#### Abstract

: Feynman's $i \epsilon$ prescription for quantum field theoretic propagators has a quite natural reinterpretation in terms of a slight complex deformation of the Minkowski spacetime metric. Though originally a strictly flat-space result, once reinterpreted in this way, these ideas can be naturally extended first to semi-classical curved-spacetime QFT on a fixed background geometry and then, (with more work), to fluctuating spacetime geometries. There are intimate connections with variants of the weak energy condition. We shall take the Lorentzian signature metric as primary, but note that allowing the complex deformation to become large leads to a variant of Wick rotation, and more importantly leads to physically motivated constraints on the configuration space of acceptable off-shell geometries to include in Feynman's functional integral when attempting to quantize gravity. Ultimately this observation allows one to connect the discussion back to recent ideas on "acceptable" complex metrics, in the Louko-Sorkin and Kontsevich-Segal-Witten sense, with Lorentzian signature spacetimes occurring exactly on the boundary of the set of "acceptable" complex metrics. By adopting the tetrad formalism we explicitly construct the most general set of acceptable complex metrics satisfying the 0 -form, 1 -form, and 2 -form acceptability conditions.

## 1 Introduction

Feynman's $i \epsilon$ prescription for the Feynman propagator was originally developed as a pragmatic trick for encoding causality into the Fourier transformed momentumspace propagators occurring in the Feynman diagram expansion [1-5]. Feynman's $i \epsilon$ prescription then justifies flat-space Wick rotation, and is an essential ingredient in Euclideanizing any loop integrals that might be of interest [1-5]. Going beyond the Feynman diagram expansion there has now been an almost 50 year history of reinterpreting Feynman's $i \epsilon$ prescription in position space, often via a slight complex deformation of the Minkowski metric [6-12].

In flat space for small $\epsilon$ it is useful to focus on the almost-real metric

$$
\begin{equation*}
\left(\eta_{\epsilon}\right)_{a b}=\eta_{a b}-i \epsilon V_{a} V_{b} . \tag{1.1}
\end{equation*}
$$

Here $V^{a}$ is at this stage some arbitrary but fixed spatially constant 4 -velocity.
Viewed as a slight complex deformation of the Minkowski metric, formal convergence of the Feynman functional integral [13] can then be related to the whether or not the underlying classical Lagrangian appearing in the path integral satisfies an integrated off-shell variant of the weak energy condition (WEC).

It is then tolerably straightforward to extend these ideas to curved spacetimes. First to curved-spacetime QFT on a fixed background, and then with considerably more work to fluctuating spacetime geometries. In curved space for small $\epsilon$ it is useful to focus on the almost-real metric

$$
\begin{equation*}
\left(g_{\epsilon}\right)_{a b}=\left(g_{L}\right)_{a b}-i \epsilon V_{a} V_{b} . \tag{1.2}
\end{equation*}
$$

Here $\left(g_{L}\right)_{a b}$ is some Lorentzian signature metric, and $V^{a}$ is some arbitrary field of unit-norm 4 -velocities. Here $\epsilon(x)>0$ is allowed to be position-dependent. We shall take the existence of the Lorentzian signature metric $\left(g_{L}\right)_{a b}$ as primary, and view the complex metric $\left(g_{\epsilon}\right)_{a b}$ as auxiliary.

We can then generalize this construction further, to considering "allowable" complex metrics of the form

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}=\sqrt{-g_{L}}\left(g_{L}\right)^{a b}+i \epsilon \sqrt{g_{E}}\left(g_{E}\right)^{a b} . \tag{1.3}
\end{equation*}
$$

Here $\left(g_{L}\right)^{a b}$ and $\left(g_{E}\right)^{a b}$ are Lorentzian signature and Euclidean signature metrics respectively, and are subject to the additional nonlinear acceptability condition

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{-\operatorname{det}\left[\sqrt{-g_{L}}\left(g_{L}\right)^{a b}+i \epsilon \sqrt{g_{E}}\left(g_{E}\right)^{a b}\right]}\right\}>0 \tag{1.4}
\end{equation*}
$$

These two conditions are a re-phrasing and explicit codification of the constraints first discussed by Louko and Sorkin [14], (the 0 -form and 1 -form constraints), and then recently revived (and extended) by Kontsevich and Segal [15], and Witten [16]. When presented in this way, the fact that Lorentzian signature metrics lie on the boundary of the acceptable complex metrics is explicitly manifest. Though the above is the most symmetric way of phrasing things, it may not always be the most computationally effective, and we shall put some effort into various simplifications.

For instance let $h^{a b}$ be a positive definite tensor, then one can recast the two LoukoSorkin acceptability conditions in an asymmetric manner:

$$
\begin{align*}
& \left(g_{\epsilon}\right)^{a b}=\frac{\left(g_{L}\right)^{a b}+i \epsilon h^{a b}}{\sqrt{\operatorname{det}\left\{\delta_{c}^{e}+i \epsilon\left(g_{L}\right)_{c d} h^{d e}\right\}}}  \tag{1.5}\\
& \operatorname{Im}\left(\sqrt{\operatorname{det}\left\{\delta_{a}^{c}+i \epsilon\left(g_{L}\right)_{a b} h^{b c}\right\}}\right)>0 . \tag{1.6}
\end{align*}
$$

We also discuss the small- $\epsilon$ version of the above. For positive definite $h^{a b}$ :

$$
\begin{equation*}
\left(g_{\epsilon}\right)^{a b}=\left(g_{L}\right)^{a b}+i \epsilon \overline{h^{a b}}+\mathcal{O}\left(\epsilon^{2}\right) ; \quad\left(g_{L}\right)_{c d} h^{c d}>\mathcal{O}(\epsilon) ; \tag{1.7}
\end{equation*}
$$

where $\overline{h^{a b}}$ denotes the usual trace-reversal process.
We shall then, following and extending the ideas of Kontsevich and Segal [15], and Witten [16], discuss the third (2-form) acceptability constraint relevant in a 4 -dimensional setting, and use it to fully characterize the positive definite tensor $h^{a b}$ by constraining its eigenvalues. (In higher $D$-dimensional spacetime one would need to consider additional constraints, up to a [ $D / 2$ ]-form constraint.) Then, adopting the tetrad formalism, we shall provide a complete and explicit characterization of all complex metrics satisfying the compatibility conditions.

Finally we make some general comments about the generic functional integration over complex manifolds, and in the appendix present a fully explicit example of a complex spacetime metric that is not acceptable.

Notation: We choose our metric conventions such that the flat space Minkowski metric is $\eta_{L}=\operatorname{diag}(-1,+1,+1,+1)$. The flat space Euclidean metric is taken to be positive definite, $\eta_{E}=\operatorname{diag}(+1,+1,+1,+1)$. Particle physicists often use the opposite signature $\eta_{L}=\operatorname{diag}(+1,-1,-1,-1)$, which can sometimes lead to annoying stray minus signs.

## 2 Flat Minkowski spacetime

### 2.1 Feynman propagator: Small $\epsilon$

The Feynman propagator in momentum space (for simplicity let us consider a massive scalar field) can be written as [1-5]

$$
\begin{equation*}
\Delta_{F}(E, p)=\frac{i}{E^{2}-p^{2}-m^{2}+i \epsilon} \tag{2.1}
\end{equation*}
$$

The whole point of Feynman's $i \epsilon$ prescription is to "dodge" around the poles, naively located at $E= \pm \sqrt{m^{2}+p^{2}}$, in an appropriate manner, by shifting the poles slightly to $E= \pm \sqrt{m^{2}+p^{2}-i \epsilon}$, see for instance [1-5].

