Abstract

In recent years, a series of scaling correction (SC) methods have been developed in the Yang laboratory to reduce and eliminate the delocalization error, which is an intrinsic and systematic error existing in conventional density functional approximations (DFAs) within density functional theory (DFT). Based on extensive numerical results, the SC methods have been demonstrated to be capable of reducing the delocalization error effectively and producing accurate descriptions for many critical and challenging problems, including the fundamental gap, photoemission spectroscopy, charge transfer excitations and polarizability. In the development of SC methods, the SC methods were mainly implemented in the QM4D package that was developed in the Yang laboratory for research development. The heavy dependency on the QM4D package hinders the SC methods from access by researchers for broad applications. In this work, we developed a reliable and efficient implementation, **LibSC** for the global scaling correction (GSC) method and the localized orbital scaling correction (LOSC) method. **LibSC** will serve as a light-weight and open-source library that can be easily accessed by the quantum chemistry community. The implementation of **LibSC** is carefully modularized to provide the essential functionalities for conducting calculations of the SC methods. In addition, **LibSC** provides simple and consistent interfaces to support multiple popular programming languages, including C, C++ and Python. In addition to the development of the library, we also integrated **LibSC** with two popular and open-source quantum chemistry packages, the **Psi4** package and the **PySCF** package, which provides immediate access for general users to perform calculations with SC methods.

Introduction

Density functional theory (DFT)¹⁻³ has been widely used nowadays to describe the electron structure of matters in chemistry, physics and materials science. In the pursuit of accurate predictions from theoretical simulations based on DFT, developing accurate density functional approximations (DFAs) within DFT has become an active research field in quantum chemistry and condensed matter physics. During the last decades, conventional DFAs, including the local density approximations (LDAs),^{4,5} generalized gradient approximations (GGAs)⁶⁻⁸ and hybrid functionals,^{7,9-12} have achieved great success. However, conventional DFAs involve the intrinsic and systematic delocalization error,¹³⁻¹⁶ which is the underlying challenge for many critical applications.^{13,15-22}

To reduce the systematic delocalization error, many approaches have been developed, including range-separated functionals,²³⁻²⁹ self-interaction error corrected functionals,^{19,30-36} Koopmans-compliant functionals,^{37,38} and generalized transition state methods³⁹ and related developments.⁴⁰

In addition to these aforementioned approaches, a series of scaling correction (SC) methods,⁴¹⁻⁴⁶ including the global scaling correction (GSC),^{41,46} the local scaling correction (LSC)⁴² and the localized orbital scaling correction (LOSC)⁴³⁻⁴⁵ methods, have been developed in the Yang laboratory to tackle the delocalization error in conventional DFAs. With extensive numerical results,^{41-43,43,47-51} these SC methods have been demonstrated to be capable of reducing the delocalization error effectively and producing accurate descriptions for many critical and challenging problems, including the fundamental gap,^{41,43,47} photoemission spectroscopy,^{43,47,50} photoexcitation energies⁴⁷⁻⁴⁹ and polarizability.^{42,51} Therefore, a reliable and stable implementation for the SC methods can be very beneficial and meaningful to the electronic structure theory community, which helps to promote DFT with commonly used DFAs and with the SC methods for broader applications.

However, along the development of SC methods, the implementation was mainly developed in the QM4D package,⁵² which is an in-house quantum chemistry package in the Yang

laboratory for research development. In this work, we developed a reliable and stable implementation for the GSC and LOSC methods in `LibSC`, which will serve as a light-weight and open-source library to provide the essential functionalities for conducting calculations of the SC methods. With the simple and consistent interface to support multiple popular programming languages, including C, C++ and Python, we aim to provide future `LibSC` users great flexibility to implement the SC methods in different quantum chemistry packages of their choices in a short development cycle. In addition to the development of the library, we also integrated `LibSC` with two popular and open-source quantum chemistry packages, the `Psi4` package⁵³ and the `PySCF` package,⁵⁴ which provides immediate access for researchers to perform calculations of SC methods easily. We will describe the philosophy and methodology of the design for `LibSC` and show its applications.

