# Quasitoposes as elementary quotient completions 

Maria Emilia Maietti*<br>Fabio Pasquali ${ }^{\dagger}$ Giuseppe Rosolini ${ }^{\ddagger}$

#### Abstract

The elementary quotient completion of an elementary doctrine in the sense of Lawvere was introduced in previous work by the first and third authors. It generalises the exact completion of a category with finite products and weak equalisers. In this paper we characterise when an elementary quotient completion is a quasitopos. We obtain as a corollary a complete characterisation of when an elementary quotient completions is an elementary topos. As a byproduct we determine also when the elementary quotient completion of a tripos is equivalent to the doctrine obtained via the tripos-to-topos construction.

Our results are reminiscent of other works regarding exact completions and put those under a common scheme: in particular, Carboni and Vitale's characterisation of exact completions in terms of their projective objects, Carboni and Rosolini's characterisation of locally cartesian closed exact completions, also in the revision by Emmenegger, and Menni's characterisation of the exact completions which are elementary toposes.

The paper contains results presented by the authors at several international meetings in the past years, in particular at Logic Colloquium 2016 and Category Theory 2017, and during the Trimester devoted to Types, Homotopy Type Theory and Verification at the Hausdorff research Institute for Mathematics in 2018. We would like to thank the organisers of these events who gave us the opportunity to present our results.

## 1 Introduction

The study of constructions for completing a category with quotients is a central topic not only in mathematics but also in computer science. In category theory a well-known related notion is that of exact completion of a category with finite limits, and that of a regular category, see CC82, CV98, which has been widely studied and applied.

In MR13b the first and third authors generalized the notion of exact completion on a category with weak finite limits to that of an elementary quotient completion of a Lawvere's elementary doctrine Law69, Law70 as an universal construction to close such a doctrine with respect to a suitable notion of quotient.

The exact completion of a category $\mathcal{C}$ with finite products and weak limits is an instance of such a construction in the sense that its subobject doctrine is the elementary quotient completion doctrine of the doctrine of variations of $\mathcal{C}$ Gra00.

In the paper we study elementary quotient completions performed on the special class of Lawvere's elementary doctrines called triposes, introduced in HJP80, to build elementary toposes by means of what is now known as the tripos-to-topos construction, see Fre15. We then characterize those triposes whose elementary quotient completion is an arithmetic quasitopos-i.e. a quasitopos equipped with a natural number object-as base category.

To obtain the characterization, we extend some known results about exact completions such as Carboni and Vitale's characterization of exact completions in terms of its projective objects in CV98, Menni's characterization of the exact completions which are toposes in Men03 and Carboni and Rosolini's characterization of the locally cartesian closed exact completions CR00. In particular, we show that

- an elementary doctrine $P: \mathbb{C}^{o p} \longrightarrow$ InfSL closed under effective quotients is the elementary quotient completion of the doctrine determined by the restriction of $P$ to the full subcategory of $\mathbb{C}$ on its projective objects;
- the base category of the elementary quotient completion of $P$ turns weak universal properties of $\mathbb{C}$ into (strong) universal properties of the base of the elementary quotient completion. Those include binary coproducts, a natural number object, a parametrized list object, a subobject classifier, a cartesian closed structure, a locally cartesian structure.
- by using results in MR16 we characterize when an elementary quotient completion is an elementary topos;
- by using results in MPR17 we characterize when an elementary quotient completion is a tripos-to-topos construction.

We conclude by pointing out some relevant examples of arithmetic quasitoposes arising as non-exact elementary quotient completions. Most notably they include the category of equilogical spaces of Sco76, Sco96, BBS04, that of assemblies over a partial combinatory algebra (see Hyl82, vO08), and the category of total setoids, in the style of E. Bishop, over Coquand and Paulin's Calculus of Inductive Constructions which is the theory at the base of the proof-assistant Coq.

## 2 Preliminary definitions on doctrines and completions

This section collects the necessary definitions to introduce the elementary quotient completion of an elementary doctrine and related properties of a doctrine. Recall from MR13a, see also EPR20, that:
2.1 Definition. A primary doctrine is an indexed inf-semilattice $P: \mathcal{C}^{\mathrm{OP}} \longrightarrow$ ISL where $\mathcal{C}$ is a category with a terminal object $T$ and with binary products

$$
C_{1} \stackrel{\mathrm{pr}_{1}}{\longleftrightarrow} C_{1} \times C_{2} \xrightarrow{\mathrm{pr}_{2}} C_{2}
$$

The category $\mathcal{C}$ is often called base of the doctrine. We say that $\alpha$ is over $A$ if $\alpha$ is an element of $P(A)$. The top element over an object $A$ of $\mathcal{C}$ is denoted by $\top_{A}$. Given $\alpha$ and $\beta$ over $A$, their meet is $\alpha \wedge_{A} \beta$ (we may drop subscripts when these are clear from the context).

We write $A \times B \times C$ for an arbitrary finite product with factors $A, B$ and $C$.
2.2 Examples. (a) An example of primary doctrine comes directly from first order logic is the Lindenbaum-Tarski algebras of well-formed formulas of a theory $\mathscr{T}$ over a first order language $\mathscr{L}$. The base category is the category $\mathcal{V}$ of lists of distinct variables and term substitutions, and the primary doctrine $L T: \mathcal{V}^{\mathrm{op}} \longrightarrow$ ISL on $\mathcal{V}$ is given on a list of variables $\vec{x}$ by taking $L T(\vec{x})$ as the Lindenbaum-Tarski algebra of well-formed formulas with free variables in
$\vec{x}$. Meets in $\operatorname{LT}(\vec{x})$ are given by conjunctions while the top element by any true formula. See MR13a for more details.
(b) Let $\mathcal{H}$ be an inf-semilattice. The functor $\mathcal{P}_{\mathcal{H}}:$ Set $^{\mathrm{op}} \longrightarrow$ ISL sending a set $A$ to $\mathcal{H}^{A}$ and a function $f: A \rightarrow B$ to $\mathcal{P}_{\mathcal{H}}(f)=-\circ f$ is a primary doctrine.
(c) If $\mathcal{C}$ has finite limits the functor $\mathrm{Sub}_{\mathcal{C}}: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL is a primary doctrine.
(d) Another categorical example is given by a category $\mathcal{C}$ with binary products and weak pullbacks, by defining the doctrine functor of variations $\Psi_{C}: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL which evaluates as the poset reflection of each comma category $\mathcal{C} / A$ at each object $A$ of $\mathcal{C}$, introduced in Gra00.
2.3 Definition. Primary doctrines are the objects of the 2-category PD where
the 1-morphisms in PD are pairs $(F, b)$ where $F: \mathcal{C} \rightarrow \mathcal{D}$ is a functor and $b: P \stackrel{\rightarrow}{\rightarrow} R \circ F^{\mathrm{op}}$ is a natural transformation as in the diagram

where the functor $F$ preserves products
the $\mathbf{2}$-morphisms are natural transformations $\theta: F \dot{\rightarrow} G$ such that
so that, for every $A$ in $C$ and every $\alpha$ in $P(A)$, one has $b_{A}(\alpha) \leq_{F(A)}$ $R_{\theta_{A}}\left(c_{A}(\alpha)\right)$.
2.4 Example. A set-theoretic model for a first order theory $\mathscr{T}$ an 1-arrow from $L T: \mathcal{V}^{\mathrm{op}} \longrightarrow$ ISL to $\operatorname{Sub}_{\mathcal{S e t}: \operatorname{Set}^{\mathrm{op}} \longrightarrow \text { ISL in ED. And a homomorphism }}$ between two set-theoretic models of $\mathscr{T}$ determines a 2 -arrow.

Given a doctrine $P: \mathcal{C}^{\mathrm{op}} \longrightarrow \mathbf{I S L}$, a category $\mathcal{D}$ with finite products and a functor $F: \mathcal{D} \longrightarrow \mathcal{C}$ that preserves products, the composition of $P$ with $F^{\mathrm{op}}: \mathcal{D}^{\mathrm{op}} \rightarrow$ $\mathcal{C}^{\mathrm{op}}$ gives a doctrine $P F^{\mathrm{op}}: \mathcal{D}^{\mathrm{op}} \longrightarrow$ ISL called change of base of $P$ along $F$.
2.5 Definition. An elementary doctrine on $\mathcal{C}$ is a primary doctrine $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL such that for every object $A$ in $\mathcal{C}$, there is an object $\delta_{A}$ over $A \times A$ such that for every arrow $e$ of the form $\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{2}, \mathrm{pr}_{2}\right\rangle: X \times A \rightarrow X \times A \times A$ in $\mathcal{C}$, the assignment

$$
\mathcal{H}_{e}(\alpha):=P_{\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{2}\right\rangle}(\alpha) \wedge_{X \times A \times A} P_{\left\langle\mathrm{pr}_{2}, \mathrm{pr}_{3}\right\rangle}\left(\delta_{A}\right)
$$

for $\alpha$ in $P(X \times A)$ determines a left adjoint to

$$
P_{e}: P(X \times A \times A) \rightarrow P(X \times A)
$$

It follows that the assignment

$$
\mathcal{H}_{\left\langle\mathrm{id}_{A}, \mathrm{id}_{A}\right\rangle}(\alpha):=P_{\mathrm{pr}_{1}}(\alpha) \wedge_{A \times A} \delta_{A}
$$

for $\alpha$ in $P(A)$ determines a left adjoint to

$$
P_{\left\langle\operatorname{id}_{A}, \mathrm{id}_{A}\right\rangle}: P(A \times A) \longrightarrow P(A)
$$

This means that $\delta_{A}$ is determined uniquely for each object $A$ in $C$ and hence we will refert to $\delta_{A}$ as the fibered equality on $A$.
2.6 Definition. An elementary doctrine $P: \mathcal{C}^{\text {op }} \longrightarrow$ ISL is said to be extensional if for every pair of parallel arrows $f, g: X \longrightarrow A$ in $\mathcal{C}$ it holds that $f=g$ if and only if $\top_{X}=P_{\langle f, g\rangle}\left(\delta_{A}\right)$.

The change of base of an elementary doctrine is again elementary, but the new elementary doctrine might fail to be extensional.
2.7 Examples. (a) Consider a theory $\mathscr{T}$ over a first order language $\mathscr{L}$ and the associated primary doctrine $L T: \mathcal{V}^{\mathrm{op}} \longrightarrow$ ISL as in Example 2.2 (a). The doctrine $L T$ is elementary if and only the equality is definable in $\mathscr{T}$.
(b) Let $\mathcal{H}$ be an inf-semilattice. The primary doctrine $\mathcal{P}_{\mathcal{H}}: S e t^{\mathrm{op}} \longrightarrow$ ISL as in Example 2.2 (b) is elementary if and only if $\mathcal{H}$ has a bottom element (see EPR20). In this case $\delta_{A}$ is the function that maps ( $a, a^{\prime}$ ) to $\top$ if $a=a^{\prime}$ and to $\perp$ otherwise. In this case $\mathcal{P}_{\mathcal{H}}$ has comprehensive diagonals.
(c) Suppose $\mathcal{C}$ has finite limits. The doctrine $\mathrm{Sub}_{C}: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL as in Example 2.2 (c) is elementary with comprehensive diagonals where $\delta_{A}$ is represented by the diagonal on $A$. (d) Suppose $C$ has finite limits and weak pullbacks. The doctrine $\Psi_{C}: C^{\mathrm{op}} \longrightarrow$ ISL as in Example $2.2(\mathrm{~d})$ is elementary with comprehensive diagonals where $\delta_{A}$ is represented by the diagonal on $A$.
2.8 Definition. Elementary doctrines are the object of ED, the 2-full subcategory PD whose 1-morphisms are those 1-morphism $(F, b): P \rightarrow R$ of PD such that for every object $A$ in $\mathcal{C}$, the functor $b_{A}: P(A) \longrightarrow R(F(A))$ commutes with the left adjoints

where $e$ is $\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{2}, \mathrm{pr}_{2}\right\rangle: X \times A \rightarrow X \times A \times A$ and $e^{\prime}$ is $\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{2}, \mathrm{pr}_{2}\right\rangle: F X \times F A \rightarrow$ $F X \times F A \times F A$.

