}} \leftarrow \text{SampleBasisRight}(\mathbf{F}'_{\text{id}}, \mathbf{R}_0, \text{FRD}(\text{H}(\text{id})), \sigma_1) \in \mathbb{Z}_q^{(m+\omega) \times (m+\omega)}$ s.t. $\mathbf{F}'_{\text{id}}\mathbf{D}'_{\text{id}} = 0$.
3. Sample $\mathbf{D}_{\text{id}} \leftarrow \text{SamplePre}(\mathbf{F}'_{\text{id}}, \mathbf{D}'_{\text{id}}, \mathbf{U}_2, \sigma_1) \in \mathbb{Z}_q^{(m+\omega) \times \lambda}$.
4. Output $\text{Tsk}_{\text{id}} \leftarrow \mathbf{D}_{\text{id}}$.

Encrypt(MPK, id, m)

On input the master public key MPK, the algorithm encrypts the message $\mathbf{m} \in \{0, 1\}^\lambda$ for identity $\text{id} = (\text{id}_1, \dots, \text{id}_\ell)$ at depth ℓ as follows:

1. Compute $\mathbf{F}_{\text{id}} = [\mathbf{A} | \mathbf{B}_{\text{id}}] = [\mathbf{A} | \mathbf{A}_1 + \text{FRD}(\text{id}_1)\mathbf{G}] \dots [\mathbf{A}_\ell + \text{FRD}(\text{id}_\ell)\mathbf{G}] \in \mathbb{Z}_q^{n \times (m+\ell\omega)}$.

2. Sample $\mathbf{k} \leftarrow \{0, 1\}^\lambda$.
3. Sample a uniformly random vector $\mathbf{s} \leftarrow \mathbb{Z}_q^n$.
4. Choose noise vectors $\mathbf{e}_0 \leftarrow \mathcal{D}_{\mathbb{Z}, r}^m$, $\mathbf{e}_1 \leftarrow \mathcal{D}_{\mathbb{Z}, 2r\tau}^{\ell\omega}$, $\mathbf{e}_2 \leftarrow \mathcal{D}_{\mathbb{Z}, r}^\lambda$, $\mathbf{e}_3 \leftarrow \mathcal{D}_{\mathbb{Z}, 2r\tau}^\lambda$, $\mathbf{e}_4 \leftarrow \mathcal{D}_{\mathbb{Z}, 2r\tau}^\omega$.
5. Set

$$\mathbf{c}_0^T = \mathbf{s}^T \mathbf{A} + \mathbf{e}_0^T, \quad \mathbf{c}_1^T = \mathbf{s}^T \mathbf{B}_{\text{id}} + \mathbf{e}_1^T, \quad \mathbf{c}_2^T = \mathbf{s}^T \mathbf{U}_1 + \mathbf{e}_2^T + \mathbf{m}^T \left\lfloor \frac{q}{2} \right\rfloor,$$

and

$$\mathbf{c}_3^T = \mathbf{s}^T \mathbf{U}_2 + \mathbf{e}_3^T + \mathbf{k}^T \left\lfloor \frac{q}{2} \right\rfloor, \quad \mathbf{c}_4^T = \mathbf{s}^T (\mathbf{A}_0 + \text{FRD}(\text{H}(\text{id}))\mathbf{G}) + \mathbf{e}_4^T.$$

6. Output $\text{CT} = (\mathbf{c}_0, \mathbf{c}_1, \mathbf{c}_2, \mathbf{c}_3, \mathbf{c}_4, \mathbf{k})$.

Decrypt(MPK, CT, SK_{id})

On input the master public key MPK, a ciphertext CT and a secret key SK_{id} where id = (id₁, ..., id_ℓ) is an identity at depth ℓ, the algorithm does:

1. Parse CT = (c₀, c₁, c₂, c₃, c₄, k); Output ⊥ if CT doesn't parse.
2. Set $\mathbf{F}_{\text{id}} = [\mathbf{A} | \mathbf{A}_1 + \text{FRD}(\text{id}_1)\mathbf{G}] \dots [\mathbf{A}_\ell + \text{FRD}(\text{id}_\ell)\mathbf{G}]$ and recover \mathbf{s} via $\text{Invert}(\text{SK}_{\text{id}}, \mathbf{F}_{\text{id}}, [\mathbf{c}_0^T | \mathbf{c}_1^T])$.
3. Recover $\tilde{\mathbf{k}} \leftarrow \text{Round}(\mathbf{c}_3^T - \mathbf{s}^T \mathbf{U}_2)$; Return ⊥ if $\tilde{\mathbf{k}} \neq \mathbf{k}$.
4. Compute $\mathbf{m} \leftarrow \text{Round}(\mathbf{c}_2^T - \mathbf{s}^T \mathbf{U}_1)$.
5. Output \mathbf{m} .

TkVer(MPK, id, Tsk_{id}, CT)

On input the master public key MPK, the algorithm uses the tracing key Tsk_{id} = D_{id} corresponding to the identity id to check whether a ciphertext CT is encrypted for the given identity id:

1. Parse CT = (c₀, c₁, c₂, c₃, c₄, k); Output ⊥ if CT doesn't parse.
2. Compute $\tilde{\mathbf{k}} \leftarrow \text{Round}(\mathbf{c}_3^T - [\mathbf{c}_0^T | \mathbf{c}_4^T] \mathbf{D}_{\text{id}})$.
3. If $\tilde{\mathbf{k}} = \mathbf{k}$ then output 1; else output 0.

3.1 Parameters

Let λ be the security parameter, d is the maximum hierarchical depth of the scheme, 1 ≤ ℓ ≤ d. We assume that all parameters are functions of λ. Now for the system to work correctly, we need to ensure:

- σ_ℓ is large enough for SampleBasisLeft and SampleBasisRight, i.e., σ_ℓ > O(m) · ω(log n) · ω(√log(ℓ + 1)m),
- τ is large enough for ReRand, i.e. τ ≥ O(m^{3/2}) · ω(log^{3/2} n),
- the error term in decryption is less than q/4 with high probability, i.e. α < (8σ_ℓτ(m + ℓω))^{−1},

Hence the following choice of parameters (n, m, q, ω, σ̄, τ, α, r) satisfies all of the above conditions, taking λ to be the security parameter:

$$\begin{aligned} n &\geq 2 \quad , \quad q \geq 2 \quad , \quad \omega = n \lceil \log q \rceil \quad , \quad 1 \leq \ell \leq d \\ m &\geq n \log q + \omega(\log n) \quad , \quad r = \alpha q \quad , \quad \sigma_1 = O(\sqrt{m}) \cdot \omega(\log n) \\ \sigma_\ell &= O(m) \cdot \omega(\log n) \cdot \omega(\sqrt{\log(\ell + 1)m}), \\ \tau &= O(m^{3/2}) \cdot \omega(\log^{3/2} n), \\ \alpha &= [(\ell + 1) \cdot O(m^{7/2}) \cdot \omega(\log^{5/2} n) \cdot \omega(\sqrt{\log(\ell + 1)m})]^{-1}. \end{aligned} \tag{1}$$

3.2 Correctness and soundness

When the cryptosystem is operated as specified, during decryption of a correctly generated ciphertext encrypted a message \mathbf{m} to an identity $\text{id} = (\text{id}_1, \dots, \text{id}_\ell)$ at depth $\ell \leq d$, with the parameters as specified in 3.1, we have:

- Since $\mathbf{e}_0 \leftarrow \mathcal{D}_{\mathbb{Z},r}^m$, $\mathbf{e}_1 \leftarrow \mathcal{D}_{\mathbb{Z},2r\tau}^{\ell\omega}$, by applying Lemma 3 and the parameters set up, we get $\|[\mathbf{e}_0^T | \mathbf{e}_1^T]\| \leq 2r\tau \cdot \sqrt{m + \ell\omega}$, which means $\|[\mathbf{e}_0^T | \mathbf{e}_1^T] \mathbf{T}_{\text{id}}\|_\infty \leq \|[\mathbf{e}_0^T | \mathbf{e}_1^T]\| \cdot \|\mathbf{T}_{\text{id}}\| \leq (2r\tau \cdot \sqrt{m + \ell\omega}) \cdot (\sigma_\ell \cdot \sqrt{m + \ell\omega}) \leq 2r\tau\sigma_\ell \cdot (m + \ell\omega) \leq q/4$.

Using Lemma 12, it is sufficient to show that the algorithm $\text{Invert}(\mathbf{T}_{\text{id}}, \mathbf{F}_{\text{id}}, [\mathbf{c}_0^T | \mathbf{c}_1^T])$ will output \mathbf{s} with overwhelming probability.

- Since $\mathbf{e}_2 \leftarrow \mathcal{D}_{\mathbb{Z},r}^\lambda$, $\mathbf{e}_3 \leftarrow \mathcal{D}_{\mathbb{Z},2r\tau}^\lambda$, by applying Lemma 3 and the parameters set up we get $\|\mathbf{e}_2\| \leq \|\mathbf{e}_3\| \leq 2r\tau\sqrt{\lambda} < q/4$.

Hence $\text{Round}(\mathbf{c}_3^T - \mathbf{s}^T \mathbf{U}_2) = \text{Round}\left(\mathbf{k} \left\lfloor \frac{q}{2} \right\rfloor^T + \mathbf{e}_3^T\right)$ and $\text{Round}(\mathbf{c}_2 - \mathbf{s}^T \mathbf{U}_1) = \text{Round}\left(\mathbf{m} \left\lfloor \frac{q}{2} \right\rfloor^T + \mathbf{e}_2^T\right)$ will correctly recover \mathbf{k} and \mathbf{m} .

In the algorithm TkVer , $\text{Round}(\mathbf{c}_3^T - [\mathbf{c}_0^T | \mathbf{c}_4^T] \mathbf{D}_{\text{id}}) = \text{Round}\left(\mathbf{k} \left\lfloor \frac{q}{2} \right\rfloor^T + \mathbf{e}_3^T + [\mathbf{e}_0^T | \mathbf{e}_4^T] \mathbf{D}_{\text{id}}\right)$ where $\|\mathbf{D}_{\text{id}}\| \leq \sigma_1 \sqrt{m + \omega}$. Hence by the parameters set up, TkVer will correctly recover the key \mathbf{k} .

4 Security analysis

4.1 Proof of Anonymity

In this part, we will prove that our proposed AHIBET scheme is ANON-sID-CPA secure in the standard model.

Theorem 1. *The AHIBET scheme $\Pi := (\text{Setup}, \text{Extract}, \text{Derive}, \text{Encrypt}, \text{Decrypt}, \text{TskGen}, \text{TkVer})$ with parameters $(\lambda, n, m, q, \omega, \bar{\sigma}, \tau, \alpha, r)$ as in (1) is ANON-sID-CPA secure for the maximal hierarchy depth d provided that the hardness of the $\text{LWE}_{n,m+\lambda,q,r}$ problem holds.*

Proof. We will proceed the proof via a sequence of games where the **Game 0** is identical to the original ANON-sID-CPA game and the adversary in the last game has advantage at most the advantage of an efficient LWE adversary.

Let \mathcal{A} be a PPT adversary that attacks the AHIBET scheme Π and has advantage $\text{Adv}_{\mathcal{A},\Pi}^{\text{ANON-sID-CPA}} = \epsilon$. We will then construct a simulator \mathcal{B} that solves the LWE problem using \mathcal{A} .

Let G_i denote the event that the adversary \mathcal{A} wins **Game i** . The adversary's advantage in **Game i** is $\left| \Pr[G_i] - \frac{1}{2} \right|$.

Game 0. This is the original ANON-sID-CPA game between the adversary \mathcal{A} against our scheme and an ANON-sID-CPA challenger.

$$\text{Adv}_{\mathcal{A},\Pi}^{\text{ANON-sID-CPA}} = \left| \Pr[G_0] - \frac{1}{2} \right| = \left| \Pr[b' = b] - \frac{1}{2} \right|.$$

Game 1. **Game 1** is analogous to **Game 0** except that we slightly modify the way that the challenger \mathcal{C} generates the master public key MPK and responds to the key derivation oracles $\mathcal{O}_{\text{Derive}}$ as well as the tracing key oracles $\mathcal{O}_{\text{TskGen}}$. Let $\text{id}^* = (\text{id}_1^*, \dots, \text{id}_\ell^*)$ ($\ell \leq d$) be the target identity that \mathcal{A} intends to attack. After receiving id^* , \mathcal{C} does:

1. Sample $\mathbf{A} \leftarrow \mathbb{Z}_q^{n \times m}$, $\mathbf{R}_0, \mathbf{R}_1, \dots, \mathbf{R}_d \leftarrow \mathcal{D}_{\mathbb{Z}, \omega(\sqrt{\log n})}^{m \times \omega}$ and $\overline{\mathbf{R}} \leftarrow \mathcal{D}_{\mathbb{Z}, \omega(\sqrt{\log n})}^{m \times \lambda}$.
2. Set $\mathbf{A}_0 \leftarrow \mathbf{A}\mathbf{R}_0 - \text{FRD}(\text{H}(\text{id}^*))\mathbf{G}$.
3. Set $\mathbf{A}_i \leftarrow \mathbf{A}\mathbf{R}_i - \text{FRD}(\text{id}_i^*)\mathbf{G}$ for $i = 1, \dots, \ell$ and $\mathbf{A}_i \leftarrow \mathbf{A}\mathbf{R}_i$ for $\ell < i \leq d$.
4. Set $\mathbf{U}_2 \leftarrow \mathbf{A}\overline{\mathbf{R}}$ and sample $\mathbf{U}_1 \leftarrow \mathbb{Z}_q^{n \times \lambda}$.
5. Send master public key

$$\text{MPK} = (\mathbf{A}, \mathbf{A}_0, \mathbf{A}_1, \dots, \mathbf{A}_d, \mathbf{U}_1, \mathbf{U}_2)$$

to \mathcal{A} and keep $\mathbf{R}_0, \mathbf{R}_1, \dots, \mathbf{R}_d, \overline{\mathbf{R}}$ secret.