Theoretical Background

We start with a brief review for the key concept of the delocalization error,^{13–16} which is the central problem that the SC methods are designed to solve. The delocalization error characterizes the incorrect behavior of conventional DFAs compared to the exact functional in DFT, and it can be understood from the perspective of systems with fractional number of electrons. According to the Perdew-Parr-Levy-Baldur (PPLB) condition,^{55–57} the exact total energy $E(N)$, as a function of electron number, should be piecewise linear between any two adjacent integer points. Critically, the manifestation of the delocalization error has been shown to be size-dependent.¹³ For small systems, conventional DFAs usually well predict total energies for integer systems. However, conventional DFAs severely underestimate the total energies for fractional systems.^{13,14} Such underestimation from conventional DFAs leads to a convex $E(N)$ curve, which is the manifestation of the delocalization error for small systems. For large systems, the behavior is different. The deviation of the $E(N)$ from the linearity condition decreases when the size of the system becomes larger, and vanishes

at the bulk limit.¹³ However, the delocalization error manifests as the underestimation for the total energies of integer systems with the addition or removal of an electron, which produces the $E(N)$ curve with wrong slopes at the bulk limit.¹³ The direct consequence for the delocalization error is the large error in the prediction of chemical potentials, which are first derivatives of the total energy with respect to the electron number, $\left.\frac{\partial E}{\partial N}\right|_{\pm}$ from the two sides of the integer N . The chemical potentials $\left.\frac{\partial E}{\partial N}\right|_{-}$ and $\left.\frac{\partial E}{\partial N}\right|_{+}$ have been rigorously proved to be the energy of the highest occupied molecular orbital (HOMO) and the energy of the lowest unoccupied molecular orbital (LUMO) respectively¹⁴ within the Kohn-Sham DFT, in which the approximate exchange-correction energy is an explicit functional of electron density, or the generalized Kohn-Sham DFT, in which the approximate exchange-correction energy is an explicit functional of the first-order density matrix. Therefore, when the PPLB condition⁵⁵ is satisfied, HOMO and LUMO energies connect the first ionization potential (IP) and the first electron affinity (EA),¹⁴ which read

$$\epsilon_{\text{HOMO}} = \left.\frac{\partial E}{\partial N}\right|_{-} = E(N) - E(N - 1) = -\text{IP}, \quad (1)$$

$$\epsilon_{\text{LUMO}} = \left.\frac{\partial E}{\partial N}\right|_{+} = E(N + 1) - E(N) = -\text{EA}. \quad (2)$$

According to Eqs. 1 and 2, the direct results of the delocalization error are the underestimation of the first IP from the HOMO energy and the overestimation of the first EA from the LUMO energy, thus the drastic underestimation of the fundamental gap from the HOMO-LUMO energy gap.¹⁴

To reduce the delocalization error, the SC methods impose the PPLB condition to associated DFAs either “globally” or “locally” to construct total energy corrections and restore the linear behavior between integers. Specifically, the global scaling correction (GSC) method⁴¹ imposes the PPLB condition globally through the canonical orbitals and their occupation numbers. Within the GSC, the total energies of integer systems remain the same as those from the parent DFA. The energy correction from the GSC is constructed as the energy com-

pensation to the corresponding linear interpolation and it is effective for fractional systems only, which is expressed as an addition to the total energy

$$\Delta_{\text{GSC}}(N + n) = (1 - n)E(N) + nE(N + 1) - E(N + n). \quad (3)$$

Based on Eq. 3, the energy correction for GSC at the second order is given as

$$\Delta_{\text{GSC}} = \frac{1}{2} \sum_{p\sigma} \kappa_{p\sigma} (n_{p\sigma} - n_{p\sigma}^2), \quad (4)$$

in which $n_{p\sigma}$ is the canonical orbital occupation number. Note that the original consideration of HOMO and LUMO⁴¹ has been generalized to all the orbitals.^{46,50} The coefficient $\kappa_{p\sigma}$ in the original work of GSC⁴¹ is approximated explicitly as

$$\kappa_{p\sigma} = \int \frac{\rho_{p\sigma}(\mathbf{r})\rho_{p\sigma}(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d\mathbf{r} d\mathbf{r}' - \frac{2\tau C_x}{3} \int [\rho_{p\sigma}(\mathbf{r})]^{\frac{4}{3}} d\mathbf{r}, \quad (5)$$

in which the first term is the Coulomb interaction, and the second term is attributed to the Slater exchange energy. The parameters are chosen as $\tau = 1$, $C_x = \frac{3}{4}(\frac{6}{\pi})^{1/3}$, and $\rho_{p\sigma}$ is the corresponding canonical orbital density $|\psi_{p\sigma}|^2$. The exact coefficient $\kappa_{p\sigma}$ has been derived in a recent development of GSC (GSC2)⁴⁶ and it is given as the second order derivative of the total energy with respect to the canonical orbital occupation number, $\kappa_{p\sigma} = \frac{\partial^2 E}{\partial n_{p\sigma}^2}$, which is a completely different and more sophisticated expression compared to Eq. 5. Note that in the recent work from Xiao and coworkers,⁵⁰ they also developed GSC to involve high order relaxation of orbitals with respect to the canonical orbital occupation number and thus the energy correction goes beyond the second order expression as shown in Eq. 4. The advantage of GSC2 is that it provides exact second order corrections for any DFA.⁴⁶

