Abstract

We provide matching upper and lower bounds of order \( \sigma^2/\log(d/n) \) for the prediction error of the minimum \( \ell_1 \)-norm interpolator, a.k.a. basis pursuit. Our result is tight up to negligible terms when \( d \gg n \), and is the first to imply asymptotic consistency of noisy minimum-norm interpolation for isotropic features and sparse ground truths. Our work complements the literature on “benign overfitting” for minimum \( \ell_2 \)-norm interpolation, where asymptotic consistency can be achieved only when the features are effectively low-dimensional.

1 Introduction

Recent experimental studies [BHMM19; ZBHRV21] reveal that in the modern high-dimensional regime, models that perfectly fit noisy training data can still generalize well. The phenomenon stands in contrast to the classical wisdom that interpolating the data results in poor statistical performance due to overfitting. Many theoretical papers have explored why, when, and to what extent interpolation can be harmless for generalization, suggesting a coherent storyline: High dimensionality itself can have a regularizing effect, in the sense that it lowers the model’s sensitivity to noise. This intuition emerges from the fast-growing literature studying min-\( \ell_2 \)-norm interpolation in the regression setting with input dimension \( d \) substantially exceeding sample size \( n \) (see [BLLT20; DW18] and references therein). Results and intuition for this setting also extend to kernel methods [GMMM21; MM19].

However, a closer look at this literature reveals that while high dimensionality decreases the sensitivity to noise (error due to variance), the prediction error generally does not vanish as \( d, n \to \infty \). Indeed, the bottleneck for asymptotic consistency is a non-vanishing bias term which can only be avoided when the features have low effective dimension \( d_{\text{eff}} = \text{Tr} \Sigma/\|\Sigma\|_{\text{op}} \ll n \), where \( \Sigma \) is the covariance matrix [TB20]. Therefore, current theory does not yet provide a convincing explanation for why interpolating models generalize well for inherently high-dimensional input data. This work takes a step towards addressing this gap.

When the input data is effectively high-dimensional (e.g. isotropic and \( d \gg n \)), we generally cannot expect any data-driven estimator to generalize well unless there is underlying structure that can be exploited. In this paper, we hence focus on linear regression on isotropic Gaussian features with the simplest structural assumption: sparsity of the ground truth in the standard basis. For this setting, the \( \ell_1 \)-penalized regressor (LASSO, [Tib96]) achieves minimax optimal rates in the presence of noise [Van08], while basis pursuit (BP, [CDS98]) – that is min-\( \ell_1 \)-norm interpolation – generalizes well in the noiseless case but is known to be very sensitive to noise [Can08; DE06].

Given recent results on high dimensionality decreasing sensitivity of interpolators to noise, and classical results on the low bias of BP for learning sparse signals, the following question naturally arises:

\textit{Can we consistently learn sparse ground truth functions with minimum-norm interpolators on inherently high-dimensional features?}

\(^*\)Equal contribution.
So far, upper bounds on the $\ell_2$-error of the BP estimator of the order of the noise level $O(\sigma^2)$ have been derived for isotropic Gaussian [KZSS21; JLL20; Woj10], sub-exponential [Fou14], or heavy-tailed [CLG21; KKR18] features. In the case of isotropic Gaussian features, even though the authors of the paper [CLG21] show a tight matching lower bound for adversarial noise, for i.i.d. noise the best known results are not tight: there is a gap between the non-vanishing upper bound $O(\sigma^2)$ [Woj10] and the lower bound $\Omega \left( \frac{\sigma^2}{\log(d/n)} \right)$ [CL21; MVSS20]. For i.i.d. noise, the authors of both papers [CLG21; KZSS21] conjecture that BP does not achieve consistency.

**Contribution.** We are the first to answer the above question in the affirmative. Specifically, we show that for isotropic Gaussian features, BP does in fact achieve asymptotic consistency, when $d$ grows superlinearly and subexponentially in $n$. Our result closes the aforementioned gap in the literature on BP: We give matching upper and lower bounds of order $\Omega \left( \frac{\sigma^2}{\log(d/n)} \right)$ on the $\ell_2$-error of the BP estimator, exact up to terms that are negligible when $d \gg n$. Further, our proof technique is novel and may be of independent interest.

**Structure of the paper.** The rest of the article is structured as follows. In Section 2, we give our main result and discuss its implications and limitations. In Section 3, we present the proof and provide insights on why our approach leads to tighter bounds than previous works. We conclude the paper in Section 4 with possible future directions.

### 2 Main result

In this section we state our main result, followed by a discussion of its implications and limitations. We consider a linear regression model with input vectors $x \in \mathbb{R}^d$ drawn from an isotropic Gaussian distribution $x \sim \mathcal{N}(0, I_d)$, and response variable $y = \langle w^*, x \rangle + \xi$, where $w^*$ is the ground truth to be estimated and $\xi \sim \mathcal{N}(0, \sigma^2)$ is a noise term independent of $x$. Given $n$ i.i.d. random samples $(x_i, y_i)^n_{i=1}$, the goal is to estimate $w^*$ and obtain a small prediction error for the estimate $\hat{w}$

$$
\mathbb{E}_{x,y}(\langle \hat{w}, x \rangle - y)^2 - \sigma^2 = \| \hat{w} - w^* \|_2^2
$$

where we subtract the irreducible error $\sigma^2$. Note that this is also exactly the $\ell_2$-error of the estimator. We study the min-$\ell_1$-norm interpolator (or BP solution) defined by

$$
\hat{w} = \arg\min_w \|w\|_1 \quad \text{such that} \quad \forall i, \langle x_i, w \rangle = y_i.
$$

Our main result, Theorem 1, provides non-asymptotic matching upper and lower bounds for the prediction error of this estimator:

**Theorem 1.** Suppose $\|w^*\|_1 \leq \kappa_1 \sqrt{\frac{\sigma^2 n}{\log(d/n)}}$ for some universal constant $\kappa_1 > 0$. There exist universal constants $\kappa_2, \kappa_3, \kappa_4, c_1, c_2 > 0$ such that, for any $n, d$ with $n \geq \kappa_2$ and $\kappa_3 d \leq d \leq \exp(\kappa_4 n^{1/5})$, the prediction error is upper- and lower-bounded as

$$
\left| \| \hat{w} - w^* \|_2^2 - \frac{\sigma^2}{\log(d/n)} \right| \leq c_1 \frac{\sigma^2}{\log(d/n)}^{3/2}
$$

with probability at least $1 - c_2 \exp \left( -\frac{n^{1/5}}{\log(d/n)} \right)$ over the draws of the dataset.

This theorem proves a statistical rate of $\frac{\sigma^2}{\log(d/n)}$ for the prediction error of the BP solution. Previously, lower bounds of order $\Omega \left( \frac{\sigma^2}{\log(d/n)} \right)$ for the same distributional setting (isotropic Gaussian features, i.i.d. noise) only applied under more restrictive assumptions, such as the zero-signal case $w^* = 0$ [MVSS20], or assuming $d > n^4$ [JLL20]. Moreover, this lower bound stood against a constant upper bound $O(\sigma^2)$ [CLG21; Woj10]. Our result both proves the lower bound in more generality and significantly improves the upper bound, showing that the lower bound is in fact tight. Furthermore, the upper bound implies that BP achieves high-dimensional asymptotic consistency when $d = o(n)$. Theorem 1
Figure 1: Prediction error as a function of (a) \( \log(d/n) \) with varying \( d \) and \( n = 400 \) fixed, and (b) \( \sigma^2 \) with \( d = 20000, n = 400 \). The features are generated by drawing from the isotropic zero-mean and unit-variance (b) Normal and (a) Normal, Log Normal and Rademacher distributions. For BP on Gaussian-distributed features (orange squares), the plots correctly reflect the theoretical rate \( \sigma^2 \log(d/n) \) (dashed curve). See Section 2.1 for further details.

Dependency on \( w^* \). Existing upper bounds in the literature are of the form\(^1\)

\[
\| \hat{w} - w^* \|_2^2 \lesssim \frac{\| \xi \|_2^2}{n} + \| w^* \|_1 \frac{\log(d/n)}{n}
\]

(see e.g. [CLG21, Theorem 3.1]). That is, they contain a first term reflecting the error due to overfitting of the noise \( \xi \), and a second term depending explicitly on \( w^* \). In particular, for a constant noise level (\( \| \xi \|_2^2 \approx \sigma^2 = \text{cst} \)) and a sparse ground truth (\( \| w^* \|_1 = \text{cst} \)), the first term clearly dominates. By contrast, our bound has no explicit dependency on \( w^* \), but holds under a condition controlling the magnitude of \( \| w^* \|_1 \) which essentially ensures that the effect of fitting the noise is dominant (\( \| w^* \|_1 \ll M(n,d) \) in the notation of the proof, Section 3).

Furthermore, note that we can rewrite the condition on \( \| w^* \|_1 \) as \( \| w^* \|_1 \leq c_1 \sqrt{s_{\text{max}}} \), with \( c_1 \) a universal constant and \( s_{\text{max}} = \frac{n}{\log(d/n)} \). This assumption is also called effective \( s_{\text{max}}\)-sparsity of the ground truth and is not very restrictive. Indeed, it holds if \( \| w^* \|_2 \) is constant and \( w^* \) is sparse with constant sparsity, or more generally with \( \| w^* \|_0 \leq s_{\text{max}} \).

2.1 Numerical simulations

We now present numerical simulations illustrating Theorem 1. Figure 1a shows the prediction error of BP plotted as a function of \( \log(d/n) \) with varying \( d \) and \( n = 400 \) fixed, for isotropic inputs generated from the zero-mean and unit-variance Normal, Log Normal and Rademacher distributions. For all three distributions, the prediction error closely follows the trend line \( \sigma^2 \log(d/n) \) (dashed curve). While Theorem 1 only applies for Gaussian features, the figure suggests that this statistical rate of BP holds more generally (see discussion in Section 2.3).

Figure 1b shows the prediction error of the min-\( \ell_1 \)-norm (BP) and min-\( \ell_2 \)-norm interpolators as a function of the noise \( \sigma^2 \), for fixed \( d \) and \( n \). The prediction error of the former again aligns with the theoretical prediction \( \sigma^2 \log(d/n) \). Furthermore, we observe that the min-\( \ell_1 \)-norm interpolator is sensitive to the noise level \( \sigma^2 \), while the min-\( \ell_2 \)-norm interpolator has a similar (non-vanishing) prediction error across all values of \( \sigma^2 \).

For both plots we use \( n = 400 \) and average the prediction error over 20 runs; in Figure 1b we additionally show the standard deviation (shaded regions). The ground truth is \( w^* = (1,0,\cdots,0) \).

\(^1\)The notation \( a \lesssim b \) means that there exists a universal constant \( c_1 > 0 \) such that \( a \leq c_1 b \) and we write \( a \asymp b \) for \( a \lesssim b \) and \( b \lesssim a \).
2.2 Implications and insights

We now discuss further high-level implications and insights that follow from Theorem 1.

High-dimensional asymptotic consistency. Our result proves consistency of BP for any asymptotic regime \( d \approx n^\beta \) with \( \beta > 1 \). In fact, we argue that those are the only regimes of interest. For \( d \) growing exponentially with \( n \), known minimax lower bounds for sparse problems of order \( \frac{\sigma^2 s \log(d/s)}{d-n} \) (with \( s \leq n \) the \( \ell_0 \)-norm of the BP estimator), preclude consistency [Ver12]. On the other hand, for linear growth \( d \approx n \), i.e., \( \beta = 1 \) – studied in detail in the paper [LW21] –, the uniform prediction error lower bound \( \frac{\sigma^2 n}{d-n} \) holding for all interpolators (see Section 3.3) also forbids vanishing prediction error. Note that for \( d \approx n^\beta (\beta > 1) \), asymptotic consistency can also be achieved by a carefully designed “hybrid” interpolating estimator [MVSS20, Section 5.2]; contrary to BP, this estimator is not a minimum-norm interpolator, and is not structured (not \( n \)-sparse).

Trade-off between structural bias and sensitivity to noise. As mentioned in the introduction, our upper bound on the prediction error shows that, contrary to min-\( \ell_2 \)-norm interpolation, BP is able to learn sparse signals in high dimensions thanks to its structural bias towards sparsity. However, our lower bound can be seen as a tempering negative result: The prediction error decays only at a slow rate of \( \sigma^2 \log(d/n) \).

Compared to min-\( \ell_2 \)-norm interpolation, BP (min-\( \ell_1 \)-norm interpolation) suffers from a higher sensitivity to noise, but possesses a more advantageous structural bias. To compare the two methods’ sensitivity to noise, consider the case \( w^* = 0 \), where the prediction error purely reflects the effect of noise. In this case, although both methods achieve vanishing error, the statistical rate for BP, \( \frac{\sigma^2}{\log(d/n)} \), is much slower than that of min-\( \ell_2 \)-norm interpolation, \( \sigma^2 \max(\frac{1}{\sqrt{n}}, \frac{1}{n}) \) [KZSS21, Theorem 3]. Contrariwise, to compare the effect of structural bias, consider the noiseless case with a non-zero ground truth. It is well known that BP successfully learns sparse signals [Can08], while min-\( \ell_2 \)-norm interpolation always fails to learn the ground truth due to the lack of any corresponding structural bias.

Thus, there appears to be a trade-off between structural bias and sensitivity to noise: BP benefits from a strong structural bias, allowing it to have good performance for noiseless recovery of sparse signals, but in return displays a poor rate in the presence of noise – while min-\( \ell_2 \)-norm interpolation has no structural bias (except towards zero), causing it to fail to recover any non-zero signal even in the absence of noise, but in return does not suffer from overfitting of the noise. This behavior is also illustrated in Figure 1b.

2.3 Limitations

In this section we discuss how restrictive the assumptions of Theorem 1 are, and whether they can be relaxed.

Gaussianity of the features. The proof of Theorem 1 crucially relies on the (Convex) Gaussian Minimax Theorem [TOH15; Gor88], and hence on the assumption that the input features are drawn from a Gaussian distribution. In Figure 1a, we include plots of the prediction error \( \| \hat{w} - w^* \|_2 \) not only for Gaussian but also for Log Normal and Rademacher distributed features. We observe that in all three cases, the prediction error closely follows the trend line \( \frac{\sigma^2}{\log(d/n)} \) (dashed curve). We therefore conjecture that Theorem 1 can be extended to a more general class of distributions.