- Recall that the adversary \mathcal{A} is not allowed to use the challenge identity id^* or its prefixes for its key derivation queries. To respond to the key derivation queries $\mathcal{O}_{\text{Derive}}$ for $\text{id} = (\text{id}_1, \dots, \text{id}_k) \neq \text{id}^* = (\text{id}_1^*, \dots, \text{id}_\ell^*)$ ($1 \leq k \leq d$), \mathcal{C} sets

$$\mathbf{F}_{\text{id}} = [\mathbf{A}|\mathbf{A}_1 + \text{FRD}(\text{id}_1)\mathbf{G}] \dots [\mathbf{A}_k + \text{FRD}(\text{id}_k)\mathbf{G}] \in \mathbb{Z}_q^{n \times (m+k\omega)}.$$

- If $k \leq \ell$, then

$$\mathbf{F}_{\text{id}} = [\mathbf{A}|\mathbf{A}\mathbf{R}_1 + (\text{FRD}(\text{id}_1) - \text{FRD}(\text{id}_1^*))\mathbf{G}] \dots [\mathbf{A}\mathbf{R}_k + (\text{FRD}(\text{id}_k) - \text{FRD}(\text{id}_k^*))\mathbf{G}].$$

Let h be the shallowest level where $\text{id}_h \neq \text{id}_h^*$ ($h \leq k$). By the property of the full-rank difference encoding FRD , $\text{FRD}(\text{id}_h) - \text{FRD}(\text{id}_h^*) \in \mathbb{Z}_q^{n \times n}$ is an invertible matrix, \mathcal{C} then samples

$$\mathbf{T}_{\text{id}_h} \leftarrow \text{SampleBasisRight}([\mathbf{A}|\mathbf{A}\mathbf{R}_h + (\text{FRD}(\text{id}_h) - \text{FRD}(\text{id}_h^*))\mathbf{G}], \mathbf{R}_h, \text{FRD}(\text{id}_h) - \text{FRD}(\text{id}_h^*), \sigma_1).$$

If $h = k = 1$, \mathcal{C} returns $\text{SK}_{\text{id}} = \mathbf{T}_{\text{id}_1}$.

If $k > 1$, \mathcal{C} uses algorithm `ExtendBasis` to extend the basis \mathbf{T}_{id_h} of $\Lambda_q^\perp([\mathbf{A}|\mathbf{A}\mathbf{R}_h + (\text{FRD}(\text{id}_h) - \text{FRD}(\text{id}_h^*))\mathbf{G}])$ to a basis \mathbf{T}_{id} of $\Lambda_q^\perp(\mathbf{F}_{\text{id}})$ then returns $\text{SK}_{\text{id}} = \mathbf{T}_{\text{id}}$.

- If $k > \ell$, then

$$\mathbf{F}_{\text{id}} = [\mathbf{A}|\mathbf{A}\mathbf{R}_1] \dots [\mathbf{A}\mathbf{R}_\ell | \mathbf{A}\mathbf{R}_{\ell+1} + \text{FRD}(\text{id}_{\ell+1})\mathbf{G}] \dots [\mathbf{A}\mathbf{R}_k + \text{FRD}(\text{id}_k)\mathbf{G}]$$

and $\text{FRD}(\text{id}_{\ell+1}) \in \mathbb{Z}_q^{n \times n}$ is an invertible matrix. The challenger \mathcal{C} samples

$$\mathbf{T}_{\text{id}_{\ell+1}} \leftarrow \text{SampleBasisRight}([\mathbf{A}|\mathbf{A}\mathbf{R}_{\ell+1} + \text{FRD}(\text{id}_{\ell+1})\mathbf{G}], \mathbf{R}_{\ell+1}, \text{FRD}(\text{id}_{\ell+1}), \sigma_1)$$

and uses algorithm `ExtendBasis` to extend the basis $\mathbf{T}_{\text{id}_{\ell+1}}$ of $\Lambda_q^\perp([\mathbf{A}|\mathbf{A}\mathbf{R}_{\ell+1} + \text{FRD}(\text{id}_{\ell+1})\mathbf{G}])$ to a basis \mathbf{T}_{id} of $\Lambda_q^\perp(\mathbf{F}_{\text{id}})$. Finally, \mathcal{C} returns $\text{SK}_{\text{id}} = \mathbf{T}_{\text{id}}$.

- To respond to the tracing key query $\mathcal{O}_{\text{TskGen}}$ for $\text{id} = (\text{id}_1, \dots, \text{id}_k) \neq \text{id}^* = (\text{id}_1^*, \dots, \text{id}_\ell^*)$, \mathcal{C} sets

$$\mathbf{F}'_{\text{id}} = [\mathbf{A}|\mathbf{A}_0 + \text{FRD}(\text{H}(\text{id}))\mathbf{G}] = [\mathbf{A}|\mathbf{A}\mathbf{R}_0 + (\text{FRD}(\text{H}(\text{id})) - \text{FRD}(\text{H}(\text{id}^*)))\mathbf{G}].$$

Since H is a collision resistant hash function, $\text{H}(\text{id}) \neq \text{H}(\text{id}^*)$ even if id is a prefix of id^* and thus $\text{FRD}(\text{H}(\text{id})) - \text{FRD}(\text{H}(\text{id}^*))$ is an invertible matrix in $\mathbb{Z}_q^{n \times n}$. Challenger \mathcal{C} samples

$$\mathbf{D}'_{\text{id}} \leftarrow \text{SampleBasisRight}(\mathbf{F}'_{\text{id}}, \mathbf{R}_0, \text{FRD}(\text{H}(\text{id})) - \text{FRD}(\text{H}(\text{id}^*))\mathbf{G}, \sigma_1)$$

then invokes the algorithm `SamplePre`

$$\mathbf{D}_{\text{id}} \leftarrow \text{SamplePre}(\mathbf{F}'_{\text{id}}, \mathbf{D}'_{\text{id}}, \mathbf{U}_2, \sigma_1) \in \mathbb{Z}_q^{(m+\omega) \times \lambda}$$

and returns $\text{Tsk}_{\text{id}} = \mathbf{D}_{\text{id}}$.

Using Lemma 4, we can easily prove that the matrices \mathbf{A}_i ($0 \leq i \leq d$) are statistically close to uniform. Hence, in the adversary's point of view, $\mathbf{A}_0, \mathbf{A}_1, \dots, \mathbf{A}_d$ in **Game 0** and **Game 1** are computationally indistinguishable.

Next, we consider the responses to the secret key derivation queries $\mathcal{O}_{\text{Derive}}$ and the tracing key queries $\mathcal{O}_{\text{TskGen}}$. For secret key derivation queries $\mathcal{O}_{\text{Derive}}$, Theorem 10 shows that when $\sigma_1 \geq 5 \cdot s_1(\mathbf{R}) \cdot \omega(\sqrt{\log n})$, $\sigma_\ell \geq \|\mathbf{T}_{\text{id}_h}\| \cdot \omega(\sqrt{\log(m + \ell\omega)})$, the algorithms **SampleBasisRight** and **ExtendBasis** generate a basis \mathbf{T}_{id} for $\Lambda_q^\perp(\mathbf{F}_{\text{id}})$ which is statistically close to the one generated in the original game. Similarly, the tracing keys generate by **SampleBasisRight** and **SamplePre** in **Game 1** have distribution statistically close to ones in **Game 0**.

