Models of gravity with dynamical signature are discussed. The different scenarios of the signature change are proposed in the framework of Einstein-Cartan gravity. We consider, subsequently, the dynamical signature in the model of the complex manifold with complex coordinates and complex metric introduced, a complexification of the manifold and coordinates through new gauge fields, an additional gauge symmetry for the Einstein-Cartan vierbein fields and non-flat tangent space for the metric in the Einstein-Cartan gravity. A new small parameter which characterizes a degree of the deviation of the signature from the background one is introduced in all models, the zero value of this parameter corresponds to the signature of an initial metric. In turn, in the models with gauge fields present, this parameter represents a coupling constant of the gauge symmetry group. The gauge fields are arising in the models as induced ones, the mechanism of an appearance of these induced fields is considered. The ways of the signature change through the gauge fields dynamics are reviewed, the consequences and applications of the proposed ideas are discussed as well.

I. INTRODUCTION

The idea of a metric with changing signature, looking unusual, attracts a lot of attention in the quantum cosmology and quantum gravity, see different aspects of the problem in \[1\]–\[13\]. Whereas all experiments and observations do not question the fact that the metric of the Universe has Lorentzian signature, these are two windows which we can not look through to check the signature. We do not know a lot about the quantum gravity world, there are theoretical models which allows change of the signature at the quantum level, see for example \[1\]. The very beginning of the Universe is another corner which can hide the possible change of the signature, see for example \[2\].

There are two parameters of the classical gravity which we do not know to explain in general, the number of space-time dimensions and signature of the metric, the last one is related as well to the arrow of time. The main purpose of the proposed article it is a construction of possibilities of the gravity formalism with metric which is not defined but can change dynamically. The meaning of the dynamical change of the metric and signature, investigated further, is simple. We consider possibilities of that these values will take place in the field of complex numbers. Particularly it means that the metric’s signature in the models can be any complex number, determination of the signature as Euclidean or Lorentzian, for example, is happening in the models due some additional mechanisms. There are a few possibilities we discussed. The first one is a complexification of the metric and manifold’s coordinates. The examples with complex metric approach are not new of course, see \[10\] for example, but in the present approach we consider the problem differently. There is no classical complex world around, therefore we introduce a small parameter which zero value corresponds to the real manifold and real coordinates. In turn, the non-zero value of the parameter adds additional dimensions to the manifold as well as an additional complex part to the metric tensor. The smallness of the parameter allows to establish a perturbative scheme related to the expansions of objects of interest with respect to the parameter that simplifies the calculation. The natural next step in this direction is a complexification of the manifold with the help of new gauge fields. In this case the coordinates phases are defined by the gauge fields, the introduced parameter in this picture is a coupling constant of the corresponding gauge group. Considering the Einstein-Cartan gravity as the base of the approach, we, consequently, obtain an additional correction to the vierbein field which depends on the introduced phases and proportional to the new parameter. Therefore, the metric components acquire a phase factor which makes it’s signature complex and non-determined in a general. When the phases of the metric’s components are defined by the gauge fields values, we discuss an determination of the special value of the signature with the help of induced values of the gauge fields which satisfy some boundary conditions. In this scenario, the signature’s value is fixed by the induced fields, the mechanism is working for the overall metric signature and for the signature’s fluctuations above some background metric.

The change of the signature throw the gauge fields in the approach is considered in two different formulations in turn. As mentioned above, the first possibility is a complexification of the manifold and metric through a complexification of the coordinates achieved by the gauge fields. The other possibilities are related to the redefinition of the structure of the Einstein-Cartan gravity with the use of the new gauge fields, i.e. we consider possible generalizations of vierbein fields. The first possibility we consider is the simplest one, we complexify the vierbein by the gauge field similarly to done to the manifold’s coordinates. In this case the metric obtain an additional part which signature depends on the value of the gauge fields, the new degree of freedom in this set-up is the gauge filed. An another possibility is the interesting one, we introduce a non-flat tangent space of vierbein fields through the additional scalar fields with

Dynamical signature: complex manifolds, gauge fields and non-flat tangent space

S. Bondarenko

Ariel University, Ariel 4070000, Israel

(Dated: November 12, 2021)
indexes related to the Lorentz group and new gauge group, the usual vierbein in this case arises as a projection of the another vierbein which we can call as gauge one. This set-up is equivalent to the introduction of kind of a metric in the tangent space, the new scalar field is the metric there. This non-flatness allows to define the usual metric and it’s signature in terms of the scalar fields which values, in turn, will depend on the values of induced gauge fields. For both cases, the usual metric can be formulated in a non-perturbative and in a perturbative manners. In the non-perturbative framework the manifold’s metric will be defined fully in terms of the gauge fields involved non-linearly through some 4D non-linear sigma model, i.e. the action for these fields will depend on the metric which in turn is defined in terms of the gauge fields. For the perturbative case, the gauge fields provide a fluctuation of the metric with undefined signature above some fixed background, in this case the action for the gauge fields can be considered in the flat space-time in the first approximation.

There are interesting additional problems which we do not consider in the article but which may have relation with the proposed idea. The complexification of the coordinates leads to the eight dimensional manifold, in this contest the generalization of the approach can be achieved, for example, by the introduction of the coordinates considered as p-adic number field on the manifold, see [17]. That will lead to the larger that 4D dimensional manifold, in this case more that one small parameter can be introduced. The zero values of all parameters will lead to usual real metric in this case as well, otherwise some complicated variant of the proposed framework will be obtained. Therefore, the metric and its signature will be valued in the field of p-adic numbers instead of complex ones. The another face of the complexification is a similarity of the introduced phases to the ”fast” variables of t’Hooft, [18], introduced in his generalization of quantum mechanics. Formally speaking, the ”fast” variables are fields in the ”t’ Huoft approach, their counterpart in the given framework are gauge fields. Therefore, in general, it is interesting to understand the consequences of the manifold’s complexification on the formulation of quantum mechanic approaches.

The paper is organized as follows. In the next section we discuss basic ideas of a definition of the complex coordinates and metric for a complex manifold. In the Section [11] we consider a simplest variant of the Einstein-Cartan gravity for the complex manifold with complex coordinates, whereas in the Section [16] we investigate the gravity for the coordinates complexified by the gauge fields. In the Section [V] and Section [VI] vierbein based approaches to the problem are considered, firstly a investigation of the additonal gauge symmetry for a new vierbein field and further a construction of a non-flat tangential space for the Einstein-Cartan gravity. The last section is a Conclusion of the paper.