Note that the GSC preserves the total energies for integer systems and only corrects fractional systems, meaning the contribution from an orbital with an integer occupation ($n_{p\sigma} = 0$ or $n_{p\sigma} = 1$) is zero. Therefore, the GSC is limited to reducing the delocalization

error for small and medium-sized systems. To treat the delocalization error for large systems, where the violation of the PPLB condition is no longer an issue and cannot be used as measure of the delocalization error,¹³ the local scaling correction (LSC)⁴² method was developed later, which focuses on the local regions of the molecular system and applies the corrections locally. Combining the strategies used in GSC and LSC, the localized orbital scaling correction (LOSC)^{43–45} was developed to provide a general approach for the systematical elimination of the delocalization error for both small and large systems. The key idea in the LOSC is to change the canonical orbitals used in GSC to the carefully designed localized orbitals, or “orbitalets”, which are one-electron orbitals that are localized both in space and in energy and are unitary combinations of both the occupied and unoccupied orbitals. The localization used in the latest version of the LOSC (called LOSC2)⁴⁴ is defined as the minimization of the following cost function

$$F^\sigma = (1 - \gamma) \sum_p \left(\langle \mathbf{r}^2 \rangle_{p\sigma} - \langle \mathbf{r} \rangle_{p\sigma}^2 \right) + \gamma C \sum_p \left(\langle H_\sigma^2 \rangle_{p\sigma} - \langle H_\sigma \rangle_{p\sigma}^2 \right), \quad (6)$$

where

$$\langle X \rangle_{p\sigma} = \langle \phi_{p\sigma} | X | \phi_{p\sigma} \rangle, \quad X = \mathbf{r}, \mathbf{r}^2, H_\sigma, H_\sigma^2, \quad (7)$$

$$\phi_{p\sigma} = \sum_q U_{pq}^\sigma \psi_{q\sigma}, \quad (8)$$

σ is the electron spin, γ is set to be 0.707, C is set to be 1000 a.u./Å, U_{pq}^σ is a unitary matrix, $\{\psi_{q\sigma}\}$ is the set of canonical orbitals, $\{\phi_{p\sigma}\}$ is the set of orbitalets, $\mathbf{r}$ is the spacial operator, and H_σ is the one-electron Hamiltonian of the parent DFA. Note that we use $\psi_{i\sigma}$ and U_{pi}^σ to express the dependence on the orbitalets of the localization functional F^σ in Eq. 6. According to Eqs. 6-8, the orbitalets can adaptively change between the canonical orbitals and the localized orbitals, which are determined by the localization for the system of interest at the given structure. According to Eq. 8, one can apply an energy window to select COs to control the dimension of the space for localization, thus improving the computational

efficiency of the localization. In practice, an energy window of $[-30, 10]$ eV that covers most of the valence occupied COs and low-lying virtual COs is applied as an approximate treatment to achieve more efficient calculations.

With the application of orbitalets, the energy correction of the LOSC is generalized from the GSC to be

$$\Delta_{\text{LOSC}} = \frac{1}{2} \sum_{pq\sigma} \kappa_{pq\sigma} \lambda_{pq\sigma} (\delta_{pq} - \lambda_{pq\sigma}), \quad (9)$$

in which $\lambda_{pq\sigma}$ is the representation of density operator under the orbitalets, namely $\lambda_{pq\sigma} = \langle \phi_{p\sigma} | \rho_s^\sigma | \phi_{q\sigma} \rangle$, and it is a matrix called the local occupation matrix. The coefficient $\kappa_{pq\sigma}$ becomes a matrix as well and is called the curvature matrix. In the original work of the LOSC (called LOSC1),⁴³ $\kappa_{pq\sigma}$ has a similar expression to the GSC case (Eq. 5) and it is given as

$$\kappa_{pq\sigma} = \int \frac{\rho_{p\sigma}(\mathbf{r}) \rho_{q\sigma}(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d\mathbf{r} d\mathbf{r}' - \frac{2\tau C_x}{3} \int [\rho_{p\sigma}(\mathbf{r})]^{\frac{2}{3}} [\rho_{q\sigma}(\mathbf{r})]^{\frac{2}{3}} d\mathbf{r}, \quad (10)$$

in which $\rho_{p\sigma} = |\phi_{p\sigma}|^2$ is the density of the corresponding orbitalet. In the LOSC2,⁴⁴ the curvature matrix is modified for better performance in molecules and given as

$$\tilde{\kappa}_{pq\sigma} = \text{erf}(\xi S_{pq\sigma}) \sqrt{\kappa_{pp\sigma} \kappa_{qq\sigma}} + \text{erfc}(\xi S_{pq\sigma}) \kappa_{pq\sigma}, \quad (11)$$

in which $\xi = 8.0$, $S_{pq\sigma} = \int \sqrt{\rho_{p\sigma}(\mathbf{r}) \rho_{q\sigma}(\mathbf{r})} d\mathbf{r}$, $\text{erf}(x)$ is the error function and $\text{erfc}(x)$ is the complementary error function.