Since the master public key MPK and responses to key derivation queries and tracing key queries in **Game 1** are statistically close to those in **Game 0**, these games are statistically indistinguishable in the view of the adversary. Thus we have

$$|\Pr[G_1] - \Pr[G_0]| \leq \text{negl}(\lambda).$$

Game 2. In this game, we change the way the challenge ciphertext CT^* for the challenge identity id^* is created. Recall that, after receiving a message $\mathbf{m} \in \{0, 1\}^\lambda$ from the adversary \mathcal{A} , the challenger \mathcal{C} then selects a random bit $b \in \{0, 1\}$.

If $b = 1$, \mathcal{C} chooses a random identity id' in the identity space which is not identical to any query identities in **Phase 1**. \mathcal{C} then runs **Encrypt**(MPK, id , \mathbf{m}) and sends the resulting ciphertext CT_1^* to \mathcal{A} .

If $b = 0$, the challenger \mathcal{C} does the following steps to generate CT_0^* and sends it to \mathcal{A} .

1. Sample $\mathbf{k} \leftarrow \{0, 1\}^\lambda$.
2. Sample $\mathbf{s} \leftarrow \mathbb{Z}_q^n$.
3. Choose noise vectors $\mathbf{e}_0 \leftarrow \mathcal{D}_{\mathbb{Z}, r}^m$, $\mathbf{e}_2 \leftarrow \mathcal{D}_{\mathbb{Z}, r}^\lambda$.
4. Set $\mathbf{c}_0^T = \mathbf{s}^T \mathbf{A} + \mathbf{e}_0^T$, $\mathbf{c}_2^T = \mathbf{s}^T \mathbf{U}_1 + \mathbf{e}_2^T + \mathbf{m}^T \lfloor \frac{q}{2} \rfloor$ and

$$\begin{aligned} \mathbf{c}_1^T &\leftarrow \text{ReRand}(\mathbf{R}, \mathbf{c}_0^T, r, \tau) \\ \mathbf{c}_3^T &\leftarrow \text{ReRand}(\overline{\mathbf{R}}, \mathbf{c}_0^T, r, \tau) + \left(\mathbf{k} \lfloor \frac{q}{2} \rfloor \right)^T \\ \mathbf{c}_4^T &\leftarrow \text{ReRand}(\mathbf{R}_0, \mathbf{c}_0^T, r, \tau) \end{aligned}$$

where $\mathbf{R} = [\mathbf{R}_1 | \dots | \mathbf{R}_\ell]$.

5. Output $\text{CT}_0^* = (\mathbf{c}_0, \mathbf{c}_1, \mathbf{c}_2, \mathbf{c}_3, \mathbf{c}_4, \mathbf{k})$.

Observe that \mathbf{c}_0 and \mathbf{c}_3 are distributed exactly as they as in the previous game. Since

$$\begin{aligned} \mathbf{F}_{\text{id}^*} &= [\mathbf{A} | \mathbf{A}_1 + \text{FRD}(\text{id}_1^*)\mathbf{G} | \dots | \mathbf{A}_\ell + \text{FRD}(\text{id}_\ell^*)\mathbf{G}] \in \mathbb{Z}_q^{n \times (m + \ell\omega)} \\ &= [\mathbf{A} | \mathbf{A}\mathbf{R}_1 | \dots | \mathbf{A}\mathbf{R}_\ell] = [\mathbf{A} | \mathbf{A}\mathbf{R}] \end{aligned}$$

by Lemma 7, we get

$$\begin{aligned} \mathbf{c}_1^T &= \text{ReRand}(\mathbf{R} = [\mathbf{R}_1 | \dots | \mathbf{R}_\ell], \mathbf{c}_0^T = \mathbf{s}^T \mathbf{A} + \mathbf{e}_0^T, r, \tau) = \mathbf{s}^T \mathbf{A}\mathbf{R} + \mathbf{e}_1^T, \\ \mathbf{c}_3^T &= \text{ReRand}(\overline{\mathbf{R}}, \mathbf{c}_0^T = \mathbf{s}^T \mathbf{A} + \mathbf{e}_0^T, r, \tau) + \left(\mathbf{k} \lfloor \frac{q}{2} \rfloor \right)^T \\ &= \mathbf{s}^T \mathbf{A}\overline{\mathbf{R}} + \mathbf{e}_3^T = \mathbf{s}^T \mathbf{U}_2 + \mathbf{e}_3^T + \mathbf{k}^T \lfloor \frac{q}{2} \rfloor, \\ \mathbf{c}_4^T &= \text{ReRand}(\mathbf{R}_0, \mathbf{c}_0^T = \mathbf{s}^T \mathbf{A} + \mathbf{e}_0^T, r, \tau) \\ &= \mathbf{s}^T \mathbf{A}\mathbf{R}_0 + \mathbf{e}_4^T = \mathbf{s}^T (\mathbf{A}_0 + \text{FRD}(\text{H}(\text{id}^*))\mathbf{G}) + \mathbf{e}_4^T \end{aligned}$$

where the distribution of $\mathbf{e}_1, \mathbf{e}_3$ and \mathbf{e}_4 are statistically close to $\mathcal{D}_{\mathbb{Z}, 2r\tau}^{\ell\omega}$, $\mathcal{D}_{\mathbb{Z}, 2r\tau}^\lambda$ and $\mathcal{D}_{\mathbb{Z}, 2r\tau}^\omega$, respectively. So we yields that **Game 1** and **Game 2** are statistically close in the adversary's point of view, the adversary's advantage against **Game 2** will be the same as **Game 1**.

$$|\Pr[G_2] - \Pr[G_1]| \leq \text{negl}(\lambda).$$

Theorem 1 then follows from the reduction from the LWE problem by the following lemma.

Lemma 13. *If there exists an adversary \mathcal{A} that wins the Game 2 with non-negligible advantage then there is an adversary \mathcal{B} that solves the LWE problem, i.e., $\text{Adv}_{\mathcal{A}}^{\text{Game2}} \leq \text{Adv}_{\mathcal{B}}^{\text{LWE}_{n,m+\lambda,q,r}}(\lambda)$ for some LWE adversary \mathcal{B} .*

Proof of Lemma 13. Recall that an LWE problem instance is provided as a sampling oracle \mathcal{O} . \mathcal{B} requests from oracle \mathcal{O} and receives a decisional $\text{LWE}_{n,m+\lambda,q,r}$ problem sample $(\mathbf{C}, \mathbf{c}^T = \mathbf{u}^T + \mathbf{e}^T)$ where \mathbf{C} is a random matrix in $\mathbb{Z}_q^{n \times (m+\lambda)}$, $\mathbf{c} \in \mathbb{Z}^{m+\lambda}$ and \mathbf{e} is sampled from the distribution $\mathcal{D}_{\mathbb{Z},r}^{m+\lambda}$. \mathcal{B} needs to decide whether \mathbf{u} is truly random \mathcal{O}_s or a noisy pseudo-random \mathcal{O}_s for some secret random $\mathbf{s} \in \mathbb{Z}_q^n$ such that $\mathbf{u}^T = \mathbf{s}^T \mathbf{C}$. \mathcal{B} simulates **Game 2** with adversary \mathcal{A} and uses the guess from \mathcal{A} to respond LWE challenges.