Since these poles occur at $E^{2}>0$, one could just as easily write

$$
\begin{equation*}
\Delta_{F}(E, p)=\frac{i}{E^{2}(1+i \epsilon)-p^{2}-m^{2}} \tag{2.2}
\end{equation*}
$$

When the propagator is written in this form the $i \epsilon$ prescription has a natural interpretation in terms of a complex "not quite Minkowski" metric [7-12]. Specifically, let us define

$$
\begin{equation*}
\left(\eta_{\epsilon}\right)_{a b}=\operatorname{diag}(-1-i \epsilon,+1,+1,+1) . \tag{2.3}
\end{equation*}
$$

Then taking the 4 -momentum to be $P^{a}=\left(E, p^{i}\right)$ we have

$$
\begin{equation*}
\Delta_{F}(E, p)=\frac{i}{-\left(\eta_{\epsilon}\right)_{a b} P^{a} P^{b}-m^{2}} . \tag{2.4}
\end{equation*}
$$

These three propagators, (2.1)-(2.2)-(2.4), all carry and imply exactly the same physics content [7-12]. Defining the 4 -velocity $V^{a}=(1,0,0,0)$ we can write

$$
\begin{equation*}
\left(\eta_{\epsilon}\right)_{a b}=\eta_{a b}-i \epsilon V_{a} V_{b} . \tag{2.5}
\end{equation*}
$$

This version of Feynman's $i \epsilon$ prescription, where the $\epsilon$ has been pushed into the spacetime metric, has a much better chance of being usefully generalizable.

### 2.2 Flat-space Wick rotation: Large $\epsilon$

While this is not the central point of the current article, there are connections to the idea of Wick rotation. When performing the usual form of flat-space Wick rotation, $E \rightarrow i E$, the contour does not pass over the poles. [The contour $(-\infty,+\infty)$ is deformed to $(-i \infty,+i \infty)$.] In terms of the "rotated" energy variable, once one takes the limit $\epsilon \rightarrow 0$, the Euclidean propagator is simply:

$$
\begin{equation*}
\Delta_{E}(E, p)=\frac{-i}{E^{2}+p^{2}+m^{2}} . \tag{2.6}
\end{equation*}
$$

When viewed as a complex metric, the energy $E$ instead remains untouched and in the complex metric $\eta_{\epsilon}=\eta-i \epsilon V \otimes V$ one would instead let $\epsilon$ travel from 0 to $2 i$, while carefully dodging around the point $i$.

Alternatively one could instead write a specific "large $\epsilon$ " version of the complex metric

$$
\begin{equation*}
\left(\eta_{\epsilon}\right)_{a b}=\eta_{a b}+(1-\exp (i \epsilon)) V_{a} V_{b}, \tag{2.7}
\end{equation*}
$$

and let $\epsilon$ travel from 0 to $\pi$ along the real axis. This version of the complexified Minkowski metric is closer in spirit to the construction adopted in a series of papers by Greensite and Carlini [17-21].

Another nice feature of putting the $i \epsilon$ into the spacetime metric is that it will then automatically take care of the polarization factors for higher spin. (Otherwise one would have to add somewhat ad hoc modifications to Wick rotation by, for instance, additionally Wick rotating the electromagnetic scalar potential, $A^{0} \rightarrow i A^{0}$ but not the vector potential $\vec{A}$, etc.)

### 2.3 Weak energy condition

Within the context of the Feynman functional integral [13] the Lorentzian partition function is

$$
\begin{equation*}
Z_{L}=\int \mathcal{D} \phi \exp (-i S(\phi, \eta)) \tag{2.8}
\end{equation*}
$$

Now $i \epsilon$-complexify the metric

$$
\begin{equation*}
Z_{\epsilon}=\int \mathcal{D} \phi \exp \left(-i S\left(\phi, \eta_{\epsilon}\right)\right) \tag{2.9}
\end{equation*}
$$

For small $\epsilon$ we now use the general result

$$
\begin{equation*}
\frac{\delta S(g, \phi)}{\delta g_{a b}}=\frac{\sqrt{-g}}{2} T(g, \phi)^{a b} \tag{2.10}
\end{equation*}
$$

to write

$$
\begin{equation*}
S\left(\eta_{\epsilon}, \phi\right)=S(\eta, \phi)-\frac{i \epsilon}{2} \int T^{a b}(\eta, \phi) V_{a} V_{b} \sqrt{-\eta} d^{4} x+\mathcal{O}\left(\epsilon^{2}\right) \tag{2.11}
\end{equation*}
$$

This implies

$$
\begin{equation*}
Z_{\epsilon}=\int \mathcal{D} \phi\left\{\exp \left(-i S\left(\phi, \eta_{\epsilon}\right)\right) \exp \left(-\frac{\epsilon}{2} \int T^{a b}(\eta, \phi) V_{a} V_{b} \sqrt{-\eta} d^{4} x+\mathcal{O}\left(\epsilon^{2}\right)\right)\right\} \tag{2.12}
\end{equation*}
$$

Thence, if the classical off-shell stress-energy tensor satisfies the WEC, (so that $\left.T^{a b}(\eta, \phi) V_{a} V_{b} \geq 0\right)$, then the $i \epsilon$-complexified metric serves to damp the oscillations in the functional integral, which is exactly what we want to make the functional integral mathematically justifiable [13]. (For related comments see also references [14] and [22].)

Unfortunately the argument cannot be run in reverse. Even with a damped functional integral the expectation value $\left\langle T^{a b}(\eta, \phi)\right\rangle$ need not satisfy the WEC, both because of the phases $\exp \left(-i S\left(\phi, \eta_{\epsilon}\right)\right)$, and because of the need to renormalize. ${ }^{1}$

[^0]Consider for instance the Casimir effect between parallel plates: The classical Maxwell Lagrangian certainly satisfies the WEC, but the renormalized electromagnetic energy density $\langle\rho\rangle$ is certainly negative [23-31].

## 3 Fixed-background curved-space: Simplified construction

When investigating curved space QFT we find it most convenient to first start the discussion with a simple and direct construction for small $\epsilon$, subsequently extended to large $\epsilon$. We shall then present a generalized construction for large $\epsilon$, and ultimately circle back from the generalized large- $\epsilon$ construction to a generalized small- $\epsilon$ construction. We then introduce a tetrad version of the construction, which allows one to generalize the whole process.

### 3.1 Small $\epsilon$

Much of the previous flat-space discussion can be carried over to fixed-background curved-space QFT. While one can no longer Fourier transform to define the original momentum-space version of Feynman's ic prescription, one can certainly define an almost-real $i \epsilon$-complexified metric

$$
\begin{equation*}
\left(g_{\epsilon}\right)_{a b}=\left(g_{L}\right)_{a b}-i \epsilon V_{a} V_{b} . \tag{3.1}
\end{equation*}
$$

Here the vector field $V$ is now a unit 4 -vector field (a 4 -velocity field) with respect to the Lorentzian metric $\left(g_{L}\right)_{a b}$, and $\epsilon(x)$ is allowed to be position-dependent but should at least be positive. While this is not the central point of the current article, this construction can now be used as the starting point for how to define a general notion of how to Wick rotate a spacetime metric [12]. See also [32-37], and related work [38-40]. For instance, as long as one has a globally defined co-tetrad $e^{A}{ }_{a}$ [41], then one could define

$$
\begin{equation*}
\left(g_{\epsilon}\right)_{a b}=\left(\eta_{\epsilon}\right)_{A B} e^{A}{ }_{a} e^{B}{ }_{b} . \tag{3.2}
\end{equation*}
$$

We shall not take this specific route in the current article; but will ultimately develop and investigate a related tetrad-based construction.

To analyze this slightly complex metric it is useful to note that

$$
\begin{equation*}
\operatorname{det}\left\{\left(g_{L}\right)^{a b}\left(g_{\epsilon}\right)_{b c}\right\}=\operatorname{det}\left\{\delta^{a}{ }_{c}-i \epsilon V^{a} V_{c}\right\}=1+i \epsilon \tag{3.3}
\end{equation*}
$$

That is

$$
\begin{equation*}
-\operatorname{det}\left\{\left(g_{\epsilon}\right)_{a b}\right\}=-\operatorname{det}\left\{\left(g_{L}\right)_{a b}\right\}(1+i \epsilon) \tag{3.4}
\end{equation*}
$$

Thence

$$
\begin{equation*}
\sqrt{-\operatorname{det}\left\{\left(g_{\epsilon}\right)_{a b}\right\}}=\sqrt{-\operatorname{det}\left\{\left(g_{L}\right)_{a b}\right\}} \sqrt{1+i \epsilon}=\sqrt{-\operatorname{det}\left\{\left(g_{L}\right)_{a b}\right\}}\left\{1+\frac{i \epsilon}{2}+\mathcal{O}\left(\epsilon^{2}\right)\right\} . \tag{3.5}
\end{equation*}
$$