Implementation Details

For the development of LibSC, we focus on the implementation of GSC, LOSC1 and LOSC2 methods at the present stage. Making this choice is for three reasons: (1) these methods have

been shown with much numerical success; (2) applying calculations from these three methods only requires a very low computational overhead on top of regular DFT calculations; (3) these three methods share a similar theoretical framework and analytical expressions, making their implementations easy and compact.

To illustrate the design of **LibSC**, we begin with the clarification for the relations and differences of these three methods in terms of implementation. First, recall the working flow of the LOSC calculations as shown in Figure 1. A general procedure for the LOSC calculation in a single self-consistent field (SCF) cycle includes three steps: (1) conducting the localization; (2) constructing the curvature matrix; (3) evaluating the corrections to the total energy and the generalized KS Hamiltonian. The way of conducting steps (1) and (2), namely, the way of generating orbitalets and constructing the curvature matrix, differentiates the different versions of the LOSC. So far, two versions of LOSC, LOSC1⁴³ and LOSC2,⁴⁴ distinguish both in the localization procedure and the curvature definition. From LOSC1 to LOSC2, both the localization and the curvature matrices are improved to achieve better performance in preserving the orbitalet symmetry and degeneracy. Accordingly, the localization

Figure 1: The flow chart of scaling correction methods.

and curvature used in LOSC1 are called `localization1` and `curvature1`. Similar names `localization2` and `curvature2` are applied to LOSC2. Second, we clarify the connections between the LOSC and the GSC. To be clear, the GSC⁴¹ is a special case in the framework of LOSC (for both LOSC1 and LOSC2), in which the localization does not take place, yielding orbitalets that are just canonical orbitals and the curvature matrix is equivalent to the one defined in Eq. 5. Therefore, the general implementation of LOSC would cover the GSC method with the localization turned off. To make a clear illustration, we show the relations and comparisons between GSC, LOSC1 and LOSC2 in Table 1. Only bolded methods in the table are supported in LibSC.

Table 1: Options in the GSC, LOSC1, LOSC2 method and the support from LibSC.

Curvature Matrix Module Localization Module	<code>curvature0</code>	<code>curvature1</code>	<code>curvature2</code>
<code>no localization</code>	GSC (v0) ⁴¹	GSC (v1)	GSC (v2)
<code>localization1</code>	N/A	L1C1 (LOSC1) ⁴³	N/A
<code>localization2</code>	N/A	L2C1	L2C2 (LOSC2) ⁴⁴

*The bolded methods are supported in LibSC.

Based on the workflow of LOSC and GSC calculations shown in Figure 1, we designed LibSC as a collection of three modules, namely, the localization module, the curvature matrix module and the correction construction module, to provide the essential functionalities for LOSC and GSC calculations. As the LOSC is a generalized case that covers the case of the GSC, the implementation of LibSC is based on the expressions from the LOSC. For the localization module, LibSC currently supports only the `localization2`.⁴⁴ The Jacob-Sweep algorithm⁵⁸ was implemented to perform the optimization problem for the localization (see the Supporting Information for details). For the curvature module, LibSC supports three versions, `curvature0`,⁴¹ `curvature1`⁴³ and `curvature2`.⁴⁴ `curvature0` is a special case of `curvature1` and can be called in LibSC by setting the curvature version to 1 and changing the default parameter τ to 1.00. Density fitting^{59,60} is used to evaluate the Coulomb interaction

contribution in the curvature matrix for better efficiency (see the first term in Eq. 10 for example). For the correction construction module, the implementation is straightforward and based on the analytical expressions (see Eq. 9).