We recall from MR13a that it is possible to add comprehensive diagonals to an elementary doctrine $P: C^{\text {op }} \longrightarrow$ ISL as follows.
2.9 Definition. Consider the category $X_{P}$, the "extensional collapse" of $P$ whose objects are are the objects of $\mathcal{C}$ and where an arrow $[f]: A \longrightarrow B$ is an equivalence class of morphisms $f: A \rightarrow B$ in $\mathcal{C}$ such that $\delta_{A} \leq_{A \times A} P_{f \times f}\left(\delta_{B}\right)$ in $P(A \times A)$ with respect to the equivalence which relates $f$ and $f^{\prime}$ when $\delta_{A} \leq_{A \times A}$ $P_{f \times f^{\prime}}\left(\delta_{B}\right)$. Composition is given by that of $\mathcal{C}$ on representatives, and identities are represented by identities of $\mathcal{C}$. We then define the doctrine $P_{\mathrm{x}}: X_{P}^{\mathrm{op}} \longrightarrow \mathbf{I S L}$ on $X_{P}$ essentially as $P$ itself.
2.10 Definition. Let ExD denote the full subcategory of ED on elementary doctrines with comprehensive diagonals.
2.11 Proposition. There is left biadjoint to the inclusion of ExD into ED which on objects associates the doctrine $P_{\mathrm{x}}:: \mathcal{X}_{P}^{o p} \longrightarrow$ ISL to an elementary doctrine $P: \mathcal{C}^{o p} \longrightarrow$ ISL.
2.12 Definition. An elementary doctrine $P: \mathcal{C}^{\mathrm{op}} \longrightarrow \operatorname{InfSL}$ is existential when, for $A_{1}$ and $A_{2}$ in $\mathcal{C}$, for a(ny) projection $\mathrm{pr}_{i}: A_{1} \times A_{2} \rightarrow A_{i}, i=1,2$, the functor $P_{\mathrm{pr}_{i}}: P\left(A_{i}\right) \rightarrow P\left(A_{1} \times A_{2}\right)$ has a left adjoint $\mathcal{G}_{\mathrm{pr}_{i}}$-we shall call such a left adjoint existential-and those left adjoints satisfy the
Beck-Chevalley Condition: for any pullback diagram

with pr a projection (hence also $\mathrm{pr}^{\prime}$ a projection), for any $\beta$ in $P(X)$, the natural inequality $\mathcal{G}_{\mathrm{pr}^{\prime}} P_{f^{\prime}}(\beta) \leq P_{f} \mathcal{G}_{\mathrm{pr}}(\beta)$ in $P\left(A^{\prime}\right)$ is an identity;

Frobenius Reciprocity: for pr: $X \rightarrow A$ a projection, $\alpha$ in $P(A), \beta$ in $P(X)$, the natural inequality $\mathcal{H}_{\mathrm{pr}}\left(P_{\mathrm{pr}}(\alpha) \wedge \beta\right) \leq \alpha \wedge \mathcal{H}_{\mathrm{pr}}(\beta)$ in $P(A)$ is an identity.
2.13 Examples. (a) Consider a theory $\mathscr{T}$ over a first order language $\mathscr{L}$ and the associated primary doctrine $L T: \mathcal{V}^{\mathrm{op}} \longrightarrow$ ISL as in Example 2.2.(a). The doctrine $L T$ is existential where left adjoints along projections are given by the existential quantification.
(b) Let $\mathcal{H}$ be an inf-semilattice. The primary doctrine $\mathcal{P}_{\mathscr{H}}: \operatorname{Set}^{\mathrm{op}} \longrightarrow$ ISL is existential if and only if $\mathcal{H}$ is a frame (see [EPR20]).
(c) Suppose $\mathcal{C}$ has finite limits. The doctrine $\operatorname{Sub}_{\mathcal{C}}: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL as in Example 2.2-(c) is existential if and only if $\mathcal{C}$ is regular (see Jac99).
(d) Suppose $\mathcal{C}$ has finite limits and weak pullbacks. The doctrine $\Psi_{C}: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL as in Example 2.2.(d) is existential where left adjoint are given by composition.
2.14 Remark. As shown by Lawvere, in an elementary existential doctrine $P: \mathcal{C}^{\text {op }} \longrightarrow$ ISL every map of the form $P_{f}$ has a left adjoint $\mathcal{G}_{f}$. For $f: A \longrightarrow B$ the maps $\mathcal{H}_{f}: P(A) \rightarrow P(B)$ is

$$
\exists_{f}(\alpha):=\mathcal{G}_{\mathrm{pr}_{2}}\left[P_{f \times \mathrm{id}_{B}}\left(\delta_{B}\right) \wedge P_{\mathrm{pr}_{1}}(\alpha)\right]
$$

see also Pit02. Moreover, these left adjoints satisfy the Frobenius Reciprocity in the sense that for every $\beta$ in $P(B)$ it holds $\mathcal{G}_{f}(\alpha) \wedge \beta=\mathcal{G}_{f}\left(\alpha \wedge P_{f}(\beta)\right)$. But they not necessarily satisfy the Beck-Chevalley condition (see MT23 for a contraexample).

This allows to give a quick description of the 2-category EED, which is the 2-full subcategory of ED on those elementary doctrines that are existential with comprehensive diagonals and whose 1-morphisms are those $(F, b): P \rightarrow R$ such that for every $f: X \rightarrow A$ in $C$ the following commute

The full subcategory of EED on those existential elementary doctrines with comprehensive diagonals is EExD.

A primary doctrine $P: \mathcal{C}^{\mathrm{op}} \longrightarrow \mathbf{I n f S L}$ is implicational if, for every object $A$ in $\mathcal{C}$, every $\alpha$ in $P(A)$, the functor $\alpha \wedge-: P(A) \longrightarrow P(A)$ has a right adjoint $\alpha \Rightarrow-: P(A) \rightarrow P(A)$. A primary doctrine $P: \mathcal{C}^{\mathrm{Op}} \longrightarrow \mathbf{I n f S L}$ is disjunctive if every $P(A)$ has finite distributive joins and every $P_{f}$ preserves them. A primary doctrine $P: \mathcal{C}^{\mathrm{op}} \longrightarrow \mathbf{I n f S L}$ is universal if, for $A_{1}$ and $A_{2}$ in $\mathcal{C}$, for a(ny) projection $\mathrm{pr}_{i}: A_{1} \times A_{2} \rightarrow A_{i}, i=1,2$, the functor $P_{\mathrm{pr}_{i}}: P\left(A_{i}\right) \rightarrow P\left(A_{1} \times A_{2}\right)$ has a right adjoint $V_{\mathrm{pr}_{i}}$, and these satisfy the Beck-Chevalley condition: for any pullback diagram

with pr a projection (hence also $\mathrm{pr}^{\prime}$ a projection), for any $\beta$ in $P(X)$, the canonical arrow $P_{f} V_{\mathrm{pr}}(\beta) \leq V_{\mathrm{pr}^{\prime}} P_{f^{\prime}}(\beta)$ in $P\left(A^{\prime}\right)$ is iso.
2.15 Definition. A first order doctrine (f.o.d.) on $\mathcal{C}$ is an existential elementary doctrine $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL which is also implicational, disjunctive and universal.
2.16 Remark. As for left adjoint in Remark 2.14 Lawvere proved that in a first order doctrine $P: \mathcal{C}^{\text {op }} \longrightarrow$ ISL every map of the form $P_{f}$ has a right adjoint $V_{f}$. For $f: A \rightarrow B$ the maps $V_{f}: P(A) \longrightarrow P(B)$ is $V_{f}(\alpha):=V_{\mathrm{pr}_{2}}\left[P_{f \times \mathrm{id}_{B}}\left(\delta_{B}\right) \Rightarrow\right.$ $\left.P_{\mathrm{pr}_{1}}(\alpha)\right]$ see also Pit02.
2.17 Examples. (a) Consider a theory $\mathscr{T}$ over a first order language $\mathscr{L}$ and the associated primary doctrine $L T: \mathcal{V}^{\mathrm{op}} \longrightarrow$ ISL as in Example 2.2-(a). If $\mathscr{L}$ then the doctrine $L T$ is first order. In each fibre joins are given by disjunctions
while the cartesian closure is provided by the implication. Right adjoints are given by universal quantification.
(b) Let $\mathcal{H}$ be a frame. Then it is a complete Heyting algebra. Hence the doctrine $\mathcal{P}_{\mathcal{H}}: \operatorname{Set}^{\mathrm{op}} \longrightarrow$ ISL is first order where in each fibre the Heyting algebra operations are computed point-wise and right adjoint are give by arbitrary infima (see Pit02 for details).
(c) Suppose $\mathcal{C}$ has finite limits. The doctrine $\mathrm{Sub}_{\mathcal{C}}: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL is first order if and only if $\mathcal{C}$ is an Heyting category (or a logos) in the sense of FS90.
(d) Suppose $\mathcal{C}$ has finite limits. If $\mathcal{C}$ has finite coproducts and is weakly locally cartesian closed, then $\Psi_{C}: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL as in Example 2.2f(d) is first order. We shall se later how to generalise the description to the case in which $\mathcal{C}$ is assumed to have weak pullbacks.