For heavy-tailed distributions, a popular theoretical framework is the small-ball method [Men14; KM15], which covers the Log Normal and Rademacher distributions. The authors of the paper [CLG21] apply this approach to min-\( \ell_1 \)-norm interpolation, and obtain the constant upper bound \( O(\sigma^2) \), under more general assumptions than our setting (in particular their analysis handles adversarial noise with magnitude controlled by \( \sigma^2 \)). Yet, it is unclear whether the looseness of their upper bound is an artifact of their proof, or whether the small-ball method itself is too general to capture the rates observed in Figure 1a.
Isotropic features. Our Theorem 1 assumes isotropic features as we are interested in showing consistency of BP for inherently high-dimensional input data. By contrast, recently there has been an increased interest in studying spiked covariance data models (see [BLLT20] and references therein). We leave it as future work to generalize our result to Gaussian features with an arbitrary covariance matrix.

3 Proof of main result

In this section, we present the proof of our main result, Theorem 1. The proof is given in Section 3.1. In Section 3.2, we give intuition on the main improvements of our novel proof technique, that we describe in Section 3.4. In Section 3.3, we discuss a universal lower bound for interpolators which follows from our proof. Full proofs for the intermediary Lemmas and Propositions are given in Appendix A.

Notation. On the finite-dimensional space $\mathbb{R}^d$, we write $||\cdot||_2$ for the Euclidean norm and $\langle \cdot, \cdot \rangle$ for the inner product. The $\ell_1$ and $\ell_\infty$-norms are denoted by $||\cdot||_1$ and $||\cdot||_\infty$, respectively. The vectors of the standard basis are denoted by $e_1, \ldots, e_d,$ and $1 \in \mathbb{R}^d$ is the vector with all components equal to 1.

For $s \leq d$ and $H \in \mathbb{R}^{d \times s}$, $H_{[i]}$ is the vector of the $i$th column. $\mathcal{N}(\mu, \Sigma)$ is the normal distribution with mean $\mu$ and covariance $\Sigma$. $\Phi(x)$ is the cumulative distribution function of the scalar standard normal distribution, $\Phi(x) = 1 - \Phi(x)$, and log denotes the natural logarithm.

For $n$ samples $x_i \in \mathbb{R}^d$ form the rows of the data matrix $X = [x_1 \ldots x_n]^\top$, with $x_{ij} \sim \mathcal{N}(0, 1)$ for each $i,j$. The scalars $y_i, \xi_i$ are also aggregated into vectors $y, \xi \in \mathbb{R}^n$ with $\xi \sim \mathcal{N}(0, \sigma^2 I_n)$ and $y = Xw^* + \xi$. To easily keep track of the dependency on dimension and sample size, we reserve the $O(\cdot)$ notation to contain only universal constants, without any hidden dependency on $d, n, \sigma^2$ or $\|w^*\|_1$. We will also use $c_1, c_2, \ldots$ and $\kappa_1, \kappa_2, \ldots$ to denote positive universal constants re-introduced each time in the proposition and lemma statements, except for $c_0$ which should be considered as fixed throughout the whole proof.

3.1 Proof of Theorem 1

We proceed by a localized uniform convergence approach, similar to the papers [CLG21; KZSS21; JLL20; MVSS20], and common in the literature, e.g., on structural risk minimization. That is, the proof consists of two steps:

1. Localization. We derive a (finer than previously known) high-probability uniform upper bound on the norm of the min-$\ell_1$-norm interpolator $\hat{w}$, by finding $M > 0$ such that

$$\min_{X(w-w^*)=\xi} \|w\|_1 - \|w^*\|_1 \leq \min_{X(w-w^*)=\xi} \|w-w^*\|_1 = \min_{Xw=\xi} \|w\|_1 =: \Phi_N \leq M \quad (P_N)$$

and consequently $\|\hat{w}\|_1 \leq \|w^*\|_1 + M$, with high probability.

2. Uniform convergence. We derive high-probability uniform upper and lower bounds on the prediction error for all interpolators of $\ell_1$-norm less than $\|w^*\|_1 + M$. Namely, we find a high-probability upper bound for

$$\max_{\|w\|_1 \leq \|w^*\|_1 + M} \|w-w^*\|_2^2 \leq \max_{\|w\|_1 \leq 2\|w^*\|_1 + M} \|w\|_2^2 =: \Phi_+ \quad (P_+)$$

and a high-probability lower bound for

$$\min_{\|w\|_1 \leq \|w^*\|_1 + M} \|w-w^*\|_2^2 \geq \min_{\|w\|_1 \leq 2\|w^*\|_1 + M} \|w\|_2^2 =: \Phi_- \quad (P_-)$$

5
By definition of $M$ in $(P_N)$, with high probability the min-$\ell_1$-norm interpolator $\hat{w}$ belongs to the set of feasible solutions in $(P_+)$ and $(P_-)$, and hence the second step yields high-probability upper and lower bounds on its prediction error $\|\hat{w} - w^*\|^2$.

The key is thus to derive tight high-probability bounds for the quantities $\Phi_N, \Phi_+ , \Phi_-$. Our derivation proceeds in two parts, described below; the first part follows arguments already used by the authors of the paper [KZSS21], while the second part is novel. The techniques developed in the latter are crucial to obtain our tight bounds and might be of independent interest.

**Part a:** (Convex) Gaussian Minimax Theorem. Since each of the quantities $\Phi_N, \Phi_+ , \Phi_-$ is defined as the optimal value of a stochastic program with Gaussian parameters, we may apply the (Convex) Gaussian Minimax Theorem ((C)GMT) [Gor88; TOH15]. On a high level, given a “primary” optimization program with Gaussian parameters, the (C)GMT relates it to an “auxiliary” optimization program, so that high-probability bounds on the latter imply high-probability bounds on the former. The following proposition applies the CGMT on $\Phi_N$ and the GMT on $\Phi_+, \Phi_-$.

**Proposition 1.** For $h \sim \mathcal{N}(0, I_d)$, define the stochastic auxiliary optimization problems:

\[
\begin{align*}
\phi_N(p) &= \min \|w\|_1 \text{ s.t. } \langle w, h \rangle^2 \geq (1 + \rho)n(\sigma^2 + \|w\|^2_2) \quad (A_N) \\
\phi_+(p) &= \max \|w\|^2_2 \text{ s.t. } \begin{cases} 
\|w\|_1 \leq M + 2\|w^*\|_1 \\
\langle w, h \rangle^2 \geq (1 - \rho)n(\sigma^2 + \|w\|^2_2) \end{cases} \quad (A_+), \\
\phi_-(p) &= \min \|w\|^2_2 \text{ s.t. } \begin{cases} 
\|w\|_1 \leq M + 2\|w^*\|_1 \\
\langle w, h \rangle^2 \geq (1 - \rho)n(\sigma^2 + \|w\|^2_2) \end{cases} \quad (A_-)
\end{align*}
\]

where $0 < \rho < 1/2$ can be any small enough quantity. For any $t \in \mathbb{R}$, it holds that

\[
\begin{align*}
\mathbb{P}(\Phi_N > t) &\leq 2\mathbb{P}(\phi_N(p) \geq t) + 6\exp \left( -\frac{n\rho^2}{100} \right), \\
\mathbb{P}(\Phi_+ > t) &\leq 2\mathbb{P}(\phi_+(p) \geq t) + 6\exp \left( -\frac{n\rho^2}{100} \right), \\
\mathbb{P}(\Phi_- < t) &\leq 2\mathbb{P}(\phi_-(p) \leq t) + 6\exp \left( -\frac{n\rho^2}{100} \right),
\end{align*}
\]

where on the left-hand side $\mathbb{P}$ denotes the probability distribution over $X$ and $\xi$, and on the right-hand side the distribution over $h$.

For the remainder of this paper, we choose $\rho = \frac{10}{\log(d/n)^{1/2}}$.\textsuperscript{2} As such, from now on, we simply write $\phi_N, \phi_+, \phi_-$.

The proof of Proposition 1, given in Appendix A.1, closely follows Lemmas 3-7 in the paper [KZSS21]. For clarity, note that the three pairs of stochastic programs $(P_N/A_N)$, $(P_+/A_+)$, $(P_-/A_-)$ are not coupled: Proposition 1 should be understood as consisting of three separate statements, each using a different independent copy of $h$.

As a result of the proposition, the goal of finding high-probability bounds on $\Phi_N, \Phi_+, \Phi_-$ now reduces to finding high-probability bounds on $\phi_N, \phi_+, \phi_-$, respectively.

**Part b:** Bounds on $\phi_N, \phi_+, \phi_-$. To obtain tight bounds on the auxiliary quantities $\phi_N, \phi_+, \phi_-$, we adopt a significantly different approach from previous works. The main idea is to reduce the optimization problems $(A_N)$, $(A_+)$ and $(A_-)$ to optimization problems over a parametric

\textsuperscript{2}This choice of $\rho$ is justified by the proof of Proposition 2. Indeed, for an arbitrary choice of $\rho < 1/2$, one could still show the same bound with just an extra factor: $(\phi_N)^2 \leq (1 + \rho)M(n, d)$, holding with still the same probability. This would translate to a bound on $\Phi_N$ holding with probability $1 - 12\exp \left( -\frac{1}{2 \log(d/n)^{1/2}} \right) - 6\exp \left( -\frac{n\rho^2}{100} \right)$. So the choice $\rho = \frac{10}{\log(d/n)^{1/2}}$ "comes at no cost" in terms of the probability with which the bound holds, while being sufficiently small to allow for a satisfactory bound (it only affects the constant $c_0$ appearing in $M(n, d)$).
path \{\gamma(\alpha)\}_\alpha \subset \mathbb{R}^d$. Here we only state the results and refer to Section 3.4 for their proofs and further intuition. For the remainder of this proof, we denote by $t_n \in \mathbb{R}$ the quantile of the standard normal distribution defined by $2\Phi^\downarrow(t_n) = n/d$.

**Proposition 2.** There exist universal constants $\kappa_2, \kappa_3, \kappa_4, c_0 > 0$ such that, if $n \geq \kappa_2$ and $\kappa_3 n \leq d \leq \exp(\kappa_4 n^{1/5})$, then

$$ (\phi_N)^2 \leq \frac{\sigma_n^2}{t_n^2} \left( 1 - \frac{2}{t_n^2} + \frac{c_0}{t_n^2} \right) =: M(n, d)^2 $$

with probability at least $1 - 6 \exp\left(\frac{5}{\log(d/n)^2}\right)$ over the draws of $h$.

Consequently, the min-$\ell_1$-norm interpolator has norm bounded by the deterministic quantity

$$ \|\hat{w}\|_1 \leq \|w^*\|_1 + M(n, d) $$

with probability at least $1 - 18 \exp\left(\frac{-n}{\log(d/n)^2}\right)$ over the draws of $X$ and $\xi$. Therefore, we henceforth set $M = M(n, d)$ in $(P_+), (P_-)$ and so in $(A_+), (A_-)$. We now establish high-probability upper/lower bounds for $\phi_+ / \phi_-$ for the specific choice of $M = M(n, d)$.

**Proposition 3.** Suppose $\|w^*\|_1 \leq \kappa_1 \sqrt{\frac{\sigma_n^2}{\log(d/n)}}$ for some universal constant $\kappa_1 > 0$. There exist universal constants $\kappa_2, \kappa_3, \kappa_4, c_1 > 0$ such that, if $n \geq \kappa_2$ and $\kappa_3 n \leq d \leq \exp(\kappa_4 n^{1/5})$, then each of the two events

$$ \phi_+ \leq \frac{\sigma_n^2}{\log(d/n)} \left( 1 + \frac{c_1}{\sqrt{\log(d/n)}} \right) \quad \text{and} \quad \phi_- \geq \frac{\sigma_n^2}{\log(d/n)} \left( 1 - \frac{c_1}{\sqrt{\log(d/n)}} \right) $$

happens with probability at least $1 - 18 \exp\left(\frac{-n}{\log(d/n)^2}\right)$ over the draws of $h$.

Theorem 1 follows straightforwardly from Propositions 1, 2 and 3.

### 3.2 Key improvements of the proof over previous results

Let us briefly point out the main features of our derivation that allow for a bound that is tighter than previous results.

**Tight bounds for the localization step.** Proposition 2 gives a high-probability upper bound $M(n, d)$ for $\|\hat{w} - w^*\|_1$. Its expression contains the quantile $t_n$ defined by $2\Phi^\downarrow(t) = n/d$, for which we have the estimate $t_n^2 = 2\log(d/n) - \log\log(d/n) + O(1)$ (see Lemma 3 in Appendix A.4). Hence, we may give the following more explicit estimate:

$$ M(n, d)^2 \leq \frac{\sigma_n^2}{2\log(d/n) - \log\log(d/n)} \left( 1 + O\left(\frac{1}{\log(d/n)}\right) \right). \quad (1) $$

While existing bounds for $\|\hat{w} - w^*\|_1^2$ in the literature are of the same asymptotic order $\Theta\left(\frac{\sigma_n^2}{\log(d/n)}\right)$ [JLL20; CLG21], using $M^2 = \text{cst} \frac{\sigma_n^2}{\log(d/n)}$ instead of $M(n, d)^2$ in our derivation of Proposition 3 would only result in the constant upper bound $\phi_+ \leq O(\sigma^2)$.

Further note that, while the estimate of $M(n, d)$ in Equation (1) would already lead to upper/lower bounds for $\phi_+ / \phi_-$ of matching order $\Theta\left(\frac{\sigma_n^2}{\log(d/n)}\right)$, in order to obtain the precise bounds presented in Proposition 3 we make use of precise properties of $\Phi^\downarrow$ not captured by Equation (1).
Parametric path optimization for the uniform convergence step. The overall structure of our proof is similar to that of Theorems 1 to 4 of the paper [KZSS21]: We use the CGMT to localize the interpolator, and then use the GMT to derive a uniform prediction error bound. The results in the paper [KZSS21] are applicable for general minimum-norm interpolators, while we focus on the $\ell_1$-norm only. However, the relaxations used in the mentioned paper are not tight enough to capture the consistency of min-$\ell_1$-norm interpolation for isotropic features (see Section 6, “Application: Isotropic features” in that paper).

To intuitively understand why their general theorems fail to give the accurate rate, let us briefly reproduce their derivation in our notation. They derive an upper bound for the prediction error at the interpolation threshold $d$ by the following simple relaxation of (A_+). For all $w \in \mathbb{R}^d$ with $\|w\|_1 \leq M + 2\|w^*\|_1 =: B$, it holds $\langle w, h \rangle \leq B \|h\|_\infty$ for any $h$, so the second constraint can be relaxed to $B^2 \|h\|_2^2 \geq (1 - \rho)n(\sigma^2 + \|w\|_2^2)$, implying the upper bound $\phi_+ \leq \frac{B^2\|h\|_2^2}{n(1 - \rho)} - \sigma^2$.