For the details of implementation, we summarize the design choices in the following:

- *Languages*: LibSC supports three programming languages, namely C++, C and Python. The core of LibSC that provides all the key functionalities of LOSC and GSC methods is implemented with morden C++11 for the consideration of computational efficiency. The C++ core of the library is bridged with C and Python programming languages to provide corresponding interfaces and avoid code duplications.
- *Style*: The object-oriented programming (OOP) technique is used to in the localization module and curvature module to deal with different versions and avoid code duplications. The functional programming is used in the correction module and the C code.
- *Data Structure*: The main data structure in the library is the matrix object, which is represented by the `MatrixXd` class provided by the `Eigen3` library⁶¹ in low level C++ code. The `Eigen3` library is highly optimized for the linear algebra manipulations, and heavily used in the SC library to achieve the best efficiency. The `MatrixXd` class is mapped to the `Numpy`^{62,63} array object in Python code and raw C array in C code.
- *Interface Bridging*: Bridging C++ library core to the C code is natural, because these two languages are compatible. Bridging C++ library core to the Python code is through the `pybind11` library,⁶⁴ which provides the supports of binding the data structure and data types in C++, like the class, function and `Eigen3` to Python environment. Within the library, most data are stored in the C++ library core in memory, and shared between interfaces to avoid unnecessary data copies. Manipulating the data from the C or Python interface is efficiently achieved by directly modifying the corresponding memory blocks through the pointers or references, which is taken care by the bridging process.

- *User Interface*: The interfaces for all the functions and classes in `LibSC` have simple and consistent designs for all the supported programming languages. The principle is that it mostly takes matrix objects, rather than complicated and customized class types, as the main input.

With the development of `LibSC`, we can easily implement GSC and LOSC methods in a quantum chemistry package. Along with `LibSC`, we integrate the library with two popular open-source packages, the `Psi4` package⁵³ and the `PySCF` package.⁵⁴ Considering that both packages use the Python environment for users to conduct calculations, we used the Python interface of `LibSC` and provided the implementation of LOSC and GSC methods as Python plugins to both packages, which are the `psi4_losc` plugin for `Psi4` and the `pyscf_losc` plugin for `PySCF`. Note that `LibSC` does not support calculations with symmetry at the current stage. Therefore, it requires that the symmetry option be turned off in both `Psi4` and `PySCF` packages to be able to use `psi4_losc` and `pyscf_losc` plugins.

For the `Psi4` package, the `Wavefunction` is the main object that stores all the data from a regular SCF calculation. Therefore, `psi4_losc` communicates with the `Psi4` package mainly through the `Wavefunction` object. Implementing the post-SCF LOSC calculation within the plugin `psi4_losc` is straightforward with assembling the three steps in a LOSC calculation according to the flowchart in Figure 1. Implementing the SCF-LOSC⁴⁵ calculation involves updating the Hamiltonian matrix (or called Fock matrix in the general SCF cycle within `Psi4` source code). This is achieved by overwriting two key functions within `Psi4` package: (1) the member function `Wavefunction.form_F()` that constructs the Fock matrix is updated to involve the LOSC effective Hamiltonian;⁴⁵ (2) the driver function `psi4.proc.scf_wavefunction_factory()` that constructs the `Wavefunction` object for the SCF calculation is updated to be compatible with the LOSC case. For the density fitting calculation of curvature matrix in plugin `psi4_losc`, the 3-center integral is constructed block-wise with respect to the fitting basis index in order to reduce the memory cost.

Listing 1: Demonstration of using `psi4_losc` plugin within `Psi4` package.

```
1 import psi4      # import the psi4 package
2 import psi4_losc # import the psi4_losc plugin for LOSC calculations
3
4 # Set up a molecule.
5 # Note the symmetry is turned off in Psi4 with setting C1 symmetry.
6 mol = psi4.geometry("""
7     O 1
8     H 0.0 0.0 -0.5
9     H 0.0 0.0 0.5
10    symmetry c1
11    """)
12
13 # Conduct the DFA SCF calculation from Psi4.
14 E_dfa, dfa_wfn = psi4.energy('BLYP', return_wfn=True)
15
16 # Configure LOSC calculation settings.
17 psi4_losc.options.set_param('localizer', 'max_iter', 1000)
18 # To turn off localization and do GSC, set to be 0.
19
20 # Conduct the post-SCF LOSC calculation
21 E_losc, Orb_losc = psi4_losc.post_scf_losc(
22     psi4_losc.BLYP, # DFA information
23     dfa_wfn,        # Psi4 wavefunction object
24     window=[-30, 10] # energy window (optional)
25 )
26
27 # Conduct the SCF-LOSC calculation
28 losc_wfn = psi4_losc.scf_losc(
29     psi4_losc.BLYP, # DFA information
30     dfa_wfn,        # Psi4 wavefunction object
31     window=[-30, 10] # energy window (optional)
32 )
```

Listing 1 demonstrates the way of using `psi4_losc` plugin within `Psi4`. As shown in Listing 1, both the post-SCF and SCF calculations of LOSC is based on a `Psi4` Wavefunction object, `dfa_wfn`, which can be requested as the returned value from the `Psi4` SCF driver function `psi4.energy()`. The post-SCF LOSC calculation is conducted by calling the function `psi4_losc.post_scf_losc()` provided from the plugin, and the returned values are the corrected total energy and orbital energies. The SCF-LOSC calculation is conducted by calling the function `psi4_losc.scf_losc()` provided by the plugin, and the returned value

is a `Psi4 Wavefunction` object, `losc_wfn`, which can be used for further calculations for property analysis in `Psi4`.