We will often deal with different doctrines on the same base and in several situations one of these is $\Psi_{\mathcal{C}}$, thus we find it convenient to adopt a specific notation to distinguish operations between doctrines and in particular operations in $\Psi_{C}$. We will use the following.
2.18 Notation. We write $\Psi_{C}(f)$ as $f^{*}$. The left adjoint to $f^{*}$ will be denoted by $\Sigma_{f}$. If $f^{*}$ has a right adjoint this will be denoted by $\Pi_{f}$. The equality predicated over $A$ will be denoted by $\left[\left\langle\operatorname{id}_{A}, \operatorname{id}_{A}\right\rangle\right]$. Binary meets in $\Psi_{C}(A)$ will be denoted by $[f] \times_{A}[g]$ while the top element over $A$ will be denoted by $\left[\mathrm{id}_{A}\right]$. Joins will be denoted by $[f]+_{A}[g]$. The bottom element will be $0_{A}$. We will freely confuse a class with any of its representatives.
2.19 Definition. Let $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL a primary doctrine. An object $\Omega$ in $\mathcal{C}$ is a weak predicate classifier if there is an element $\epsilon_{1}$ over $\Omega$ such that for every $\phi$ in $P(A)$ there is a (not necessarily unique) morphism $\chi_{\phi}: A \longrightarrow \Omega$ satisfying $P_{\chi_{\phi}}\left(\epsilon_{1}\right)=\phi$.
$P$ has a strong predicate classifier, or simply a predicate classifier if it has a weak predicate classifier and arrows of the form $\chi_{\phi}$ are unique.
$P$ has weak power objects if for every $\mathcal{C}$-object $A$ there exists an object $\mathbb{P} A$ in $C$ and an object $\epsilon_{A}$ in $P(A \times \mathbb{P} A)$ such that for every $Y$ and relation $\phi$ in $P(A \times Y)$ there is a (not necessarily unique) morphism $\chi_{\phi}: Y \rightarrow \mathbb{P} A$ satisfying $P_{\operatorname{id}_{A} \times \chi_{\phi}}\left(\epsilon_{A}\right)=\phi . P$ has a strong power object if it has a weak power objects and arrows of the form $\chi_{\phi}$ are unique.

Observe the following relation between power objects and predicate classifiers. This is well known when $P$ is $\operatorname{Sub}_{\mathcal{C}}$ for a finite limit category $\mathcal{C}$ and it can be proved analogously for a generic $P$ :
2.20 Proposition. If $P$ as (weak) power objects, then it has also a (weak) predicate classifier (it suffices to choose $\mathbb{P} 1$ as $\Omega$ ). Moreover, if the base $\mathcal{C}$ is weakly cartesian closed, then $P$ has a (weak) predicate classifier if and only if it has (weak) power objects, where $\mathbb{P} A$ can be chosen as the weak exponential of $\Omega$ to the power of $A$.
2.21 Examples. (a) The doctrine $L T: \mathcal{V}^{\text {op }} \longrightarrow$ ISL built out of a theory $\mathscr{T}$ over a first order language $\mathscr{L}$ has no predicate classifiers.
(b) Let $\mathcal{H}$ be an inf-semilattice. The underlying set of $\mathcal{H}$ is denoted $|\mathcal{H}|$ and is a strong predicate classifier of the functor $\mathcal{P}_{\mathcal{H}}$ where $\epsilon_{1}$ is the identity id ${ }_{|\mathcal{H}|}$.
(c) Suppose $\mathcal{C}$ has finite limits. The doctrine $\operatorname{Sub}_{\mathcal{C}}: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL as a predicate classifier if and only if it has a subobject classifier.
(d) Suppose $\mathcal{C}$ has finite products and weak pullbacks. If $\mathcal{C}$ has a weak predicate classifier if and only if it has a weak proof classifier in the sense of Men03.
2.22 Definition. A primary doctrine $P: C^{\mathrm{op}} \longrightarrow \mathbf{I S L}$ is a tripos if $P$ is a first order doctrine with weak power objects. $P$ is a strong tripos if it is a tripos with strong power objects.
2.23 Examples. (a) The doctrine $L T: \mathcal{V}^{\mathrm{op}} \longrightarrow$ ISL built out of a theory $\mathscr{T}$ over a first order language $\mathscr{L}$ is not a tripos as it has no predicate classifiers.
(b) Let $\mathcal{H}$ be an inf-semilattice. The doctrine $\mathcal{P}_{\mathcal{H}}$ as in Example 2.2 is a tripos if and only if $\mathcal{H}$ is a frame.
(c) Suppose $\mathcal{C}$ has finite limits. The doctrine $\operatorname{Sub}_{C}: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL is a strong tripos if and only if $\mathcal{C}$ is an elementary topos.
(d) Suppose $\mathcal{C}$ has finite products and pullbacks. If $\mathcal{C}$ has a weak predicate classifier if and only if it has a weak proof classifier in the sense of Men03.

A proof of the following proposition is in [Pas16].
2.24 Proposition. If the doctrine $P$ is a tripos then $P_{x}$ is a tripos, too.

Elementary doctrines are the cloven Eq-fibrations of Jac99 and, as explained in loc.cit. and MR16, there is a deductive calculus associated to those which is that of the $\wedge=$-fragment over type theory with just a unit type and a binary product type constructor. To fix notation, we will use the following.
2.25 Notation. Let $P: C^{\text {op }} \longrightarrow$ ISL be elementary. Write

$$
a_{1}: A_{1}, \ldots, a_{k}: A_{k} \mid \phi_{1}, \ldots, \phi_{n} \vdash \psi
$$

in place of

$$
\phi_{1} \wedge \ldots \wedge \phi_{n} \leq \psi \quad \text { in } P\left(A_{1} \times \ldots \times A_{k}\right)
$$

and call such an expression sequent. Note that, in line with loc.cit., $\delta_{A}$ in $P(A \times A)$ will be written as $a: A, a^{\prime}: A \mid a={ }_{A} a^{\prime}$. Also write $a: A \mid \alpha \dashv \vdash \beta$ to abbreviate $a$ : $A \mid \alpha \vdash \beta$ and $a: A \mid \beta \vdash \alpha$. Say that $\alpha$ in $P(A)$ is true over $A$ if $\top_{A} \leq \alpha$. An element of $P(1)$ will be called sentence. An arrow $r: 1 \longrightarrow A$ will be called constant (of type $A$ ) and for $\alpha$ in $P(A)$ we write $\alpha(r)$ in place of $P_{r}(\alpha)$. If $P$ is existential and $a: A, x: X \mid \phi$, i.e. $\phi$ is in $P(A \times X)$, write $a: A \mid \exists_{x: X} \phi$ in place of $\exists_{\mathrm{pr}_{1}} \phi$ in $P(A)$. Similarly when $P$ is first order, for $\alpha, \beta$ in $P(A)$ and $\phi$ in $P(A \times X)$ write $a: A \mid \alpha \vee \beta$ and $a: A \mid \alpha \Rightarrow \beta$ and $a: A \mid \forall_{x: X} \phi$ in place of $\alpha \vee \beta$ and $\alpha \rightarrow \beta$ and $V_{\operatorname{pr}_{1}} \phi$ in $P(A)$. If $P$ is a tripos write $a: A, U: \mathbb{P} A \mid a \in_{A} U$ in place of $\epsilon_{A}$ in $P(A \times \mathbb{P} A)$.

From now on we feel free to employ this logical language in our proofs or definitions whenever we feel that readability is improved.

### 2.1 Comprehensions and strong monomorphisms

2.26 Definition. A primary doctrine $P: \mathcal{C}^{\text {op }} \longrightarrow$ ISL is said to have weak comprehensions if for every $A$ in $C$ and every $\alpha$ in $P(A)$ there is an arrow $\{\alpha\}: X \rightarrow A$ with $\top_{X}=P_{\{\alpha\}}(\alpha)$ such that for every arrow $f: Y \rightarrow A$ with $\top_{Y} \leq P_{f}(\alpha)$ there is a (not necessarily unique) arrow $k: Y \rightarrow X$ with $\{\alpha\} k=f$. We shall say that comprehensions are strong if the mediating arrow $k$ is the unique such arrow. We shall say that comprehensions are full if for every $A$ and every $\alpha, \beta$ over $A$ it holds that $\alpha \leq \beta$ if and only if $\top_{X}=P_{\{\alpha\}}(\beta)$.

It is an easy check that a doctrine $P$ with weak comprehensions has strong comprehension if and only if arrows of the form are monic.
2.27 Examples. (a) The doctrine $L T: \mathcal{V}^{\mathrm{op}} \longrightarrow$ ISL built out of a theory $\mathscr{T}$ over a first order language $\mathscr{L}$ has no comprehensions.
(b) When $\mathcal{H}$ is an inf-semilattice, the doctrine $\mathcal{P}_{\mathscr{H}}$ has strong comprehensions. Given $\alpha$ in $\mathcal{P}_{\mathcal{H}}(A)$ the arrow $\{\alpha\}$ is the inclusion of $\{a \in A \mid \alpha(a)=\top\}$ into $A$. This comprehension is not full as one can see taking $\alpha^{\prime}: A \rightarrow \mathcal{H}$ that agrees with $\alpha$ only on those elements $a$ of $A$ such that $\alpha(a)=\top$. Then $\alpha$ and $\alpha^{\prime}$ have the same comprehension arrow, even if they are not necessarily equivalent in the fibre.
(c) Suppose $\mathcal{C}$ has finite limits. The doctrine $\operatorname{Sub}_{C}: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL as full strong

(d) Suppose $\mathcal{C}$ has finite products and weak pullbacks. The doctrine $\Psi_{\mathcal{C}}: \mathcal{C}^{\mathrm{op}} \longrightarrow$

ISL has full weak comprehensions. The comprehension $\alpha$ in $\operatorname{Sub}_{\mathcal{C}}(A)$ is any representative of $\alpha$ (that need not be monic).

An arrow of the form $\{\alpha\}$ will be often called comprehension arrow of $\alpha$. We recall from MR13a the following definition:
2.28 Definition. An elementary doctrine $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL has comprehensive diagonals if and only if diagonals in $\mathcal{C}$ are the strong comprehension arrows of the corresponding fibered equalities, i.e. $\left\langle i d_{A}, i d_{A}\right\rangle=\left\{\delta_{A}\right\}$.

Comprehensive diagonals were introduced originally in MR13b with the name of "comprehensive equalizers" since the following holds:
2.29 Proposition. Let $P$ be an elementary doctrine $P: \mathcal{C}^{o p} \longrightarrow$ ISL. The following are equivalent:

## 1. $P$ has comprehensive diagonals

2. $P$ is extensional as in Definition [2.6, i.e. for any $f, g: X \rightarrow A \top_{X}=$ $P_{\langle f, g\rangle}\left(\delta_{A}\right)$ if and only $f=g$.

Proof. See Proposition 4.6 of MR13b
2.30 Proposition. If $P: C^{o P} \longrightarrow$ ISL is elementary with comprehensive diagonals and strong comprehensions, then $\mathcal{C}$ has finite limits.

Proof. The equalizer of $f, g: X \rightarrow A$ is $\left\{P_{\langle f, g\rangle}\left(\delta_{A}\right)\right\}$.
2.31 Proposition. Suppose $P$ is elementary existential with weak comprehensions. Weak comprehensions are full if and only if for every $\{\alpha\}: X \rightarrow A$ it holds $\mathcal{B}_{\{\alpha\}}\left(\top_{X}\right)=\alpha$.

Proof. Let $\mathcal{B}_{\{\alpha\}} \dashv P_{\{\alpha\}}$, from $\top_{X}=P_{\{\alpha\}}(\alpha)$ it follows $\mathcal{G}_{\{\alpha\}}\left(\top_{X}\right) \leq \alpha$. Instead $\alpha \leq \mathcal{G}_{\{\alpha\}}\left(\top_{X}\right)$ follows by fullness from the adjunction unit $\top_{X} \leq P_{\{\alpha\}}\left(\mathcal{G}_{\{\alpha\}}\left(\top_{X}\right)\right)$.