However this bound is loose, even when we plug in our tight localization bound by setting $B = M(n,d) + 2\|w^*\|_1$. Indeed, by the estimate in Equation (1) and by Gaussian concentration results, the above bound reads for $d \gg n$

$$\phi_+ \leq \frac{B^2\|h\|_2^2}{n(1 - \rho)} - \sigma^2 \approx \frac{\sigma^2}{2}\log(d/n) - \sigma^2 = \sigma^2 \frac{\log(n)}{\log(d/n)}.$$ 

Note that this bound is constant in any polynomial growth regime $d \asymp n^2$, while we prove an upper bound in Theorem 1 which vanishes in these regimes as $d, n \to \infty$. So the relaxation performed in the paper [KZSS21] is not sufficiently tight. In order to obtain tighter bounds, we instead carry out a more refined analysis taking into account the relationship between $\langle w, h \rangle, \|w\|_2$ and $\|w\|_1$, by reducing the optimization problems $(A_N), (A_+)$, and $(A_-)$ to optimization problems over a parametric path (see Section 3.4.1).

3.3 Implication of the proof: Universal lower bound for interpolators

Interestingly, Proposition 1 immediately implies a lower bound for all interpolators holding with high probability. Indeed, consider the uniform lower bound $(P_-)$ with $M = \infty$ so that the $\ell_1$-constraint is vacuous, meaning that $\Phi_-$ is a lower bound for the prediction error of all interpolating estimators. Using an additional convergence argument as in Lemma 4 in the paper [KZSS21], one can show that the GMT is still applicable in the limit where $M \to \infty$, and results in the auxiliary optimization problem $(A_-)$ with $M = \infty$, i.e., with a vacuous first constraint.

By the Cauchy-Schwarz inequality, we can relax the second constraint to $\|w\|_2^2 \|h\|_2^2 \geq (1 - \rho)n(\sigma^2 + \|w\|_2^2)$. Simple manipulations and concentration results for Gaussians then yield the high-probability bound

$$\phi_- \geq \frac{(1 - \rho)n\sigma^2}{\|h\|_2^2 - (1 - \rho)n} \approx \frac{\sigma^2}{d - n}.$$ 

By the GMT, this implies a high-probability lower bound of order $\frac{\sigma^2}{d - n}$ on the prediction error of all interpolators uniformly. In particular, this bound implies that no linear interpolator can achieve asymptotic consistency in the regime where $d \asymp n$. A weaker lower bound of order $\frac{\sigma^2}{d - n}$ was already noted in [MVSS20, Corollary 1, case 3], which however does not capture the divergence of the prediction error at the interpolation threshold $d = n$.

3.4 Proof of Propositions 2 and 3

In this section we detail our analysis of the auxiliary optimization problems $(A_N), (A_+)$ and $(A_-)$. We start by a remark that considerably simplifies notation: The definitions of $\phi_+, \phi_-$ are unchanged if, in $(A_N), (A_+), (A_-)$, $h$ is replaced by the reordered vector of its absolute order statistics, i.e., by $H$ such that $H_i$ is the $i$-th largest absolute value of $h$. Throughout this proof, we condition on the event where $H$ has distinct and positive components: $H_1 > ... > H_d > 0$, which holds with probability one. Henceforth, unless specified otherwise, references to the optimization problems $(A_N)$,
\((A_+)\) and \((A_-)\) refer to the equivalent problems where \(h\) is replaced by \(H\). Also recall that we choose \(\rho = \frac{10}{\log_2[\alpha(\alpha+n^2)]}\). The key steps in the proof of Propositions 2 and 3 are as follows.

- For each of the three optimization problems \((A_N), (A_+)\) and \((A_-)\), we show that the argmax (or argmin) is of the form \(b\gamma(\alpha)\) for some \(b > 0\) and a parametric path \(\Gamma = \{\frac{\gamma(\alpha)}{\alpha}\}\), (which depends on \(H\)). Hence we can restate \((A_N), (A_+)\) and \((A_-)\) as optimization problems over a scalar variable \(\alpha\) and a scale variable \(b > 0\). (Section 3.4.1)

- Still conditioning on \(H\), we explicitly characterize the parametric path \(\Gamma\). In particular, we show that it is piecewise linear with breakpoints \(\gamma(\alpha_+)\) having closed-form expressions. (Section 3.4.2)

- Thanks to the concentration properties of \(H\) (Section 3.4.3), evaluating at one of the breakpoints yields the desired high-probability upper bound on \(\phi_N\) (Section 3.4.4).

- A fine-grained study of the intersection of \(\mathbb{R}_+\Gamma = \{b\gamma|b \in \mathbb{R}_+, \gamma \in \Gamma\}\) with the constraint set of \((A_+)\) and \((A_-)\), as well as the concentration properties of \(H\), yield the desired high-probability bounds on \(\phi_+\) and \(\phi_-\). (Section 3.4.5)

### 3.4.1 Parametrizing the argmax/argmin

Note that in the optimization problems \((A_N), (A_+)\) and \((A_-)\), the variable \(w\) only appears through \(\|w\|_2, \|w\|_1\) and \(\langle w, H \rangle\). Thus, we can add the constraint that \(\forall i, w_i \geq 0\) without affecting the optimal solution. We will show that the path \(\Gamma = \{\frac{\gamma(\alpha)}{\alpha}\}\) can be used to parametrize the solutions of the optimization problems, where \(\gamma : [1, \alpha_{\text{max}}] \rightarrow \mathbb{R}^d\) is defined by

\[
\gamma(\alpha) = \arg \min_w \|w\|_2^2 \quad \text{s.t.} \quad \begin{cases} 
\langle w, H \rangle \geq \|H\|_\infty \\
\forall i, w_i \geq 0 \\
\mathbf{1}^\top w = \|w\|_1 = \alpha
\end{cases}
\]

and \(\alpha_{\text{max}} = \sigma \frac{\|H\|_\infty}{\|H\|_\infty - \|h\|_\infty}\). Specifically, the following key lemma states that (at least one element of) the argmax/argmin of \((A_N), (A_+)\) and \((A_-)\) is of the form \(b\frac{\gamma(\alpha)}{\alpha}\) for some \(b > 0\) and \(\alpha \in [1, \alpha_{\text{max}}]\). This allows to reduce the optimization problems to a single scalar variable and a scale variable.

**Lemma 1.** For concision, define \(B = M + 2\|w^*\|_1\). We have:

1. The variable \(w\) in \((A_N)\) can equivalently be constrained to belong to the set \(\mathbb{R}_+\Gamma\), i.e.,

\[
\phi_N = \min_{b > 0, 1 \leq \alpha \leq \alpha_{\text{max}}} b \quad \text{s.t.} \quad b^2 \|H\|_\infty^2 \geq (1 + \rho)n(\sigma^2 \|\gamma(\alpha)\|_1^2 + b^2 \|\gamma(\alpha)\|_2^2).
\]

2. The variable \(w\) in \((A_+)\) can equivalently be constrained to belong to the set \(\mathbb{R}_+\Gamma\), i.e.,

\[
\phi_+ = \max_{1 \leq \alpha \leq \alpha_{\text{max}}} \frac{B^2 \|\gamma(\alpha)\|_2^2}{\|\gamma(\alpha)\|_1^2} \\ \text{s.t.} \quad B^2 \|H\|_\infty^2 \geq (1 - \rho)n(\sigma^2 \|\gamma(\alpha)\|_1^2 + B^2 \|\gamma(\alpha)\|_2^2).
\]

3. The variable \(w\) in \((A_-)\) can equivalently be constrained to belong to the set \((0, B]\Gamma\), i.e.,

\[
\phi_- = \min_{1 \leq \alpha \leq \alpha_{\text{max}}} \frac{B^2 \|\gamma(\alpha)\|_2^2}{\|\gamma(\alpha)\|_1^2} \\ \text{s.t.} \quad B^2 \|H\|_\infty^2 \geq (1 - \rho)n(\sigma^2 \|\gamma(\alpha)\|_1^2 + b^2 \|\gamma(\alpha)\|_2^2).
\]

The proof of the lemma is given in Appendix A.2. To give an intuitive explanation for the equivalence between \((A_N)\) and \((A_N')\), consider a penalized version of \((A_N)\): \(\min_w \|w\|_1 - \lambda \left(\langle w, h \rangle^2 - (1 + \rho)n(\sigma^2 + \|w\|_2^2)\right)\) with \(\lambda > 0\). For fixed values of \(\|w\|_1\) and \(\langle w, h \rangle\), minimizing this penalized objective is equivalent to minimizing \(\|w\|_2^2\). Hence, we can expect the argmin to be attained at \(b\frac{\gamma(\alpha)}{\alpha}\) for some \(b > 0, \alpha\).
3.4.2 Characterizing the parametric path

As $\gamma(\alpha)$ is defined as the optimal solution of a convex optimization problem, we are able to obtain a closed-form expression, by a straightforward application of Lagrangian duality. The only other non-trivial ingredient is to notice that, at optimality, the inequality constraint $\langle w, H \rangle \geq \|H\|_\infty$ necessarily holds with equality. Denote $H_s$ the vector equal to $H$ on the first $s$ components and 0 on the last $(d-s)$, and similarly for $1_{[s]}$. Define, for any integer $2 \leq s \leq d$,

$$\alpha_s = \frac{\|H_s\|_1 - sH_s \|H\|_\infty}{\|H_s\|_2^2 - \|H_s\|_1 H_s}.$$

Note that $\alpha_2 = 1$. Let $\alpha_{d+1} = \alpha_{\text{max}}$.

**Lemma 2.** For all $1 < \alpha \leq \alpha_{\text{max}}$, denote $s$ the unique integer in $\{2, \ldots, d\}$ such that $\alpha_s < \alpha \leq \alpha_{s+1}$. Then $\gamma(\alpha) = \lambda H_s - \mu 1_s$ where the dual variables $\lambda$ and $\mu$ are given by

$$\lambda = \frac{1}{s\|H_s\|_2^2 - \|H_s\|_1^2} \left( s\|H\|_\infty - \alpha\|H_s\|_1 \right)$$

and

$$\mu = \frac{1}{s\|H_s\|_2^2 - \|H_s\|_1^2} \left( \|H_s\|_1 \|H\|_\infty - \alpha\|H_s\|_1^2 \right).$$

The proof of the lemma is given in Appendix A.3.

3.4.3 Concentration of norms of $\gamma(\alpha_s)$

Given the explicit characterization of the parametric path, we now study its breakpoints $\gamma(\alpha_s)$ ($s \in \{2, \ldots, d\}$), and more precisely we estimate $\|\gamma(\alpha_s)\|_1$ and $\|\gamma(\alpha_s)\|_2$ as a function of $s$ (we have by definition $\langle \gamma(\alpha_s), H \rangle = \|H\|_\infty$). Namely, we prove the following concentration result, where, analogously to $t_n$, we let $t_s \in \mathbb{R}$ denote the quantity such that $2\Phi(t_s) = s/d$.

**Proposition 4.** There exist universal constants $\kappa_1, \kappa_2, \kappa_3, c_1 > 0$ such that for any $s, d$ with $s \geq \kappa_2$ and $\kappa_3 s \leq d \leq \exp(\kappa_4 s^{1/5})$,

$$\left| \frac{\|\gamma(\alpha_s)\|_1}{\|H\|_\infty} - \left( \frac{1}{t_s} - \frac{2}{t_s^2} \right) \right| \leq \frac{c_1}{t_s^2} \quad \text{and} \quad \left| \frac{\|\gamma(\alpha_s)\|_2^2}{\|H\|_\infty^2} - \frac{2}{st_s^2} \right| \leq \frac{c_1}{st_s^4},$$

with probability at least $1 - 6 \exp \left( -2 \log(d/s)/s \right)$ over the draws of $h$.

This proposition relies on and extends the literature studying concentration of order statistics [BT12; LXG20]. An important ingredient for the proof of the proposition is the following lemma, which gives a tight approximation for $t_s$.

**Lemma 3.** There exist universal constants $\kappa_3, c_1 > 0$ such that, for all $s \leq d/\kappa_3$, $t_s$ satisfies

$$\tilde{t}_s^2 - c_1 \leq t_s^2 \leq \tilde{t}_s^2$$

where

$$\tilde{t}_s = \sqrt{2 \log(d/s) - \log \log(d/s) - \log(\frac{\pi}{2})}.$$

Furthermore, $\kappa_3$ and $c_1$ can be chosen (e.g. $\kappa_3 = 11$ and $c_1 = 1$) such that $\log(d/s) \leq \tilde{t}_s^2 \leq 2 \log(d/s)$.

The proofs of Proposition 4 and of Lemma 3 are given in Appendix A.4.
3.4.4 Localization: Proof of Proposition 2 (upper bound for \( \phi_N \))

We now use the concentration bounds of Proposition 4 to obtain a high-probability upper bound for \( \phi_N \). Recall from Lemma 1 that it is given by \( (A_N)^2 \):

\[
(\phi_N)^2 = \min_{b > 0, 1 \leq s \leq n_{\max}} b^2 \text{ s.t. } b^2 \|H\|_\infty^2 \geq (1 + \rho)n(\sigma^2 \|\gamma(\alpha)\|_1^2 + b^2 \|\gamma(\alpha)\|_2^2).
\]

We may rewrite the constraint as

\[
b^2 \|H\|_\infty^2 \left(1 - (1 + \rho)n \frac{\|\gamma(\alpha)\|_1^2}{\|H\|_\infty^2}\right) \geq (1 + \rho)n\sigma^2 \|\gamma(\alpha)\|_1^2
\]

\[
\iff b^2 \geq \frac{\|\gamma(\alpha)\|_1^2}{\|H\|_\infty^2} \frac{\sigma^2 n(1 + \rho)}{1 - (1 + \rho)n \frac{\|\gamma(\alpha)\|_2^2}{\|H\|_\infty^2}} \text{ and } (1 + \rho)n \frac{\|\gamma(\alpha)\|_2^2}{\|H\|_\infty^2} < 1.
\]

Thus minimizing over \( b \) shows that \( (\phi_N)^2 = \min_{1 \leq \alpha \leq n_{\max}} f(\alpha)^2 \text{ s.t. } (1 + \rho)n \frac{\|\gamma(\alpha)\|_2^2}{\|H\|_\infty^2} < 1 \). Since we want to upper-bound this minimum, it is sufficient to further restrict the optimization problem by the constraint \( \alpha \in \{\alpha_s | s \in \{2, \ldots, d\}\} \), yielding

\[
(\phi_N)^2 \leq \min_{2 \leq s \leq d+1} f(\alpha_s)^2 \text{ s.t. } (1 + \rho)n \frac{\|\gamma(\alpha_s)\|_2^2}{\|H\|_\infty^2} < 1.
\]

We now show that for the choice \( s = n \), the constraint is satisfied with high probability, and we give a high-probability estimate for the resulting upper bound \( f(\alpha_n)^2 \). See Remark 1 below for a justification of this choice. For the remainder of the proof of Proposition 2, we condition on the event where the inequalities in Equation (2) hold for \( s = n \). By the concentration bound for \( \|\gamma(\alpha_n)\|_2^2 \), a sufficient condition for the choice \( s = n \) to be feasible is

\[
(1 + \rho)\frac{2}{t_n^2} \left(1 + \frac{c}{t_n^2}\right) < 1
\]

with \( c > 0 \) some universal constant. Now \( t_n^2 \geq \log(d/n) \) by Lemma 3, and we chose \( \rho = \frac{10}{\log(d/n)^{5/2}} \).