II. COMPLEX METRICS FOR A COMPLEX MANIFOLD

In order to clarify the ideas of the framework we, first of all, consider the following construction. Let’s define a complex manifold on the base of the usual real four-dimensional manifold by simple complexification of it’s points coordinates:

\[ p = (p^1, \ldots, p^n) \rightarrow z = (z^1, \ldots, z^n) = (p^1 e^{i \phi_1}, \ldots, p^n e^{i \phi_n}). \]  

Defining the tangential vector fields in each \( z \) of the complex and each \( p \) of the real manifolds

\[ X_z \in T_z^C, \quad X_p \in T_p^R \]  

we observe that the fields are connected as

\[ X_z = M X_p \]  

with \( M \) as \( U(4) \) diagonal matrix, see Appendix A example. Using the usual definition metric for the real manifold

\[ g(X_{p_1}, Y_{p_2}) = g((x^1, \ldots, x^n), (y^1, \ldots, y^n)) = g_{ij} x^i y^j, \]  

we correspondingly define the quadratic complex form on the complex manifold as

\[ g(X_{z_1}, Y_{z_2}) = g((x^1 e^{i \phi_1}, \ldots, x^n e^{i \phi_n}), (y^1 e^{i \phi_1}, \ldots, y^n e^{i \phi_n})) = e^{i(\phi_1 + \phi_2)} g_{ij} x^i y^j. \]  

Now we introduce the following complex metric in a local coordinate basis defining it as

\[ g = e^{i \alpha_\phi (\phi_1 + \phi_2)} g_{ij} dx^i \otimes dx^j, \]  

with the \( g_{ij} \) as a metric field of the real manifold and \( \alpha_\phi \) as some parameter, see further. The inverse metric field is defining correspondingly, in the dual basis it reads as

\[ g^{-1} = e^{-i \alpha_\phi (\phi_1 + \phi_2)} g^{ij} e_i \otimes e_j. \]
where

\[ g_{ij} g^{jk} = \delta^k_i \]  

(8)

for the real manifold. The parameter \( a_\phi \) redefines the angles in this expressions as

\[ \phi \rightarrow a_\phi \phi = \frac{l_0}{R_0} \phi \]  

(9)

and has two purposes. First of all, the real metric appears in the model as the first term of the expansion of the complex one with respect to \( a_\phi \). The limit

\[ a_\phi \rightarrow 0 \]  

(10)

provides the expansion with the usual metric as a leading contribution term. The second important role of this parameter is that its smallness allows to decouple the additional metric’s components in the corresponding expressions. Namely, for a general complex metric in eight dimensional space we have \( g_{\phi \phi} \propto a_\phi \) that provides \( a_\phi^2 \) order contribution in the corresponding gravity action. Therefore, preserving everywhere \( a_\phi \) order, i.e. linear with respect to parameter precision, we can limit calculations by the four dimensional metric of the real Riemann manifold modified in correspondence to Eq. (6) prescription. The components of the Eq. (6) form, in turn, depend on complex coordinates \( z \) and the corresponding angles appear in any expression as some internal parameters of the problem consequently.

We note, that the additional example of the complex metric we obtain if we consider the angles as some internal parameters related to the additional symmetry of the covariant and contravariant bases of the real manifold:

\[ e^i \rightarrow e^{ia_\phi \phi} e^i, \quad e_i \rightarrow e^{-ia_\phi \phi} e_i \]  

(11)

i.e. the complexification of the basic vectors leads to the same results as complex coordinates in Eq. (1) and Eq. (5). In the following we will use the Einstein-Cartan formulation of the gravity. Therefore, considering a four dimensional real Riemann manifold and introducing the real Lorentz vierbein (tetrad) \( e^a_{\mu} \) as usual

\[ g_{\mu \nu} = \eta^{ab} e^a_{\mu} e^b_{\nu} \]  

(12)

we can consider the corresponding complex metric defined as following:

\[ g_{\mu \nu} = \eta^{ab} e^{ia_\phi (\phi_a + \phi_b)} e^a_{\mu} e^b_{\nu} \]  

(13)

This metric can be obtained from the real one by the complexification of the tetrad:

\[ e^a_{\mu} \rightarrow e^{ia_\phi \phi_a} e^a_{\mu} \]  

(14)

and

\[ E^a_{\mu} \rightarrow e^{-ia_\phi \phi_a} E^a_{\mu} \]  

(15)

for the inverse vierbein. This construction can be considered as particular example of the non-flat tangent space which we will discuss further.

It is important to notice, that the Eq. (13) expression can be considered as an approximate one and metric’s complexification in this formulation arises as consequence of the decoupling of the corresponding coordinates. The Eq. (11)-Eq. (13) construction, in contrast to that, is precise and the angles arise there due the introduced additional symmetries related to vierbein’s complexification. Therefore, in the first case we consider a complex manifold with real functions which depend on the complex coordinates, there is a integration over the angles in the action. In the second case, correspondingly, we have a real manifold with angles as parameters of corresponding independent \( U(1) \) symmetry groups for each real coordinate with action invariant with respect to the symmetries, there is still only four real coordinates to integrate. Also, whereas in the first case we need to consider small \( a_\phi \) parameter in the problem because so far we have no observable complex manifolds, in the second case we can take \( a_\phi = 1 \) of course. Consequently, this formulation of the approach will lead to the variant of the framework with complex metric which was defined and discussed in [16] for example, we do not consider this case further.
III. EINSTEIN-CARTAN ACTION FOR THE COMPLEX METRIC IN THE COMPLEX MANIFOLD

In order to derive the analog of the Einstein-Cartan action for the complex metric introduced above, we, first of all, consider the transformation of the vector with Lorentz index projected with the help of the new vierbein:

\[ \delta \tilde{e}^a = \delta \left( e^{ia \phi} e^a \right) = e^{ia \phi} \delta e^a = e^{ia \phi} \omega_{a \ b} e^b = \left( e^{ia \phi} \omega_{a \ b} e^{-ia \phi} \right) \left( e^{ia \phi} e^b \right) = \tilde{\omega}_{a \ b} e^b, \]

we see that the expression is invariant in respect to the internal symmetry transformation of the covariant and contravariant Lorentz indexes performed in correspondence to the Eq. (13)-Eq. (15) definitions. In the following, denoting the complex vierbein as the usual one, we will remember that the Lorentz indexes allows to rotate the corresponding objects in correspondence to this symmetry without mixing with the Lorentz transformations.