Conversely, if $\mathcal{G}_{\{\alpha\}}\left(\top_{X}\right)=\alpha$ from $\top_{X}=P_{\{\alpha\}}(\beta)$ it follows $\alpha=\mathcal{G}_{\{\alpha\}}\left(\top_{X}\right)=$ $\mathcal{H}_{\{\alpha\}} P_{\{\alpha\}}(\beta) \leq \beta$ by the adjunction counit of $\mathcal{H}_{\{\alpha\}} \dashv P_{\{\alpha\}}$.
2.32 Proposition. If $P$ has full weak comprehensions and comprehensive diagonals, then for every weak pullback $f g=h k$ one has $P_{f} \mathcal{G}_{h}=\mathcal{G}_{g} P_{k}$.

Proof. This is Theorem 2.19 in MPR17.
Suppose that $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL has weak comprehensions. For every $f: Y \longrightarrow B$ in $\mathcal{C}$ and every $\alpha$ in $P(B)$ there is a commutative square

where $m$ is the mediating arrow coming from the universal property of $\{\alpha\}$ as $P_{f\left\{P_{f}(\alpha)\right\}}(\alpha)=P_{\left\{P_{f}(\alpha)\right\}}\left(P_{f}(\alpha)\right)=\top_{X}$.
2.33 Proposition. If $k: Z \rightarrow A$ and $h: Z \rightarrow Y$ are such that $\{\alpha\} k=f h$, then $h$ factors through $\left\{P_{f}(\alpha)\right\}$. If $\{\alpha\}$ is a strong comprehension, the square above is a weak pullback. If both $\{\alpha\}$ and $\left\{P_{f}(\alpha)\right\}$ are strong comprehensions the square is a pullback.

Proof. Consider $k$ and $h$ such that $\{\alpha\} k=f h$. Then $P_{h}\left(P_{f}(\alpha)\right)=P_{k}\left(P_{\{\alpha\}}(\alpha)\right)=$ $\top_{Z}$. Weak universality of $\left\{P_{f}(\alpha)\right\}$ guarantees the existence of $u: Z \longrightarrow X$ with $\left\{P_{f}(\alpha)\right\} u=h$. If $\{\alpha\}$ is strong, then it is also monic. Hence $m u=k$ if and only if $\{\alpha\} m u=\{\alpha\} k$, which is true as $\{\alpha\} m u=f\left\{P_{f}(\alpha)\right\} u=f h=\{\alpha\} k$. Finally if $\left\{P_{f}(\alpha)\right\}$ is monic the mediating arrow $u$ is necessarily unique.

If $P$ is elementary, we say that an arrow $f: X \rightarrow A$ of $\mathcal{C}$ is $P$-injective if $P_{f \times f}\left(\delta_{A}\right)=\delta_{X}$. While if $P$ is also existential we say that $f$ is $P$-surjective if $\mathcal{B}_{f}\left(\top_{X}\right)=\top_{A}$.

It is immediate to show that if $P$ has comprehensive diagonals, if an arrow is $P$-injective, then it is also monic and if an arrow is $P$-surjective, then it is also epic. Observe the following about monics:
2.34 Proposition. Suppose $P$ is a variational doctrine on $C$. An arrow $m$ : $X \longrightarrow$ $A$ is $P$-injective if and only if it is monic.

Proof. If $m: X \rightarrow A$ is $P$-injective then it is clearly monic thanks to comprehensive diagonals. Conversely, if $m$ is monic the square $\left\langle\mathrm{id}_{A}, \mathrm{id}_{A}\right\rangle m=$ $(m \times m)\left\langle\mathrm{id}_{X}, \mathrm{id}_{X}\right\rangle$ is a pullback. Since $P$ has comprehensive diagonals, and the equalizer of $m$ with itself is $\left\{P_{\langle m, m\rangle}\left(\delta_{A}\right)\right\}$ by Proposition 2.30, it follows that $\left\langle\mathrm{id}_{X}, \mathrm{id}_{X}\right\rangle=\left\{P_{\langle m, m\rangle}\left(\delta_{A}\right)\right\}$ and since $\left\langle i d_{X}, i d_{X}\right\rangle=\left\{\delta_{X}\right\}$ by fullness of comprehensions we conclude $P_{\langle m, m\rangle}\left(\delta_{A}\right)=\delta_{X}$, i.e. $m$ is $P$-injective.

Let $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL be an elementary existential doctrine. Using the language in 2.25, a $F$ in $P(A \times B)$ is
total (or entire) if $\exists_{b: B} F(a, b)$ is true over $A$
single-valued (or functional) if $a: A, b: B, b^{\prime}: B \mid F(a, b) \wedge F\left(a, b^{\prime}\right) \vdash b={ }_{B} b^{\prime}$
2.35 Definition. We say that $P$ satisfies the rule of unique choice (RUC) if for every total and single-valued $F$ in $P(A \times B)$ there is $f: A \longrightarrow B$ such that $a: A, b: B \mid F(a, b) \dashv f(a)={ }_{B} b$.
2.36 Definition. We say that $P$ satisfies the rule of choice (RC) if for every total $F$ in $P(A \times B)$ there is $f: A \longrightarrow B$ such that $a: A \mid \exists_{b: B} F(a, b) \dashv F(a, f(a))$.
2.37 Proposition. Suppose $P$ is an existential m-variational doctrine on $\mathcal{C}$. The following are equivalent:

1. Every arrow which is both $P$-injective and $P$-surjective is an isomorphism the subobject doctrine Sub $_{C}$;
2. $P$ satisfies (RUC);
3. $P$ is equivalent to the subobject doctrine $\operatorname{Sub}_{C}$.

Proof. To prove the equivalence between (1) and (2) we use the notation in 2.25. If (1) holds, take $F$ in $P(A \times B)$ and consider $\{F\}: X \rightarrow A \times B$. If $F$ is total and single-valued. Then $\operatorname{pr}_{1}\{F\}: X \rightarrow A$ is $P$-injective and $P$-surjective so it has an inverse $h$. The arrow $\operatorname{pr}_{1} h: A \rightarrow B$ is the desired arrow. Conversely, suppose (RUC) holds and take a $P$-injective and $P$-surjective arrow $f: A \rightarrow B$. The formula $b: B, a: A \mid b=_{B} f(a)$ is entire and single-valued. By (RUC) there is $k: B \rightarrow A$ which is the inverse of $f$. The equivalence between (2) and (3) follows from point $(i)$ of Theorem 2.7 in MPR19.

Recall also from Theorem 5.9 in MPR17 the following
2.38 Proposition. Suppose $P$ is an existential variational doctrine on C. $P$ satisfies (RC) if and only if $P$ is $\Psi_{C}$.

Primary doctrines with full strong comprehensions form the category CED, the 2-full sub category of the category of elementary doctrines ED whose arrows are those arrow $(F, b): P \rightarrow R$ in ED that preserve comprehensions, i.e. for every $A$ and $\alpha$ in $P(A)$ the arrow $F\{\alpha\}$ is isomorphic to $\left\{b_{A} \alpha\right\}$.

We recall from MR13b MR13a that there is a left biadjoint to the forgetful 2-functor from ED to CED. which associates to an elementary doctrine $P: C^{\mathrm{op}} \longrightarrow$ ISL the elementary doctrine with full strong comprehensions the doctrine $P_{\mathrm{c}}: \mathcal{C}_{\mathrm{c}}{ }^{\text {op }} \longrightarrow$ ISL whose description is as follows.
2.39 Definition. Let $P$ be an elementary doctrines on $\mathcal{C}$. The doctrine $P_{\mathrm{c}}: \mathcal{C}_{\mathrm{c}}{ }^{\mathrm{op}} \longrightarrow$ ISL obtained by freely adding full comprehensions to $P$ has a base $\mathcal{C}_{\mathrm{C}}$, whose objects are pairs $(A, \alpha)$ where $\alpha$ is in $P(A)$ and an arrow $f:(A, \alpha) \longrightarrow(B, \beta)$ is an arrow $f: A \rightarrow B$ in $\mathcal{C}$ such that $\alpha \leq P_{f}(\beta) . \quad P_{\text {c }}$ maps each $(A, \alpha)$ to $P_{\mathrm{c}}(A, \alpha)=\{\phi \in P(A) \mid \phi \leq \alpha\}$ and each $f:(A, \alpha) \longrightarrow(B, \beta)$ to the function $P_{\mathrm{c}}(f): P_{\mathrm{c}}(B, \beta) \rightarrow P_{\mathrm{c}}(A, \alpha)$ determined by the assignment $\psi \mapsto P_{f}(\psi) \wedge \alpha$. For $\phi$ in $P_{\mathrm{c}}(A, \alpha)$ it is $\{\phi\}=\operatorname{id}_{A}:(A, \phi) \longrightarrow(A, \alpha)$.

Doctrines with comprehensive diagonals and full weak comprehensions form the class of doctrines which we will mainly concerned with throughout this paper. In MPR17, taking the terminology from Gra00, we called them variational. While we called $\boldsymbol{m}$-variational doctrines those variational doctrines in which comprehension is strong. We aim at giving a characterisation of variational doctrines in 3.8. To do this we first need some instrumental definitions and propositions.

Existential variational doctrines will be the main mathematical tool that we will employ throughout the whole paper. They form the category EV which is the full subcategory of EExD on those doctrines that are also existential. We denote by $\mathbf{E m V}$ the subcategory of $\mathbf{E V}$ on m-variational doctrines and on those morphisms of doctrine that preserves strong comprehension. The adjoint situation described in Definition 2.39 and in Definition 2.9 compose to give the following

### 2.1.1 Factorization systems from doctrines

Suppose $\mathcal{C}$ is a category with weak pullbacks. A right weak factorization system is a pair ( $\mathcal{E}, \mathcal{R}$ ) of classes of arrows of $\mathcal{C}$ such that
(i) for every $f$ in $\mathcal{C}$ there is $e$ in $\mathcal{E}$ and $r$ in $\mathcal{R}$ with $f=r e$
(ii) for every commutative square $r f=g e$ with $e$ in $\mathcal{E}$ and $r$ in $\mathcal{R}$ there is $k$ with $r k=g$.

A right weak factorization system is stable if any weak pullback of an arrow of $\mathcal{E}$ is in $\mathcal{E}$. A proper factorisation system $(\mathcal{E}, \mathcal{R})$ in the sense of FK72 is a right weak factorization system such that every arrow in $\mathcal{R}$ is monic and every arrow in $\mathcal{E}$ is epic. Every proper stable factorisation $\operatorname{system}(\mathcal{E}, \mathcal{R})$ on a category $\mathcal{C}$ with pullbacks gives rise to an existential m-variational doctrine $\mathcal{R}_{C}: \mathcal{C}^{\mathrm{op}} \rightarrow$ ISL where $\mathcal{R}_{C}$ is the sub-infsemilattice of $\Psi_{C}(A)$ on those arrows represented by arrows in $\mathcal{R}$, which are monic and hence also in $\operatorname{Sub}_{\mathcal{C}}(A)$ HJ03. Analogously, to what shown in loc.cit. and observed in MR16]) we can show that category of existential elementary doctrines with full strong comprehensions is equivalent to the category of proper stable factorisation systems. More precisely,
2.40 Proposition. In every m-variational doctrine comprehension arrows and $P$-surjective arrows form a factorization system. Moreover, the category of
existential m-variational doctrines is equivalent to the category of proper stable factorisation systems where diagonals are in the right class.