So we can choose \( \kappa_3 \) sufficiently large such that the above inequality holds for any \( n, d \) with \( \kappa_3 r \leq d \).

Moreover, by the concentration bounds for \( \|\gamma(\alpha_n)\|_2^2 \) and \( \|\gamma(\alpha_n)\|_1 \), \( f(\alpha_n)^2 \) is upper-bounded by

\[
f(\alpha_n)^2 \leq \frac{(1 - \frac{1}{t_n^2} + O(\frac{1}{n^2})) \sigma^2 n(1 + \rho)}{t_n^2 - 2(1 + \rho)(1 + O(\frac{1}{t_n^2}))} \leq \frac{\sigma^2 n(1 + \rho)}{t_n^2}(1 + \rho) \left(1 - \frac{2}{t_n^2} + O\left(\frac{1}{n^2}\right)\right).
\]

Furthermore, \( \rho = O\left(\frac{1}{t_n^2}\right) \) by Lemma 3, so \( f(\alpha_n)^2 \leq \frac{\sigma^2 n(1 + \rho)}{t_n^2} \left(1 - \frac{2}{t_n^2} + \frac{2}{t_n^2}\right) =: M(n, d^2) \) for a universal constant \( c_0 > 0 \). This concludes the proof of Proposition 2.

**Remark 1.** Let us informally justify why we can expect the choice \( s = n \) to approximately minimize \( f(\alpha_s) \).

A first justification is that the min-\( \ell_1 \)-norm interpolator \( \hat{w} \), which is the solution of the optimization problem \( (P_N) \), is well-known to be \( n \)-sparse. Since the optimization problems \( (P_N) \) and \( (A_N) \) are intimately connected via the CGMT (Proposition 1), we can expect the optimal solution of \( (A_N) \) to have similar properties to \( \hat{w} \) – in particular, to have the same sparsity \( s = n \). A second, more technical, justification is as follows. Note that if we replace \( \|\gamma(\alpha)\|_2 \) and \( \|\gamma(\alpha)\|_1 \) by their estimates from Proposition 4 and ignore the higher-order terms, we have

\[
f(\alpha_s)^2 \approx \frac{1}{t_n^2} \frac{\sigma^2 n(1 + \rho)}{1 - (1 + \rho)n \frac{\sigma^2}{t_n^2}} = \frac{\sigma^2 (1 + \rho)}{t_n^2 - (1 + \rho)\frac{\sigma^2}{t_n^2}}.
\]
Thus a good choice for $s$ is given by maximizing the denominator. By using the estimate $\frac{t^2}{n} \approx 2 \log(d/s)$ from Lemma 3, we can approximate it by

$$\frac{t^2}{n} - (1 + \rho) \frac{2}{s} \approx 2 \log(d/s) - (1 + \rho) \frac{2}{s} =: g(s).$$

Interpreting $s$ as a continuous variable and setting $\frac{d}{ds}g(s) = 0$ yields the choice $s = (1 + \rho)n \approx n$.

### 3.4.5 Uniform convergence: Proof of Proposition 3 (bounds for $\phi_+$ and $\phi_-$)

To obtain an upper bound for the maximization problem defining $\phi_+$ (resp. lower bound for the minimization for $\phi_-$), a typical approach would be to find a tractable relaxation of the problem. However, the more obvious relaxations already explored in the paper [KZSS21] turn out to be unsatisfactorily loose, as discussed in Section 3.2. Here, thanks to the one-dimensional structure of our reformulations ($A'_+$) and ($A'_-$), we take a different approach and study the monotonicity of the objectives.

We can decompose our proof in three steps. Firstly, we describe our overall monotonicity-based approach. Secondly, we find values $\alpha, \overline{\alpha}$ that allow us to unroll our approach. Finally, we evaluate the bound that the first two steps give us, thus proving the proposition.

**Step 1: Studying the feasible set of ($A'_+$) and ($A'_-$)**. Recall that $\phi_+$, $\phi_-$ are respectively given by Equations ($A'_+$), ($A'_-$). We can also write them in the following form, using the fact that $\|\gamma(\alpha)\|_2 = \alpha$:

$$\phi_+ = \max_{1 \leq \alpha \leq \alpha_{\text{max}}} \frac{B^2 \|\gamma(\alpha)\|_2^2}{\alpha^2} \text{ s.t. } B^2 \|H\|_\infty^2 \geq (1 - \rho)n(\sigma^2\alpha^2 + B^2 \|\gamma(\alpha)\|_2^2)$$

$$\phi_- = \min_{0 \leq \beta \leq B} \frac{b^2 \|\gamma(\alpha)\|_2^2}{\alpha^2} \text{ s.t. } b^2 \|H\|_\infty^2 \geq (1 - \rho)n(\sigma^2\alpha^2 + b^2 \|\gamma(\alpha)\|_2^2).$$

We first study the sets of feasible solutions of ($A'_+$) and ($A'_-$). Denote by $I$ the former set, i.e.,

$$I := \{\alpha \in [1, \alpha_{\text{max}}] \mid B^2 \|H\|_\infty^2 \geq (1 - \rho)n(\sigma^2\alpha^2 + B^2 \|\gamma(\alpha)\|_2^2)\}.$$

Also let $\alpha_{d+1/2} = \frac{\|H\|_\infty \|H\|_\infty}{\|H\|_\infty^2}$; this choice of notation is purely symbolic, and is justified by the fact that $\alpha_d < \alpha_{d+1/2} < \alpha_{d+1}$.

**Lemma 4.** The following statements hold:

1. The mapping $\alpha \mapsto \|\gamma(\alpha)\|_2^2$ is convex over $[1, \alpha_{\text{max}}]$.
2. It is decreasing over $[1, \alpha_{d+1/2}]$ and increasing over $[\alpha_{d+1/2}, \alpha_{\text{max}}]$.
3. $I$ is an interval.
4. The map $\alpha \mapsto \frac{\|\gamma(\alpha)\|_2^2}{\|\gamma(\alpha)\|_1^2}$ is monotonically decreasing.

These monotonicity properties lead us to a proof strategy that can be summarized as follows.

**Lemma 5.** Denote $I = [\underline{\alpha}_I, \overline{\alpha}_I]$ the endpoints of $I$. For any $\underline{\alpha} \leq \alpha_I$,

$$\phi_+ \leq B^2 \frac{\|\gamma(\alpha)\|_2^2}{\|\gamma(\alpha)\|_1^2}.$$

If $\overline{\alpha}_I < \alpha_{d+1/2}$, then for any $\overline{\alpha}_I \leq \overline{\alpha} \leq \alpha_{d+1/2}$,

$$\phi_- \geq \frac{\sigma^2 n (1 - \rho)}{\|H\|_\infty^2 - (1 - \rho)n \|\gamma(\overline{\alpha})\|_2^2} \|\gamma(\overline{\alpha})\|_2^2.$$

The proofs of Lemma 4 and Lemma 5 are given in Appendix A.5.
Step 2: A tight admissible choice for \( \alpha \) and \( \overline{\alpha} \). To apply Lemma 5 and obtain bounds on \( \phi_+ \), \( \phi_- \), we need to find \( \alpha \) and \( \overline{\alpha} \) lying on the left, respectively on the right of the interval \( I \), and such that \( \overline{\alpha} \leq \alpha_{d+1/2} \). By having a closer look at the way we derived the expression of \( M(n, d) \), we have by construction that with high probability, \( \alpha_n \in I \). In fact, we show that there exist integers \( s \) and \( \overline{s} \) very close to \( n \) such that \( \alpha_{\frac{s}{n}} \) already falls to the left of \( I \), and \( \alpha_{\frac{\overline{s}}{n}} \) to the right of \( I \), with high probability.

**Lemma 6.** Suppose \( \|w^s\|_1 \leq \kappa_1 \sqrt{\frac{\sigma^2 n}{\log(d/n)}} \) for some universal constant \( \kappa_1 > 0 \). There exist universal constants \( \kappa_2, \kappa_3, \kappa_4, \lambda > 0 \) such that, for any \( d, n \) with \( n \geq \kappa_2 \) and \( \kappa_3 n \leq d \leq \exp(\kappa_4 n^{1/5}) \), we can find integers \( s, \overline{s} \in \mathbb{N}_+ \) satisfying

\[
s = n \exp\left(\frac{\lambda}{2t_n}\right) \left(1 + O\left(\frac{1}{t_n^2}\right)\right) \quad \text{and} \quad \overline{s} = n \exp\left(\frac{\lambda}{2t_n}\right) \left(1 + O\left(\frac{1}{t_n^2}\right)\right)
\]

and

\[
\alpha_s < \alpha_I \leq \alpha_n \leq \overline{\alpha}_I \leq \overline{\alpha}_\sigma \leq \alpha_{d+1/2},
\]

with probability at least \( 1 - 18 \exp\left(-\frac{n}{\log(d/n)}\right) \) over the draws of \( h \). Moreover, \( t_n^2 = t_n^2 + O(1) \) and \( t_n^2 = t_n^2 + O(1) \).

The proof of the lemma is given in Appendix A.6. It relies in particular on the assumption that \( \|w^s\|_1 \leq \kappa_1 \sqrt{\frac{\sigma^2 n}{\log(d/n)}} \) for some universal constant \( \kappa_1 \), which implies that \( M(n, d) \) from Proposition 2 is the dominating term in \( B \), and hence \( B^2 = (M(n, d) + 2 \|w^s\|_1)^2 = \sigma^2 n \left(1 - \frac{2}{t_n^2} + O\left(\frac{1}{t_n^2}\right)\right) \). Furthermore, the equations in the lemma hold conditionally on the event where the inequalities in Equation (2) hold simultaneously for \( s = n, s = \overline{s} \), and \( s = \overline{\sigma} \) which indeed occurs with the announced probability. These two elements of the proof will be reused in the following step.

Step 3: Applying Lemma 5. Lemma 6 provides us with a choice of \( \alpha = \alpha_s \) and \( \overline{\alpha} = \alpha_{\overline{s}} \) that satisfy the conditions of Lemma 5 with high probability. To conclude the proof of Proposition 3, all that remains to be done is to compute the bounds given by Lemma 5, i.e.,

\[
\phi_+ \leq B^2 \|\gamma(\alpha_s)\|_2^2 \quad \text{and} \quad \phi_- \geq \frac{\sigma^2 n (1 - \rho)}{\|H\|_\infty^2 - (1 - \rho) n \|\gamma(\alpha_\overline{s})\|_2^2} \|\gamma(\alpha_\overline{s})\|_2^2.
\]

For the remainder of the proof of Proposition 3, we condition on the event where the inequalities in Equation (2) hold simultaneously for \( s = n, s = \overline{s} \), and \( s = \overline{\sigma} \). In particular, the conclusions of Lemma 6 hold, as discussed just above. We also recall that, because of the assumption on the growth of \( \|w^s\|_1 \), we have \( B^2 = \frac{\sigma^2 n}{t_n^2} \left(1 - \frac{2}{t_n^2} + O\left(\frac{1}{t_n^2}\right)\right) \). By applying the concentration inequalities from Equation (2), and using the above estimate for \( B^2 \), we obtain

\[
\phi_+ \leq \frac{\sigma^2 n}{t_n^2} \left(1 + O\left(\frac{1}{t_n^2}\right)\right) \frac{2}{\sigma^2 n} t_n^2 \left(1 + O\left(\frac{1}{t_n^2}\right)\right) \quad \text{and} \quad \phi_- \geq \frac{2\sigma^2 n}{\sigma^2 n} \left(1 + O\left(\frac{1}{t_n^2}\right)\right).
\]

By plugging in the approximate expressions of \( s \) and \( \overline{s} \) from Equation (3), as well as the estimates \( t_n^2 = t_n^2 + O(1) \) and \( t_n^2 = t_n^2 + O(1) \) from Lemma 6, we further obtain

\[
\phi_+ \leq \frac{2\sigma^2}{t_n^2} \exp\left(\frac{\lambda}{2t_n}\right) \left(1 + O\left(\frac{1}{t_n^2}\right)\right) \quad \text{and} \quad \phi_- \geq \frac{2\sigma^2}{t_n^2} \exp\left(-\frac{\lambda}{2t_n}\right) \left(1 + O\left(\frac{1}{t_n^2}\right)\right).
\]

Finally, by the expansion \( t_n^2 = 2\log(d/n) + O(\log(\log(d/n))) \) from Lemma 3 and by the Taylor series approximation \( \exp(x) = 1 + x + O(x^2) \) (for bounded \( x \)), we obtain the desired bounds

\[
\phi_+ \leq \frac{\sigma^2}{\log(d/n)} \left(1 + O\left(\frac{1}{\sqrt{\log(d/n)}}\right)\right) \quad \text{and} \quad \phi_- \geq \frac{\sigma^2}{\log(d/n)} \left(1 + O\left(\frac{1}{\sqrt{\log(d/n)}}\right)\right).
\]

This concludes the proof of Proposition 3.
4 Conclusion

By introducing a novel proof technique, we derive matching upper and lower bounds of order $\frac{\sigma^2}{\log(d/n)}$ on the prediction error of basis pursuit (BP, or min-$\ell_1$-norm interpolation) in noisy sparse linear regression. Our result closes a gap in the minimum-norm interpolation literature, and is the first to imply asymptotic consistency of a minimum-norm interpolator for isotropic features. Furthermore, the prediction error decays with the amount of overparametrization $d/n$, confirming that BP also benefits from the regularization effect of high dimensionality, as suggested by the modern storyline on interpolating models.