The implementation of `pyscf_losc` is similar to that of `psi4_losc`, with only a few changes to accommodate to features of PySCF. For the PySCF package, data for a restricted Kohn-Sham (RKS) or a unrestricted Kohn-Sham (UKS) calculation is stored in a `pyscf.dft.rks.RKS` or a `pyscf.dft.uks.UKS` object respectively. Take the UKS calculation as an example. All the matrices that are needed for LOSC calculations can be directly accessed from attributes of the `pyscf.dft.uks.UKS` object or be constructed by the corresponding built-in PySCF functions. For the density fitting calculation of the curvature matrix, an auxiliary molecule is constructed by the PySCF function `pyscf.df.addons.make_auxmol()`, and the 3-center integrals and the 2-center integrals are calculated directly by using the PySCF built-in functions that interface with its internal `Libcint` package.⁶⁵ The implementation of post-SCF LOSC within `pyscf_losc` plugin follows the flowchart as shown in Figure 1, which is similar to the case of the `psi4_losc` plugin. The implementation of SCF-LOSC provided in the `pyscf_losc` plugin is achieved by overwriting two member functions, `get_fock()` and `energy_tot()` of the `PySCF.dft.uks.UKS` object, to update the Hamiltonian matrix and include LOSC contributions within each SCF cycles.

Listing 2: Demonstration of using `pyscf_losc` plugin in PySCF package.

```
1 import pyscf          # import the pyscf package
2 import pyscf_losc     # import pyscf_losc plugin for LOSC calculations
3
4 # Initialize a molecule in PySCF
5 mol = pyscf.gto.Mole()
6 mol.atom = """
7     H  0.0  0.0  -0.5
8     H  0.0  0.0   0.5
9 """
10 mol.symmetry = False # turn off symmetry in PySCF
11 mol.build()
12
13 # Conduct the DFA SCF calculation from PySCF.
14 mf = pyscf.scf.UKS(mol)
15 mf.xc = "BLYP"
```

```

16 mf.kernel()
17
18 # Configure LOSC calculation settings.
19 pyscf_losc.options.set_param('localizer', 'max_iter', 1000)
20 # To turn off localization and do GSC, set to be 0.
21
22 # Conduct the post-SCF LOSC calculation
23 Elosc, Orblosc = pyscf_losc.post_scf_losc(
24     pyscf_losc.BLYP, # DFA information
25     mf,               # PySCF DFT object
26     window=[-30, 10] # energy window (optional)
27 )
28
29 # Conduct the SCF-LOSC calculation
30 loscmf = pyscf_losc.scf_losc(
31     pyscf_losc.BLYP, # DFA information
32     mf,               # PySCF DFT object
33     window=[-30, 10] # energy window (optional)
34 )

```

Listing 2 demonstrates the way of using the `pyscf_losc` plugin within PySCF. The usage of the `pyscf_losc` plugin is the same as the `psi4_losc` plugin. The only difference is changing the Wavefunction object used in `psi4_losc` to be the `pyscf.dft.uks.UKS` object used in `pyscf_losc`.

The source code and documentations for the LibSC library and `psi4_losc` and `pyscf_losc` plugins are hosted on Github.⁶⁶

Applications and Results

Computational Details

The performance of LibSC was first tested by reproducing a series of calculations that have been done with QM4D.⁵² For more information about molecular structures and reference values, refer to previous works on the LOSC.^{67 68 44} For G2-1 atomization energy (AE) test set, Hydrocarbon AE test set, NonHydrocarbon AE test set, SubHydrocarbon AE test set, Radical AE test set, IP test set, EA test set, HTBH38 reaction barrier (RB) test set, and

NHTBH38 RB test set, both B3LYP and BLYP calculations were done using 6-311++G(3df, 3pd) basis set with `Psi4`. Quasiparticle energies (QE) of a series of systems were calculated using B3LYP functional and cc-pVTZ basis set with `Psi4`. To compare the results from `psi4_losc` and from `pyscf_losc`, both B3LYP/cc-pVTZ and BLYP/cc-pVTZ calculations of IP values for polyacetylene (PA) molecules with 1 to 10 units were done with both `Psi4` and `PySCF`. Photoemission spectra of maleic anhydride were calculated using B3LYP/cc-pVTZ with `QM4D`, `Psi4`, and `PySCF`. To test the stability of the localization procedure, post-LOSC2 calculations of the 4-unit polyacene molecule were performed starting from random initial U matrices with `QM4D` based on B3LYP/cc-pVTZ calculations. The aug-cc-pVTZ-RIFIT basis set is used as the density fitting basis for the construction of curvature matrices for all calculations. Detailed results are documented in the Supporting Information.