### 2.2 The elementary quotient completion

We now recall the definition of $P$-equivalence relation for any elementary doctrine $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL and the related notion of quotients from MR13a:
2.41 Definition. A $P$-equivalence relation $\rho$ over an object $A$ of $C$ is an element in $P(A \times A)$ such that
(i) $\delta_{A} \leq \rho$
(ii) $\rho=P_{\left\langle\operatorname{pr}_{2}, \mathrm{pr}_{1}\right\rangle}(\rho)$
(iii) $P_{\left\langle\operatorname{pr}_{1}, \mathrm{pr}_{2}\right\rangle}(\rho) \wedge P_{\left\langle\mathrm{pr}_{2}, \mathrm{pr}_{3}\right\rangle}(\rho) \leq P_{\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{3}\right\rangle}(\rho)$

Where in (ii) $\mathrm{pr}_{1}, \mathrm{pr}_{2}: A \times A \rightarrow A$ are the first and the second projection, while in (iii) $\mathrm{pr}_{i}$, with $i=1,2,3$, are projections from $A \times A \times A$ to each of the factors.

When no confusion arises, we shall refer at $P$-equivalence relations simply as equivalence relations, without specifying the doctrine $P$. Note that in every elementary doctrine, fibered equalities are equivalence relations.
2.42 Examples. (a) Recall from Example 2.2-(a) the syntactic doctrine $L T: V^{\text {op }}$ ISL built out of a theory $\mathscr{T}$ over a first order language $\mathscr{L}$. A $L T$-equivalence relation over $x$ is a formula $\phi$ of $\mathscr{L}$ such that $\mathscr{T} \vdash \forall x \phi(x, x)$ and $\mathscr{T} \vdash$ $\forall x y(\phi(x, y) \rightarrow \phi(y, x))$ and $\mathscr{T} \vdash \forall x y z(\phi(x, y) \& \phi(y, z) \rightarrow \phi(x, z))$.
(b) When $\mathcal{H}$ is an inf-semilattice, a $\mathcal{P}_{\mathcal{H}}$-equivalence relation over a set $A$ is an $\mathcal{H}$-valued ultra-pseudodistance on $A$ after inverted the order, i.e. a function $\rho: A \times A \rightarrow \mathcal{H}$ such that for all $a, a^{\prime}, a^{\prime \prime}$ in $A$ it is $\rho(a, a)=\top$ and $\rho\left(a, a^{\prime}\right)=$ $\rho\left(a^{\prime}, a^{\prime \prime}\right)$ and $\rho\left(a, a^{\prime}\right) \wedge \rho\left(a^{\prime}, a^{\prime \prime}\right) \leq \rho\left(a, a^{\prime \prime}\right)$.
(c) Suppose $\mathcal{C}$ has finite limits, then $\rho$ is a $\operatorname{Sub}_{C^{C}}$-equivalence relation over $A$ if and only if $\rho$ is an equivalence relation of $\mathcal{C}$ in the usual categorical sense (see for example [MM92]).
(d) Suppose $\mathcal{C}$ has finite products and weak pullbacks, then $\rho$ is a $\Psi_{\mathcal{C}}$-equivalence relation over $A$ if and only if it is a pseudo-equivalence relation of $\mathcal{C}$ in the sense of Car95.
2.43 Definition. An elementary doctrine $P: \mathcal{C}^{\mathrm{op}} \longrightarrow \mathbf{I S L}$ is said to have quotients if for every $A$ in $\mathcal{C}$ and every equivalence relation $\rho$ over $A$ there exists a morphism $q: A \rightarrow A / \rho$ such that $\rho \leq P_{q \times q}\left(\delta_{A / \rho}\right)$ and for every morphism $f: A \rightarrow Y$ such that $\rho \leq P_{f \times f}\left(\delta_{Y}\right)$ there exists a unique $h: A / \rho \longrightarrow Y$ with $h q=f$. Maps of the form $q: A \rightarrow A / \rho$ will be called quotient arrow of $\rho$. The quotient $q: A \rightarrow A / \rho$ is effective if $\rho=P_{q \times q}\left(\delta_{A / \rho}\right)$.
2.44 Definition. An elementary doctrine $P$ is said to have stable quotients if for every pullback $q p=f h$, if $q$ is a quotient arrow of $\rho$, then $h$ is a quotient arrow of $P_{p \times p}(\rho)$.
2.45 Definition. Given an elementary doctrine $P: C^{\text {op }} \longrightarrow$ InfSL and a $P$ equivalence relation $\rho$ over $A$ in $\mathcal{C}$, The inf-semilattice of descent data $\mathscr{D}^{\text {des }}{ }_{\rho}$ is the sub-inf-semilattice of $P(A)$ on those $\alpha$ such that

$$
P_{\mathrm{pr}_{1}}(\alpha) \wedge \rho \leq P_{\mathrm{pr}_{2}}(\alpha)
$$

where $\mathrm{pr}_{1}, \mathrm{pr}_{2}: A \times A \rightarrow A$ are the projections.
For $f: A \rightarrow B$ in $C$ the map $P_{f}: P(B) \longrightarrow P(A)$ takes values in $\mathscr{D} e s_{P_{f \times f}\left(\delta_{B}\right)}$. We shall say that $f$ is of effective descent if $P_{f}: P(B) \rightarrow \mathscr{D} s_{P_{f \times f}\left(\delta_{B}\right)}$ is an isomorphism. In particular this means that the functor $P_{f}$ is of effective descent type as defined in BW84.
2.46 Definition. An elementary doctrine $P$ is said to have descent effective quotients if $P$ has stable effective quotients and the quotient arrows are of effective descent.
2.47 Examples. (a) In general doctrines of the form $L T: \mathcal{V}^{\mathrm{op}} \longrightarrow$ ISL do not have quotients.
(b) For $\mathcal{H}$ an inf-semilattice, the doctrine $\mathcal{P}_{\mathcal{H}}$ has quotient. Let $\rho: A \times A \rightarrow \mathcal{H}$ be a $\mathcal{H}$-valued ultra-pseudodistance on $A$ as in Example 2.42-(b) and define on $A$ the equivalence relation $a \sim a^{\prime}$ generated by $\rho\left(a, a^{\prime}\right)=\top$. Then canonical surjection $q: A \longrightarrow A / \sim$ is a quotient arrow. These quotients are not effective (unless $\rho$ is the boolean equality on $A$ ) and hence not of effective descent.
(c) If $\mathcal{C}$ has finite limits, then $\operatorname{Sub}_{\mathcal{C}}$ has effective quotient if and only if $\mathcal{C}$ is exact. In this case quotients are of effective descent (this follows also from the more general situation of Definition 2.45 in the following).
(d) In general doctrines of the form $\Psi_{\mathcal{C}}$ do not have quotients (unless $\Psi_{\mathcal{C}}$ is equivalent to $\mathrm{Sub}_{\mathcal{C}}$ for $\mathcal{C}$ exact).
2.48 Lemma. Let $P: C^{o p} \longrightarrow$ ISL an elementary and existential doctrine and $q: A \rightarrow A / \rho$ an effective descent arrow. Then, the inverse of $P_{q}: P(B) \rightarrow \mathscr{D} e s_{\rho}$ is the restriction of $\mathcal{H}_{q}$ to $\mathscr{D} e s_{\rho}$ and, hence, any $\phi$ of $P(A)$ is a descent data if and only if $\phi=P_{q} \exists_{q} \phi$.
2.49 Remark. For elementary and existential doctrines $P: C^{\text {op }} \longrightarrow$ ISL we could have simply define an effective quotient arrow $q: A \rightarrow A / \rho$ of effective descent if and only if $P_{q}$ restricts to an isomorphisms toward its image in $P(A)$. Then, trivially an object $\phi$ is in the image of $P_{q}$ if and only if $\phi=P_{q} \mathcal{B}_{q} \phi$, which holds if and only if $\phi$ is a descent data in the sense of Definition 2.45 by Beck-Chevalley conditions applied to the description of $D_{q}$ in remark 2.13 p. 381 in MR13b.
2.50 Lemma. If $P: C^{o p} \longrightarrow$ ISL is elementary and existential, an effective quotient arrow $q: A \rightarrow A / \rho$ is of effective descent if and only if the arrow $q$ is $P$-surjective, i.e. $\exists_{q} \top_{A}=\top_{A / \rho}$.

Proof. If $q$ is of effective descent, then $P_{q}: P(A / \rho) \rightarrow \mathscr{D} e s_{\rho}$ is an isomorphism with inverse the restriction of $\mathcal{G}_{q}$ to $\mathscr{D} e s_{\rho}$ by Lemma 2.48. Hence, for all descent
data $\phi$, we have that $\phi=\mathcal{G}_{q} P_{q} \phi$ from which $\top_{A / \rho}=\mathcal{G}_{q} \top_{A}$. Conversely, if $q$ is $P$-surjective, observe, that for every $\psi$ in $P(A / \rho)$, by Frobenius condition $\mathcal{G}_{q} P_{q} \psi=\psi \wedge \mathcal{G}_{q} \top_{B}=\psi$ and hence $P_{q}$ is an isomorphism towards $\mathscr{D} e s_{\rho}$ with inverse $\mathcal{H}_{q}$ since by Lemma 2.48 we also know that every descent data satisfies $\phi=P_{q} \mathcal{B}_{q} \phi$.
2.51 Proposition. The quotient arrows of an existential m-variational doctrine $P: \mathcal{C}^{o p} \longrightarrow$ ISL with stable effective quotients are of effective descent.

Proof. By 2.40 each quotient arrow $q: A \longrightarrow A / \rho$ can be factored as $q=\left\{\mathcal{G}_{q}\left(\top_{A}\right)\right\} g$ where $g: A \rightarrow C$ is $P$-surjective. Since $\left\{\mathcal{G}_{q}\left(\top_{A}\right)\right\}$ is monic, it is also $P$-injective by 2.34, whence $\rho=P_{q \times q}\left(\delta_{A}\right)=P_{g \times g} P_{\left\{\mathbb{Z}_{q}\left(\top_{A}\right)\right\} \times\left\{\mathbb{B}_{q}\left(\top_{A}\right)\right\}}\left(\delta_{A}\right)=P_{g \times g}\left(\delta_{C}\right)$. The universal property of quotients implies the existence of an arrow $s: A / \rho \rightarrow C$ with $g=s q$ and hence $q=\left\{\mathcal{B}_{q}\left(\top_{A}\right)\right\} s q$, so $\left\{\mathcal{G}_{q}\left(\top_{A}\right)\right\} s=\operatorname{id}_{B}$ as $q$ is epic. Since $\left\{\left\{\mathcal{G}_{q}\left(\top_{A}\right)\right\}\right.$ is a monomorphism with a section it is an isomorphism. Therefore $q$ is isomorphic to $g$ and hence $P$-surjective. An application of Lemma 2.50 concludes the proof.