After receiving the challenge identity $\text{id}^* = (\text{id}_1^*, \dots, \text{id}_\ell^*)$ ($\ell \leq d$) from \mathcal{A} , \mathcal{B} constructs the simulator as follows:

- Split $\mathbf{C} = [\mathbf{A} | \mathbf{U}_1]$ where $\mathbf{A} \in \mathbb{Z}_q^{n \times m}$ and $\mathbf{U}_1 \in \mathbb{Z}_q^{n \times \lambda}$.
- Sample $\mathbf{R}_0, \mathbf{R}_1, \dots, \mathbf{R}_d \leftarrow \mathcal{D}_{\mathbb{Z}, \omega(\sqrt{\log n})}^{m \times \omega}$, $\bar{\mathbf{R}} \leftarrow \mathcal{D}_{\mathbb{Z}, \omega(\sqrt{\log n})}^{m \times \lambda}$ and set $\mathbf{R} = [\mathbf{R}_1 | \dots | \mathbf{R}_\ell]$.
- Set $\mathbf{A}_0 \leftarrow \mathbf{A}\mathbf{R}_0 - \text{FRD}(\text{H}(\text{id}^*))\mathbf{G}$.
- Set $\mathbf{A}_i \leftarrow \mathbf{A}\mathbf{R}_i - \text{H}(\text{id}_i^*)\mathbf{G}$ for $i = 1, \dots, \ell$ and $\mathbf{A}_i \leftarrow \mathbf{A}\mathbf{R}_i$ for $\ell < i \leq d$.
- Set $\mathbf{U}_2 \leftarrow \mathbf{A}\bar{\mathbf{R}}$ and sample $\mathbf{U}_1 \leftarrow \mathbb{Z}_q^{n \times \lambda}$.
- Send the master public key

$$\text{MPK} = (\mathbf{A}, \mathbf{A}_0, \mathbf{A}_1, \dots, \mathbf{A}_d, \mathbf{U}_1, \mathbf{U}_2)$$

to \mathcal{A} and keep $\mathbf{R}_0, \mathbf{R}_1, \dots, \mathbf{R}_d, \bar{\mathbf{R}}$ secret.

- Respond to the key derivation queries and tracing key queries as in Game 2.
- Split $\mathbf{c}^T = (\bar{\mathbf{c}}^T | \tilde{\mathbf{c}}^T) \in \mathbb{Z}_q^{m+\lambda}$ where $\bar{\mathbf{c}}^T = \bar{\mathbf{u}}^T + \bar{\mathbf{e}}^T \in \mathbb{Z}_q^m$ and $\tilde{\mathbf{c}}^T = \tilde{\mathbf{u}}^T + \tilde{\mathbf{e}}^T \in \mathbb{Z}_q^\lambda$.
- Create the challenge ciphertext CT^* :
 1. Sample $\mathbf{k} \leftarrow \{0, 1\}^\lambda$.
 2. Set $\mathbf{c}_0^T = \bar{\mathbf{c}}^T$, $\mathbf{c}_2^T = \tilde{\mathbf{c}}^T + \mathbf{m}^T \left\lfloor \frac{q}{2} \right\rfloor$.
 3. Set

$$\begin{aligned} \mathbf{c}_1^T &\leftarrow \text{ReRand}(\mathbf{R}, \mathbf{c}_0^T, r, \tau) \\ \mathbf{c}_3^T &\leftarrow \text{ReRand}(\bar{\mathbf{R}}, \mathbf{c}_0^T, r, \tau) + \mathbf{k}^T \left\lfloor \frac{q}{2} \right\rfloor \\ \mathbf{c}_4^T &\leftarrow \text{ReRand}(\mathbf{R}_0, \mathbf{c}_0^T, r, \tau) \end{aligned}$$

4. Send $\text{CT}^* = (\mathbf{c}_0, \mathbf{c}_1, \mathbf{c}_2, \mathbf{c}_3, \mathbf{c}_4, \mathbf{k})$ to \mathcal{A} .

When LWE oracle is pseudorandom (i.e. $\mathcal{O} = \mathcal{O}_s$) then $\mathbf{c}_0^T = \mathbf{s}^T \mathbf{A} + \mathbf{e}_0^T$, $\mathbf{c}_2^T = \mathbf{s}^T \mathbf{U}_1 + \mathbf{e}_2^T + \mathbf{m}^T \left\lfloor \frac{q}{2} \right\rfloor$, meaning that CT^* is a valid challenge ciphertext that encrypts challenge message \mathbf{m} for the target identity id^* .

When LWE oracle is a random oracle (i.e. $\mathcal{O} = \mathcal{O}_\$$), \mathbf{c}^T is uniformly random in $\mathbb{Z}_q^{m+\lambda}$ and thus CT^* distributes as a ciphertext encrypted for a random identity in the identity space. Indeed, we have

$$\begin{aligned} \mathbf{c}_0^T &= \bar{\mathbf{u}}^T + \mathbf{e}_0^T \\ \mathbf{c}_1^T &= \text{ReRand}(\mathbf{R}, \mathbf{c}_0^T, r, \tau) = \bar{\mathbf{u}}^T \mathbf{R} + \mathbf{e}_1^T \\ \mathbf{c}_2^T &= \tilde{\mathbf{u}}^T + \mathbf{e}_2^T + \mathbf{m}^T \left\lfloor \frac{q}{2} \right\rfloor \\ \mathbf{c}_3^T &= \text{ReRand}(\bar{\mathbf{R}}, \mathbf{c}_0^T, r, \tau) + \mathbf{m}^T \left\lfloor \frac{q}{2} \right\rfloor = \bar{\mathbf{u}}^T \bar{\mathbf{R}} + \mathbf{e}_3^T + \mathbf{k}^T \left\lfloor \frac{q}{2} \right\rfloor \\ \mathbf{c}_4^T &= \text{ReRand}(\mathbf{R}_0, \mathbf{c}_0^T, r, \tau) = \bar{\mathbf{u}}^T \mathbf{R}_0 + \mathbf{e}_4^T \end{aligned}$$

where $\mathbf{e}_1, \mathbf{e}_3$ and \mathbf{e}_4 are statistically close to $\mathcal{D}_{\mathbb{Z}, 2r\tau}^{\ell\omega}$, $\mathcal{D}_{\mathbb{Z}, 2r\tau}^\lambda$ and $\mathcal{D}_{\mathbb{Z}, 2r\tau}^\omega$, respectively. Since $\mathbf{u} = (\bar{\mathbf{u}}|\tilde{\mathbf{u}})$ is a random vector, the following distributions are negligibly close by using Lemma 4:

$$(\mathbf{A}, \mathbf{A}\mathbf{R}, \mathbf{A}\bar{\mathbf{R}}, \mathbf{A}\mathbf{R}_0, \bar{\mathbf{u}}^T, \bar{\mathbf{u}}^T \mathbf{R}, \bar{\mathbf{u}}^T \bar{\mathbf{R}}, \bar{\mathbf{u}}^T \mathbf{R}_0) \approx (\mathbf{A}, \mathbf{B}_{\text{id}'}, \mathbf{U}_2, \mathbf{A}_0 + \text{FRD}(\text{H}(\text{id}^*))\mathbf{G}, \bar{\mathbf{u}}^T, \mathbf{u}_1^T, \mathbf{u}_2^T, \mathbf{u}_3^T)$$