Now, as mentioned above, we have to distinguish between the cases when we consider a complex manifold or we introduce the additional symmetry in the problem related to the \( U(1) \) global gauge symmetry for each Lorentz index. There is the following form of Palatini action we have for the first case:

\[ S = C \frac{m_P^2}{2} \int d^4 z \, e^{\mu \nu \rho \sigma} e_{abcd} e^\rho e^\sigma \left( D_\mu \omega^a_{\nu b} \right) \]

with \( C \) as some normalizations constant, \( \partial z \) in the covariant derivative and \( z \) as complex coordinates, see an use of the complex coordinates in the formulation of the Quantum Mechanics in [19] for example. Our next step is an assumption that the integration functions are analytical in the whole region of interest, except, perhaps, some extreme boundary points. Consequently, to first approximation, we can choose the integration paths for each variable \( z_\mu \) taking \( x_\mu \in [-\infty, \infty] \) at some fixed constant \( \phi_\mu \) angles. Therefore, assuming a smallness of \( a_\phi \) parameter, we write the action till the requested precision order as following:

\[ S \approx C e^{ia_\phi \sum_{\nu=0}^3 \phi_{\nu \phi}} m_P^2 \int d^4 x \, e^{\alpha \beta \rho \sigma} e_{abcd} e^\rho e^\sigma \left( D_\alpha \omega^a_{\beta b} \right) + \]

\[ + 1 \ a_\phi C \frac{m_P^2}{2} \sum_{\mu, \nu \neq \mu} e^{ia_\phi \sum_{\nu=0}^3 \phi_{\nu \phi}} \int x_0^\mu \ d\phi_\mu \ d^3 x \, e^{ia_\phi \phi_\mu} e^{\alpha \beta \rho \sigma} e_{abcd} e^\rho e^\sigma \left( D_\alpha \omega^a_{\beta b} \right). \]

The condition when the usual Einstein-Cartan formalism is reproduced in the first order approximation is the following one:

\[ C e^{ia_\phi \sum_{\nu=0}^3 \phi_{\nu \phi}} = 1 \]

with some arbitrary constant \( \phi_{i 0} \) angles, this condition can be considered as definition of the \( C \) constant as well. We also note, that the expression under the integration is function of \( z \) and in general it must be expanded as well in order to provide all \( a_\phi \) order corrections to the real action.

The interesting consequence of the form of Eq. (18) action is that it does not define nor preferable direction of time neither preferable value of the signature. Indeed, let’s choose the special coordinate system, \( x \)-system, with

\[ \phi_{\mu \phi} = 0, \quad \mu = 0 \ldots 3; \quad C = 1. \]

At the same way we can choose any other angles such that

\[ \sum_{\mu=0}^3 \phi_{\mu \phi} \neq 0, \quad \phi_{\mu \phi} \neq 0, \quad C = 1, \]

the angles define a new coordinate system different from the special one. Namely, for the non-zero \( \phi_{i 0} \) there are new coordinates

\[ y^\mu = x^\mu e^{ia_\phi \phi_{\mu \phi}}. \]
In terms of the new coordinates the action acquires the following form:

\[ S = \frac{m_p^2}{2} \int d^4 y \varepsilon^{\alpha\beta\rho\sigma} \varepsilon_{abcd} e_\sigma^d (D_\alpha \omega^b_{\beta}) + \]

\[ + \frac{\iota}{a_\phi} \sum_{\mu=0}^3 \int y_0^\mu d\chi_\mu d^3 y \varepsilon^{\iota a_\phi x_\mu} \varepsilon^{\alpha\beta\rho\sigma} \varepsilon_{abcd} e_\sigma^d (D_\alpha \omega^b_{\beta}) \]

where

\[ \phi_\mu = \phi_{\mu 0} + \chi_\mu. \quad (24) \]

With redefinition of the arguments of the integral functions performed in Eq. (22) and subsequent deformation of the integration contours, the form of the redefined action is the same as Eq. (18) with Eq. (20) values of the angles. The only different contribution into the action, therefore, can come from the end points of the integration over real \( y^\mu \) which acquire complex phases in the case of Eq. (22) variables change, we assume that these contributions are zero.

We see, that as a result of the complexification of the manifold and arose symmetry we have an infinite number of the equivalent directions of time and foliations of the spatial coordinates for the given value of a signature. An another interesting consequence of the model is that the Eq. (23) action quite naturally acquires a small term additional to the leading one. This term can be considered as a type of the cosmological constant in the action in the framework of the perturbative scheme based on the \( a_\phi \) smallness. In general it means that the term must be finite after the integration over \( \chi_\mu \) angle at some \( y_\mu \to y_{\mu 0} \) limits taken in the corresponding contour integral.

Now, expanding the vierbein field in the new perturbative scheme as

\[ e_\nu^c = e_\nu^c + e_\nu^{c 1} \quad (25) \]

and taking a variation of the Eq. (18) action with respect to \( e_\nu^c \) connections we will obtain:

\[ \partial_\mu e_\nu^{c 1} = - \iota a_\phi \sum_{\rho=0}^3 x^\rho (x^\rho - x_0^\rho) \int d\phi_\rho e^{\iota a_\phi \phi_\rho} \partial_\mu e_\nu^c \]

or, equivalently

\[ \int d^4 x \left( \partial_\mu e_\nu^{c 1} + \iota a_\phi \sum_{\rho=0}^3 x^\rho (x^\rho - x_0^\rho) \int d\phi_\rho e^{\iota a_\phi \phi_\rho} \partial_\mu e_\nu^c \right) = 0. \quad (27) \]

Providing a some initial value of \( e_\nu^{c 1} (x) \) at \( x_0^\mu \) we can write the solution of Eq. (26) as

\[ e_\nu^{c 1} = e_\nu^{c 1} (x_0^\mu) - \iota a_\phi \sum_{\rho=0}^3 \int_{x_0^\mu}^{x^\nu} dx^\mu (x^\rho (x^\rho - x_0^\rho)) \int d\phi_\rho e^{\iota a_\phi \phi_\rho} \partial_\mu e_\nu^c \quad (28) \]

This additional vierbein’s part provides a correction to the metric through Eq. (12) definition, it can be of any signature depending on the value of the integral in Eq. (28) r.h.s..