We recall from MR13b the construction called elementary quotient completion that freely adds descent effective quotients to any elementary doctrine.
2.52 Definition. Given an elementary doctrine $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL we call $Q_{P}$ the category whose objects are pairs $(A, \rho)$ in which $A$ is in $C$ and $\rho$ is an equivalence relation over $A$. An arrow $[f]:(A, \rho) \longrightarrow(B, \sigma)$ is an equivalence class of arrows $f: A \rightarrow B$ in $C$ such that $\rho \leq P_{f \times f}(\sigma)$, with respect to the equivalence $f \sim g$ if and only if

$$
\top_{A}=P_{\langle f, g\rangle}(\sigma)
$$

The category $Q_{P}$ has finite products: if $(A, \rho)$ and $(B, \sigma)$ are objects of $Q_{P}$, their product is

$$
(A, \rho) \stackrel{\left[\mathrm{pr}_{1}\right]}{\rightleftarrows}(A \times B, \rho \boxtimes \sigma) \xrightarrow{\left[\mathrm{pr}_{2}\right]}(B, \sigma)
$$

where $\rho \boxtimes \sigma=P_{\left\langle\operatorname{pr}_{1}, \operatorname{,r}_{2}\right\rangle}(\rho) \wedge P_{\left\langle\operatorname{pr}_{3}, \mathrm{pr}_{4}\right\rangle}(\sigma)$. The elementary quotient completion of $P$ is the doctrine $\widehat{P}: Q_{P}^{\text {op }} \longrightarrow$ ISL where

$$
\widehat{P}(A, \rho)=\mathscr{D}^{e} s_{\rho} \quad \widehat{P}_{[f]}=P_{f}
$$

It is proved in MR13b that the assignment on arrows does not depend on the choice of representatives. The doctrine $\widehat{P}$ is elementary with $\delta_{(A, \rho)}=\rho$. It is immediate to see that $\widehat{P}$ as stable descent effective quotient: if $\sigma$ is an equivalence relation over $(A, \rho)$, then its quotient arrow is $\left[\mathrm{id}_{A}\right]:(A, \rho) \longrightarrow(A, \sigma)$. Moreover these quotients are stable.
2.53 Examples. (a) The elementary quotient completion of doctrines of the form $L T: \mathcal{V}^{\mathrm{op}} \longrightarrow$ ISL is connected to elimination of imaginaries as analysed in EPR20.
(b) Assuming choice, in the sense that epimorphism in Set split, the base of $\widehat{\mathcal{P}_{\mathcal{H}}}: \operatorname{Set}_{\mathcal{P}_{\mathscr{H}}}^{\mathrm{op}} \longrightarrow$ ISL is equivalent to $\mathbf{U M}_{\mathscr{H}}$, the category of $\mathcal{H}$-valued ultrametric spaces. Indeed the functor that maps $f:(A, \rho) \rightarrow(B, \sigma)$ in $\mathbf{U M}_{\mathcal{H}}$ to $[f]:(A, \rho) \longrightarrow(B, \sigma)$ in $\operatorname{Set}_{\mathcal{P}_{\mathcal{H}}}$ is full and faithful as Leibniz's principle of identity of indiscernibles holds. For essential surjectivity, take $(A, \rho)$ in $\operatorname{Set}_{\mathcal{P}_{\mathscr{H}}}$ and consider the quotient $(A, \rho) \longrightarrow\left(A / \sim, \delta_{A / \sim}\right)$ where $\sim$ is the equivalence relation described in Example 2.47(b). Any of its section represent an inverse in $\operatorname{Set}_{\mathcal{P}_{\mathscr{H}}}$. (d) One the motivating examples for the study of the elementary quotient completion is given by doctrines of the form $\Psi_{C}$ where $\mathcal{C}$ has finite products and weak pullbacks. As proved in MR13b the doctrine $\widehat{\Psi}_{C}$ is $\operatorname{Sub}_{\mathcal{C}_{\text {ex/lex }}}$, i.e. the subobject doctrine of the exact completion $\mathcal{C}_{\text {ex }} /$ lex of $\mathcal{C}$.

It is quite apparent that the elementary structure plays no role in the definitions of $\widehat{P}$ (see Pas15, EPR20) but it is crucial to embed $\mathcal{C}$ into $Q_{P}$. The embedding is given by the functor $\nabla_{P}: \mathcal{C} \longrightarrow Q_{P}$ that assigns to each $f: X \longrightarrow Y$ the arrow $[f]:\left(X, \delta_{X}\right) \rightarrow\left(Y, \delta_{Y}\right)$. This functor is full and preserves binary products and when $P$ has comprehensive diagonals it is also faithful (see MR13b). In this case it is immediate to check that $P$ is the change of base of $\widehat{P}$ along $\nabla_{P}$.

Denote by QEExD the subcategory of EExD on those doctrines with effective descent quotients and on those arrows that preserves quotients, i.e. on those $(F, b)$ from $P: C^{\mathrm{op}} \longrightarrow$ ISL to $R: \mathcal{D}^{\mathrm{op}} \longrightarrow$ ISL such that the action of $F$ on $q: A \rightarrow A / \rho$ is $F q: F A \rightarrow F A /\left(b_{A \times A} \rho\right)$.

The following theorem is proved in MR13b MR13a.
2.54 Proposition. There is a left biadjoint to the inclusion of QEExD into EExD which associates the doctrine $\widehat{P}: Q_{P}^{o p} \longrightarrow \mathbf{I S L}$ to an elementary doctrine $P$.

We also recall from MR16
2.55 Proposition. An elementary and existential doctrine $P$ satisfies (RC) if and only if its completion $\widehat{P}$ satisfies (RUC).
2.56 Remark. Let $\mathbf{E E x} \mathbf{D}^{R U C}$ and $\mathbf{E E x} \mathbf{D}^{R C}$ be the full subcategories of $\mathbf{E E x D}$ on doctrines satisfying (RUC) and (RC) respectively and similarly $\mathbf{Q E E x} \mathbf{D}^{R U C}$ and $\mathbf{Q E E x} \mathbf{D}^{R C}$ are the full subcategories of $\mathbf{Q E E x D}$ on doctrines satisfying (RUC) and (RC) respectively. These categories fit in the following diagram of inclusions.

The vertical left adjoint in diagram (22) are given by the elementary quotient completion. The biadjoint to the inclusion of $\mathbf{Q E E x} \mathbf{D}^{R U C}$ into QEExD is the
functor that maps $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL to $P_{F}: \mathcal{E} \mathcal{F}_{P}^{\mathrm{op}} \longrightarrow$ ISL where $\mathcal{C}_{F}$ has the objects of $C$ and an arrow $F: A \longrightarrow B$ is a total and single-valued relation in $P(A \times B)$. The functor $P_{F}$ maps $A$ to $P_{F}(A)=P(A)$ and given $\beta$ in $P(B)$ it is $P_{F}(\beta)$ is the formula $a: A \mid \exists_{b: B}[F(a, b) \wedge \beta(b)]$ over $A$ (see [Pas16]).

It is worth noting that if we start with an elementary doctrine $P$ without comprehensive diagonals and just with weak full comprehensions we can get anyway a m-variational doctrine closed under effective quotients. Moreover, adding comprehensive diagonals to $P$ before completing it with quotients does produce the same doctrine as that obtained by completing $P$ itself.
2.57 Theorem. Let $P$ an elementary doctrine with weak full comprehensions. Then $\widehat{P}$ is a $m$-variational doctrine with stable effective quotients. Moreover, the doctrine $\widehat{P_{x}}$ is equivalent to $\widehat{P}$.

## 3 Topology on a doctrine

Consider the following two diagrams in PD.

where the adjointness symbols in the diagram on the right means that for every $A$ in $\mathcal{C}$ and every $\alpha$ in $P(A)$ and every $\beta$ in $R(A)$ the inequalities $l r \alpha \leq \alpha$ and $\beta \leq r l \beta$ both hold.
3.1 Definition. Given two primary doctrines $P, R$ We say that $P$ and and $R$ form an adjoint-retraction pair and we write $P \triangleleft R$ if they fit in a diagram as the one on the right and moreover $l r=\operatorname{id}_{P}$.
3.2 Definition. Let $P$ a primary doctrine. An endomorphism of primary doctrine of the form $\left(\mathrm{id}_{C}, j\right): P \rightarrow P$ is called a topology on $P$ if $j$ is extensive and idempotent, i.e. for every $A$ in $\mathcal{C}$ and every $\alpha$ in $P(A)$ it holds $\alpha \leq j_{A} \alpha$ and $j_{A} j_{A} \alpha=j_{A} \alpha$. An element $\alpha$ in $P(A)$ is $j$-closed if $\alpha=j_{A}(\alpha)$.

Every topology $j$ on $P$ determines a doctrine $P_{j}: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL as follows:
3.3 Definition. If $j$ is a topology on the primary doctrine $P$, we call doctrine of $j$-closed element of $P$ the doctrine $P_{j}: C^{\text {op }} \longrightarrow$ ISL where $P_{j}(A)$ is the sub-infsemilattice of $P(A)$ on those $\alpha$ such that $j_{A} \alpha=\alpha$.

The following is proved in [Pas16], but see also [MPR19].
3.4 Proposition. If $P \triangleleft R$ then there is $L: Q_{R} \rightarrow Q_{P}$ and $R: Q_{P} \rightarrow Q_{R}$ with $L$ left adjoint to $R$ and $R$ is full and faithful.

Proof. $L$ maps $[f]:(A, \rho) \rightarrow(B, \sigma)$ to $[f]:\left(A, l_{A \times A}(\rho)\right) \rightarrow\left(B, l_{B \times B}(\sigma)\right)$. The functor $R$ is built analogously.
3.5 Proposition. Suppose $P: \mathcal{C}^{o p} \longrightarrow$ ISL and $R: C^{o p} \longrightarrow$ ISL are functors based on $\mathcal{C}$. Then $P \triangleleft R$ if and only if $P$ is isomorphic to $R_{j}$ for some topology $j$ on $R$.

Proof. Suppose $P \triangleleft R$ as in the diagram above. The composition $r l$ is clearly extensive and also idempotent as $l r=\operatorname{id}_{P}$. The morphism $\left(\operatorname{Id}_{C}, r\right): P \longrightarrow R_{r l}$ is then the inverse of $\left(\mathrm{id}_{C}, l\right): R_{r l} \rightarrow P$, whence $j=r l$ is the desired topology on $R$. Conversely let $j$ be a topology on $R$. There is an morphism $\left(\operatorname{Id}_{C}, \iota\right): R_{j} \rightarrow$ $R$ where $\iota$ is a family of inclusions and a morphism $\left(\operatorname{Id}_{C}, j\right): R \rightarrow R_{j}$. It is immediate to see that $R_{j} \triangleleft R$.
3.6 Proposition. Suppose $P: \mathcal{C}^{o p} \longrightarrow$ ISL is a primary doctrine and $j$ is a topology on $P$. We have the following:

1. If $P$ is elementary, then so is $P_{j}$.
2. If $P$ is existential, then so is $P_{j}$.
3. If $P$ is disjunctive, then so is $P_{j}$.
4. If $P$ is implicational, then so is $P_{j}$.
5. If $P$ is universal, then so is $P_{j}$.
6. If $P$ has a weak predicate classifier, then so does $P_{j}$.