Future work. As discussed in Section 2.3, a challenging direction for future work would be to inspect how our assumptions on the distribution of the input data could be generalized. Indeed our proof heavily relies on the Gaussianity assumption to apply the CGMT, while numerical experiments hint that our result could be generalized to heavy-tailed input distributions. Furthermore, we leave it as future work to adapt our proof technique for minimum-norm interpolators with general norms, and for classification tasks.

A Proof details

In this appendix, we provide details of the proof of our main result, Theorem 1, omitted in Section 3. We refer to that section for notation.

A.1 Proof of Proposition 1: Application of the (C)GMT

Proposition 1 reduces the estimation of the quantities $\Phi_N, \Phi_+, \Phi_-$ in Equations $(P_N), (P_+), (P_-)$ to the estimation of auxiliary quantities $\tilde{\phi}_N, \tilde{\phi}_+, \tilde{\phi}_-$, using the (C)GMT.

As a first step, we apply the CGMT to $\Phi_N$ and the GMT to $\Phi_+$ analogously to [KZSS21, Lemmas 4&7]. We only restate the results here and refer the reader to that paper for details and proofs. Note that the (C)GMT is applied on $X$ conditionally on $\xi$, so that the Gaussianity of the noise is not crucial.

Lemma 7 ([KZSS21, Lemma 7], Application of CGMT). Define
\[ \tilde{\phi}_N = \min_w \|w\|_1 \quad \text{s.t.} \quad \|\xi - g\|_2 \leq (w, h), \]
where $g \sim \mathcal{N}(0, I_n)$ and $h \sim \mathcal{N}(0, I_d)$ are independent random variables. Then, for all $t \in \mathbb{R}$,
\[ \mathbb{P}(\Phi_N > t) \leq 2\mathbb{P}(\tilde{\phi}_N > t), \]
where the probabilities on the left and on the right are over the draws of $X, \xi$ and of $g, h, \xi$, respectively.

Lemma 8 ([KZSS21, Lemma 4], Application of GMT). Define
\[ \tilde{\phi}_+ = \max_w \|w\|_2^2 \quad \text{s.t.} \quad \|\xi - g\|_2 \leq (w, h) \]
where $g \sim \mathcal{N}(0, I_n)$ and $h \sim \mathcal{N}(0, I_d)$ are independent random variables. Then, for all $t \in \mathbb{R}$,
\[ \mathbb{P}(\Phi_+ > t) \leq 2\mathbb{P}(\tilde{\phi}_+ > t), \]
where the probabilities on the left and on the right are over the draws of $X, \xi$ and of $g, h, \xi$, respectively.

Following the same argument as in [KZSS21, Lemma 4], we can show a corresponding lemma for $\Phi_-$ which we state without proof:

Lemma 9 (Application of GMT). Define
\[ \tilde{\phi}_- = \min_w \|w\|_2^2 \quad \text{s.t.} \quad \|\xi - g\|_2 \leq (w, h) \]
where $g \sim \mathcal{N}(0, I_n)$ and $h \sim \mathcal{N}(0, I_d)$ are independent random variables. Then, for all $t \in \mathbb{R}$,
\[ \mathbb{P}(\Phi_- < t) \leq 2\mathbb{P}(\tilde{\phi}_- < t), \]
where the probabilities on the left and on the right are over the draws of $X, \xi$ and of $g, h, \xi$, respectively.

Next, by using Gaussian concentration results, we can formulate simpler versions of the above optimization problems defining the quantities $\tilde{\phi}$'s.

Simplify $\tilde{\phi}_N$. Following the same argument as in the first part of the proof of [KZSS21, Lemma 8] (Equations (68)-(70)), we can show that for any $0 < \rho < 1/2$, with probability at least $1 - 6\exp(-np^2/100)$, uniformly over $w$,
\[ \|\xi - g\|_2^2 \leq (1 + \rho)n(\sigma^2 + \|w\|_2^2). \quad (4) \]
So on the event where Equation (4) holds, we have that
\[ \tilde{\phi}_N \leq \min_w \|w\|_1 \quad \text{s.t.} \quad (w, h)^2 \geq (1 + \rho)n(\sigma^2 + \|w\|_2^2) = \phi_N \]
which proves the first inequality in Proposition 1.

16
Simplify $\tilde{\phi}_+, \tilde{\phi}_-$. By the same argument as for $\tilde{\phi}_N$, we can show that for any $0 < \rho < 1/2$, with probability at least $1 - 6 \exp(-n\rho^2/100)$, uniformly over $w$,

$$
\|\xi - g\|_2^2 \geq (1 - \rho)n(\sigma^2 + \|w\|_2^2).
$$

(5)

So on the event where Equation (5) holds, we have that

$$
\tilde{\phi}_+ \leq \max_w \|w\|_2^2 \text{ s.t. } \left\{ \begin{array}{l}
\|w\|_1 \leq M + 2\|w^*\|_1 \\
\langle w, h \rangle^2 \geq (1 - \rho)n(\sigma^2 + \|w\|_2^2) = \phi_+,
\end{array} \right.
$$

and similarly $\tilde{\phi}_- \geq \phi_-$. This proves the second and third inequalities in Proposition 1 and thus completes the proof.

### A.2 Proof of Lemma 1: Parametrizing the argmax/argmin

We now prove our first key lemma: we show that, up to scaling, the argmax/argmin in $(\alpha)$, where $\alpha = \frac{1}{n\|w\|_2^2}$, is given by $\tilde{\alpha} = \frac{1}{M + 2\|w^*\|_1}$.

Throughout this section and the next, we consider $h$ as a fixed vector such that $H_1 > \ldots > H_d > 0$. In other words, all of our statements should be understood as holding conditionally on $h$, and with $h$ in general position.

For all $\beta \in [\frac{1}{2}, 1]$, define

$$
\tau(\beta) = \arg\max_w \langle w, H \rangle \text{ s.t. } \begin{cases} \|w\|_2^2 \leq \beta \\
\forall i, w_i \geq 0 \\
1^T w = \|w\|_1 = 1 \end{cases}.
$$

(6)

Importantly, note that the constraint $\|w\|_2^2 \leq \beta$ in the definition of $\tau(\beta)$ necessarily holds with equality at optimality. Indeed, suppose by contradiction $\|\tau(\beta)\|_2^2 < \beta \leq 1 = \|\tau(\beta)\|_1^2$. This implies that $\tau(\beta)$ has at least two nonzero components; denote $i \neq 1$ such that $\tau(\beta)_i > 0$. Then there exists some $\varepsilon > 0$ such that $\tau(\beta) + \varepsilon e_1 - \varepsilon e_i$ satisfies the constraints and achieves a higher objective value than $\tau(\beta)$, contradicting its optimality.

The first step of the proof is to show that (at least one element) of the argmax/argmin belongs to the set $\mathbb{R}_+ \Gamma$, where $\Gamma = \{\tau(\beta); \frac{1}{2} \leq \beta \leq 1\}$.

**Claim 1.** For each of the optimization problems $(A_N)$, $(A_+)$, and $(A_-)$, there exist $b > 0$ and $\beta \in [\frac{1}{2}, 1]$ such that $b\tau(\beta)$ is an optimal solution.

**Proof.** Let $v$ be an optimal solution of $(A_N)$. It is straightforward to check that we may assume w.l.o.g. that $\forall i, v_i \geq 0$. Choose $b = \|v\|_1$ and $\beta = \frac{\|v\|_1^2}{\|v\|_2^2}$; note that $\beta \in [\frac{1}{2}, 1]$. By definition, $\|b\tau(\beta)\|_2 = \|v\|_2$ and $\|b\tau(\beta)\|_1 = \|v\|_1$, and $v/b$ is feasible for (6) so $b\tau(\beta), H \geq \langle v, H \rangle$. Therefore, $b\tau(\beta)$ satisfies the constraint of $(A_N)$ and achieves the optimal objective value, so is also an optimal solution of $(A_N)$.

The statements for $(A_+)$ and $(A_-)$ follow by the exact same argument.

Next, we show that $\{\tau(\beta)\}_\beta$ and $\{\frac{\gamma(\alpha)}{\alpha}\}_{\alpha}$ are two parametrizations of the same path.

**Claim 2.** We have the equality

$$
\Gamma := \left\{ \tau(\beta) \beta \in [\frac{1}{2}, 1] \right\} = \left\{ \frac{\gamma(\alpha)}{\alpha}; \alpha \in [1, \alpha_{\max}] \right\} := \Gamma
$$

where $\alpha_{\max} = \frac{d\|H\|_2}{\|H\|_1}$.

**Proof.** First note that we can characterize $\frac{\gamma(\alpha)}{\alpha}$ as the optimal solution of

$$
\frac{\gamma(\alpha)}{\alpha} = \arg\min_w \|w\|_2^2 \text{ s.t. } \begin{cases} \langle w, H \rangle \geq \frac{\|H\|_2}{\alpha} \\
\forall i, w_i \geq 0 \\
1^T w = \|w\|_1 = 1 \end{cases}.
$$

(7)
The optimization problems (6) and (7) are both convex and both satisfy the Linear Independence Constraint Qualification conditions. So, denoting $\Delta_d = \{ w \in [0,1]^d; 1^T w = 1 \}$ the standard simplex, by the Lagrangian duality theorem (a.k.a. Karush-Kuhn-Tucker theorem) we have that for all $w \in \mathbb{R}^d$,

$$\exists \beta > 0; w = \gamma(\beta) \iff \exists \lambda > 0; w = \arg \max_{w \in \Delta_d} \langle w, H \rangle - \lambda \|w\|^2_2$$

$$\iff \exists \mu > 0; w = \arg \min_{w \in \Delta_d} \|w\|^2_2 - \mu \langle w, H \rangle \iff \exists \alpha > 0; w = \gamma(\alpha) \frac{\alpha}{\alpha}.$$ 

Thus, $\{ \gamma(\beta); \beta > 0 \} = \left\{ \frac{\gamma(\alpha)}{\alpha}; \alpha > 0 \right\}$. However it is straightforward to check that $\{ \gamma(\beta); \beta > 0 \} = \Gamma$ and that $\left\{ \frac{\gamma(\alpha)}{\alpha}; \alpha > 0 \right\} = \Gamma$, which concludes the proof. 

Just as the first constraint in (6) holds with equality at optimality, so does the first constraint in (7); that is, $\gamma(\alpha), H = \|H\|_\infty$ for all $\alpha \in [1, \alpha_{\text{max}}]$. This would follow from a careful study of the equivalence between the two problems, but here we give a more direct proof.

**Claim 3.** The inequality constraint $\langle w, H \rangle \geq \|H\|_\infty$ in the problem defining $\gamma(\alpha)$ holds with equality, at optimality.

**Proof.** Denote $w = \gamma(\alpha)$. Suppose by contradiction $\langle w, H \rangle > \|H\|_\infty$. Let $i$ resp. $j$ the index of the largest resp. smallest component of $w$. First note that if $w_i = w_j$, then $w \propto 1$, i.e., $w = \frac{1}{w} 1$ and so $\langle w, H \rangle = \frac{1}{2} \|H\|_1 > \|H\|_\infty$, which would contradict $\alpha \leq \alpha_{\text{max}}$; so we have the strict inequality $w_i > w_j$. Now for some $\varepsilon > 0$ to be chosen, let $w' = w - \varepsilon e_i + \varepsilon e_j$. Clearly $\varepsilon > 0$ can be chosen small enough so that $w'$ satisfies all three constraints in the optimization problem defining $\gamma(\alpha)$. Furthermore, for small enough $\varepsilon$, $\|w\|^2_2 - ||w'||^2_2 = w_i^2 - (w_i - \varepsilon)^2 + w_j^2 - (w_j + \varepsilon)^2 = 2\varepsilon (w_i - w_j - \varepsilon)$ is positive, i.e $\|w'||^2_2 < \|w\|^2_2$, which contradicts optimality of $w = \gamma(\alpha)$.

We now have all the necessary ingredients to prove Lemma 1. The equivalence between $(A_N)$ and $(A'_{N})$ follows immediately from constraining the variable $w$ (in the former) to belong to the set $\mathbb{R}_+ \Gamma$. The equivalence between $(A_-)$ and $(A'_{-})$ also follows immediately, noting that $\|b \gamma(\alpha) \|_1 = b$ by definition. Finally, the equivalence between $(A_{\delta})$ and $(A'_{\delta})$ follows by noticing that the inequality constraint $\|w\|_1 \leq B$ (in the former) is necessarily saturated at optimality.

### A.3 Proof of Lemma 2: Characterizing the parametric path

We now give a precise characterization of the parametric path $\Gamma$, by studying the optimization problem defining $\gamma(\alpha)$.

Throughout this section (just as in the previous one), we consider $H$ as a fixed vector such that $H_1 > ... > H_d > 0$. In other words, all of our statements should be understood as holding conditionally on $h$, and with $h$ in general position.

Throughout the proof, consider a fixed $1 < \alpha \leq \alpha_{\text{max}}$. The goal is to derive a closed-form expression of $\gamma(\alpha)$. We proceed by a Lagrangian duality approach, and first identify the dual variables $\lambda, \nu, \mu$ (a.k.a. Lagrangian multipliers, a.k.a. KKT vectors) of the optimization problem defining $\gamma(\alpha)$. This first analysis yields an expression for $\gamma(\alpha)$ involving an unknown “sparsity” integer $s$, which depends on $\lambda, \nu, \mu$ and hence indirectly on $\alpha$. We finish by showing how to determine $s$ explicitly from $\alpha$.

**Karush-Kuhn-Tucker (KKT) conditions.** Recall that $\gamma(\alpha)$ is defined by the following optimization problem (note that the additional factor $\frac{1}{2}$ in the objective does not change the arg min):

$$\gamma(\alpha) = \arg \min_w \frac{1}{2} \|w\|^2_2 \quad \text{s.t.} \begin{cases} \langle w, H \rangle \geq \|H\|_\infty \\
\forall i, w_i \geq 0 \\
1^T w = \|w\|_1 = \alpha \end{cases}$$

18
This is a convex optimization problem with Lagrangian

\[ L(w; \lambda, \mu, \nu) = \frac{1}{2} \|w\|^2 - \lambda \langle w, H \rangle - \|H\|_\infty + \mu (1^T w - \alpha) - \nu^T w. \]

The objective is convex and all the constraints are affine. So by Lagrangian duality, \( w = \gamma(\alpha) \) if and only if there exist \( \lambda, \mu \in \mathbb{R} \) and \( \nu \in \mathbb{R}^d \) satisfying the KKT conditions:

- (Stationarity) \( w - \lambda H + \mu 1 - \nu = 0 \) i.e. \( w = \lambda H - \mu 1 + \nu \)
- (Primal feasibility) \( \begin{cases} (w, H) \geq \|H\|_\infty \\ \forall i, w_i \geq 0 \\ 1^T w = \alpha \end{cases} \)
- (Dual feasibility) \( \lambda \geq 0 \) and \( \forall i, \nu_i \geq 0 \)
- (Complementary slackness) \( \lambda \langle w, H \rangle - \|H\|_\infty = 0 \), and \( \forall i, \nu_i w_i = 0 \).