where \mathbf{A} is a random matrix in $\mathbb{Z}_q^{n \times m}$, $\mathbf{R}_0, \mathbf{R}_1, \dots, \mathbf{R}_d \leftarrow \mathcal{D}_{\mathbb{Z}, \omega(\sqrt{\log n})}^{m \times \omega}$, $\bar{\mathbf{R}} \leftarrow \mathcal{D}_{\mathbb{Z}, \omega(\sqrt{\log n})}^{m \times \lambda}$, $\mathbf{R} = [\mathbf{R}_1 | \dots | \mathbf{R}_\ell]$ ($\ell \leq d$), $\mathbf{B}_{\text{id}'} = [\mathbf{A}_1 + \text{FRD}(\text{id}'_1)\mathbf{G} | \dots | \mathbf{A}_\ell + \text{FRD}(\text{id}'_\ell)\mathbf{G}]$ for a random identity $\text{id}' = (\text{id}'_1, \dots, \text{id}'_\ell)$ of level ℓ , and $\mathbf{u}_1 \in \mathbb{Z}_q^{\ell\omega}$, $\mathbf{u}_2 \in \mathbb{Z}_q^\lambda$, $\mathbf{u}_3 \in \mathbb{Z}_q^\omega$ are uniformly random vectors. Therefore, in the view of the adversary \mathcal{A} , when the LWE oracle is random, CT^* distributes as a ciphertext encrypted message \mathbf{m} for a random identity. This implies that

$$\text{Adv}_{\mathcal{A}}^{\text{Game2}} \leq \text{Adv}_{\mathcal{B}}^{\text{LWE}_{n,q,m+\lambda,r}}(\lambda).$$

□

4.2 Proof of Ciphertext Indistinguishability

Finally, we will prove that our proposed AHIBET scheme is IND-sID-CPA secure in the standard model. Recall that indistinguishable from random meaning that the challenge ciphertext encrypted for a given message \mathbf{m}^* is computationally indistinguishable from a challenge ciphertext encrypted for a random message \mathbf{m} in the message space on the same challenge identity id^* .

Theorem 2. *The AHIBET scheme $\Pi := (\text{Setup}, \text{Extract}, \text{Derive}, \text{Encrypt}, \text{Decrypt}, \text{TskGen}, \text{TkVer})$ with parameters $(\lambda, n, m, q, \omega, \bar{\sigma}, \tau, \alpha, r)$ as in (1) is IND-sID-CPA secure for the maximal hierarchy depth d provided that the hardness $\text{LWE}_{n,q,m+\lambda,r}$ assumption holds.*

Proof. We will proceed the proof via a sequence of games where the **Game 0** is identical to the original IND-sID-CPA game and the adversary has no advantage in winning the last game. Let \mathcal{A} be a PPT adversary that attacks the AHIBET scheme Π and has advantage $\text{Adv}_{\mathcal{A}, \Pi}^{\text{IND-sID-CPA}} = \epsilon$. We will then construct a simulator \mathcal{B} that solves the LWE problem using \mathcal{A} .

In **Game i** , let G_i denote the event that the adversary \mathcal{A} win the game. The adversary's advantage in **Game i** is $|\Pr[G_i] - \frac{1}{2}|$.

Game 0. This is the original IND-sID-CPA game between the adversary \mathcal{A} against our scheme and an IND-sID-CPA challenger.

$$\text{Adv}_{\mathcal{A}, \Pi}^{\text{IND-sID-CPA}} = \left| \Pr[G_0] - \frac{1}{2} \right| = \left| \Pr[b' = b] - \frac{1}{2} \right|.$$

Game 1. **Game 1** is similar to **Game 0** except that we slightly modify the way that the challenger \mathcal{C} generates the master public key MPK and responds to the key derivation oracles $\mathcal{O}_{\text{Derive}}$ and tracing key oracles $\mathcal{O}_{\text{TskGen}}$. Let $\text{id}^* = (\text{id}_1^*, \dots, \text{id}_\ell^*)$ ($\ell \leq d$) be the identity that \mathcal{A} intends to attack. After receiving id^* , \mathcal{C} does:

1. Sample $\mathbf{A} \leftarrow \mathbb{Z}_q^{n \times m}$, $\mathbf{R}_0, \mathbf{R}_1, \dots, \mathbf{R}_d \leftarrow \mathcal{D}_{\mathbb{Z}, \omega(\sqrt{\log n})}^{m \times \omega}$ and $\mathbf{D}_0 \leftarrow \mathcal{D}_{\mathbb{Z}, \sigma_1}^{m \times \lambda}$, $\mathbf{D}_1 \leftarrow \mathcal{D}_{\mathbb{Z}, \sigma_1}^{\omega \times \lambda}$.
2. Set $\mathbf{A}_i \leftarrow \mathbf{A}\mathbf{R}_i - \text{FRD}(\text{id}_i^*)\mathbf{G}$ for $i = 1, \dots, \ell$ and $\mathbf{A}_i \leftarrow \mathbf{A}\mathbf{R}_i$ for $\ell < i \leq d$.
3. Set $\overline{\mathbf{R}} \leftarrow \mathbf{D}_0 + \mathbf{R}_0\mathbf{D}_1$.
4. Set $\mathbf{A}_0 \leftarrow \mathbf{A}\mathbf{R}_0 - \text{FRD}(\text{H}(\text{id}^*))\mathbf{G}$, $\mathbf{U}_2 \leftarrow \mathbf{A}\overline{\mathbf{R}}$ and sample $\mathbf{U}_1 \leftarrow \mathbb{Z}_q^{n \times \lambda}$.
5. Output the master public key

$$\text{MPK} = (\mathbf{A}, \mathbf{A}_0, \mathbf{A}_1, \dots, \mathbf{A}_d, \mathbf{U}_1, \mathbf{U}_2)$$

and keep $\mathbf{R}_0, \mathbf{R}_1, \dots, \mathbf{R}_d, \overline{\mathbf{R}}$ secret.

- The adversary \mathcal{A} is not allowed to ask for the key derivation queries of the challenge identity id^* and its prefixes. To respond to a key derivation query $\mathcal{O}_{\text{Derive}}$ for an identity $\text{id} = (\text{id}_1, \dots, \text{id}_k)$, \mathcal{C} sets:

$$\mathbf{F}_{\text{id}} = [\mathbf{A}|\mathbf{A}_1 + \text{FRD}(\text{id}_1)\mathbf{G} | \dots | \mathbf{A}_k + \text{FRD}(\text{id}_k)\mathbf{G}] \in \mathbb{Z}_q^{n \times (m+k\omega)}.$$

- If $k \leq \ell$, then

$$\mathbf{F}_{\text{id}} = [\mathbf{A}|\mathbf{A}\mathbf{R}_1 + (\text{FRD}(\text{id}_1) - \text{FRD}(\text{id}_1^*))\mathbf{G} | \dots | \mathbf{A}\mathbf{R}_k + (\text{FRD}(\text{id}_k) - \text{FRD}(\text{id}_k^*))\mathbf{G}].$$

Let h be the shallowest level where $\text{id}_h \neq \text{id}_h^*$ ($h \leq k$). By the property of the full-rank difference encoding FRD, $\text{FRD}(\text{id}_h) - \text{FRD}(\text{id}_h^*) \in \mathbb{Z}_q^{n \times n}$ is an invertible matrix, \mathcal{C} then samples

$$\mathbf{T}_{\text{id}_h} \leftarrow \text{SampleBasisRight}([\mathbf{A}|\mathbf{A}\mathbf{R}_h + (\text{FRD}(\text{id}_h) - \text{FRD}(\text{id}_h^*))\mathbf{G}], \mathbf{R}_h, \text{FRD}(\text{id}_h) - \text{FRD}(\text{id}_h^*), \sigma_1).$$

If $h = k = 1$, \mathcal{C} returns $\text{SK}_{\text{id}} = \mathbf{T}_{\text{id}_1}$.