Proof. Standard argument: for $f: A \rightarrow B$ and $\alpha, \beta$ in $P_{j}(A)$ note that $V_{f}(\alpha)$ and $\alpha \rightarrow \beta$ determines the universal and the implicational structure in $P_{j}$ (if they already exists in $P$ ) while for the left adjoints and the disjunctive structure one takes the closure of the corresponding ones of $P$ so $j_{B}\left(\mathcal{B}_{f}(\alpha)\right)$ and $j_{A}(\alpha) \vee j_{A}(\beta)$. The weak power object of $A$ is $\mathbb{P} A$ with membership predicate $j_{A \times \mathbb{P} A}\left(\epsilon_{A}\right)$.
3.7 Example. Given a first order doctrine $P$ a major example of topology is the double negated topology associating $\neg \neg \alpha$ to $\alpha$ of $P$. Then $P_{\neg \neg}$ is a boolean first order doctrine by Proposition 3.6 which is an algebraic rendering of GödelGentzen double negation translation extended to first order equality.
3.8 Proposition. Suppose $P: \mathcal{C}^{o p} \longrightarrow$ ISL is elementary existential and $\mathcal{C}$ has weak pullbacks. The following are equivalent

1. $P$ is isomorphic to $\Psi_{C j}$ for some topology $j$ over $\Psi_{C}$
2. $P \triangleleft \Psi_{C}$
3. $P$ has full weak comprehensions.

Proof. The equivalence between items 1 and 2 is a special case of 3.5, while $3 \Rightarrow 2$ is Proposition 2.3 of MPR19 It remains $2 \Rightarrow 3$. Take $\alpha$ in $P(A)$ and let $\{\alpha\}: X \rightarrow A$ be any representative of $\mathbf{r}_{A}(\alpha)$. We first need prove that $\top_{X} \leq P_{\{\alpha\}}(\alpha)$. Observe that

$$
\left.\alpha=\mathbf{I r}_{A}(\alpha)=\mathbf{l}\left(\Sigma_{\mathbf{r}_{A}(\alpha)}\right) \mathrm{id}_{X}\right)=\exists_{\mathbf{r}_{A}(\alpha)} \mathbf{l}\left(i d_{X}\right)=\exists_{\mathbf{r}_{A}(\alpha)} \mathbf{l}\left(\mathbf{r}\left(\top_{X}\right)\right)=\exists_{\mathbf{r}(\alpha)} \top_{X}
$$

Hence $\top_{X} \leq P_{\mathbf{r}_{A}(\alpha)}\left(\exists_{\mathbf{r}_{A}(\alpha)} \top_{X}\right)=P_{\mathbf{r}_{A}(\alpha)}(\alpha)=P_{\{\alpha\}}(\alpha)$. Take $f: Y \rightarrow A$ with $\top_{Y} \leq P_{f}(\alpha)$. Then $\operatorname{id}_{Y}=\mathbf{r}_{A}\left(\top_{Y}\right) \leq \mathbf{r}_{A} P_{f}(\alpha)=f^{*} \mathbf{r}_{A}(\alpha)=f^{*}\{\alpha\}$ from which we conclude that $\{\alpha\}$ is a full weak comprehension of $\alpha$.

Since $\operatorname{id}_{X}$ factors through the weak pullback of $\{\alpha\}$ along itself, it is

$$
\mathbf{r}_{X}\left(\top_{X}\right)=\left[\operatorname{id}_{X}\right] \leq\{\alpha\}^{*}\{\alpha\}=\{\alpha\}^{*} \mathbf{r}_{A}(\alpha)=\mathbf{r}_{X} P_{\{\alpha\}}(\alpha)
$$

The equality $\mathbf{r l}=\operatorname{id}_{P}$ implies that components of $\mathbf{r}$ reflect the order, so $\top_{X} \leq$ $P_{\{\alpha\}}(\alpha)$. Then $\left[\operatorname{id}_{Y}\right]=\mathbf{I}_{Y}\left(\top_{Y}\right) \leq \mathbf{I}_{Y} P_{f}(\alpha)=f^{*}\{\alpha\}$. This means that $\operatorname{id}_{Y}$ factors through the weak pullback of $\{\alpha\}$ along $f$, so $f$ factors through $\{\alpha\}$. To show that $P$ has comprehensive diagonals take $h, k: X \rightarrow A$ and suppose $\top_{X} \leq P_{\langle h, k\rangle}\left(\delta_{A}\right)$. Using again $\mathbf{r}$ (and the fact that it is a morphism of elementary doctrines) it holds

$$
\left[\mathrm{id}_{X}\right]=\mathbf{r}_{X}\left(\top_{X}\right) \leq \mathbf{r}_{X} P_{\langle h, k\rangle}\left(\delta_{A}\right)=\langle h, k\rangle^{*} \mathbf{r}_{A}\left(\delta_{A}\right)=\langle h, k\rangle^{*}\left[\left\langle\operatorname{id}_{A}, \operatorname{id}_{A}\right\rangle\right]
$$

so $h=k$. The second part of the theorem is analogous once one observes that a comprehension arrow is strong if and only if it is monic.

The following proposition is stated without a proof as one is perfectly analogous to that of Proposition 3.8
3.9 Proposition. Suppose $P: \mathcal{C}^{o p} \longrightarrow$ ISL is elementary existential and $\mathcal{C}$ has pullbacks. Then $P$ is isomorphic to $\operatorname{Sub}_{\mathcal{C}}$ for some topology $j$ over $\mathrm{Sub}_{\mathcal{C}}$ if and only if $P \triangleleft \mathrm{Sub}_{\mathcal{C}}$ if and only if $P$ has full comprehensions.
3.10 Remark. Our notion of topology on $\mathrm{Sub}_{\mathcal{C}}$ for a category $\mathcal{C}$ with finite limits coincides with the notion of topology in BW84. It includes the well notion of Lawvere-Tierney topology as examples.
3.11 Definition. Given such a topology on a doctrine $P: C^{\text {op }} \longrightarrow$ ISL, an object $A$ of $\mathcal{C}$ is $j$-separated if $j_{A \times A} \delta_{A}=\delta_{A}$.
3.12 Proposition. Suppose $P: \mathcal{C}^{o p} \longrightarrow$ ISL is elementary existential and $\mathcal{C}$ has weak pullbacks. The following are equivalent

1. $P$ is isomorphic to $\Psi_{C j}$ for some topology $j$ over $\Psi_{C}$ and objects of $\mathcal{C}$ are all $j$-separated.
2. $P \triangleleft \Psi_{C}$ and the right adjoint is an elementary morphism of doctrines.
3. $P$ has full weak comprehensions and comprehensive diagonals.

Proof. It follows from Proposition 3.6 .

The elementary quotient completion presented in 2.2 very well behaves with respect to comprehensions, in particular we have the following.
3.13 Proposition. $P$ is variational if and only if $\widehat{P}$ is m-variational.

Proof. The necessary condition is immediate. Suppose $P$ has weak comprehensions. For an element $\alpha$ in $\widehat{P}(A, \rho) \subseteq P(A)$ its comprehension is

$$
[\{\alpha\}]:\left(X, P_{\{\alpha\} \times\{\alpha\}}(\rho)\right) \longrightarrow(A, \rho)
$$

where $\{\alpha\}: X \rightarrow A$ is the weak comprehension of $\alpha$ in $P$. Since $\widehat{P}$ has comprehensive diagonals, the arrow $[\{\alpha\}]$ is monic (2.34).
3.14 Proposition. If $P$ is variational, then $Q_{P}$ has finite limits.

Proof. By $3.13 \widehat{P}$ is m-variational, then apply 2.30 .
Every topology $j$ on a primary doctrine $P$ determines a topology $\widehat{j}$ on the elementary quotient completion $\widehat{P}$. The topology $\widehat{j}$ is simply the restriction of $j$ to the poset of descent data, i.e. for $\rho$ a $P$-equivalence relation over $A$ and $\alpha$ in $\mathscr{D} e s_{\rho}$ it is $\widehat{j}_{(A, \rho)}(\alpha)=j_{A}(\alpha)$ (see also Men01). Indeed (using notation as in 2.25)

$$
a: A, a^{\prime}: A \mid j \alpha(a) \wedge \rho\left(a, a^{\prime}\right) \vdash j \alpha(a) \wedge j \rho\left(a, a^{\prime}\right) \vdash j\left(\alpha(a) \wedge \rho\left(a, a^{\prime}\right)\right) \vdash j \alpha\left(a^{\prime}\right)
$$

After Proposition 3.8 we know that every existential variational doctrine $P$ on a category $\mathcal{C}$ with weak pullbacks generates a topology on $\Psi_{C}$.
3.15 Definition. Let $P$ an existential variational doctrine. The canonical topology given by $P$ is the topology induced on $\Psi_{C}$ and denoted with the symbol $j_{P}$, i.e. $j_{P}(f)$ is $\left\{\exists_{f} \top_{A}\right\}$ for $f: A \rightarrow B$ in $\mathcal{C}$.
3.16 Proposition. Suppose $P: \mathcal{C}^{o p} \longrightarrow$ ISL is an existential variational doctrine. Then $Q_{P}$ is the category of $\widehat{j_{P}}$-separated objects for the topology $\widehat{j_{P}}$ induced over $\operatorname{Sub}_{\mathcal{C}_{\text {ex/lex }}}$.
Proof. By 3.4 there is a full and faithful $R: Q_{P} \rightarrow Q_{\Psi_{c}}$ which is right adjoint to $L: Q_{\Psi_{c}} \rightarrow Q_{P}$.Take a $\Psi_{C^{-}}$equivalence relation $[k: X \longrightarrow A \times A]$ over $A$. The object $(A,[k])$ in $Q_{\Psi_{c}}$ is equivalent to one in $Q_{P}$ if and only if $(A,[k]) \simeq R L(A,[k])$. From the construction of $L$ and $R$ as in 3.4 this happens if and only if

$$
\delta_{(A,[k])}=[k]=j_{P_{A \times A}}[k]=\widehat{j_{P}(A,[k]) \times(A,[k])}\left(\delta_{(A,[k])}\right)
$$

Note that $\widehat{j_{P}}$ is a topology on $\widehat{\Psi_{C}}$ which is $\operatorname{Sub}_{\mathcal{C}_{\mathrm{ex} / \text { lex }}}$, whence the claim.
A first order doctrine $P: \mathcal{C}^{\mathrm{op}} \longrightarrow \mathbf{I S L}$ is boolean if for every $A$ and $\alpha$ in $P(A)$ it holds $\top_{A}=\alpha \vee \neg \alpha$ where $\neg \alpha$ is short for $\alpha \rightarrow \perp$.
3.17 Proposition. A first order variational doctrine $P: C^{o p} \longrightarrow$ ISL on a base $C$ with weak pullbacks and an initial object 0 such that $\{\perp\}=$ un where un:o $\rightarrow 1$ in $\mathcal{C}$, is boolean if and only if $P$ is isomorphic to $\Psi_{\mathcal{C}\urcorner \neg}$, the doctrine of $\neg \neg$-closed elements of $\Psi_{\mathcal{C}}$. A first order m-variational doctrine $P: \mathcal{C}^{o p} \longrightarrow \mathbf{I S L}$ on a base $\mathcal{C}$ is boolean if and only if $P$ is isomorphic to $\operatorname{Sub}_{\mathcal{C} \neg \neg \text {, the doctrine of } \neg \neg \text {-closed }}$ elements of $\mathrm{Sub}_{\mathcal{C}}$.
Proof. We show the non-trivial direction. Suppose $P$ is boolean. By 3.8 there is a topology $j$ on $\Psi_{C}$ such that $P$ is isomorphic to $\Psi_{C j}$ and for $[f: X \rightarrow A]$ in $\Psi_{C}(A)$ it is $j_{A}[f]=\left[\left\{\mathcal{G}_{f} \top_{X}\right\}\right]$. It is

$$
\left[\left\{\left\{\mathcal{G}_{f} \top_{X}\right\}\right\}\right]=\left[\left\{\neg V_{f} \neg \top_{X}\right\}\right]=\left[\neg \Pi_{f} \neg\left\{\top_{X}\right\}\right]=\neg \neg\left[\Sigma_{f}\left\{\top_{X}\right\}\right]=\neg \neg\left[\Sigma_{f}\left(\mathrm{id}_{X}\right)\right]
$$

and hence the claim as $\left[\Sigma_{f}\left(\operatorname{id}_{X}\right)\right]=[f]$.