In the rest of this proof, denote \( w = \gamma(\alpha) \), and let \( \lambda, \mu, \nu \) as above.

**Sparsity structure of \( w \).** Let \( s \) denote the largest \( s' \in \{1, ..., d\} \) such that \( \lambda H_{s'} > \mu \). Since \( \lambda \geq 0 \) and \( H \) is ordered, we have \( \lambda H_1 \geq ... \geq \lambda H_s > \mu \geq \lambda H_{s+1} \geq ... \)

Consider the complementary slackness condition \( \forall i, \nu_i w_i = 0 \).

- If \( w_i > 0 \), then \( \nu_i = 0 \) so \( w_i = \lambda H_i - \mu > 0 \), and so \( i \leq s \).
- If \( \nu_i > 0 \), then \( w_i = \lambda H_i - \mu + \nu_i = 0 \) so \( \lambda H_i - \mu < 0 \), and so \( i > s \).

So by contraposition, for all \( i \leq s, \nu_i = 0 \) and \( w_i = \lambda H_i - \mu \).

Thus, \( \text{supp}(w) \subset \{1, ..., s\} \) and \( w = \lambda H_{[s]} - \mu 1_{[s]} \), where \( H_{[s]} \) is the vector equal to \( H \) on the first \( s \) components and 0 on the last \( (d - s) \), and similarly for \( 1_{[s]} \).

Furthermore, note that the case \( s = 1 \) occurs only if \( w \propto e_1 \), and one can check that it implies \( \alpha = 1 \), which we excluded.

**Closed-form expression of the dual variables \( \lambda, \mu \).** We can compute \( \lambda \) and \( \mu \) by substituting \( w = \lambda H_{[s]} - \mu 1_{[s]} \) into the primal feasibility conditions.

- Since we know from Claim 3 (in Section A.2) that the first constraint in the problem defining \( \gamma(\alpha) \) holds with equality at optimality, this means that the first primal feasibility condition holds with equality, i.e.,
  \[ (w, H) = \lambda \|H_{[s]}\|_2 - \mu \|H_{[s]}\| = \|H\|_\infty. \]
- By the last primal feasibility condition, \( 1^T w = \lambda \|H_{[s]}\|_1 - \mu s = \alpha \).

So \( \lambda \) and \( \mu \) are given by

\[
\begin{cases}
\lambda \|H_{[s]}\|_2 - \mu \|H_{[s]}\| = \|H\|_\infty \\
\lambda \|H_{[s]}\|_1 - \mu s = \alpha \\
\end{cases} \iff \begin{cases}
\lambda = \frac{1}{\|H_{[s]}\|_2 - \|H_{[s]}\|_1} (s \|H\|_\infty - \alpha \|H_{[s]}\|_1) \\
\mu = \frac{1}{\|H_{[s]}\|_2 - \|H_{[s]}\|_1} \left( \|H_{[s]}\|_1 \|H\|_\infty - \alpha \|H_{[s]}\|_2^2 \right). \\
\end{cases}
\]

Note that the denominator is positive, since \( H_{[s]} \) has distinct components.
Closed-form characterization of $s$. We now show that there exists an increasing sequence $\alpha_2 = 1 < \cdots < \alpha_d < \alpha_{d+1} = \alpha_{\max}$ such that for all $\alpha$, the sparsity $s$ of $w$ is exactly the index which satisfies $s \in (\alpha_s, \alpha_{s+1}]$. By plugging the expressions of $\lambda$ and $\mu$ into the condition defining $s$: $\lambda H_s > \mu \geq \lambda H_{s+1}$, we obtain

$$\left( s \| H \|_\infty - \alpha \| H(s) \|_1 \right) H_s > \| H(s) \|_1 \| H \|_\infty - \alpha \| H(s) \|_2^2 \geq \left( s \| H \|_\infty - \alpha \| H(s) \|_1 \right) H_{s+1}.$$  

Rearranging, this is equivalent to

$$\alpha \left( \| H(s) \|_2^2 - \| H(s) \|_1 H_s \right) > \left( \| H(s) \|_1 - s H_s \right) \| H \|_\infty$$

and

$$\alpha \left( \| H(s) \|_2^2 - \| H(s) \|_1 H_{s+1} \right) \leq \left( \| H(s) \|_1 - s H_{s+1} \right) \| H \|_\infty.$$

One can check that $\| H(s) \|_2^2 - \| H(s) \|_1 H_{s+1} > \| H(s) \|_2^2 - \| H(s) \|_1 H_s > 0$. So the above is equivalent to

$$\alpha_s := \frac{\| H(s) \|_1 - s H_s \| H \|_\infty}{\| H(s) \|_2^2 - \| H(s) \|_1 H_s} < \alpha \leq \frac{\| H(s) \|_1 - s H_{s+1} \| H \|_\infty}{\| H(s) \|_2^2 - \| H(s) \|_1 H_{s+1}} =: \overline{\alpha}(s).$$

A straightforward calculation shows that $\overline{\alpha}(s) = \alpha_{s+1}$. Thus, using the convention $\alpha_{s+1} = \alpha_{\max}$, $s$ is uniquely characterized by $\alpha_s < \alpha \leq \alpha_{s+1}$. This concludes the proof of Lemma 2.

### A.4 Proof of Proposition 4: Concentration of norms of $\gamma(\alpha_s)$

In this section we prove Proposition 4 and Lemma 3 which establish concentration inequalities for $\gamma(\alpha)$ at the breakpoints $\alpha_s$ for $2 \leq s \leq d$. More precisely, we give high-probability estimates (with respect to the draws of $h$) of their $\ell_1$ and $\ell_2$ norms, since those are the quantities that appear in the stochastic optimization problems $(A_\gamma)$, $(A'_\gamma)$ and $(A'_\gamma)$.

Plugging in $\alpha = \alpha_s$ into the closed-form expressions of $\lambda$ and $\mu$ in Lemma 2, we obtain $\gamma(\alpha_s) = \frac{\| H(s) \|_2}{\langle v_s, H \rangle} v_s$ where $v_s := H(s) - H_s 1_{[s]}$. Thus, to estimate the norms of $\gamma(\alpha_s)$ it suffices to estimate the quantities

$$\| v_s \|_2^2 = \| H(s) \|_2^2 - \| H(s) \|_1 H_s + s H_s^2$$

$$\| v_s \|_1 = \| H(s) \|_1 - s H_s$$

$$\langle v_s, H \rangle = \| H(s) \|_2^2 - \| H(s) \|_1 H_s.$$

Throughout the proofs in this section, we will use $c > 0$ to denote a universal constant (in particular, independent of $d$ and $s$) which may change from display to display. Furthermore, in this section we let $Z$ denote a standard normal distributed random variable, and recall that $\Phi(x) = \mathbb{P}(Z > x) = \frac{1}{2} \mathbb{P}(|Z| > x)$ for $x > 0$ denotes its complementary cumulative distribution function.

#### A.4.1 Preliminary facts

We start by stating some auxiliary facts about $\Phi(x)$.

**Fact 1.** Denote $h(x)$ the function such that $\forall x > 0$, $\Phi(x) = \frac{\exp(-x^2/2)}{\sqrt{2\pi}} h(x)$. We have the first-order and higher-order upper and lower bounds

$$1 - \frac{1}{1 + x^2} \leq h(x) \leq 1$$

and

$$h(x) - \left( 1 - \frac{1}{x^2} + \frac{3}{x^4} - \frac{15}{x^6} \right) \leq \frac{c}{x^6}$$

for all $x > 0$.

**Proof.** The first-order estimate follows from straightforward analysis. The higher-order estimate follows from the exact asymptotic expansion of the complementary error function $\text{erfc}$, since $2\Phi(x) = \text{erfc}(x/\sqrt{2})$. $\square$
We will show the following lemmas successively, in which $t - 1$ with $C_2\Phi$ (Concentration of Lemma 10)
and making the appropriate simplifications.

**A.4.2 Proof of Proposition 4**

We will show the following lemmas successively, in which $t \in \mathbb{R}$ denotes the quantity such that $2\Phi(t) = s/d$ (we drop the explicit dependency on $s$ for concision in this section).

**Lemma 10** (Concentration of $H_s$). Assume that $s < d/2$. With probability at least $1 - 2\delta$, we have

$$|H_s - t| \leq c\left(\frac{1}{\sqrt{s}} + \sqrt{\frac{\log(1/\delta)}{s}} + \frac{\log(1/\delta)}{s}\right).$$

**Lemma 11** (Concentration of $\|H_s\|_2^2$). Assume $s < d/5$. With probability at least $1 - 2\delta$, we have

$$\|H_s\|_2^2 - s\mathbb{E}[Z^2] |Z \geq t| \leq c\sqrt{s}(1 + \sqrt{\log(1/\delta)}) \left(\frac{1}{\sqrt{s}}(1 + \sqrt{\log(1/\delta)}) + t\right).$$

**Lemma 12** (Concentration of $\|H_s\|_1$). With probability at least $1 - 2\delta$, we have

$$\|H_s\|_1 - s\mathbb{E}[Z] |Z \geq t| \leq c\left(\sqrt{s} + \sqrt{\log(1/\delta)s}\right).$$

**Lemma 13** (Concentration of $v_s$). Assume $s < d/5$. For $\delta \geq \exp(-s)$, with probability at least $1 - 6\delta$, we have

$$\|v_s\|_2 - s\left(\frac{2}{t^2} - \frac{10}{t^4}\right) \leq s\left(\frac{c}{t^6} + C_{s,\delta}\right)$$
and

$$\|v_s\|_1 - s\left(\frac{1}{t^2} - \frac{2}{t^3}\right) \leq s\left(\frac{c}{t^5} + \frac{C_{s,\delta}}{t}\right)$$
and

$$|\langle v_s, H \rangle - s| \leq sC_{s,\delta}$$

with $C_{s,\delta} = \frac{t + t\sqrt{\log(1/\delta)}}{\sqrt{s}}$.

The proposition follows as a consequence of this last lemma:

**Proof of Proposition 4.** Let $c_1, c_2, \bar{t}$ as in Lemma 3, and assume $s \leq d/c_1$. In particular, $\log(d/s) \leq t^2 \leq 2\log(d/s)$.

We apply Lemma 13 with $\delta = \exp\left(-2\frac{s}{\log(d/s)}\right)$. Since $t^2 \leq 2\log(d/s)$, this choice ensures that $\frac{t\sqrt{\log(1/\delta)}}{\sqrt{s}} \leq 8/t^4$. Moreover, the assumption that $d \leq \exp(\kappa_4 s^{1/5})$ ensures that $\frac{t^2}{s} \leq c/t^4$. So we have $C_{s,\delta} \leq c/t^4$.

The proposition follows by substituting the estimates of $\|v_s\|_2^2$, $\|v_s\|_1$, $\langle v_s, H \rangle$ into $\gamma(\alpha_s) = \frac{\|H\|_{v_s, H}}{\|v_s\|_1} v_s$, and making the appropriate simplifications.

\[\square\]
A.4.3 Proofs of the concentration lemmas

Proof of Lemma 10: Concentration of $H_s$. By observing that the random variable $\max\{s; H_s > t\}$ is binomially distributed with parameters $d$ and $p = \mathbb{P}(|Z| > t)$, [LXG20] show the following upper and lower tail bounds for $H_s$.

Claim 4. Assume that $s < d/2$ and let $t$ be such that $2\Phi^c(t) = s/d$. Then for all $\varepsilon > 0$, we have the lower resp. upper tail bounds

$$
\mathbb{P}(H_s \leq t - \varepsilon) \leq \exp\left(-c s \varepsilon^2 \log(d/s)\right)
$$
and

$$
\mathbb{P}(H_s \geq t + \varepsilon) \leq \exp\left(-c s \varepsilon^2 \log(d/s) \exp\left(-2\varepsilon \sqrt{2 \log(d/s) - \log(d/s) - \log\left(\frac{\pi}{2}\right) - \varepsilon^2}\right)\right).
$$

Proof. This follows straightforwardly from Lemma 2 of [LXG20] and from the estimate of $t$ in Lemma 3.

The lower tail bound is already sufficiently tight to show our high-probability lower bound on $H_s - t$. However we remark that the upper tail bound is too loose; indeed it is only reasonable when $\varepsilon$ is sufficiently small. So to prove our high-probability upper bound, we instead start from the following one-sided concentration inequality from [BT12].

Claim 5. Assume $d \geq 3$ and $s < d/2$, then for all $z > 0$,

$$
\mathbb{P}(H_s - \mathbb{E}H_s \geq c(\sqrt{z/s} + z/s)) \leq \exp(-z).
$$

Proof. The proof follows from the same argument as in Proposition 4.6 of [BT12].

It only remains to bound the distance between $t$ and $\mathbb{E}H_s$.

Claim 6. Assume that $s < d/2$ and let $t$ be such that $2\Phi^c(t) = s/d$. Then

$$
|\mathbb{E}H_s - t| \leq c_1 \sqrt{s}.
$$

Proof. According to Proposition 4.2 of [BT12],

$$
\text{Var}(H_s) \leq \frac{1}{s \log 2} \log\left(\frac{2d}{s}\right) - \log(1 + \frac{4}{s} \log\left(\frac{2d}{s}\right))
$$
so by Chebyshev’s inequality,

$$
\mathbb{P}(\{|H_s - \mathbb{E}H_s| > \varepsilon\}) \leq \frac{c'_1}{s \varepsilon^2}.
$$

On the other hand, recall from Claim 4 that

$$
\mathbb{P}(\{|H_s - t| > \varepsilon\}) \leq 2 \exp\left(-c s \varepsilon^2 \log(d/s) \exp\left(-2\varepsilon \sqrt{2 \log(d/s) - \log(d/s) - \log\left(\frac{\pi}{2}\right) - \varepsilon^2}\right)\right)
$$

One can check that there exist universal constants $c_1, c_2$ such that, by picking $\varepsilon = c_1/\sqrt{s \log(d/s)}$ and $\varepsilon' = c_2/\sqrt{s}$, the sum of the right-hand sides is less than 1.