We can rewrite this more compactly as

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}=\sqrt{-g_{L}} \sqrt{1+i \epsilon}=\sqrt{-g_{L}}\left\{1+\frac{i \epsilon}{2}+\mathcal{O}\left(\epsilon^{2}\right)\right\} \tag{3.6}
\end{equation*}
$$

Furthermore, inverting the covariant metric, we have

$$
\begin{equation*}
\left(g_{\epsilon}\right)^{a b}=\left(g_{L}\right)^{a b}+i \epsilon V^{a} V^{b}+\mathcal{O}\left(\epsilon^{2}\right) \tag{3.7}
\end{equation*}
$$

Thence we have

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}=\sqrt{-g_{L}}\left\{1+\frac{i \epsilon}{2}+\mathcal{O}\left(\epsilon^{2}\right)\right\}\left[\left(g_{L}\right)^{a b}+i \epsilon V^{a} V^{b}+\mathcal{O}\left(\epsilon^{2}\right)\right] \tag{3.8}
\end{equation*}
$$

We can expand this as

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}=\sqrt{-g_{L}}\left[\left(g_{L}\right)^{a b}+i \epsilon\left\{V^{a} V^{b}+\frac{1}{2}\left(g_{L}\right)^{a b}\right\}+\mathcal{O}\left(\epsilon^{2}\right)\right] . \tag{3.9}
\end{equation*}
$$

But if we now define

$$
\begin{equation*}
\left(g_{E}\right)^{a b}=\left(g_{L}\right)^{a b}+2 V^{a} V^{b} \tag{3.10}
\end{equation*}
$$

then $\left(g_{E}\right)^{a b}$ is a Euclidean signature metric, and furthermore

$$
\begin{equation*}
\operatorname{det}\left\{\left(g_{L}\right)_{a b}\left(g_{E}\right)^{b c}\right\}=\operatorname{det}\left\{\delta_{a}^{c}+2 V_{a} V^{b}\right\}=-1 \tag{3.11}
\end{equation*}
$$

That is, we see that in this particular situation we have $\operatorname{det}\left\{\left(g_{E}\right)^{a b}\right\}=-\operatorname{det}\left\{\left(g_{L}\right)^{a b}\right\}$, or more briefly $g_{E}=-g_{L}$. But then we can write

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}=\sqrt{-g_{L}}\left(g_{L}\right)^{a b}+i \frac{\epsilon}{2} \sqrt{g_{E}}\left(g_{E}\right)^{a b}+\mathcal{O}\left(\epsilon^{2}\right) \tag{3.12}
\end{equation*}
$$

From (3.6) and the above we have

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\right\}=\frac{\epsilon}{2} \sqrt{-g_{L}}+\mathcal{O}\left(\epsilon^{2}\right) \tag{3.13}
\end{equation*}
$$

and

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}\right\}=\frac{\epsilon}{2} \sqrt{g_{E}}\left(g_{E}\right)^{a b}+\mathcal{O}\left(\epsilon^{2}\right) ; \tag{3.14}
\end{equation*}
$$

both of which are positive as long as $\epsilon$ is positive.

But these are simply small- $\epsilon$ versions of the Louko-Sorkin acceptability conditions [14]:

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\right\}>0 ; \quad \operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}\right\}>0 ; \tag{3.15}
\end{equation*}
$$

These two conditions were explored by Louko and Sorkin [14], almost 25 years ago, to guarantee the quantum stability of a (free) massive scalar field described by the action

$$
\begin{equation*}
S\left(g_{\epsilon}, \phi\right)=\frac{1}{2} \int \sqrt{-g_{\epsilon}}\left\{-\left(g_{\epsilon}\right)^{a b} \partial_{a} \phi \partial_{b} \phi-m^{2} \phi^{2}\right\} . \tag{3.16}
\end{equation*}
$$

In the language of Kontsevich and Segal [15], and Witten [16] these are the 0 -form and 1-form constraints. In $(3+1) \sim 4$ dimensions there is also a 2-form constraint, which we shall discuss in due course.

It is perhaps worth noting that the the combination $\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}$ also shows up elsewhere in general relativity. Specifically, in defining the harmonic gauge $\Delta x^{a}=0$, which is a coordinate gauge fixing condition equivalent to $\partial_{a}\left\{\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}\right\}=0$. This is the strong-field generalization of the weak-field Einstein-Hilbert-Fock-De Donder gauge.

Louko and Sorkin then partially generalized their construction [14], by defining the equivalent of

$$
\begin{equation*}
\left(g_{\epsilon}\right)_{a b}=\left(g_{L}\right)_{a b}-i \epsilon \sum_{j} w_{j}\left(V^{j}\right)_{a}\left(V^{j}\right)_{b} . \tag{3.17}
\end{equation*}
$$

Here one is now performing a positive-weight $\left(w_{j}>0\right)$ sum over timelike (or null) vector fields $\left(V^{j}\right)_{a}$. But can we generalize this construction even further? That is our goal in the next subsection.

### 3.2 Large $\epsilon$

First let us verify that the $\left(g_{\epsilon}\right)_{a b}=\left(g_{L}\right)_{a b}-i \epsilon V_{a} V_{b}$ satisfies the two Louko-Sorkin constraints for arbitrarily large $\epsilon>0$, and then further generalize the construction. Note that, (adopting Riemann normal coordinates and going to the rest frame of the 4 -velocity $V$ ), the eigenvalues of $\left(g_{\epsilon}\right)_{a b}$ are

$$
\begin{equation*}
\lambda \in\{-(1+i \epsilon), 1,1,1\} . \tag{3.18}
\end{equation*}
$$

Then $\sqrt{-g_{\epsilon}}=\sqrt{1+i \epsilon}$ and the eigenvalues of $\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}$ are:

$$
\begin{equation*}
\lambda \in\left\{-\frac{1}{\sqrt{1+i \epsilon}}, \sqrt{1+i \epsilon}, \sqrt{1+i \epsilon}, \sqrt{1+i \epsilon}\right\} . \tag{3.19}
\end{equation*}
$$

The two Louko-Sorkin acceptability conditions are then

$$
\begin{equation*}
\operatorname{Im}(\sqrt{1+i \epsilon})>0 ; \quad \operatorname{Im}\left(-\frac{1}{\sqrt{1+i \epsilon}}\right)>0 \tag{3.20}
\end{equation*}
$$

But

$$
\begin{equation*}
\operatorname{Im}\left(-\frac{1}{\sqrt{1+i \epsilon}}\right)=\operatorname{Im}\left(-\frac{1}{\sqrt{1+i \epsilon}} \frac{\sqrt{1-i \epsilon}}{\sqrt{1-i \epsilon}}\right)=\frac{\operatorname{Im}(-\sqrt{1-i \epsilon})}{\sqrt{1+\epsilon^{2}}}=\frac{\operatorname{Im}(\sqrt{1+i \epsilon})}{\sqrt{1+\epsilon^{2}}} \tag{3.21}
\end{equation*}
$$

So for the specific metric $\left(g_{\epsilon}\right)_{a b}=\left(g_{L}\right)_{a b}-i \epsilon V_{a} V_{b}$ the two Louko-Sorkin acceptability conditions are actually degenerate, and amount to the same assertion that $\epsilon>0$. This now works for arbitrarily large values of $\epsilon$.

### 3.3 Rephrasing the construction in terms of tetrad formalism

Let us now collect these ideas, and recast them in terms of the tetrad formalism. Let $e_{A}{ }^{a}(x)$ denote an arbitrary (not necessarily orthonormal) tetrad. The only things we need to insist on is that the contravariant vectors $e_{A}{ }^{a}(x)=\left[e^{a}(x)\right]_{A}$ form a basis for the tangent space. Thence in particular $\operatorname{det}\left(e_{A}{ }^{a}(x)\right) \neq 0$, and the co-tetrad $e^{A}{ }_{a}(x)$ is simply the matrix inverse of $e_{A}{ }^{a}(x)$, with the co-vectors $e^{A}{ }_{a}(x)=\left[e_{a}\right]^{A}$ now forming a basis for the cotangent space.