Numerical Results

Table 2: IP values (in eV) of polyacetylene with different unit numbers calculated from B3LYP and compared with the first IP from RASPT2. The localization procedure was carried out with the energy window of $[-30, 10]$.

Figure 2: Photoemission spectrum of maleic anhydride calculated from B3LYP, GSC, and post-LOSC2, compared with the experimental result.⁶⁹

with the results from QM4D as shown in Table 2. These three software packages give mostly the same results for parent DFA calculations. The mean absolute errors (MAEs) differ by 0.01 eV for post-LOSC2 results and 0.02 eV for SCF-LOSC2 results. This shows that the integration of LibSC with both Psi4 and PySCF is correct.

MAEs for the same test sets calculated with Psi4 and QM4D are listed in Table 3. The difference between the numbers is due to the fact that the MAE values are not calculated with exactly the same systems for each set. We could only get the results for a subset of the systems because of the SCF convergence issue of DFT. Detailed results are documented in the Supporting Information.

The photoemission spectrum of maleic anhydride is calculated from B3LYP, GSC, and post-LOSC2 with all the three software packages. The results are plotted and compared with both experimental⁶⁹ and B3LYP spectra in Figure 2. For the B3LYP spectrum, only QM4D result is shown because the three software packages produce the same result. These spectra show that both GSC and post-LOSC2 greatly correct the behavior of the parent DFA. On the experimental curve, the peak with the highest energy represents the LUMO energy, which is about -1.3 eV. The second peak from the right represents the HOMO energy, which should be about -11 eV. The HOMO-LUMO gap is about 10 eV. However, B3LYP gives a HOMO of about -8.5 eV and a LUMO of about -3.5 eV, and the HOMO-LUMO gap is about 5 eV, which is about 5 eV smaller than the experimental one. Both GSC and post-LOSC2 give nearly the same LUMO energy as the experimental one. The GSC HOMO is about 1 eV higher than the experimental HOMO energy, which gives a HOMO-LUMO gap about 1 eV smaller than the experimental gap. The post-LOSC2 HOMO energy is about 1 eV lower than the experimental value, and the HOMO-LUMO gap is about 1 eV wider than the experimental gap. Compared with the B3LYP spectrum, GSC and post-LOSC2 spectra can describe the energy structure of this system better.

Multi-minimum Problem with the Localization Procedure

The spectra shown in Figure 2 also indicate that the minimization of the cost function can have different local solutions. For GSC calculations, the localization process in Figure 1 is skipped, and the SC correction only comes from the curvature. As shown in Figure 2(a), without the localization process, the GSC spectra have no noticeable difference. On the other hand, for the post-LOSC2 calculations, the SC correction comes from both localization contribution and curvature contribution. With the contribution from the localization process included, as shown in Figure 2(b), difference between post-LOSC2 spectra shows up. There is one peak at around 13 eV in the PySCF spectrum which does not exist in other two spectra, and the peak at around 15.7 eV which appears in the Psi4 curve and the QM4D curve is missing from the PySCF curve. These differences, especially the differences between the PySCF spectrum and the Psi4 spectrum, which were calculated using the same C++ core code, indicate that the localization process happened differently for this system.

The problem is not with the implementation of LibSC. Repeating the same calculation with QM4D but starting the localization process from different initial guesses can also result in different solutions. Table 4 shows the results of 9 tests, for which the localization procedure started with 9 random U matrices. Seven of the nine tests gave similar HOMO energies which are around -7.19 eV, while the other two HOMO energies are about -6.67 eV. The HOMO energy difference between these two groups is about 0.5 eV, which is close to the MAE of post-LOSC2 for the IP test set as shown in Table 3. In principle, the global minimum of the localization cost function, Eq. 6, should be the unique answer. However, as shown in the fifth column of the table, the cost function can have different values. For a given system, $\langle r^2 \rangle$ is a constant, and can be subtracted from the the cost function. Column 6 lists the relative cost function values of each test with respect to that of the first test. Tests 7 and 8 have the closest values of the cost function, but the HOMO energies differ by about 0.5 eV. On the other hand, the multi-minimum issue does not have significant influence on the total energy. When the HOMO energy is about -6.67 eV, the total energy is a little lower, but

the maximum difference is less than 0.0001 Hartree. Although tests 8 and 9 give lower total energies, it is not evident that they offer better solutions. The cost function but not the total energy is the target function of the localization procedure. Unfortunately, the values of the cost function differ by about 0.5 a.u.² for tests 8 and 9, which means that they give very different local solutions.