Thus, with positive probability we have

$$
|\mathbb{E}H_s - t| \leq |H_s - \mathbb{E}H_s| + |H_s - t| \leq \frac{c_1/\sqrt{\log(2)} + c_2}{\sqrt{s}}.
$$

\[\square\]
Proof of Lemma 11: Concentration of $\|H_s\|_2^2$. Let us first restate Proposition 2 of [LXG20] in our notation. We remark that their statement contained an additional $\log(d/s)$ factor due to a mistake in the proof. Correcting this mistake, we have that with probability at least $1 - 2\delta$,

$$\left| \frac{1}{\sqrt{s}} \left\| H_s \right\|_2^2 - \sqrt{E[Z^2]Z \geq t} \right| \leq c \frac{1}{\sqrt{s}} (1 + \sqrt{\log(1/\delta)}).$$

Since for all $a, b, \varepsilon > 0$, $|a - b| \leq \varepsilon \implies |a^2 - b^2| \leq \varepsilon (a + b)$, this implies

$$\left| \frac{1}{s} \left\| H_s \right\|_2^2 - \sqrt{E[Z^2]Z \geq t} \right| \leq c \frac{1}{\sqrt{s}} (1 + \sqrt{\log(1/\delta)}) \left( \frac{1}{\sqrt{s}} (1 + \sqrt{\log(1/\delta)}) + \sqrt{E[Z^2]Z \geq t} \right).$$

Now $E[Z^2|Z \geq t] = 1 + \frac{t^2}{h(t)} \leq ct^2$ whenever $t \geq 1$, which is ensured by our assumption that $s/d = \Phi(t) \leq 0.2$. So

$$\left| \frac{1}{s} \left\| H_s \right\|_2^2 - \sqrt{E[Z^2]Z \geq t} \right| \leq c \frac{1}{\sqrt{s}} (1 + \sqrt{\log(1/\delta)}) \left( \frac{1}{\sqrt{s}} (1 + \sqrt{\log(1/\delta)}) + t \right).$$

Proof of Lemma 12: Concentration of $\|H_s\|_1$. We use exactly the same argument as in the proof of Proposition 2 of [LXG20]. Namely, start by decomposing

$$\frac{1}{s} \left\| H_s \right\|_1 - E[Z|Z \geq t] \leq \frac{1}{s} \left\| H_s \right\|_1 - \frac{1}{s} E \left\| H_s \right\|_1 + \frac{1}{s} E \left\| H_s \right\|_1 - E[Z|Z \geq t].$$

For the first term, note that by rearrangement inequality, $Z \mapsto \frac{1}{s} \sum_{i=1}^s |Z_i|$ is $\frac{1}{s}$-Lipschitz for the $\|\cdot\|_2$ norm, where $(Z_{(1)}, ..., Z_{(d)})$ is the nondecreasing reordering of the absolute values of $Z$. So by concentration of Lipschitz-continuous functions of Gaussians,

$$\mathbb{P} \left( \left| \frac{1}{s} \sum_{i=1}^s H_i - E \left[ \frac{1}{s} \sum_{i=1}^s H_i \right] \right| \geq \varepsilon \right) \leq 2 \exp(-s\varepsilon^2/2).$$

For the second term, we can apply exactly the same arguments as in the proof of Proposition 2 of [LXG20], adapting equations (42) to (46), to obtain the bound

$$\left| E \left[ \frac{1}{s} \sum_{i=1}^s H_i - E[Z|Z \geq t] \right] \right| \leq cE |H_{s+1} - t| \leq c \frac{1}{\sqrt{s}}.$$

In particular, we use the fact that $x \mapsto E[Z|Z \geq x]$ is a smooth function, which follows from its explicit expression given in Fact 2.

Proof of Lemma 13: Concentration of $v_s$. For brevity of notation, let $C_{s, \delta} = \frac{t + t^2 \sqrt{\log(1/\delta)}}{\sqrt{s}}$. Assume $\delta \geq e^{-s}$; in particular, $C_{s, \delta} \leq ct$. Collecting and simplifying the above results, so far we showed that

$$t |H_s - t| \leq C_{s, \delta} \text{ and } \left| \frac{1}{s} \left\| H_s \right\|_2^2 - (1 + \frac{t^2}{h(t)}) \right| \leq C_{s, \delta} \text{ and } \left| \frac{t}{s} \left\| H_s \right\|_1 - \frac{t}{h(t)} \right| \leq C_{s, \delta}.$$
• Substituting the deterministic estimates in the expression of $\|v_s\|^2_2$ and carrying over the above concentration bounds, we obtain

$$\left| \|v_s\|^2_2 - \left(s(1 + \frac{t^2}{h(t)}) - 2 \frac{st}{h(t)} + st^2 \right) \right| \leq sC_{s,d}(1 + C_{s,d})$$

and the deterministic estimate can be simplified to

$$s(1 + \frac{t^2}{h(t)}) - t^2 = s \frac{2c^2}{1 - \frac{c}{t}} + O \left( \frac{1}{t^2} \right)$$

(where the $O(\cdot)$ hides a universal constant).

• Likewise for $\|v_s\|_1$ we get

$$\left| \|v_s\|_1 - \left(\frac{st}{h(t)} - st \right) \right| \leq sC_{s,d}$$

and the deterministic estimate can be simplified to

$$st \left( \frac{1}{h(t)} - 1 \right) = s \left( \frac{1}{t^2} - \frac{2c}{t^3} + O \left( \frac{1}{t^4} \right) \right).$$

• Likewise for $\langle v_s, H \rangle$ we get

$$\left| \langle v_s, H \rangle - \left[s \left(1 + \frac{t^2}{h(t)} \right) - \frac{st}{h(t)} t \right] \right| \leq 3sC_{s,d}$$

and the deterministic estimate simplifies to $s$.

### A.4.4 Proof of Lemma 3

Using the upper bound $\Phi^\dagger(x) \leq \exp(-x^2/2)$ from the first part of Fact 1, it is straightforward to check that $2\Phi^\dagger(\overline{t}) \leq s/d = 2\Phi^\dagger(t)$, and so $\overline{t} \geq t$.

Let $\xi^2 = \overline{t}^2 - c_1$ for some constant $c_1 > 0$ to be chosen. Using the lower bound $\Phi^\dagger(x) \geq \exp(-x^2/2) \frac{x^2}{x + c}$, one can check that $c_1$ can be chosen such that $2\Phi^\dagger(\overline{t}) \leq s/d = 2\Phi^\dagger(t)$, and so $\xi \leq t$.

Going through the calculations reveals that $\kappa_3 \geq e^{2/\xi} \approx 2$ ensures $\overline{T}^2 \leq 2\log(d/s)$, that $2\Phi^\dagger(\overline{T}) \leq s/d$ is always true, that $c_1 = 1 - \log(\frac{\overline{T}}{\overline{t}}) \approx 0.5$ ensures $\xi^2 \geq \log(d/s)$ for all $s, d$, and that $\kappa_3 \geq e^{2.3415...} \approx 10.4$ ensures $2\Phi^\dagger(\overline{T}) \geq s/d$. This concludes the proof of the lemma.

**Remark 2.** Tighter bounds for $t$ can be derived while still only using the first-order estimate of $h(x)$ (the first part of Fact 1). Namely, by similar straightforward calculations as above, one can check that there exist universal constants $\kappa, \alpha_1, \alpha_2 > 0$ such that, for all $s \leq d/\kappa$, $t$ is bounded as $\frac{\overline{t}}{t} \leq t \leq \overline{T}$ where

$$\xi^2 = 2\log(d/s) - \log(\log(d/s)) - \log(\pi) + \frac{\log(\log(d/s))}{\frac{2\log(d/s)}{\log(\log(d/s))} + \frac{\alpha_1}{\log(\log(d/s))}}$$

and

$$\overline{T}^2 = 2\log(d/s) - \log(\log(d/s)) - \log(\pi) + \frac{\log(\log(d/s))}{\frac{2\log(d/s)}{\log(\log(d/s))} + \frac{\alpha_2}{\log(\log(d/s))}}.$$ 

Verifying whether the constants $\kappa, \alpha_1, \alpha_2$ are of reasonable magnitude is more involved, however.

### A.5 Proofs of Lemmas 4 and 5: Studying the feasible set of $(A'_+)$ and $(A'_-)$

#### A.5.1 Proof of Lemma 4

We give separate proofs for the statements 1-4 in the Lemma:

**First statement:** The mapping $\alpha \mapsto \|\gamma(\alpha)\|^2_2$ is convex over $[1, \alpha_{\max}]$. 

Recall that $\|\gamma(\alpha)\|_2^2$ is given by

$$
\|\gamma(\alpha)\|_2^2 = \min_w \|w\|_2^2 \text{ s.t. } \begin{cases}
\langle w, H \rangle \geq \|H\|_\infty \\
\forall i, w_i \geq 0 \\
1^T w = \|w\|_1 = \alpha
\end{cases}
$$

Since $\alpha$ appears on the right-hand side of a linear constraint, it is straightforward to check directly that $\alpha \mapsto \|\gamma(\alpha)\|_2^2$ is convex. In detail: Let any $\alpha_0$ and $\alpha_1$, let $w_i = \gamma(\alpha_i)$ for $i \in \{1, 2\}$, and $\alpha_t = (1-t)\alpha_0 + t\alpha_1$ and $w_t = (1-t)w_0 + tw_1$ for $t \in [0, 1]$; then $w_t$ is feasible for the optimization problem defining $\gamma(\alpha_t)$, so $\|\gamma(\alpha_t)\|_2^2 \leq \|w_t\|_2^2 \leq t\|w_0\|_2^2 + (1-t)\|w_1\|_2^2$ by convexity.

**Second statement:** It is decreasing over $[1, \alpha_{d+1/2}]$ and increasing over $[\alpha_{d+1/2}, \alpha_{\text{max}}]$.

Using the notation of Section A.3, the optimization problem defining $\gamma(\alpha)$ has Lagrangian

$$
L(w; \lambda, \mu, \nu) = \frac{1}{2} \|w\|_2^2 - \lambda\langle w, H \rangle - \|H\|_\infty + \mu(1^T w - \alpha) - \nu^T w,
$$

(up to the constant factor $\frac{1}{2}$ in the first term). By the envelope theorem, the marginal effect on the optimal value of increasing $\alpha$, is equal to the associated Lagrangian multiplier at optimum: $\frac{d\|\gamma(\alpha)\|_2^2}{d\alpha} = -\mu$. A straightforward computation using the expression of $\mu$ from Lemma 2 reveals that $\mu > 0$ for $1 < \alpha < \alpha_{d+1/2}$ and $\mu < 0$ for $\alpha_{d+1/2} < \alpha \leq \alpha_{\text{max}}$; hence the monotonicity of $\alpha \mapsto \|\gamma(\alpha)\|_2^2$.

**Third statement:** $I$ is an interval.

$I$ is the $B$-sublevel set of the function $\alpha \mapsto (1-\rho)n \left(\sigma^2\alpha^2 + B^2\|\gamma(\alpha)\|_2^2 \right)$, which is convex, by the first statement.

**Fourth statement:** The map $\alpha \mapsto \frac{\|\gamma(\alpha)\|_2^2}{\|\gamma(\alpha)\|_1}$ is monotonically decreasing.

Note that for each $\alpha \in [1, \alpha_{\text{max}}]$, $\frac{\gamma(\alpha)}{\alpha}$ is the optimal solution of the optimization problem

$$
\frac{\gamma(\alpha)}{\alpha} = \arg\min_w \|w\|_2^2 \text{ s.t. } \begin{cases}
\langle w, H \rangle \geq \frac{\|H\|_\infty}{\alpha} \\
\forall i, w_i \geq 0 \\
1^T w = \|w\|_1 = 1
\end{cases}
$$

In particular, the constraint set is only increasing with $\alpha$, implying that $\alpha \mapsto \frac{\|\gamma(\alpha)\|_2^2}{\alpha}$ is monotonically decreasing with $\alpha$.

**A.5.2 Proof of Lemma 5**

The upper bound for $\phi_+$ immediately follows from Equation ($A'_+$) and from the monotonicity of $\alpha \mapsto \frac{\|\gamma(\alpha)\|_2^2}{\alpha}$, which is the last statement of Lemma 4.

For $\phi_-$, there is an extra scale variable $0 < b \leq B$ which we first minimize out, similarly to the proof of Proposition 2 in Section 3.4.4. Starting from Equation ($A'_-$), first rewrite the constraint as

$$
b^2 \|H\|_\infty^2 \geq (1-\rho)n \left(\sigma^2\alpha^2 + b^2\|\gamma(\alpha)\|_2^2 \right)
$$

$$
\iff b^2 \geq \frac{(1-\rho)n\sigma^2\alpha^2}{\|H\|_\infty^2 - (1-\rho)n\|\gamma(\alpha)\|_2^2 } + \frac{(1-\rho)n\|\gamma(\alpha)\|_2^2}{\alpha^2} \iff
$$

$$
(1-\rho)n\|\gamma(\alpha)\|_2^2 < \|H\|_\infty^2.
$$
A.6 Proof of Lemma 6: A tight admissible choice for $\alpha$ and $\overline{\alpha}$

For brevity of notation, define $B = M(n, d) + 2\|w^*\|_1$ where $M(n, d)$ is given by Proposition 2. We seek integers $\underline{\alpha}, \overline{\alpha}$ such that $\alpha < \alpha_\overline{}$ and $\alpha_\underline{}$ lie on the left, respectively on the right of the interval $I$, and such that $\alpha_\underline{} \leq \alpha_\overline{}$, with high probability over the draws of $h$.

A.6.1 Preliminaries

We recall the notations $B = M(n, d) + 2\|w^*\|_1$ and

$$I = \left\{ \alpha \in [1, \alpha_{\text{max}}] : B^2 \|H\|_{\infty}^2 \geq (1 - \rho) n \left( \sigma^2 \alpha^2 + B^2 \|\gamma(\alpha)\|_2^2 \right) \right\}$$

and $\forall \alpha \in [1, \alpha_{\text{max}}], \overline{\alpha}^2 = \frac{(1 - \rho) n \sigma^2 \alpha^2}{\|H\|_{\infty}^2 - (1 - \rho) n \|\gamma(\alpha)\|_2^2}$.