Now let $\theta(x)$ be any smooth function bounded by $0<\theta(x)<\pi / 2$. The variable $\theta$ is effectively a nonlinear way of encoding the parameter $\epsilon$ via the relation $\theta=\frac{1}{2} \arctan \epsilon$; we shall soon see why this is worthwhile. Define

$$
\begin{equation*}
\left(\eta_{\theta}\right)_{A B}=\operatorname{diag}\{-\exp (+i 2 \theta(x)), 1,1,1\} ; \tag{3.22}
\end{equation*}
$$

and

$$
\begin{equation*}
\left(\eta_{\theta}\right)^{A B}=\operatorname{diag}\{-\exp (-i 2 \theta(x)), 1,1,1\} . \tag{3.23}
\end{equation*}
$$

Construct the complex metric

$$
\begin{align*}
\left(g_{\theta}\right)_{a b} & =\left(\eta_{\theta}\right)_{A B} e^{i}{ }_{A}(x) e^{B}{ }_{b}(x)  \tag{3.24}\\
& =-\exp [+i 2 \theta(x)] e^{0}{ }_{a}(x) e^{0}{ }_{b}(x)+\sum_{i=1}^{3} e^{i}{ }_{a}(x) e^{i}{ }_{b}(x) . \tag{3.25}
\end{align*}
$$

Then the inverse metric is

$$
\begin{align*}
\left(g_{\theta}\right)^{a b} & =\left(\eta_{\theta}\right)^{A B} e_{A}{ }^{a}(x) e_{B}{ }^{b}(x)  \tag{3.26}\\
& =-\exp [-i 2 \theta(x)] e_{0}{ }^{a}(x) e_{0}{ }^{b}(x)+\sum_{i=1}^{3} e_{i}^{a}(x) e_{i}^{b}(x) . \tag{3.27}
\end{align*}
$$

Note that $\sqrt{-\operatorname{det}\left(g_{\theta}\right)}=\exp [+i \theta(x)]$ and thence

$$
\begin{align*}
\sqrt{-\operatorname{det}\left(g_{\theta}\right)}\left(g_{\theta}\right)^{a b} & =\exp [+i \theta(x)]\left(\eta_{\theta}\right)^{A B} e_{A}{ }^{a}(x) e_{B}{ }^{b}(x)  \tag{3.28}\\
& =-\exp (-i \theta(x)) e_{0}{ }^{a}(x) e_{0}{ }^{b}(x)+\exp (+i \theta(x)) \sum_{i=1}^{3} e_{i}^{a}(x) e_{i}^{b}(x) . \tag{3.29}
\end{align*}
$$

Thence, this rather general class of complex metrics manifestly satisfies the LoukoSorkin (0-form and 1-form) acceptability conditions, and we shall soon see that it also satisfies the Kontsevich-Segal and Witten 2-form acceptability condition. This is not the most general class of complex metrics satisfying the compatibility conditions, but it is a good basis for ultimately deriving the most general class of such complex metrics.

The corresponding Lorentzian and Euclidean metrics are given by

$$
\begin{equation*}
\sqrt{-g_{L}}\left(g_{L}\right)^{a b}=\cos [\theta(x)]\left\{-e_{0}{ }^{a}(x) e_{0}{ }^{b}(x)+\sum_{i=1}^{3} e_{i}{ }^{a}(x) e_{i}^{b}(x)\right\}, \tag{3.30}
\end{equation*}
$$

and

$$
\begin{equation*}
\sqrt{-g_{E}}\left(g_{E}\right)^{a b}=\sin [\theta(x)]\left\{+e_{0}{ }^{a}(x) e_{0}{ }^{b}(x)+\sum_{i=1}^{3} e_{i}{ }^{a}(x) e_{i}^{b}(x)\right\} . \tag{3.31}
\end{equation*}
$$

We shall ultimately seek to fully generalize this construction.

## 4 Fixed-background curved-space: Generalized construction

We shall now generalize the construction beyond simply using the 4 -velocity vector $V^{a}$, to allow for a more complicated matrix-based relation between $\left(g_{L}\right)_{a b}$ and $\left(g_{E}\right)_{a b}$. After dealing with the 0 -form and 1-form acceptability conditions (the Louko-Sorkin conditions), we then turn to the additional 2-form acceptability condition relevant in 4 dimensions.

### 4.1 Large $\epsilon$

Let us now construct the general solution to the two Louko-Sorkin acceptability conditions, allowing arbitrarily "large" values of $\epsilon$; so we are no longer demanding that the metric is "close" to real. Take the Louko-Sorkin conditions as primary [14]:

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\right\}>0 ; \quad \operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}\right\}>0 . \tag{4.1}
\end{equation*}
$$

We note that $\operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}\right\}$ is by construction a tensor density, and since it is asserted to be a positive definite matrix, we can use it to define a Euclidean metric:

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}\right\}=\epsilon \sqrt{g_{E}}\left(g_{E}\right)^{a b} \tag{4.2}
\end{equation*}
$$

The overall scale of $\left(g_{E}\right)^{a b}$ is arbitrary, as it can always be absorbed into a redefinition of $\epsilon$, and vice versa. Similarly, we note that $\operatorname{Re}\left\{\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}\right\}$ is also by construction a tensor density. Since the whole point of the exercise was to start with a Lorentzian metric $\left(g_{L}\right)^{a b}$ and somehow complexify it, the physically appropriate choice is to demand:

$$
\begin{equation*}
\operatorname{Re}\left\{\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}\right\}=\sqrt{-g_{L}}\left(g_{L}\right)^{a b} \tag{4.3}
\end{equation*}
$$

Combining these observations we have one of our main results:

- The Louko-Sorkin matrix condition can be written as:

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}=\sqrt{-g_{L}}\left(g_{L}\right)^{a b}+i \epsilon \sqrt{g_{E}}\left(g_{E}\right)^{a b} . \tag{4.4}
\end{equation*}
$$

- The Louko-Sorkin determinant condition, from (4.1), can be written as

$$
\begin{equation*}
\operatorname{Im}\left(\sqrt{-\operatorname{det}\left\{\sqrt{-g_{L}}\left(g_{L}\right)^{a b}+i \epsilon \sqrt{g_{E}}\left(g_{E}\right)^{a b}\right\}}\right)>0 \tag{4.5}
\end{equation*}
$$

This is the cleanest theoretical way I have come up with for encoding the LoukoSorkin acceptability conditions. However, it is sometimes worthwhile to re-express these "symmetric" results in a slightly more asymmetric, but computationally more useful, manner. Taking the determinant of equation (4.4) we have

$$
\begin{equation*}
-g_{\epsilon}=-g_{L} \operatorname{det}\left\{\delta_{a}^{c}+i \epsilon \frac{\sqrt{g_{E}}}{\sqrt{-g_{L}}}\left(g_{L}\right)_{a b}\left(g_{E}\right)^{b c}\right\} . \tag{4.6}
\end{equation*}
$$

This suggests that one can make some progress by defining the rescaled positive definite tensor (not a tensor density)

$$
\begin{equation*}
h^{a b}=\frac{\sqrt{g_{E}}}{\sqrt{-g_{L}}}\left(g_{E}\right)^{a b} . \tag{4.7}
\end{equation*}
$$

Then the Louko-Sorkin determinant condition (4.5) can now be rewritten as

$$
\begin{equation*}
\operatorname{Im}\left(\sqrt{\operatorname{det}\left\{\delta_{a}{ }^{c}+i \epsilon\left(g_{L}\right)_{a b} h^{b c}\right\}}\right)>0 \tag{4.8}
\end{equation*}
$$

In contrast the Louko-Sorkin matrix condition (4.4) can now be written as

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}=\sqrt{-g_{L}}\left\{\left(g_{L}\right)^{a b}+i \epsilon h^{a b}\right\} . \tag{4.9}
\end{equation*}
$$

If we try to invert the general formula for $\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}$, to explicitly extract $\left(g_{\epsilon}\right)^{a b}$ as a function of $\left(g_{L}\right)^{a b}$ and $h^{a b}$, then the best we can do is this:

$$
\begin{equation*}
\left(g_{\epsilon}\right)^{a b}=\frac{\left(g_{L}\right)^{a b}+i \epsilon h^{a b}}{\sqrt{\operatorname{det}\left\{\delta_{c}^{e}+i \epsilon\left(g_{L}\right)_{c d} h^{d e}\right\}}} . \tag{4.10}
\end{equation*}
$$

This, together with the determinant condition (4.8), now completely characterizes the set of Luoko-Sorkin "acceptable" complex metrics in terms of the underlying Lorentzian metric $\left(g_{L}\right)^{a b}$ and a positive-definite distortion tensor $h^{a b}$. This is the cleanest practical way I have come up with for encoding the Louko-Sorkin acceptability conditions.