**IV. COMPLEXIFICATION OF THE MANIFOLD THROUGH GAUGE FIELDS**

If we consider the simplest generalization of the Eq. (1) complexification through the replacement of the \( \phi_\mu \) angles by \( \phi_\mu (p) \) functions then we immediately realize that this construction does not work. Namely, in this setup there is no self-consistent definition of the coordinates and corresponding functions in the integrals. Therefore, in order to discuss the case of the local complexification of the real manifold, we will consider the following model. We introduce a set of real coordinates \( x^\mu \) and determine the new coordinates of the manifold as transform of \( x \):

\[ z^\alpha = M^\alpha_\mu (x) x^\mu \]

\[ z_\alpha = M_\alpha^\mu (x) x^\mu \quad (29) \]

---

3 This statement can be understood in terms of any evolution equations, the equations will have the same form for any redefined \( x \) coordinate.
with new vierbein like gauge fields $M$, where the new indexes are transforming in correspondence to some group $G$. Accordingly, we will consider the integrals as taken over the Riemann $x^\mu$ with functions defined as depending on $z^\alpha$ similarly to done before. Introducing an another form of the gauge fields, suitable for the perturbative calculations we can define the complex coordinates in this case as

$$z^\alpha = \left( \delta^\alpha_\mu + i a_\phi A^\alpha_\mu(x) \right) x^\mu$$

(30)

with $A$ as some gauge field related to the $G$ group. The coupling constant $a_\phi$ is small again and determines a measure of the complexification, in this setup it plays a role of the coupling constant of the new gauge group $G$.

The new gravity action of the model preserves the form of the Eq. (17) action and we have:

$$S = C \frac{m^2}{2} \int d^4x \varepsilon^{\mu\nu\rho\sigma} \varepsilon_{abcd} e^e_\rho e^d_\sigma \left( D_\mu \omega^a_\nu \right)$$

(31)

with functions in integral depending on $z$ coordinates. There is, correspondingly, additional part in the action which correspond to the new introduced field which we consider as a gauge one. Using an usual determination of the field's strength of the new gauge field $A$ through the covariant derivative

$$[D_G D_G] = - i a_\phi G^\alpha_\mu \omega^\alpha_\mu$$

(32)

for some representation of the $G(N)$

$$[t^0, t^\beta] = i f^{\alpha\beta\gamma} t^\gamma$$

(33)

we define this action as

$$S_A = \kappa \int d^4x \varepsilon^{\mu\nu\rho\sigma} \varepsilon_{abcd} e^e_\rho e^d_\sigma \left( D_\mu \omega^a_\nu \right)$$

(34)

with

$$\omega^{ab;\alpha_1\beta_1} = \kappa_1 \eta^{\alpha_1\beta_1} + \kappa_2 \eta^{\alpha_1\beta} + \kappa_3 \eta^{\alpha_1\beta}$$

(35)

with $\eta$ as Lorentz metric of the flat space. The action is similar, for example, to QCD action in the curved space time. The interaction between these two parts of the action can be written in terms of the expansion of Eq. (31) functional with respect to the complex part of the $z$ coordinates.

Our next step it is an introduction of the non-trivial $A$ gauge fields in the action. The idea is the following, we can introduce in the action a following additional term:

$$S_{ind} = \frac{m^2}{2} \sum_i \int d^4x T_{\mu i}(A) \omega^\mu_\mu$$

(36)

which we call induced part of the action in correspondence to definition of. The purpose of this part of the action is to introduce in the equations of motion the classical values of the $A$ gauge field, denoted as $\omega$, which satisfy some boundary conditions at the edges of time interval. Namely, we define the boundary conditions at some different limits of $t$ coordinate:

$$\delta_\omega T_{\mu i}(A) = J_{\mu i}(A) \delta A$$

$$J_{\mu i}(t_j) \to 0, \ t \to t_{0j} \neq i$$

(37)

$$A_{cl\mu} = \sum_i \omega_{\mu i}$$

(38)

with the last equation fixed by the structure of Eq. (36) term and obtained from the usual equations of motion:

$$\delta_A \left( S_A + S_{ind} \right) = 0$$

(39)

In general, the effective currents $T_{\mu i}$ can be consequently reconstructed by requests of the gauge invariance of the induced part of the action, the details of that can be found in. Fixing the boundary conditions, i.e. fixing the

4 We note that there is a difference between gauge actions written in terms of $M$ and $A$ fields.
values of $A_{cl}$ at the edges of the overall time interval for example, we will obtain an action with some space-time foam above the background space-time of a fixed signature. The example of this construction is given in the Appendix B, taking only one boundary field from Eq. (B.7) expression for example, we will have

$$A_{cl\mu} = A_\mu. \quad (40)$$

Now, writing the equations of motion for $\omega$ connections

$$D[\mu \epsilon_\nu] = 0, \quad \frac{\partial}{\partial x^\mu} = \frac{\partial z^\nu}{\partial x^\mu} \frac{\partial}{\partial z^\nu}, \quad (41)$$

and expanding the vierbein in a perturbative scheme related with the parameter $a_\phi$ as

$$\epsilon_\nu = \epsilon_{\nu 0} + \epsilon^{c}_{\nu 1}, \quad (42)$$

we will obtain then

$$\partial_\mu \epsilon_{\nu 1} = -i a_\phi \partial_\mu (A_\sigma x^\sigma) \partial_\alpha \epsilon_{\nu 0} \quad (43)$$

with solution

$$\epsilon_{\nu 1} = \epsilon_{\nu 1}(x_0^\mu) - i a_\phi \int_{x_0^\mu}^{x^\mu} dx^\mu \partial_\mu (A_\sigma x^\sigma) \partial_\alpha \epsilon_{\nu 0} \quad (44)$$

for the additional vierbein’s part. We see, that the vierbein acquires a correction which structure is defined by the value of the boundary $A_\mu$ fields, the corresponding Eq. (12) metric will obtain an additional part as well and the signature of this metric’s correction will depend on the $A_\mu$ fields. This situation, as we will see further, will realized in other models with gauge field involved.

It is interesting to note also, that assuming an existing of the transform opposite to Eq. (29)

$$x^\mu = N^\mu_\alpha(z) z^\alpha \quad (45)$$

we can rewrite the Eq. (44) action fully in terms of $z$ variable as follows

$$S = C \frac{m_D^2}{2} \int d^4 z \tilde{N} \epsilon^{\mu \nu \rho \sigma} \epsilon_{abcd} \epsilon_{\rho \epsilon^d} (D_\mu \omega_{\nu}) \quad (46)$$

with $\tilde{N}$ as Jacobian of the Eq. (B.7) coordinates transform given by the

$$\tilde{N}^\mu_\alpha = N^\mu_\alpha + \frac{\partial N^\mu_\beta}{\partial z^\alpha} z^\beta \quad (47)$$

matrix. In this case the value of the factor in front of the action in the path integral will be determined by the value of the $\tilde{N}$. Therefore, again, the redefinition of the $C$ factor in Eq. (46) will lead to the equivalent actions for the different metrics with different phases for their components.