If $k > 1$, \mathcal{C} uses algorithm `ExtendBasis` to extend the basis \mathbf{T}_{id_h} of $\Lambda_q^\perp([\mathbf{A}|\mathbf{A}\mathbf{R}_h + (\text{FRD}(\text{id}_h) - \text{FRD}(\text{id}_h^*))\mathbf{G}])$ to a basis \mathbf{T}_{id} of $\Lambda_q^\perp(\mathbf{F}_{\text{id}})$ then returns $\text{SK}_{\text{id}} = \mathbf{T}_{\text{id}}$.

- If $k > \ell$, then

$$\mathbf{F}_{\text{id}} = [\mathbf{A}|\mathbf{A}\mathbf{R}_1 | \dots | \mathbf{A}\mathbf{R}_\ell | \mathbf{A}\mathbf{R}_{\ell+1} + \text{FRD}(\text{id}_{\ell+1})\mathbf{G} | \dots | \mathbf{A}\mathbf{R}_k + \text{FRD}(\text{id}_k)\mathbf{G}]$$

and $\text{FRD}(\text{id}_{\ell+1}) \in \mathbb{Z}_q^{n \times n}$ is an invertible matrix. The challenger \mathcal{C} samples

$$\mathbf{T}_{\text{id}_{\ell+1}} \leftarrow \text{SampleBasisRight}([\mathbf{A}|\mathbf{A}\mathbf{R}_{\ell+1} + \text{FRD}(\text{id}_{\ell+1})\mathbf{G}], \mathbf{R}_{\ell+1}, \text{FRD}(\text{id}_{\ell+1}), \sigma_1)$$

and uses algorithm `ExtendBasis` to extend the basis $\mathbf{T}_{\text{id}_{\ell+1}}$ of $\Lambda_q^\perp([\mathbf{A}|\mathbf{A}\mathbf{R}_{\ell+1} + \text{FRD}(\text{id}_{\ell+1})\mathbf{G}])$ to a basis \mathbf{T}_{id} of $\Lambda_q^\perp(\mathbf{F}_{\text{id}})$. Finally, \mathcal{C} returns $\text{SK}_{\text{id}} = \mathbf{T}_{\text{id}}$.

- To respond to the tracing key query $\mathcal{O}_{\text{TskGen}}$ for $\text{id} = (\text{id}_1, \dots, \text{id}_k) \neq \text{id}^* = (\text{id}_1^*, \dots, \text{id}_\ell^*)$, \mathcal{C} sets:

$$\mathbf{F}'_{\text{id}} = [\mathbf{A}|\mathbf{A}\mathbf{R}_0 + (\text{FRD}(\text{H}(\text{id})) - \text{FRD}(\text{H}(\text{id}^*)))\mathbf{G}]$$

Since H is a collision resistant hash function, $\text{H}(\text{id}) \neq \text{H}(\text{id}^*)$ even if id is a prefix of id^* and thus $\text{FRD}(\text{H}(\text{id})) - \text{FRD}(\text{H}(\text{id}^*))$ is an invertible matrix in $\mathbb{Z}_q^{n \times n}$. The challenger \mathcal{C} samples

$$\mathbf{D}'_{\text{id}} \leftarrow \text{SampleBasisRight}(\mathbf{F}'_{\text{id}}, \mathbf{R}_0, \text{FRD}(\text{H}(\text{id})) - \text{FRD}(\text{H}(\text{id}^*))\mathbf{G}, \sigma_1)$$

then invokes the algorithm `SamplePre`

$$\mathbf{D}_{\text{id}} \leftarrow \text{SamplePre}(\mathbf{F}'_{\text{id}}, \mathbf{D}'_{\text{id}}, \mathbf{U}_2, \sigma_1) \in \mathbb{Z}_q^{(m+\omega) \times \lambda}$$

and returns $\text{Tsk}_{\text{id}} = \mathbf{D}_{\text{id}}$.

To respond to the tracing key query of $\text{id}^* = (\text{id}_1^*, \dots, \text{id}_\ell^*)$, the challenger \mathcal{C} sets:

$$\text{Tsk}_{\text{id}^*} = \mathbf{D}_{\text{id}^*} = \begin{bmatrix} \mathbf{D}_0 \\ \mathbf{D}_1 \end{bmatrix} \in \mathbb{Z}^{(m+\omega) \times \lambda}$$

so that

$$[\mathbf{A} | \mathbf{A}_0 + \text{FRD}(\text{H}(\text{id}^*))\mathbf{G}] \mathbf{D}_{\text{id}^*} = [\mathbf{A} | \mathbf{A}\mathbf{R}_0] \begin{bmatrix} \mathbf{D}_0 \\ \mathbf{D}_1 \end{bmatrix} = \mathbf{A}\mathbf{D}_0 + \mathbf{A}\mathbf{R}_0\mathbf{D}_1 = \mathbf{A}\bar{\mathbf{R}} = \mathbf{U}_2.$$

Using Lemma 4 with $\sigma_1 \geq O(\sqrt{m}) \cdot \omega(\log n)$ we have: the distribution of \mathbf{U}_2 is statistically close to uniform over \mathbb{Z}_q^λ and \mathbf{D}_{id^*} has the distribution $\mathcal{D}_{\mathbb{Z}, \sigma_1}^{(m+\omega) \times \lambda}$. Since the master public key MPK and responses to key derivation queries and the tracing key queries are statistically close to those in **Game 0**, the adversary's advantage in **Game 1** is at most negligibly different from its advantage in **Game 0**.

$$|\Pr[\mathbf{G}_1] - \Pr[\mathbf{G}_0]| \leq \text{negl}(\lambda).$$

Game 2. **Game 2** is similar to **Game 1** except that we modify the construction of the challenge ciphertext CT^* . The challenger \mathcal{C} sets $\mathbf{m}_0 = \mathbf{m}^*$, chooses a random bit $b \in \{0, 1\}$, a random message \mathbf{m}_1 in the message space and generates the ciphertext CT_b^* for a message $\mathbf{m}_b \in \{0, 1\}^\lambda$ of the identity id^* as follows:

1. Sample $\mathbf{k} \leftarrow \{0, 1\}^\lambda$.
2. Sample $\mathbf{s} \leftarrow \mathbb{Z}_q^n$.
3. Choose noise vectors $\mathbf{e}_0 \leftarrow \mathcal{D}_{\mathbb{Z}, r}^m$, $\mathbf{e}_2 \leftarrow \mathcal{D}_{\mathbb{Z}, r}^\lambda$.
4. Set $\mathbf{c}_0^T = \mathbf{s}^T \mathbf{A} + \mathbf{e}_0^T$, $\mathbf{c}_2^T = \mathbf{s}^T \mathbf{U}_1 + \mathbf{e}_2^T + \mathbf{m}_b^T \left\lfloor \frac{q}{2} \right\rfloor$ and

$$\begin{aligned} \mathbf{c}_1^T &\leftarrow \text{ReRand}(\mathbf{R}, \mathbf{c}_0^T, r, \tau) \\ \mathbf{c}_3^T &\leftarrow \text{ReRand}(\bar{\mathbf{R}}, \mathbf{c}_0^T, r, \tau) + \left(\mathbf{k} \left\lfloor \frac{q}{2} \right\rfloor \right)^T \\ \mathbf{c}_4^T &\leftarrow \text{ReRand}(\mathbf{R}_0, \mathbf{c}_0^T, r, \tau) \end{aligned}$$

where $\mathbf{R} = [\mathbf{R}_1 | \dots | \mathbf{R}_\ell]$ and $\bar{\mathbf{R}} = \mathbf{D}_0 + \mathbf{R}_0\mathbf{D}_1$. Note that $\|\bar{\mathbf{R}}\| < \tau$ by the way that the game generates the matrices $\mathbf{R}_0, \mathbf{D}_0$ and \mathbf{D}_1 .

5. Output $\text{CT}_0^* = (\mathbf{c}_0, \mathbf{c}_1, \mathbf{c}_2, \mathbf{c}_3, \mathbf{c}_4, \mathbf{k})$.

We have that $\mathbf{c}_0, \mathbf{c}_2$ are distributed exactly as in the previous game, besides

$$\begin{aligned} \mathbf{c}_1^T &= \text{ReRand}(\mathbf{R} = [\mathbf{R}_1 | \dots | \mathbf{R}_\ell], \mathbf{c}_0^T = \mathbf{s}^T \mathbf{A} + \mathbf{e}_0^T, r, \tau) \\ &= \mathbf{s}^T \mathbf{A}\mathbf{R} + \mathbf{e}_1^T \\ \mathbf{c}_3^T &= \text{ReRand}(\bar{\mathbf{R}}, \mathbf{c}_0^T = \mathbf{s}^T \mathbf{A} + \mathbf{e}_0^T, r, \tau) + \mathbf{k}^T \left\lfloor \frac{q}{2} \right\rfloor = \mathbf{s}^T \mathbf{A}\bar{\mathbf{R}} + \mathbf{e}_2^T + \mathbf{k}^T \left\lfloor \frac{q}{2} \right\rfloor \\ &= \mathbf{s}^T \mathbf{A}(\mathbf{D}_0 + \mathbf{R}_0\mathbf{D}_1) + \mathbf{e}_3^T + \mathbf{k}^T \left\lfloor \frac{q}{2} \right\rfloor = \mathbf{s}^T \mathbf{U}_2 + \mathbf{e}_3^T + \mathbf{k}^T \left\lfloor \frac{q}{2} \right\rfloor \\ \mathbf{c}_4^T &= \text{ReRand}(\mathbf{R}_0, \mathbf{c}_0^T = \mathbf{s}^T \mathbf{A} + \mathbf{e}_0^T, r, \tau) \\ &= \mathbf{s}^T \mathbf{A}\mathbf{R}_0 + \mathbf{e}_4^T = \mathbf{s}^T (\mathbf{A}_0 + \text{FRD}(\text{H}(\text{id}^*))\mathbf{G}) + \mathbf{e}_4^T \end{aligned}$$

where the distribution of \mathbf{e}_1 , \mathbf{e}_3 and \mathbf{e}_4 are statistically close to $\mathcal{D}_{\mathbb{Z}, 2r\tau}^{\ell\omega}$, $\mathcal{D}_{\mathbb{Z}, 2r\tau}^\lambda$ and $\mathcal{D}_{\mathbb{Z}, 2r\tau}^\omega$, respectively. So we yields that **Game 1** and **Game 2** are statistically close in the adversary's point of view, the adversary's advantage against **Game 2** will be the same as **Game 1**.

$$|\Pr[G_2] - \Pr[G_1]| \leq \text{negl}(\lambda).$$

Game 3. In this game, we keep changing how the challenge ciphertext is created. The challenger \mathcal{C} does:

1. Sample $\mathbf{k} \leftarrow \{0, 1\}^\lambda$.
2. Sample $\tilde{\mathbf{u}} \leftarrow \mathbb{Z}_q^m$ and $\tilde{\mathbf{u}} \leftarrow \mathbb{Z}_q^\lambda$
3. Choose noise vectors $\mathbf{e}_0 \leftarrow \mathcal{D}_{\mathbb{Z}, r}^m$, $\mathbf{e}_2 \leftarrow \mathcal{D}_{\mathbb{Z}, r}^\lambda$.
4. Set $\mathbf{c}_0 = \tilde{\mathbf{u}} + \mathbf{e}_0$, $\mathbf{c}_2 = \tilde{\mathbf{u}} + \mathbf{e}_2 + \mathbf{m}_b \lfloor \frac{q}{2} \rfloor$ and

$$\begin{aligned} \mathbf{c}_1^T &\leftarrow \text{ReRand}(\mathbf{R}, \mathbf{c}_0^T, r, \tau) \\ \mathbf{c}_3^T &\leftarrow \text{ReRand}(\overline{\mathbf{R}}, \mathbf{c}_0^T, r, \tau) + \left(\mathbf{k} \lfloor \frac{q}{2} \rfloor \right)^T \\ \mathbf{c}_4^T &\leftarrow \text{ReRand}(\mathbf{R}_0, \mathbf{c}_0^T, r, \tau) \end{aligned}$$

where $\mathbf{R} = [\mathbf{R}_1 | \dots | \mathbf{R}_\ell]$.

5. Output $\text{CT}_0^* = (\mathbf{c}_0, \mathbf{c}_1, \mathbf{c}_2, \mathbf{c}_3, \mathbf{c}_4, \mathbf{k})$.

Observe that the ciphertext $\mathbf{c}_2 = \tilde{\mathbf{u}} + \mathbf{e}_2 + \mathbf{m}_b \lfloor \frac{q}{2} \rfloor$ in **Game 3** is uniformly random over \mathbb{Z}_q^λ . Therefore, the ciphertext is independent from \mathbf{m}_b in the adversary \mathcal{A} 's view. Hence, both CT_0^* and CT_1^* is statistically close to the uniform distribution over the ciphertext space, and the adversary \mathcal{A} has no advantage in winning the game. We have

$$\left| \Pr[G_3] - \frac{1}{2} \right| \leq \text{negl}(\lambda).$$

Moreover, using the same reduction technique as in the Anonymity Game in the previous subsection, we can construct a simulator \mathcal{B} that solves LWE problem if adversary \mathcal{A} is able to distinguish between **Game 2** and **Game 3**. Therefore we have

$$|\Pr[G_3] - \Pr[G_2]| \leq \text{Adv}_{\mathcal{B}}^{\text{LWE}_{n, q, m+\lambda, r}}(\lambda),$$

which completes the proof of Theorem 2. □

5 Conclusion

In this paper, we propose a Lattice-based Anonymous Hierarchical Identity-Based Encryption scheme with Traceable Identities (AHIBET) and prove that our scheme is secure in the standard model based on the decisional LWE assumption.