### 4.2 Back to small $\epsilon$

One place where we can make significant further progress with equation (4.10) is in the small- $\epsilon$ limit. In this limit we note that the determinant can be approximated as

$$
\begin{equation*}
\left(g_{\epsilon}\right)^{a b}=\frac{\left(g_{L}\right)^{a b}+i \epsilon h^{a b}}{\sqrt{1+i \epsilon\left(g_{L}\right)_{c d} h^{c d}+\mathcal{O}\left(\epsilon^{2}\right)}} \tag{4.11}
\end{equation*}
$$

Thence

$$
\begin{equation*}
\left(g_{\epsilon}\right)^{a b}=\left\{\left(g_{L}\right)^{a b}+i \epsilon h^{a b}\right\}\left\{1-i \epsilon \frac{1}{2}\left(g_{L}\right)_{c d} h^{c d}+\mathcal{O}\left(\epsilon^{2}\right)\right\} \tag{4.12}
\end{equation*}
$$

That is

$$
\begin{equation*}
\left(g_{\epsilon}\right)^{a b}=\left(g_{L}\right)^{a b}+i \epsilon\left\{h^{a b}-\frac{1}{2}\left[\left(g_{L}\right)_{c d} h^{c d}\right]\left(g_{L}\right)_{a b}\right\}+\mathcal{O}\left(\epsilon^{2}\right) \tag{4.13}
\end{equation*}
$$

But the quantity

$$
\begin{equation*}
\overline{h^{a b}}=h^{a b}-\frac{1}{2}\left\{\left(g_{L}\right)_{c d} h^{c d}\right\}\left(g_{L}\right)_{a b} \tag{4.14}
\end{equation*}
$$

is the familiar "trace-reversal" process, commonly encountered when perturbing the spacetime metric around some chosen background. Specifically, we now have

$$
\begin{equation*}
\left(g_{\epsilon}\right)^{a b}=\left(g_{L}\right)^{a b}+i \epsilon \overline{h^{a b}}+\mathcal{O}\left(\epsilon^{2}\right), \tag{4.15}
\end{equation*}
$$

where $h^{a b}$ is an arbitrary positive definite tensor.
Furthermore the Louko-Sorkin determinant condition now reduces to inspecting

$$
\begin{align*}
\operatorname{Im}\left\{\sqrt{1+i \epsilon\left(g_{L}\right)_{c d} h^{c d}+\mathcal{O}\left(\epsilon^{2}\right)}\right\} & =\operatorname{Im}\left\{1+i \epsilon \frac{1}{2}\left(g_{L}\right)_{c d} h^{c d}+\mathcal{O}\left(\epsilon^{2}\right)\right\} \\
& =\epsilon \frac{1}{2}\left(g_{L}\right)_{c d} h^{c d}+\mathcal{O}\left(\epsilon^{3}\right) \tag{4.16}
\end{align*}
$$

So to verify the Louko-Sorkin determinant condition one need merely check whether or not the trace $\left(g_{L}\right)_{c d} h^{c d}$ is positive.

The two formulae

$$
\begin{equation*}
\left(g_{\epsilon}\right)^{a b}=\left(g_{L}\right)^{a b}+i \epsilon \overline{h^{a b}} ; \quad\left(g_{L}\right)_{c d} h^{c d}>0 ; \tag{4.17}
\end{equation*}
$$

represent the cleanest practical way I have come up with for encoding the small- $\epsilon$ Louko-Sorkin acceptability conditions. If these two formulae are satisfied then there will at the very least be some finite interval $\epsilon \in\left(0, \epsilon_{*}\right)$ over which the Louko-Sorkin acceptability conditions are satisfied. Sometimes this can be extended to the entire positive half line $\epsilon \in(0, \infty)$.

### 4.3 The 2-form constraint

In $(3+1) \sim 4$ dimensions there is also an additional 2 -form constraint. See for instance the discussion in Kontsevich and Segal [15], and Witten [16].

### 4.3.1 Large $\epsilon$

The key idea is to demand that the electromagnetic, (or more generally, the nonabelian gauge fields), satisfy:

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a c}\left(g_{\epsilon}\right)^{b d} F_{a b} F_{c d}\right\}>0 \tag{4.18}
\end{equation*}
$$

The field strengths $F_{a b}$ are taken to be real, so this is equivalent to demanding that the object

$$
\begin{equation*}
M^{[a b][c d]}=\operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\left[\left(g_{\epsilon}\right)^{a c}\left(g_{\epsilon}\right)^{b d}-\left(g_{\epsilon}\right)^{a d}\left(g_{\epsilon}\right)^{b c}\right]\right\} \tag{4.19}
\end{equation*}
$$

be a positive definite matrix when acting on 2 -forms. This can be converted into a statement about the eigenvalues $\lambda_{A}$ of $\left(g_{\epsilon}\right)_{a b}$. With minor changes in notation and conventions as compared to references [15, 16], the 2 -form acceptability condition can be cast as

$$
\begin{equation*}
\operatorname{Im}\left\{\frac{\sqrt{-g_{\epsilon}}}{\lambda_{A} \lambda_{B}}\right\}>0 ; \quad(A \neq B) \quad\{A, B\} \in[0 . .3] \tag{4.20}
\end{equation*}
$$

For completeness, when cast in this form the two Louko-Sorkin conditions, the 0 -form and 1-form acceptability conditions, are:

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\right\}>0 ; \quad \text { and } \quad \operatorname{Im}\left\{\frac{\sqrt{-g_{\epsilon}}}{\lambda_{A}}\right\}>0 \tag{4.21}
\end{equation*}
$$

While we have seen how to interpret the 0 -form and 1-form conditions geometrically, a simple geometric interpretation for the 2 -form condition is trickier.

Recall that from the 1-form condition we had

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}=\sqrt{-g_{L}}\left\{\left(g_{L}\right)^{a b}+i \epsilon h^{a b}\right\} . \tag{4.22}
\end{equation*}
$$

Let us now go to Riemann local coordinates for the Lorentzian metric $\left(g_{L}\right)_{a b}$, then locally we have

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}=\eta^{a b}+i \epsilon \hat{h}^{a b} . \tag{4.23}
\end{equation*}
$$

Here the coordinate transformed $\hat{h}^{a b}$ is still positive definite, and because it is positive definite, it must be of Hawking-Ellis type I, and so can be diagonalized via a local Lorentz transformation. (To check this one merely needs to verify that Hawking-Ellis types II, III, and IV are not positive definite. See for instance [42, 43].)
Thus we can without loss of generality assume $\hat{h}^{a b}$ is diagonal, with positive diagonal entries $h_{A},(A \in\{0, i\})$. Then in this coordinate system, with this choice of basis, we have

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}=\operatorname{diag}\{-1,1,1,1\}+i \epsilon \operatorname{diag}\left\{h_{0}, h_{1}, h_{2}, h_{3}\right\} . \tag{4.24}
\end{equation*}
$$

Note that this manifestly satisfies the 1-form acceptability condition. Furthermore, taking the determinant

$$
\begin{equation*}
g_{\epsilon}=-\left(1-i \epsilon h_{0}\right) \prod_{i=1}^{3}\left(1+i \epsilon h_{i}\right) . \tag{4.25}
\end{equation*}
$$

So

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}=\sqrt{\left(1-i \epsilon h_{0}\right) \prod_{i=1}^{3}\left(1+i \epsilon h_{i}\right)} . \tag{4.26}
\end{equation*}
$$

Then the 0 -form acceptability condition reduces to the nonlinear condition

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{\left(1-i \epsilon h_{0}\right) \prod_{i=1}^{3}\left(1+i \epsilon h_{i}\right)}\right\}>0 \tag{4.27}
\end{equation*}
$$

which constrains the values of $h_{0}$ and the $h_{i}$. If one wishes the 0 -form acceptability condition to hold for all $\epsilon>0$ then in particular it must hold for small $\epsilon$ and so one must demand $h_{0}<\sum_{i=1}^{3} h_{i}$. This is equivalent to demanding $\eta_{a b} h^{a b}>0$.