V. GAUGE SYMMETRY FOR THE VIERBEIN FIELD

The complexification mechanism discussed in the previous Section can be applied for the vierbein fields as well. Considering the usual vierbein use in definition of the metric

$$g_{\mu \nu} = \eta_{ab} e^a_\mu e^b_\nu, \quad (48)$$

we can generalize the Eq. (14)-Eq. (15) definition of the complex vierbein:

$$e^a_\mu = M^\alpha_\mu (x) e^a_\alpha \quad (49)$$

or similarly to done before as

$$e^0_\mu = (\delta^\alpha_\mu + i a_\phi A_\mu^\alpha(x)) e^a_\alpha. \quad (50)$$
In these cases the Eq. (48) metric acquires an additional part with signature which depends on the value of the fields. We have for the first metric:

\[ g_{\mu\nu} = \eta_{ab} M_\mu^\alpha(x) M_\nu^\beta(x) e^a_\alpha e^b_\beta \]  

and correspondingly for the second at linear approximation with respect to \( a_\phi \) parameter:

\[ g_{\mu\nu} = \eta_{ab} e^a_\mu e^b_\nu + i a_\phi \eta_{ab} \left( A_\mu^\alpha(x) e^b_\alpha + A_\nu^\alpha(x) e^b_\alpha e^a_\mu \right) . \]  

The Eq. (51)-Eq. (52) expressions are different in general. Whereas Eq. (51) metric describe a manifold with arbitrary signature which depends on the value of \( M \) matrix, the Eq. (52) metric determines a manifold with additional part above the background metric with given signature. We note that this additional metric’s part can be of any signature as well, it depends on the value of \( A \) gauge field. In both cases, the values of the gauge fields are determining dynamically through the corresponding Lagrangians.

The Einstein-Cartan action can be easily rewritten in terms of new vierbein in this case. We request that the additional metricity condition must be satisfied:

\[ \nabla_\mu (A_\nu^\alpha e^a_\alpha) = (\nabla_\mu A_\nu^\alpha) e^a_\alpha + A_\nu^\alpha (D_\mu e^a_\alpha) = 0 \]  

with

\[ \nabla_\mu A_\nu^\alpha = \partial_\mu A_\nu^\alpha - \Gamma^\alpha_{\mu\nu} A_\rho^\alpha \]  

\[ D_\mu e^a_\alpha = \partial_\mu e^a_\alpha + \omega^a_{\mu\nu} e^b_\nu e^a_\alpha , \]

here \( \Gamma \) and \( \omega \) are Christoffel and Lorentz connections correspondingly. We will obtain then:

\[ S = \frac{m^2}{2} \int d^4x \varepsilon^{\mu\nu\rho\sigma} \varepsilon_{abcd} M_\rho^\alpha M_\sigma^\beta e^a_\alpha e^d_\beta (D_\mu \omega^a_{\rho\sigma}) \]  

with obvious corresponding redefinition in terms of \( A \) field. This part of the full action is correct for any form of the metric, the non-triviality of the construction, therefore, is manifested through the additional gauge field. Introducing the gauge field strength

\[ [D_{G,\mu} D_{G,\nu}] = -i a_\phi G_{\mu\nu} \]  

for some symmetry group \( G \), we define the additional part of the action as

\[ S_A = \kappa \int d^4x e M \text{tr} [G_{\mu\nu} G_{\mu_1\nu_1}] \mathcal{F}^{\mu_1\nu_1} \]  

with

\[ \mathcal{F}^{\mu_1\nu_1} = \kappa_1 g^{\mu_\nu} g^{\mu_1\nu_1} + \kappa_2 g^{\mu_1\nu_1} g^{\mu_1\nu} + \kappa_3 g^{\mu_1\nu} g^{\mu_1\nu} , \]

and

\[ M = \det(M_\mu^\alpha), \quad e = \det(e^a_\alpha) , \]

with matrix \( M \) determined or through Eq. (51) or through Eq. (52) expressions. The metric \( g^{\mu\nu} \), in turn, as well depends on the corresponding gauge field, in this extend the Eq. (48) Lagrangian describes a variant of 4D non-linear gravitational sigma-model. Correspondingly, further, we will consider only Eq. (52) formulation of the metric, there is no a simply perturbative expansion in respect to \( a_\phi \) for the \( M \) field in Eq. (51). Therefore, a self-consistent solution of equations of motion for \( M \) field through Eq. (55) is a non-trivial task, we will consider it in an separate publication. Concerning Eq. (52) metric and \( A \) gauge field, there is the \( a_\phi \) parameter in the Eq. (52) definition of the metric so we need to know a solution for the gauge field till \( a_\phi \) precision only and, therefore, for our purposes it will be enough to consider the Eq. (55) action in the flat space-time. In this case, with the help of Appendix B results, we obtain:

\[ A^{\alpha}_{cl} = A^{\alpha}_{1} + A^{\alpha}_{2} . \]

Correspondingly, the Eq. (52) metric will acquires an additional part determined by the \( A^{\alpha}_{1} \) fields:

\[ g_{\mu\nu} = \eta_{ab} e^a_\mu e^b_\nu + i a_\phi \eta_{ab} \left( A^{\alpha}_{1} e^b_\alpha + A^{\alpha}_{1} (x) e^b_\alpha e^a_\mu \right) , \]

we see that the metric’s fluctuations as well as their signature are determined by the induced boundary fields of the problem.

Considering the same approach for the Eq. (49) \( M \) fields, we will have a difference between covariant and contravariant gauge fields. The \( M \) gauge fields provide a non-flat metric initially, the field will appear in the relations between covariant and contravariant components in the Eq. (55) action therefore. It makes the problem even more non-linear, there are different vectors in the power of the Eq. (55) ordered exponential and in the induced action.
VI. NON-FLAT TANGENTIAL SPACE CONSTRUCTION

Geometrizing the proposed ideas, we can define the Lorentz vierbein and its inverse as a projection of another vierbein fields:

\[
e^a_\mu = M^{a\alpha} e_{\mu\alpha}, \quad E^a_\mu = M_{a\alpha} E^{\mu\alpha};
\]

\[
e_{\mu\alpha} E^{\mu\beta} = \delta^\beta_\alpha, \quad e_{\mu\alpha} E^{\nu\alpha} = \delta^\nu_\mu; \\
e_{\mu\alpha} e^\mu_\beta = M_{\alpha\beta}, \quad E^{\mu\alpha} E^\beta_\mu = M^{\alpha\beta},
\]

(63)

here Greek indexes $\alpha, \beta$ belong to some group $G$, Latin indexes denote the Lorentz transforms, the $\mu, \nu$ are used as usual Riemann type indexes. We note, that there is no general prescription to consider the dimension of the $G$ equal to the one of the Lorentz group, see for example [15]. Nevertheless, in the following we will take $\alpha, a = 0 \ldots 3$. Also, unlike the previous Chapter, the $M$ field here is a scalar one, there is an additional dynamics present therefore.