Table 4: HOMO energies (in eV), LUMO energies (in eV), HOMO-LUMO gap (in eV), cost function ($F^\sigma - \langle r^2 \rangle$) values (in a.u.²), relative cost function values (in a.u.), and total energies (in a.u.²) from post-LOSC2 calculations with default γ (0.707) for the 4-unit polyacene molecule starting from random initial guesses. The calculations were done with QM4D. The localization procedure was done with the energy window of $[-30, 10]$.

To further investigate the multi-minimum problem, additional post-LOSC2 calculations were performed, with the energy component of the cost function ignored by setting the value of γ in Eq. 6 to 0. The results are shown in Table 5. With only the spacial component included in the cost function, the absolute ΔF^α values are smaller than those in Table 4. This suggests that including the energy component in the cost function can cause the surface of the cost function to be more rugged. The total energies agree to 0.001 a.u.. This is another evidence that the localization procedure does not affect the total energy by much.

Data in Tables 4 and 5 show that the energy component can cause the cost function surface to be more rugged. To study the effect of including virtual orbitals, a new set of tests were done with only all the occupied orbitals included in the localization procedure. The results are shown in Table 6. With γ set to zero and no virtual orbital included, the

Table 5: HOMO energies (in eV), LUMO energies (in eV), HOMO-LUMO gap (in eV), cost function ($F^\sigma - \langle r^2 \rangle$) values (in a.u.²), relative cost function values (in a.u.²), and total energies (in a.u.) from post-LOSC2 calculations with $\gamma = 0.00$ for the 4-unit polyacene molecule starting from random initial guesses. The calculations were done with QM4D. Energy window: $[-30, 10]$.

localization procedure becomes the original Foster-Boys localization.⁷⁰ The value of the cost function is very stable. There is no noticeable difference between the cost function values of these tests, and the HOMO energies agree to the fifth digits after the decimal point. Thus, only one solution was found for the Foster-Boys localization. Compared with Table. 5, this suggests that including virtual orbitals in the localization procedure causes the smooth surface of the original Foster-Boys target function to become more rugged.

We conclude that the localization procedure is very sensitive to the starting point. Both including the virtual orbitals in the localization process and adding the energy component in the cost function contribute to the roughness of the cost function landscape. While multiple patterns of localization were observed, the total energy is not significantly affected, and the HOMO energy difference is about the same magnitude of the MAE of post-LOSC2 for the IP test set. Differences between post-LOSC2 spectra shown in Figure 2 can be attributed to the slight differences between the converged DFT results from the three software packages. Currently, it remains a challenge to overcome this multi-minimum problem.

Fortunately, the multi-minimum problem may not be a serious issue in practical calculations. Using a random U matrix as the starting point of the localization is just for a testing

purpose. In practical calculations, the initial U matrix is usually an identity matrix, meaning the use of CO as the initial guess. Ten tests, for which the localization procedure started from an identity U matrix, were performed on each of three different computers. Detailed data from these tests are documented in the Supporting Information. The behavior of the localization procedure is very stable. Results calculated by the same computers including frontier orbital energies, cost function values, and total energies are completely identical. The difference between data calculated by different computers is negligible. The difference between HOMO energies is about 2×10^{-5} eV. Although currently there is no effective way to make sure that the global minimum of the cost function is obtained, the same local minimum can be obtained by keep using the identity matrix as the initial U matrix. This can also be verified by the fact that the Psi4 results agree with the QM4D results.

Table 6: HOMO energies (in eV), cost function ($F^\alpha - \langle r^2 \rangle$) values (in a.u.²), relative cost function values (in a.u.²), and total energies (in a.u.) from post-LOSC2 calculations with $\gamma = 0.00$ for the 4-unit polyacene molecule starting from random initial guesses of the U matrix. The calculations were done with QM4D. Only occupied orbitals were included in the localization procedure.

Conclusion

In summary, we developed a reliable, flexible and open-source library LibSC for the scaling correction methods, which supports the GSC and LOSC methods at the present stage. The consistent and simple interfaces to multiple programming languages, including C, C++

and Python, are carefully designed to be user-friendly. We also applied LibSC in two open-source quantum chemistry packages, Psi4 and PySCF. With the distribution of LibSC and its implementation, the scaling correction methods should be available for broader applications.