Furthermore the eigenvalues of $\left(g_{\epsilon}\right)_{a b}$ are then

$$
\begin{equation*}
-\frac{\sqrt{-g_{\epsilon}}}{1-i \epsilon h_{0}} ; \quad \frac{\sqrt{-g_{\epsilon}}}{1+i \epsilon h_{i}} ; \tag{4.28}
\end{equation*}
$$

and the 2 -form acceptability conditions deduce to

$$
\begin{equation*}
\operatorname{Im}\left\{-\frac{\left(1-i \epsilon h_{0}\right)\left(1+i \epsilon h_{j}\right)}{\sqrt{-g_{\epsilon}}}\right\}>0 ; \quad \operatorname{Im}\left\{\frac{\left(1+i \epsilon h_{j}\right)\left(1+i \epsilon h_{k}\right)}{\sqrt{-g_{\epsilon}}}\right\}>0 . \tag{4.29}
\end{equation*}
$$

Here $j \neq k$.

But then, given our explicit formula for $g_{\epsilon}$, this can be rewritten as

$$
\begin{equation*}
\operatorname{Im}\left\{-\sqrt{\frac{\left(1-i \epsilon h_{0}\right)\left(1+i \epsilon h_{j}\right)}{\left(1+i \epsilon h_{k}\right)\left(1+i \epsilon h_{l}\right)}}\right\}>0 ; \quad \operatorname{Im}\left\{\sqrt{\frac{\left(1+i \epsilon h_{j}\right)\left(1+i \epsilon h_{k}\right)}{\left(1-i \epsilon h_{0}\right)\left(1+i \epsilon h_{l}\right)}}\right\}>0, \tag{4.30}
\end{equation*}
$$

where the indices $j, k$, and $l$ must all be distinct. We can also write this as

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{\frac{\left(1+i \epsilon h_{0}\right)\left(1-i \epsilon h_{j}\right)}{\left(1-i \epsilon h_{k}\right)\left(1-i \epsilon h_{l}\right)}}\right\}>0 ; \quad \operatorname{Im}\left\{\sqrt{\frac{\left(1+i \epsilon h_{j}\right)\left(1+i \epsilon h_{k}\right)}{\left(1-i \epsilon h_{0}\right)\left(1+i \epsilon h_{l}\right)}}\right\}>0 \tag{4.31}
\end{equation*}
$$

Using the identity

$$
\begin{equation*}
\frac{1}{1 \pm i \epsilon h_{A}}=\frac{1 \mp i \epsilon h_{A}}{1+\epsilon^{2} h_{A}^{2}} \propto 1 \mp i \epsilon h_{A} \tag{4.32}
\end{equation*}
$$

and rearranging some indices, the two conditions in (4.31) actually collapse to one nonlinear constraint:

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{\left(1+i \epsilon h_{0}\right)\left(1+i \epsilon h_{j}\right)\left(1+i \epsilon h_{k}\right)\left(1-i \epsilon h_{l}\right)}\right\}>0 \tag{4.33}
\end{equation*}
$$

where the indices $j, k$, and $l$ must all be distinct. Overall, the compatibility conditions now reduce to the statement that $h_{0}$ and the $h_{i}$ are all positive, and are subject to the constraints (4.27) and (4.33).

One obvious solution to these acceptability constraints is $h_{0}=h_{i}=1$ with $\epsilon>0$. That is $\hat{h}^{a b}=\delta^{a b}$, whence after trace reversal $\overline{h^{a b}}=\operatorname{diag}\{2,0,0,0\}$. But this just corresponds to $\left(g_{\epsilon}\right)_{a b}=\eta_{a b}+i \epsilon V_{a} V_{b}$, which is where we started the discussion but now we see that this object also satisfies the 2 -form acceptability condition. There are also many other solutions to the acceptability conditions. For instance, in the symmetric case $h_{i}=h_{\text {space }}$, taking $h_{0}<3 h_{\text {space }}$ with $\epsilon>0$ also satisfies these constraints.

Subject to these nonlinear constraints on the $h_{A}$, where $A \in\{0, i\}$, for a suitable tetrad $e_{A}{ }^{a}$ we now have $\hat{h}^{a b}=\sum_{A=0}^{3} h_{A} e_{A}{ }^{a} e_{A}{ }^{b}$, which is manifestly positive definite. This quantity can then be inserted into (4.23), to recreate $\left(g_{\epsilon}\right)_{a b}$ in the Riemann normal coordinate system, and thus, via (4.22), implicitly recreate the metric $\left(g_{\epsilon}\right)_{a b}$ in an arbitrary coordinate system. Overall at this stage we have a somewhat tedious set of nonlinear constraints on the $h^{a b}$, which in principle will fully characterize the allowable complex metrics $\left(g_{\epsilon}\right)_{a b}$. (These nonlinear constraints simplify considerably in the small- $\epsilon$ limit, and furthermore, we shall then introduce a variant of the tetrad formalism to effectively linearize them in general.)

### 4.3.2 Small $\epsilon$

If we want the 2 -form constraints to hold for all $\epsilon>0$, then in particular for small $\epsilon$ we must demand $h_{0}+\sum_{i} h_{i}>2 h_{j}$, in addition to the 0 -form result that $h_{0}<\sum_{i} h_{i}$. That is, for $\epsilon \rightarrow 0^{+}$the 2 -form and 0 -form constraints reduce to

$$
\begin{equation*}
h_{0}+\sum_{i} h_{i}>2 h_{j} ; \quad \quad h_{0}<\sum_{i} h_{i} . \tag{4.34}
\end{equation*}
$$

This can be rewritten as

$$
\begin{equation*}
h_{A}<\frac{1}{2} \sum_{B} h_{B} . \tag{4.35}
\end{equation*}
$$

If we now define $\langle h\rangle=\frac{1}{4} \sum_{B} h_{B}$, then between the positivity constraint and the 0 -form and 2 -form constraints we have

$$
\begin{equation*}
0<h_{A}<2\langle h\rangle, \tag{4.36}
\end{equation*}
$$

or equivalently

$$
\begin{equation*}
\left|h_{A}-\langle h\rangle\right|<\langle h\rangle \tag{4.37}
\end{equation*}
$$

We again have $\hat{h}^{a b}=\sum_{A=0}^{3} h_{A} e_{A}{ }^{a} e_{A}{ }^{b}$. Thence, for small $\epsilon$ the matrix $h_{a b}$ is not just positive definite, but once the 0 -form and 2 -form constraints are taken into account, has very tightly interrelated eigenvalues - $h_{a b}$ cannot deviate too far from a multiple $\langle h\rangle \delta_{a b}$ of the identity matrix. This now guarantees that there will at the very least be some finite interval $\epsilon \in\left(0, \epsilon_{*}\right)$ over which the all of the acceptability conditions are satisfied. Sometimes, as in the examples given at the end of the previous subsection, this can be extended to the entire positive half line $\epsilon \in(0, \infty)$.

### 4.4 Rephrasing the construction in terms of the tetrad formalism

Let us recast this generalized construction in terms of the tetrad formalism. As for the simplified construction, let $e_{A}{ }^{a}(x)$ denote an arbitrary (not necessarily orthonormal) tetrad; the co-tetrad $e^{A}{ }_{a}(x)$ is simply the matrix inverse of $e_{A}{ }^{a}(x)$.