Now, using again the usual definition of flat metric in terms of Lorentzian vierbein

\[
g_{\mu\nu} = \eta_{ab} e^a_\mu e^b_\nu,
\]

(64)

with $\eta_{ab}$ as a flat metric of the tangent space with some signature $S$, we rewrite it as follows:

\[
g_{\mu\nu} = \eta_{ab} M^{a\alpha} M^{b\beta} e_{\mu\alpha} e_{\nu\beta} = M^{a\beta} e_{\mu\alpha} e_{\nu\beta}, \quad M^{a\beta} = M^{\beta a}
\]

(65)

and

\[
g^{\mu\nu} = \eta^{ab} M_{a\alpha} M_{b\beta} E^{\mu\alpha} E^{\nu\beta} = M^{a\beta} E^{\mu\alpha} E^{\nu\beta}
\]

(66)

with signature $S'$ which can be different from $S$. Here we define

\[
M_{a\alpha} M^{b\alpha} = \delta^b_a, \quad M_{a\alpha} M^{\alpha\beta} = \delta^\alpha_a.
\]

(67)

The invariance of the new scalar product in respect to the new group of the symmetry is provided by the ordinary transformation rules for the new upper and lower indexes

\[
e_{\mu\alpha} = G^\alpha_\beta e_{\nu\beta}, \quad E^\alpha_\mu = \tilde{G}^\alpha_\beta E^\beta_\mu,
\]

(68)

with $\tilde{G}$ matrix as inverse to $G$

\[
G^\alpha_\beta \tilde{G}^\beta_\gamma = \left(G \tilde{G}^T\right)^\beta_\gamma = \left(\tilde{G}^T G\right)^\beta_\gamma = \delta^\beta_\gamma.
\]

(69)

both $G$ and $\tilde{G}$ matrices are belong to the group of interest of course. Correspondingly, we introduce the new covariant derivatives of the vierbein and $M$ fields in respect to the $G$ symmetry group:

\[
D_{G\mu} e_{\nu\alpha} = \partial_\mu e_{\nu\alpha} - \Omega^\beta_{\mu\alpha} e_{\nu\beta}
\]

(70)

and

\[
D_{G\mu} M^{a\alpha} = \partial_\mu M^{a\alpha} + \Omega^a_{\mu\beta} M^{a\beta}.
\]

(71)

Here

\[
\Omega^a_{\mu\beta} = t_a \phi_{\mu a} \Omega^a_{\mu \beta} (t_a)_\beta^\alpha
\]

(72)

is a new gauge field additional to the usual connection field in the corresponding covariant derivative of the Einstein-Cartan gravity Lagrangian.

Form of the Einstein-Cartan gravity action is changing trivially in this version of the formalism, we request the metricity property of the new vierbein in respect to the full covariant derivative

\[
\nabla E^\mu_\alpha = \nabla (M_{a\alpha} E^{\mu a}) = 0
\]

(73)

---

5 An another variant of the non-flat tangent space is simply define $g_{\mu\nu} = M_{a\beta} e^a_\mu e^\beta_\nu$ with $M$ belongs to some extended symmetry group with changing signature, see [23].
and obtain
\[ S_\omega = -m_\omega^2 \int d^4 x \sqrt{-g} \, E^\alpha_a \, E^\nu_b \, \mathcal{R}_{\mu\nu}^{ab} \to S = -m_p^2 \int d^4 x \, e \, M (M_{a\alpha} E^{\mu\alpha}) \, (M_{b\beta} E^{\nu\beta}) \, \mathcal{R}_{\mu\nu}^{ab} \] (74)
in correspondence to Eq. (65) definition, here
\[ M = \det (M^{\alpha\alpha}) . \] (75)

The invariant action for the \( M \) field we can write as usual action for a scalar field:
\[ S_M = \int d^4 x \, e \, M \, e^\mu_a e^\nu_b \, (D_{G\mu} M)_{c}^{\gamma} \, (D_{G\nu} M)_{c}^{\rho} \, \mathcal{F}_{\gamma\rho}^{\alpha\beta} \] (76)
with
\[ \mathcal{F}_{\gamma\rho}^{\alpha\beta} = \alpha_1 M^{\alpha\beta} M_{\gamma\rho} + \alpha_2 M^{\alpha} M_{\gamma} M^{\beta} M_{\rho} + \alpha_3 M^{\alpha} M_{\rho} M^{\beta} M_{\gamma} . \] (77)

A new, in comparison to the previous section, term of the action is a free action term of the \( \Omega \) gauge field. Determining the field’s strength of the new gauge field
\[ [D_{G\mu} D_{G\nu}] = -G_{\mu\nu} \] (78)
we define this action as
\[ S_\Omega = \kappa \int d^4 x \, e \, M \, e^\mu_a e^\nu_b \, \text{tr} \left[ G_{\mu\nu} G_{\mu_1\nu_1} \right] \, \mathcal{F}_{\alpha\beta:\alpha_1\beta_1}^{\alpha\beta} \] (79)
with
\[ \mathcal{F}_{\alpha\beta:\alpha_1\beta_1}^{\alpha\beta} = \kappa_1 M^{\alpha\alpha_1} M^{\beta\beta_1} + \kappa_2 M^{\alpha}\gamma M^{\beta}\rho + \kappa_3 M^{\alpha\rho} M^{\beta}\gamma . \] (80)

The action is similar, for example, to QCD action in the curved space time, we do not consider a torsion and a cosmological constant terms in the action.