Note that we have the equivalence

$$\alpha \in I \iff (1 - \rho) n \|\gamma(\alpha)\|_2^2 < \|H\|_{\infty}^2 \text{ and } \overline{\alpha}^2 \leq B.$$  (8)

Reference point: $\alpha_{\underline{\alpha}} \in I$. We have by construction that, conditionally on the event where the inequalities in Equation 2 hold for $s = n$, $\alpha_{\underline{\alpha}} \in I$ in particular this holds with probability at least $1 - 6 \exp \left( -\frac{n}{\log(d/n)^2} \right)$. Indeed, let us take a closer look at the way we chose $M(n, d)$, from the proof of Proposition 2 (Section 3.4.4). We showed that, conditionally on that event, $\alpha_{\underline{\alpha}}$ satisfies

$$(1 + \rho) n \|\gamma(\alpha)\|_2^2 < \|H\|_{\infty}^2 \text{ and } f(\alpha) \leq M(n, d)$$

where $f(\alpha) = \frac{(1 + \rho) n \sigma^2 \alpha^2}{\|H\|_{\infty}^2 - (1 + \rho) n \|\gamma(\alpha)\|_2^2}$. Since $\overline{\alpha}^2 < f(\alpha_{\underline{\alpha}})$ and $M(n, d) \leq B$, clearly $\alpha_{\underline{\alpha}}$ satisfies the condition (8), i.e., $\alpha_{\underline{\alpha}} \in I$.

Summary of (in)equalities to be used in the proof. For ease of presentation, let us recall some assumptions or definitions that we will use throughout this proof. For each integer $s$, $t_s \in \mathbb{R}$ denotes the quantity such that $2\Phi(t_s) = s/d$, and $t_s^2 = \log(d/s)$ by Lemma 3. By assumption, $\|w^*\|_1 \leq \kappa_1 \sqrt{(\sigma^2 n) \log(d/s)}$ for some universal constant $\kappa_1 > 0$. By definition, $M(n, d)^2 = \frac{\sigma^2 n}{t_n^2} \left( 1 - \frac{2}{\kappa_1} + \frac{1}{t_n} \right)$ for some universal constant $\kappa_0 > 0$. In particular, this implies that

$B^2 = (M(n, d) + 2\|w^*\|_1)^2 = \frac{\sigma^2 n}{t_n^2} \left( 1 - \frac{2}{\kappa_1} + O\left( \frac{1}{t_n^2} \right) \right).$  (9)
A.6.2 Finding $s$ such that $\alpha_s \leq \alpha_I$

We want to find an $s$ such that $\alpha_s$ is on the left of the interval $I$, i.e., $\alpha_s \leq \alpha_I$. Conditioning on the event where $\alpha_n \in I$, it suffices to have $\alpha_s < \alpha_n$ i.e. $s < n$, and $\alpha_s \notin I$ i.e.

$$
\frac{1}{B^2\|H\|_\infty} \left(1 - \rho\right)n \left(\sigma^2 \|\gamma(\alpha_s)\|_1^2 + B^2 \|\gamma(\alpha_s)\|_2^2\right) = (1 - \rho)n \left(\sigma^2 \|\gamma(\alpha_s)\|_1^2 + (1 - \rho)n \frac{\|\gamma(\alpha_s)\|_2^2}{\|H\|_\infty^2} \right) > 1.
$$

Instead of working directly with $s$, it is more convenient to define $s$ implicitly through a condition on $t_s$. Namely, we choose $s$ such that $t_s^2 \approx t_n^2 + \frac{\lambda_s}{t_n}$. For some constant $\lambda > 0$. We now make this choice formal and show that $s$ is very close to $n$; the following step will be to show that this choice guarantees $\alpha_s \notin I$.

**Claim 7.** Assume $\kappa_3 n \leq d$. Let any fixed constant $0 < \lambda \leq \sqrt{\log(\kappa_3)}$, and let $s$ be the largest integer $s$ such that $t_s^2 \geq t_n^2 + \frac{\lambda_s}{t_n}$. Then,

$$
s = n \exp \left(-\frac{\lambda_s}{2t_n}\right) \left(1 + O\left(\frac{1}{t_n^2}\right)\right)
$$

and $\left|t_s^2 - \left(t_n^2 + \frac{\lambda_s}{t_n}\right)\right| \leq O\left(\frac{1}{n}\right)$.

The first equation quantifies the fact that this choice of $s$ is very close to $n$; the second equation controls the error due to rounding (due to the fact that there is no integer $s$ such that $t_s^2 = t_n^2 + \frac{\lambda_s}{t_n}$ exactly).

**Proof.** For concision, in this proof we write $s$ instead of $\bar{s}$. Denote $t_n^2 = t_n^2 + \frac{\lambda_s}{t_n}$. By definition, $t_s^2 \geq t_n^2 > t_{s+1}^2$.

For the first part of the claim, we apply Fact 1 several times. Firstly,

$$
2\Phi^\circ(t_s) = \frac{s}{d} \leq \frac{2}{\sqrt{2\pi t_n}} \frac{1}{t_s} \exp\left(-\frac{t_s^2}{2t_n}\right) \leq \frac{2}{\sqrt{2\pi t_n}} \frac{1}{t_n} \exp\left(-\frac{t_n^2}{2t_n}\right) = \frac{2}{\sqrt{2\pi t_n}} \frac{1}{\sqrt{2\pi t_n}} \exp\left(-\frac{\lambda_s}{2t_n}\right).
$$

Secondly,

$$
\frac{t_n^2}{1 + t_n^2} \cdot \frac{2}{\sqrt{2\pi t_n}} \frac{1}{t_n} \exp\left(-\frac{t_n^2}{2t_n}\right) \leq 2\Phi^\circ(t_n) \hspace{1cm} \text{and hence} \hspace{1cm} \frac{2}{\sqrt{2\pi t_n}} \frac{1}{t_n} \exp\left(-\frac{t_n^2}{2t_n}\right) \leq \frac{n}{d} \left(1 + \frac{1}{t_n^2}\right).
$$

This proves the upper bound on $s$. The lower bound can be proved in a similar fashion, by applying Fact 1 to lower-bound $\frac{s+1}{d} = 2\Phi^\circ(t_{s+1})$, and again to upper-bound $\frac{1}{t_n^2} \exp\left(-\frac{t_n^2}{t_n^2}\right)$. In this way we obtain

$$
\frac{s+1}{d} \geq \frac{n}{d} \exp\left(-\frac{\lambda_s}{2t_n}\right) \left(1 - \frac{1}{1 + t_{s+1}^2}\right),
$$

and the bound $t_s^2 - t_{s+1}^2 \leq \frac{2}{s} \leq 2$ shown below implies that $\frac{1}{t_s^2} = O\left(\frac{1}{t_n^2}\right)$.

We now turn to the second part of the claim. By mean value theorem applied on $\Phi^\circ$, there exists $\xi \in [t_{s+1}, t_s]$ such that

$$
\frac{\Phi^\circ(t_{s+1}) - \Phi^\circ(t_s)}{t_{s+1} - t_s} = \frac{1}{2d} \frac{1}{t_{s+1} - t_s} = (\Phi^\circ)'(\xi) = -\frac{1}{\sqrt{2\pi}} \exp(-\xi^2/2)
$$

and $0 < t_s - t_{s+1} = \frac{\sqrt{2\pi}}{2} t_{s+1} \exp(-\xi^2/2) \leq \frac{\sqrt{2\pi}}{2d} \exp(-t_{s+1}^2/2)$. 

27
Now, by Fact 1, this can be further upper-bounded as
\[ \frac{\sqrt{2\pi}}{2d} s t_n^{d/2} \leq \frac{1}{2d} \varphi_n(t_n) \frac{1}{s t_n}. \]
So we have the bound:
\[ t_n^2 - t_n^2 \leq t_n^2 - t_n^2 \leq \frac{t_n + t_{n+1}}{s t_n} \leq \frac{2}{s}. \]
(This completes the proof of the first part of the claim, for the lower bound.) We can conclude by substituting \( s \) by its estimate from the first part of the claim, noting that \( \frac{1}{t_n} \) is uniformly bounded by assumption since \( \lambda \leq \sqrt{\log(\kappa_3)} \leq \sqrt{\log(d/n)} \leq t_n \) by Lemma 3 (for an appropriate choice of \( \kappa_3 \)).

We now show that we can choose the constant \( \lambda > 0 \) such that \( \alpha_n \notin 1 \) with high probability.

**Claim 8.** The constants \( \kappa_2, \kappa_3, \kappa_4, \lambda > 0 \) can be chosen such that for any \( n, d \) with \( n \geq \kappa_2 \) and \( \kappa_3 n \leq d \leq \exp(\kappa_4 n) \),
\[ (1 - \rho)n \sigma^2 \frac{\|\gamma(\alpha_n)\|^2}{\|H\|^2} + (1 - \rho)n \frac{\|\gamma(\alpha_n)\|^2}{\|H\|^2} > 1 \]
with probability at least \( 1 - 12 \exp\left(-\frac{n}{\log(d/n)^2}\right) \) over the draws of \( h \), where \( \varphi \) is defined as in Claim 7.

**Proof.** We will repeatedly use the following inequalities, which follow from Lemma 3 and Claim 7:
\[ t_n^2 = \log(d/n) + O(\log \log(d/n)) \]
\[ t_n^2 = \log(d/n) + O(\log \log(d/n)) \]
\[ \frac{t_n^2}{s} = \frac{1}{1 + \frac{\lambda}{t_n} + O\left(\frac{1}{t_n^2}\right)} = 1 - \frac{\lambda}{t_n^2} + O\left(\frac{1}{t_n^2}ight) + O\left(\frac{\lambda^2}{t_n^4}\right). \]

Note that for appropriate choices of \( \kappa_2, \kappa_3, \kappa_4 \), Equation (2) in Proposition 4 holds simultaneously
\[ (1 - \rho)n \frac{\sigma^2}{B^2} \frac{\|\gamma(\alpha_n)\|^2}{\|H\|^2} \geq 1 \]
for \( s = \kappa_4 n \) and for \( s = \kappa_4 n \). We condition on this event throughout the remainder of the proof.

We begin with the first term, where we use the upper estimate of \( B^2 \) from Equation (9):
\[ (1 - \rho)n \frac{\sigma^2}{B^2} \frac{\|\gamma(\alpha_n)\|^2}{\|H\|^2} \geq \frac{t_n^2}{s} = \frac{1}{1 + \frac{\lambda}{t_n} + O\left(\frac{1}{t_n^2}\right)} \]
\[ \geq \left(1 - \frac{\lambda}{t_n^2} + O\left(\frac{1}{t_n^2}\right)\right) \left(1 - \frac{\lambda}{t_n^2} + O\left(\frac{1}{t_n^2}\right)\right) \]
\[ = 1 - \frac{2\lambda}{t_n^2} + O\left(\frac{\lambda^2}{t_n^4}\right) + O\left(\frac{\lambda^2}{t_n^4}\right). \]

Next the second term:
\[ (1 - \rho)n \frac{\|\gamma(\alpha_n)\|^2}{\|H\|^2} \geq \frac{2}{t_n^2} \left(1 + O\left(\frac{1}{t_n^2}\right)\right) \]
\[ \geq \frac{2}{t_n^2} \exp\left(\frac{\lambda}{t_n}\right) \left(1 + O\left(\frac{1}{t_n^2}\right)\right) \]
\[ \geq \frac{2}{t_n^2} \left(1 + \frac{\lambda}{t_n} + \frac{\lambda^2}{4t_n^2} + O\left(\frac{\lambda^3}{t_n^4}\right)\right) \left(1 + O\left(\frac{1}{t_n^2}\right)\right). \]
Summing up (10) and (11), we get:

\[(1 - \rho)n \frac{\sigma^2}{B^2} \frac{\|\gamma(\alpha_s)\|^2}{\|H\|^2} + (1 - \rho)n \frac{\|\gamma(\alpha_s)\|^2}{\|H\|^2} \geq 1 + \frac{\lambda^2}{2t_n^4} + O \left( \frac{1}{t_n^4} \right) + O \left( \frac{\lambda^2}{t_n^6} \right) + O \left( \frac{\lambda}{t_n^2} \right).
\]

Clearly, we can choose the constants $\lambda, \kappa_2, \kappa_3, \kappa_4 > 0$ such that the right-hand side of the above equation is strictly greater than 1 for any $n, d$ with $\kappa_3 n \leq d$, since $t_n^2 \asymp \log(d/n)$. \qed

A.6.3 Finding $s$ such that $\pi_s \leq \alpha_\pi \leq \alpha_{d+1/2}$

We take the exact same approach to find $\bar{s} \geq n$ such that $\alpha_\pi$ is on the right of the interval $I$, i.e., $\pi_s \leq \alpha_\pi$. The derivations can be straightforwardly adapted, and we get the analogous results:

Claim 9. Assume $\kappa_3 n \leq d$. Let any fixed constant $0 < \lambda \leq \sqrt{\log(\kappa_3)}$, and let $\bar{s}$ be the smallest integer $s$ such that $t_s^2 \leq t_n^2 - \frac{\lambda}{t_n}$. Then,

$$\bar{s} = n \exp \left( \frac{\lambda}{2t_n^2} \right) \left( 1 + O \left( \frac{1}{t_n^2} \right) \right) \quad \text{and} \quad \left| t_s^2 - \left( t_n^2 - \frac{\lambda}{t_n} \right) \right| \leq O \left( \frac{1}{n} \right).$$

Claim 10. The constants $\kappa_2, \kappa_3, \kappa_4, \lambda > 0$ can be chosen such that for any $n, d$ with $n \geq \kappa_2$ and $\kappa_3 n \leq d \leq \exp(\kappa_4 n)$,

\[(1 - \rho)n \frac{\sigma^2}{B^2} \frac{\|\gamma(\alpha_s)\|^2}{\|H\|^2} + (1 - \rho)n \frac{\|\gamma(\alpha_s)\|^2}{\|H\|^2} > 1
\]

with probability at least $1 - 12 \exp \left( -\frac{n}{\log(d/n)^2} \right)$ over the draws of $h$, where $\bar{s}$ is defined as in Claim 9.

It remains to check that this choice of $\bar{s}$ satisfies $\alpha_\pi < \alpha_{d+1/2}$. But this is clearly the case, because $\bar{s} < d$ (by the first part of Claim 9, for appropriate choices of $\kappa_3$) and $\alpha_d < \alpha_{d+1/2}$ by definition. This concludes the proof of Lemma 6.