Now let $\theta_{A}(x)$ be any four smooth functions bounded by $0<\theta_{A}(x)<\pi / 4$. The variables $\theta_{A}$ are effectively a nonlinear way of encoding the parameter $\epsilon$ via the relations $\theta_{A}=\arctan \left(\epsilon h_{A}\right)$, we shall soon see why this is worthwhile. Define

$$
\begin{equation*}
\theta_{A B}=\operatorname{diag}\left\{\theta_{A}\right\}, \tag{4.38}
\end{equation*}
$$

and the corresponding trace-reversed quantities

$$
\begin{equation*}
\bar{\theta}_{A B}=\operatorname{diag}\left\{\bar{\theta}_{A}\right\}=\theta_{A B}-\frac{1}{2} \eta_{A B}\left(\eta^{C D} \theta_{C D}\right) \tag{4.39}
\end{equation*}
$$

Then $\overline{\bar{\theta}}_{A B}=\theta_{A B}$, trace-reversal is an involution.
Explicitly

$$
\begin{gather*}
\bar{\theta}_{0}=\frac{1}{2}\left(\theta_{0}+\sum_{i=1}^{3} \theta_{i}\right) ;  \tag{4.40}\\
\bar{\theta}_{i}=\frac{1}{2}\left(\theta_{i}+\theta_{0}-\sum_{j \neq i} \theta_{i}\right) . \tag{4.41}
\end{gather*}
$$

Now define the matrix

$$
\begin{equation*}
\left(\eta_{\bar{\theta}}\right)_{A B}=\operatorname{diag}\left\{-\exp \left(+i 2 \bar{\theta}_{0}(x)\right) ; \quad \exp \left(-i 2 \bar{\theta}_{i}(x)\right)\right\} ; \tag{4.42}
\end{equation*}
$$

and its matrix inverse

$$
\begin{equation*}
\left(\eta_{\bar{\theta}}\right)^{A B}=\operatorname{diag}\left\{-\exp \left(-i 2 \bar{\theta}_{0}(x)\right) \exp \left(+i 2 \bar{\theta}_{i}(x)\right)\right\} \tag{4.43}
\end{equation*}
$$

Construct the complex metric

$$
\begin{align*}
\left(g_{\theta}\right)_{a b} & =\left(\eta_{\bar{\theta}}\right)_{A B} e^{i}{ }_{A}(x) e^{B}{ }_{b}(x)  \tag{4.44}\\
& =-\exp \left(+i 2 \bar{\theta}_{0}(x)\right) e^{0}{ }_{a}(x) e^{0}{ }_{b}(x)+\sum_{i=1}^{3} \exp \left(-i 2 \bar{\theta}_{i}(x)\right) e^{i}{ }_{a}(x) e^{i}{ }_{b}(x) . \tag{4.45}
\end{align*}
$$

Then the inverse metric is

$$
\begin{align*}
\left(g_{\theta}\right)^{a b} & =\left(\eta_{\bar{\theta}}\right)_{A B} e_{A}{ }^{a}(x) e_{B}{ }^{b}(x)  \tag{4.46}\\
& =-\exp \left(-i 2 \bar{\theta}_{0}(x)\right) e_{0}{ }^{a}(x) e_{0}^{b}(x)+\sum_{i=1}^{3} \exp \left(+i 2 \bar{\theta}_{i}(x)\right) e_{i}^{a}(x) e_{i}^{b}(x) \tag{4.47}
\end{align*}
$$

Note that $\sqrt{-\operatorname{det}\left(g_{\theta}\right)}=\exp \left(-i \eta^{A B} \bar{\theta}_{A B}\right)=\exp \left(+i \eta^{A B} \theta_{A B}\right)$ and thence

$$
\begin{align*}
\sqrt{-\operatorname{det}\left(g_{\theta}\right)}\left(g_{\theta}\right)^{a b} & =\exp \left(-i \eta^{C D} \bar{\theta}_{C D}\right)\left(\eta_{\bar{\theta}}\right)_{A B} e_{A}^{a}(x) e_{B}{ }^{b}(x)  \tag{4.48}\\
& =-\exp \left(-2 i \theta_{0}(x)\right) e_{0}{ }^{a}(x) e_{0}{ }^{b}(x)+\sum_{i=1}^{3} \exp \left(+2 i \theta_{i}(x)\right) e_{i}^{a}(x) e_{i}^{b}(x) . \tag{4.49}
\end{align*}
$$

(Carefully note that due to a subtle combination of phases, it is the $\theta_{A}$, not the $\bar{\theta}_{A}$, that finally occur in the expression (4.49) for the tensor density $\sqrt{-\operatorname{det}\left(g_{\theta}\right)}\left(g_{\theta}\right)^{a b}$. .)

The corresponding Lorentzian and Euclidean metrics are given by

$$
\begin{equation*}
\sqrt{-g_{L}}\left(g_{L}\right)^{a b}=\left\{-\cos \left[2 \theta_{0}(x)\right] e_{0}{ }^{a}(x) e_{0}{ }^{b}(x)+\sum_{i=1}^{3} \cos \left[2 \theta_{i}(x)\right] e_{i}^{a}(x) e_{i}^{b}(x)\right\}, \tag{4.50}
\end{equation*}
$$

and

$$
\begin{equation*}
\sqrt{-g_{E}}\left(g_{E}\right)^{a b}=\left\{+\sin \left[2 \theta_{0}(x)\right] e_{0}{ }^{a}(x) e_{0}{ }^{b}(x)+\sum_{i=1}^{3} \sin \left[2 \theta_{i}(x)\right] e_{i}{ }^{a}(x) e_{i}{ }^{b}(x)\right\} . \tag{4.51}
\end{equation*}
$$

We note that:

- This construction satisfies the 1-form acceptability condition if and only if we have $\theta_{A} \in(0, \pi / 4)$.
- This construction satisfies the 0 -form acceptability condition if and only if we have $\eta^{A B} \theta_{A B}>0$, implying $\theta_{0}<\sum_{i=1}^{3} \theta_{i}$.
- Finally, the construction satisfies the 2-form acceptability condition if and only if in terms of the eigenvalues $\lambda_{A}$ of $\left(g_{\theta}\right)_{a b}$ we have

$$
\begin{equation*}
\operatorname{Im}\left\{\frac{\sqrt{-g_{\theta}}}{\lambda_{A} \lambda_{B}}\right\}>0 ; \quad(A \neq B) \tag{4.52}
\end{equation*}
$$

But in terms of the $\theta_{A}$ variables, suitably modifying the discussion of the previous subsection, this now translates to the bound

$$
\begin{equation*}
\theta_{A}<\frac{1}{2} \sum_{B} \theta_{B} . \tag{4.53}
\end{equation*}
$$

Between the positivity (1-form) and the above (0-form plus 2-form) acceptability conditions we have

$$
\begin{equation*}
0<\theta_{A}<\frac{1}{2} \sum_{B} \theta_{B}<\pi / 2 . \tag{4.54}
\end{equation*}
$$

We note

$$
\begin{equation*}
\sum_{B} \theta_{B}=\sum_{B} \bar{\theta}_{B}-\left(-\bar{\theta}_{0}+\sum_{i} \bar{\theta}_{i}\right)=2 \bar{\theta}_{0} . \tag{4.55}
\end{equation*}
$$

For the $\bar{\theta}_{A}$ this leads to the less symmetrical looking conditions ${ }^{2}$

$$
\begin{equation*}
0<\bar{\theta}_{0}=\frac{1}{2} \sum_{B} \theta_{B}<\pi / 2 ; \quad\left|\bar{\theta}_{i}\right|<\min \left\{\bar{\theta}_{0}, \pi / 4\right\} \tag{4.56}
\end{equation*}
$$

[^1]This construction now yields the most general class of complex metrics satisfying the compatibility conditions. By adopting the tetrad formalism, we have managed to construct a complete and comprehensive classification of all the complex metrics satisfying the (4-dimensional) compatibility conditions.

## 5 Fluctuating spacetime geometries

When one wants to include fluctuating spacetime geometries in the functional integral the situation becomes much messier. Fundamentally one is interested in

$$
\begin{equation*}
Z_{L}=\int \mathcal{D} g_{L} \exp \left(-i S\left(g_{L}\right)\right) \tag{5.1}
\end{equation*}
$$

But to make the functional integral more plausibly convergent it seems better to integrate over Euclidean geometries:

$$
\begin{equation*}
Z_{E}=\int \mathcal{D} g_{E} \exp \left(S\left(g_{E}\right)\right) \tag{5.2}
\end{equation*}
$$

For an overview of the standard point of view in Euclidean quantum gravity see references [44, 45]. For some early work see [46]. For rather recent developments see $[15,16,47]$. For slightly heterodox points of view see [48, 49], and [27, page 69]. See also the "causal dynamical triangulation" programme [50-54].

The heterodoxy has to do with selecting a priori constraints on the configuration space of Euclidian geometries to functionally integrate over - the partition function seems to be much better behaved when one integrates only over those Euclidean geometries that are compatible with the existence of a Lorentzian signature metric [48-54].