The dynamics of the theory given by Eq. (76) and Eq. (79) actions is non-linear and pretty complicated. Therefore, postponing the precise derivation for an additional publication, we can understand a dynamical signature in this variant of the theory by the following simple observations. First of all, we assume that for Eq. (79) action exists a classical solution for the gauge fields provided by the mechanism described in the Appendix B, we will have then:
\[ \Omega^{\alpha}_{\mu\beta \text{cl}} = \mathcal{A}_\mu^{\alpha} , \] (81)
where the \( \mathcal{A}_\mu \) fields, again, are known and satisfy some boundary conditions. This result, of course, is a consequence of the constant form of the vierbeins fields \( e \) and \( M \) in Eq. (79), we take these fields as normalized to the delta functions with respect to the corresponding indexes in the first approximation. In this case the Eq. (79) will acquire the form of Eq. (82) action. Secondly, we put attention, that the classical solution of Eq. (76) action is provided by the following equation:
\[ D_{G\mu} M^{\alpha\alpha} = 0 \] (82)
which solution is simple, particularly we can write:
\[ M^{\alpha\alpha}(x) = M_0^{\alpha\beta} \left( P e^{-1 a_0 \int_{-\infty}^{x} dz^\mu a_\mu(z)} \right)^\alpha_\beta . \] (83)

Again, the signature of Eq. (65) metric is determined by the values of the boundary gauge fields \( \mathcal{A}_\mu \)
\[ g_{\mu\nu} = \eta_{ab} M_0^{\alpha_1} M_0^{\beta_2} \left( P e^{-1 a_0 \int_{-\infty}^{x} dz^\mu a_\mu(z)} \right)^\alpha_\alpha_1 \left( P e^{-1 a_0 \int_{-\infty}^{x} dz^\mu a_\mu(z)} \right)^\beta_\beta_2 e_\mu e^\nu_\beta . \] (84)
and in principle can be arbitrary, see Appendix A for the similar simple example.
VII. CONCLUSION

In this note we consider approaches where the signature of the metric is undefined and takes values in the field of complex numbers. We discuss a few possibilities for the definition of this type of metric, with signs of its components are not fixed in general. The change of the signature was widely discussed in the literature, see for example [1–7], for a description of the transition form Lorentzian to Euclidean manifold types in the quantum gravity and quantum cosmology. Nevertheless, mostly, this transition was introduced by the time’s coordinate Wick rotation. We, instead, propose the formalism where the domain of the metric’s signature is expanded, the metric in the proposed approaches is a dynamical object with signature determined or by the complexification of the space-time manifold or by new gauge fields. Therefore, the signature can be changed smoothly between any predefined signatures, Lorentzian and Euclidean for example, with the help of the gauge fields.

The simplest from the possibilities we consider is a direct complexification of the manifold by complexification of the manifold’s coordinates. The additional phase, i.e. additional coordinate, is factorized in the equations in this case with the help of a small parameter

\[ a_\phi = \frac{l_0}{R_0}. \]  

The obvious choice of the lengths in the definition is \( l_0 \) as Plank length and \( R_0 \) a manifold’s curvature. A consequence of that is a factorization of the real and complex parts of the metric, i.e. factorization of real and complex parts of the corresponding manifold. namely, the smallness of the parameter guarantees that the complexification is important and not small only when the both parameters are of the same order. This situation is possible only at some extremal points of the manifold’s evolution, otherwise this is pure small distance effect, i.e. effect of quantum gravity.

In any case, the complexification of the gravity action by the complexification of the coordinates results in the additional part to the "bare", real Einstein-Cartan action. This additional part provides a complex part to the classical "bare" vierbein and consequently a complex additional part to the usual metric. For this type of the complexification we need to separate two cases. When we introduce a global phase factor for the coordinates then the additional metric’s part is a complex fluctuation above the usual metric, see Eq. (28). In general, for the non-expanded with respect to \( a_\phi \) metric, the action is a functional of the complex Eq. (17) Lagrangian, that in fact is not unusual, see [19] and [20]. The interesting question, therefore, is a proper definition and properties of such complex action in the path integral, see discussions in [20]. Introducing a local complex phase in the definition of the complex coordinates, see Eq. (29)–Eq. (31), we introduce new gauge fields and their symmetry group G, in this case the \( a_\phi \) parameter can be considered as a coupling constant of the group. This complexification of the manifold is more complicated than the first one of course, there is a possibility to obtain again complex fluctuations above the real metric, see Eq. (11), but, additionally, there is a possibility to introduce a metric with non-determined signature from the very beginning with the help of Eq. (23) \( M \) field. This last case is a non-perturbative and complicated, we do not discuss it much in the paper postponing it for an additional publication.

There are following interesting properties of the actions Eq. (17) and Eq. (31) we obtained. First of all, there is no any preferable axis of time direction, the any metric’s component can be of any sign in the situation with the undefined signature and any coordinate can serve as the time coordinate therefore. Moreover, fixing the metric, as usual Lorentzian for example, we still have a freedom to change the phases of the metrics components, i.e. to rotate the coordinate axes determining infinitely many ways of a foliation of the space-time. Each from these possibilities is described by the same action and, therefore, provide the same physics. In this case the preferable signature can be given or by a random selection from the infinitely many possibilities or by some fixation procedure similar to some extend to the spontaneous symmetry breaking. The later is possible when we talk about the complexification by the gauge fields. namely, in this case there is a possibility to define the requested classical values of the fields as a projection of some predefined boundary fields. The approach is described in Appendix 4 the procedure provides a signature of the bulk by the value of the gauge fields on the boundaries of the manifold. The mutual property of all the actions with gauge fields involved is an appearance of the new factor in the front of the actions which is a determinant of the gauge fields. The value of the factor is determined by the boundary values of the fields and defines the relative weight of the action in the corresponding generating functional, otherwise it is arbitrary. The dynamics of such complex system with many different parts of the general action in the generating functional is not clear and requests an additional investigation.

Different way to introduce the dynamical signature of the metric is a generalization of the tangent space and an introduction of an additional, auxiliary, metric in the tangent space which makes the tangent space curved. This can be achieved or by the complexification of the vierbein with the help of the gauge fields, see Eq. (41) and Eq. (50), or by the direct definition of the usual vierbein fields as projection of some "gauge" vierbein performed by the gauge field of some symmetry group G, see Eq. (53). In both cases the final signature is dynamical and determined or directly by the gauge fields, see Eq. (62), or by scalar fields and gauge fields together, see Eq. (84). Again, for these mechanisms
the projection procedure of Appendix B is important, without it the dynamics and correspondingly the signature can be arbitrary. Namely, as in the previous cases, there is no preferable geometrical time nor preferable spatial coordinates and the given and only foliation in the approaches must be fixed separately, if required. We did not consider a matter issue in the frameworks, therefore it is interesting to understand if the matter fields are invariant in respect to the change of signature of the manifold and if it can define some determined foliation of the space-time through mechanisms which we do not know yet. This problem requests an additional research and clarification of the properties of the matter fields in respect to the manifold’s symmetries.

Discussing the applications of the proposed approaches we note that they can be useful in an investigation of different aspects of the topology transition in both quantum gravity and cosmology. In the paper we discussed a few possible mechanisms of that transition, it is interesting to understand which one can be realized in the nature. For that we need to understand the dynamics of the models with matter fields included. Namely, there is an interesting problem to determine the form of the action for the spinor of scalar fields in the new curved spaces of different signatures and investigate the dynamics of these fields in corresponding models, see different aspects of this problem in references. An another interesting application of the dynamical signature is a clarification of it in correspondence to the possible new approaches to the classical gravity introduced and discussed at the last decade, see for example references. In general, as it seems, at the last years arise a lot of new approaches to the problems of quantum gravity, structure of space-time at small distances, cosmology and singularities, clarification of cosmological constant value, dark matter and dark energy issues. Hopefully, an unification of the new ideas and approaches will lead to the solution of these puzzles in the framework of theory which is going to be established.
Appendix A: Complex metric through complex vierbein

In order to illustrate how the Eq. (63) and Eq. (65) construction reproduce the set-up, we firstly can consider as example the action of the following two-dimensional fixed unitary matrix

\[ M = \begin{pmatrix} 1 & 0 \\ 0 & i \end{pmatrix}, \quad \tilde{M} = M^T = \begin{pmatrix} 1 & 0 \\ 0 & -i \end{pmatrix}, \quad \tilde{M} M = 1 \]  

(A.1)

on flat metric:

\[ M \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} M = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \]

Therefore, considering as \( G \) the \( U(4) \) group for example, we will obtain a complex phases for the metric’s components. Namely, consider the spectral decomposition for the unitary matrix

\[ M^{a\alpha} = \sum_{i=1}^{4} \lambda_i u^a_i \tilde{u}^\alpha_i \]  

(A.2)

with \( \lambda \) and \( u \) as eigenvalues and eigenvectors, we obtain for the metric:

\[ g_{\mu\nu} = \frac{1}{2} \sum_{i,j=1}^{4} \lambda_i \lambda_j \left( u^a_i \eta_{S ab} u^b_j \right) \tilde{u}^\alpha_i \tilde{u}^\beta_j \left( e^\mu_{\mu\alpha} e^\nu_{\beta\beta} + e^\nu_{\mu\alpha} e^\mu_{\beta\beta} \right). \]

(A.3)

Defining the local set of the vierbein through the identities

\[ e^\mu_{\mu\alpha} \tilde{u}^\alpha_i = \delta^\mu_i \]  

(A.4)

we will have finally

\[ g_{\mu\nu} = \frac{1}{2} \lambda_\mu \lambda_\nu \left( u^a_\mu \eta_{S ab} u^b_\nu + u^a_\nu \eta_{S ab} u^b_\mu \right). \]

(A.5)

Now, if we restrict ourselves by the diagonal unitary matrices, the corresponding eigenvectors are real and orthonormal. Therefore, for the arbitrary four dimensional diagonal unitary matrix

\[ M^{a\alpha} = \begin{pmatrix} e^{i\alpha_1} & 0 & 0 & 0 \\ 0 & e^{i\alpha_2} & 0 & 0 \\ 0 & 0 & e^{i\alpha_3} & 0 \\ 0 & 0 & 0 & e^{i\alpha_4} \end{pmatrix} \]  

(A.6)

we obtain a simple expression for the generalized flat metric:

\[ g_{\mu\nu} = e^{i(\alpha_\mu + \alpha_\nu)} \eta_{S_{\mu\nu}}. \]

(A.7)

We see, that in terms of Eq. (63) transform we simply can write the vierbein transform as

\[ e^\mu_{\mu\alpha} = e^{i\phi_\alpha} \delta^{a\alpha} e^\mu_{\mu\alpha} \]

(A.8)

obtaining for the metric

\[ g_{\mu\nu} = e^{i(\phi_\alpha + \phi_\beta)} \eta_{S_{\mu\nu}} e^a_{\mu} e^b_{\nu}. \]

(A.9)

which describes, at a first sight, a metric with indefinite complex signature. Nevertheless, we remind that the \( \phi \) angles are dynamical fields in the approach, therefore the final leading order expression for the metric will be determined by the classical values of these fields.
Appendix B: Induced part of the action

Following to the lines of [22, 23] we consider the following action. For the Eq. (58) expression in the flat-space time we have:

\[ S_A = - \frac{1}{4} \int d^4x \text{tr} \left[ G_{\mu\nu} G^{\mu\nu} \right] \]  

(B.1)

and the following term we write for the induced part of the action

\[ S_{\text{ind}} = - \sum_i \int d^4x \text{tr} \left[ \left( \partial_{\mu} O(A_{\mu}) \right) \left( \partial^{\mu} \mathcal{A}_{i}^{\mu} \right) \right], \]  

(B.2)

here the Riemann indexes are summed up through the Minkowski metric as usual. The \( \mathcal{A}^\mu \) fields are defined at boundaries and they intend to provide the signature of the additional part in the Eq. (52) metric. For example, we can define the two complete sets of the boundary fields which satisfy

\[ \partial_{\mu} \mathcal{A}_{i}^{\mu} = 0 \]  

(B.3)

and the following boundary conditions:

\[ \begin{cases} \mathcal{A}_{1}^{\mu}(x) \rightarrow 0 & x^0 \rightarrow \infty, \\ \mathcal{A}_{2}^{\mu}(x) \rightarrow 0 & x^0 \rightarrow -\infty. \end{cases} \]  

(B.4)

There is also the following term must be added to the action

\[ S_{\mathcal{A}} = \sum_i \int \mathcal{A}_{i}^{\mu} \partial^{\mu} \mathcal{A}_{i}^{\mu}, \]  

(B.5)

it preserves the correct form of the propagators in the full action, see discussions in [22, 23]. Therefore, for the gauge fields

\[ \partial_{\mu} A^{\mu} = 0 \]  

(B.6)

we obtain as a solution of the equations of motion [22]

\[ A_{cl}^{\mu} = \mathcal{A}_{1}^{\mu} + \mathcal{A}_{2}^{\mu}. \]  

(B.7)

The operator \( O \) in Eq. (B.2) action is defined similarly to definitions of [22, 23], in the simplest variant it is

\[ O(A_{\mu}) = \frac{1}{a_0} \int C(R) P e^{a_0 \int_{-\infty}^{\infty} dx^{\mu} A_{\mu}(x')} A_{\mu}(x). \]  

(B.8)

There is no summation on \( \mu \) index in the ordered exponential and the index is fixed in correspondence to the Eq. (B.2) expression, \( C(R) \) is the eigenvalue of Casimir operator in the representation \( R \) for the chosen gauge symmetry group. The different form of this operator and discussion about can be found in [22, 23].

---

\[ ^6 \] Following analogy with the high energy scattering approach, we can consider the Eq. (B.1) action with additional induced term as describing a “scattering” between two boundary fields with boundaries defined at the edges of time.