Note that our central result for allowable complex metrics, either in the symmetric form

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}=\sqrt{-g_{L}}\left(g_{L}\right)^{a b}+i \epsilon \sqrt{g_{E}}\left(g_{E}\right)^{a b} \tag{5.3}
\end{equation*}
$$

or in the asymmetric form

$$
\begin{equation*}
\left(g_{\epsilon}\right)^{a b}=\frac{\left(g_{L}\right)^{a b}+i \epsilon h^{a b}}{\sqrt{\operatorname{det}\left\{\delta_{c}^{e}+i \epsilon\left(g_{L}\right)_{c d} h^{d e}\right\}}}, \tag{5.4}
\end{equation*}
$$

will automatically force us to work only with those manifolds that are compatible with the existence of a Lorentzian signature metric.

One may wish to add additional constraints on the configuration space of Lorentzian metrics $\left(g_{L}\right)_{a n}$. Stable causality? Global hyperbolicity? Fixed topological structure? Unimodular (more precisely, fixed modulus) gravity? There is a veritable multitude of possible choices, but any such choices should be constrained by the explicit versions of the Louko-Sorkin and Kontsevich-Segal-Witten acceptability conditions derived above.

## 6 Conclusions

We have developed several fully explicit versions of the Louko-Sorkin (0-form and 1-form) and Kontsevich-Segal-Witten (2-form) acceptability conditions for complex metrics on spacetime. We have back-tracked the derivation of these acceptability conditions to the fundamental physics of Feynman's $i \epsilon$ prescription, which we used to justify the notion of an "almost real" spacetime metric.

These "almost real" metrics can then be extended to more general settings, where the complex metric is explicitly given in terms of the underlying Lorentzian metric, (the physical metric), and a positive-definite auxiliary tensor, which can be viewed as being proportional to a Euclidean metric.

We then provided a tetrad construction explicitly codifying the set of all acceptable complex metric. Finally we briefly discuss the implications for the functional integral over spacetime geometries, and in the appendix provide a specific example of how the acceptability conditions can fail, even for finite-action solutions to the classical field equations.

## A Example: Explicit physically unacceptable complex metric

It is worthwhile to give a specific and fully explicit example of a complex metric that is not "acceptable", and does not satisfy the Louko-Sorkin conditions. Based on the construction given by Witten [16], consider the specific metric

$$
\begin{equation*}
\mathrm{d} s^{2}=-\mathrm{d} t^{2}+\left(1+i \frac{\mathrm{~d} \epsilon(r)}{\mathrm{d} r}\right)^{2} \mathrm{~d} r^{2}+(r+i \epsilon(r))^{2} \mathrm{~d}^{2} \Omega \tag{A.1}
\end{equation*}
$$

Here $\epsilon(r)$ is an even function of $r$ defined on the entire real line, with $\epsilon(r)=0$ for $|r|>a$ and $\epsilon(r)>0$ for $|r|<a$. For all $r$ this geometry is Riemann flat, ${ }^{3}$ so it solves the (complex) Einstein equations. For $|r|>a$ one simply has two portions of Minkowski space, with the usual $(-+++)$ signature. So this is a wormhole geometry - it is however not a Lorentzian (traversable) wormhole geometry, but is instead a "complexified" wormhole geometry.

[^2]At the throat ( $r=0$ ) we have by the assumption of evenness enforced $\mathrm{d} \epsilon / \mathrm{d} r \rightarrow 0$ so the signature there is (-+--), there are 3 "time" directions. In the regions $r \in(0, a)$ and $r \in(-a, 0)$ the geometry is explicitly complex and the usual notion of signature makes little to no sense. So we should expect this geometry to be pathological.

Indeed we have

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}=\left(1+i \frac{\mathrm{~d} \epsilon(r)}{\mathrm{d} r}\right)(r+i \epsilon(r))^{2} \sin \theta=\frac{1}{3} \frac{\mathrm{~d}}{\mathrm{~d} r}\left[(r+i \epsilon(r))^{3}\right] \sin \theta . \tag{A.2}
\end{equation*}
$$

Thence

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\right\}=\left\{\frac{\mathrm{d} \epsilon(r)}{\mathrm{d} r}\left(r^{2}-\epsilon(r)^{2}\right)+2 r \epsilon(r)\right\} \sin \theta \tag{A.3}
\end{equation*}
$$

But this is an odd function of $r$. So the Louko-Sorkin determinant condition (the 0 -form condition) must be violated somewhere in the interval ( $-a, a$ ). If it is satisfied at $+r$ it will be violated at $-r$ and vice versa.

The second Louko-Sorkin matrix condition (the 1-form condition) now amounts to investigating the matrix

$$
\begin{align*}
\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{a b}=(1 & \left.+i \frac{\mathrm{~d} \epsilon(r)}{\mathrm{d} r}\right)(r+i \epsilon(r))^{2} \sin \theta \\
& \times\left[\begin{array}{cccc}
-1 & 0 & 0 & 0 \\
0 & \left(1+i \frac{\mathrm{~d} \epsilon(r)}{\mathrm{d} r}\right)^{-2} & 0 & 0 \\
0 & 0 & (r+i \epsilon(r))^{-2} & 0 \\
0 & 0 & 0 & \frac{(r+i \epsilon(r))^{-2}}{\sin ^{2} \theta}
\end{array}\right] . \tag{A.4}
\end{align*}
$$

Concentrate on the $t t$ part of the tensor density:

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{t t}=-\sqrt{-g_{\epsilon}} . \tag{A.5}
\end{equation*}
$$

Thence

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{t t}\right\}=-\operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\right\} . \tag{A.6}
\end{equation*}
$$

But this is incompatible with the first Louko-Sorkin condition. Indeed we have already seen that this quantity is odd. So the second Louko-Sorkin condition is also violated somewhere in the interval $(-a, a)$.

We mention in passing that in any ultra-static spacetime (block diagonal metric, with $g_{t t}=-1$ ) the two Louko-Sorkin conditions are incompatible with each other, so no calculation was actually needed.

Furthermore, consider the angular parts of the tensor density. For example

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{\theta \theta}=\left(1+i \frac{\mathrm{~d} \epsilon(r)}{\mathrm{d} r}\right) \sin \theta . \tag{A.7}
\end{equation*}
$$

Whence

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{\theta \theta}\right\}=\frac{\mathrm{d} \epsilon(r)}{\mathrm{d} r} \sin \theta \tag{A.8}
\end{equation*}
$$

But this is again an odd function of $r$. So again the second Louko-Sorkin condition is violated somewhere in the interval $(-a, a)$.

Similarly

$$
\begin{equation*}
\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{\phi \phi}=\frac{1+i \frac{\mathrm{~d} \epsilon(r)}{\mathrm{d} r}}{\sin \theta} . \tag{A.9}
\end{equation*}
$$

Whence

$$
\begin{equation*}
\operatorname{Im}\left\{\sqrt{-g_{\epsilon}}\left(g_{\epsilon}\right)^{\phi \phi}\right\}=\frac{1}{\sin \theta} \frac{\mathrm{~d} \epsilon(r)}{\mathrm{d} r} . \tag{A.10}
\end{equation*}
$$

But this is again an odd function of $r$. So again the second Louko-Sorkin condition is violated.

Consequently curved-space QFT on this particular complex wormhole background will exhibit uncontrolled anti-damping in the functional integral, and so this background should be rejected as physically unacceptable. Despite the fact that this geometry is a zero-action classical solution of the Einstein equations, this geometry should not be used as a saddle point in the functional integral.

[^0]:    ${ }^{1}$ And if you try to Wick rotate first, there are other issues to deal with. Yes, the phases are now all real, but once one is in Euclidean signature the spacelike/timelike/null distinction no longer applies, and NEC/WEC/SEC/DEC are either ill-defined or all collapse to the SEC [23]. Furthermore you would still need to renormalize, and the implied subtraction process could easily vitiate the WEC for $\left\langle T^{a b}(\eta, \phi)\right\rangle$.

[^1]:    ${ }^{2}$ Note this is compatible with the first simplified example we considered, where with current normalization one has $\theta_{A B}=\theta \delta_{A B}$, with $0<\theta<\pi / 4$, while $\bar{\theta}_{A B}=\operatorname{diag}\{2 \theta, 0,0,0\}$.

[^2]:    ${ }^{3}$ Consider the coordinate $\tilde{r}=r+i \epsilon(r)$.