## 4 Decomposition of the elementary quotient completion

In this section we recall from MR13a that the construction of the elementary quotient completion of an elementary introduced in MR13b is not primitive because it can be obtained by applying two other free constructions to $P$. First, we apply to $P$ the intensional quotient completion of an elementary doctrine which freely adds just effective descent quotients, second we apply the extensional collapse construction of an elementary doctrine which freely adds comprehensive diagonals. Both constructions were introduced in MR13a and the second had been already recalled in 2.9. We now recall the first construction.
4.1 Definition. Given a elementary $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL we call $Q_{P i}$ the category whose objects are pairs $(A, \rho)$ in which $A$ is in $\mathcal{C}$ and $\rho$ is an equivalence relation over $A$. An arrow $f:(A, \rho) \rightarrow(B, \sigma)$ is an arrow $f: A \rightarrow B$ in $\mathcal{C}$ such that $\rho \leq P_{f \times f}(\sigma)$.

Then we define an elementary doctrine called intensional quotient completion of $P$

$$
\begin{gathered}
P_{i q}(A, \rho)=\left\{\phi \in P(A) \mid P_{\mathrm{pr}_{1}}(\phi) \wedge \rho \leq P_{\mathrm{pr}_{2}}(\phi)\right\} \\
\left(P_{i q}\right)_{[f]}=P_{f}
\end{gathered}
$$

where $\mathrm{pr}_{1}$ and $\mathrm{pr}_{2}$ are the first and the second projection form $A \times A$. It is proved in MR13a that the assignment on arrows does not depend on the choice of representatives.
4.2 Theorem. There is a left biadjoint to the forgetful 2-functor from the full 2-category of elementary doctrines with stable effective descent quotients into the 2-category ED of elementary doctrines which associates the doctrine $P_{i q}: Q_{P i}^{o p} \longrightarrow \mathbf{I S L}$ to an elementary doctrine $P: C^{o p} \longrightarrow$ ISL.

As shown in MR13a the intensional quotient completion of a doctrine has stable effective descent quotients: if $\sigma$ is an equivalence relation over $(A, \rho)$, then its quotient is given by

$$
\left[\operatorname{id}_{A}\right]:(A, \rho) \longrightarrow(A, \sigma)
$$

Observe that in the doctrine $Q_{P i}$, the equality predicate over $(A, \rho)$ is $\rho$ itself MR13a, i.e.

$$
\delta_{(A, \rho)}=\rho
$$

Note that for any elementary doctrine $Q: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL with effective quotients, the doctrine $Q_{\mathrm{x}}$ has only a weak form of quotients. But when $Q=Q_{P i}$ of an elementary doctrine $P$, in MR13a it is shown that:
4.3 Proposition. Let $P: C^{o p} \longrightarrow$ ISL be an elementary doctrine. The morph$\operatorname{ism}(K, k): Q_{P i} \rightarrow Q_{P i_{X}}$ preserves quotients and therefore $Q_{P i_{X}}$ has effective descent quotients of $Q_{P i_{x}}$-equivalence relations and coincides with the elementary quotient completion of $P$.

Further properties and applications of the intensional quotient completion can be found in Pas15, EPR20.

## 5 A characterisation of elementary quotient completions

In this section we give a characterisation of those elementary doctrines with effective descent quotients that arise as elementary quotient completions by using the concept of regular projective relative to a doctrine. This characterization generalizes the well known characterization given in CV98 for the exact completion of a lex category. Indeed, recall that the ex/lex completion of a category $\mathcal{C}$ with finite products and weak pullbacks is the base of the elementary quotient completion of the doctrine of variations of $\mathcal{C}$. Then, our characterisation arises as a generalisation to the framework of doctrines of the fact that an exact category with enough regular projectives is equivalent to the ex/lex completion of its full subcategory on projective objects.
5.1 Definition. Suppose $P: \mathcal{C}^{\mathrm{op}} \longrightarrow \mathbf{I S L}$ is an elementary doctrine. An object $X$ of $\mathcal{C}$ is said $P$-projective if for every diagram of the form

where $q$ is a quotient arrow of $P$, there is an arrow $k: X \rightarrow Y$ with $q k=f$.
5.2 Definition. Suppose $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL is an elementary doctrine. We say that $\mathcal{C}$ has enough $P$-projectives if for every $A$ in $C$ there is a $P$-projective object $X$ and a quotient arrow $q: X \rightarrow A$, called $P$-cover of $A$.

Suppose $\mathcal{E}$ is a class of morphisms of a category $\mathcal{C}$.
5.3 Lemma. Suppose $P: \mathcal{C}^{o p} \longrightarrow$ ISL is an elementary doctrine. Denote by $\mathcal{D}$ the full subcategory of $C$ consisting only of $P$-projective objects. If $\mathcal{M}$ is a full subcategory of $\mathcal{D}$ closed under binary products and such that every object of $\mathcal{D}$ is covered by one in $\mathcal{M}$, then $\mathcal{D}$ is closed under binary products.

Proof. Suppose $A$ and $B$ are in $\mathcal{D}$ and consider the diagram

where $q$ is quotient map. Let $q_{A}: X_{A} \rightarrow A$ and $q_{B} X_{B}^{\prime} \rightarrow B$ be $P$-covers respectively of $A$ and $B$, i.e. $X_{A}$ and $X_{B}$ are in $\mathcal{M}$. Since both $A$ and $B$ $P$-projectives each cover has a section $s_{A}$ and $s_{B}$. i.e. $q_{A} s-A=i d_{A}$ and $q_{B} s-A=i d_{B}$. Since $X_{A} \times X_{B}$ is $P$-projective because in $\mathcal{M}$, then there is $\bar{f}: X_{A} \times X_{B} \rightarrow X$ with $q \bar{f}=f\left(q_{A} \times q_{B}\right)$. Hence $\bar{f}\left(s_{A} \times s_{B}\right): A \times B \rightarrow X$ is such that $q \bar{f}\left(s_{A} \times s_{B}\right)=f\left(q_{A} \times q_{B}\right)\left(s_{A} \times s_{B}\right)=f$ proving that $A \times B$ is $P$-projective and hence in $\mathcal{D}$.

Note that:
5.4 Lemma. Suppose $P: \mathcal{C}^{o p} \longrightarrow$ ISL is an elementary doctrine. If $q: X \longrightarrow X / \rho$ and $q^{\prime}: X^{\prime} \longrightarrow X^{\prime} / \rho^{\prime}$ are quotient arrows, and if $X$ is $P$-projective, then for every arrow $f: X / \rho \longrightarrow X^{\prime} / \rho^{\prime}$ there is an arrow $g: X \longrightarrow X^{\prime}$ with $\top_{X}=P_{\left\langle f q, q^{\prime} g\right\rangle}\left(\delta_{X^{\prime} / \rho^{\prime}}\right)$. Obviously if the doctrine has comprehensive diagonals it is $f q=q^{\prime} g$.
5.5 Theorem. Suppose $P: \mathcal{C}^{o p} \longrightarrow \mathbf{I S L}$ is an elementary doctrine with comprehensive diagonals and effective descent quotients. The following are equivalent
i) $P: \mathcal{C}^{o p} \longrightarrow$ ISL is of the form $\widehat{P_{0}}: Q_{P^{0}}^{o p} \longrightarrow$ InfSL for some elementary doctrine $P_{0}: \mathcal{C}_{0}^{o p} \longrightarrow$ ISL with comprehensive diagonals.
ii) $P: \mathcal{C}^{o p} \longrightarrow$ ISL has enough $P$-projectives and these are closed under binary products.
When one of the conditions holds, then $P$ is the intensional elementary quotient completion of its restriction to the full subcategory of $\mathcal{C}$ made of $P$-projectives.
Proof. i) $\Rightarrow$ ii) All quotient arrows in $Q_{P_{0}}$ are of the form $\left[\operatorname{id}_{A}\right]:(A, \rho) \longrightarrow(A, \sigma)$, thus objects of the form $\left(A, \delta_{A}\right)$ are $P$-projective and they determine a full subcategory of $Q_{P_{0}}$ which is closed under products. Hence $Q_{P_{0}}$ has enough $P$-projectives and these are closed under binary products by 5.3
$\mathrm{ii} \Rightarrow$ i) Denote by $\mathcal{C}_{0}$ the full subcategory of $\mathcal{C}$ on all its $P$-projectives and by $P_{0}$ the restriction of $P$ to $\mathcal{C}_{0}$ (i.e. the change of base of $P$ along the inclusion of $\mathcal{C}_{0}$ into $\mathcal{C}$ ). Since $\mathcal{C}_{0}$ is closed under products $P_{0}$ is an elementary doctrine with comprehensive diagonals. We need prove that $Q_{P_{0}}$ is equivalent to $\mathcal{C}$. Consider $[f]:(A, \rho) \rightarrow(B, \sigma)$ in $Q_{P_{0}}$. Every representative of $[f]$ determines a commutative diagram

where $\bar{f}$ is the map determined by the universal property of quotients. The diagram above extends a functor from $Q_{P_{0}} \rightarrow \mathcal{C}$. Which is faithful by effectiveness of quotients. Since $A$ and $B$ are projective every arrow $A / \rho \rightarrow B / \sigma$ determines an arrow $A \rightarrow B$, then the functor is also full. Essential surjectivity is a straightforward consequence of the hypothesis that $\mathcal{C}$ has enough $P$-projectives. Since quotients are of effective descent, for every $(A, \rho)$ in $Q_{P_{0}}$ the poset $\widehat{P_{0}}(A, \rho)$ is isomorphic to $P(A / \rho)$ : this completes the proof.
5.6 Theorem. Suppose $P: \mathcal{C}^{o p} \longrightarrow$ ISL is an elementary doctrine with comprehensive diagonals, full comprehensions and effective descent quotients. The following are equivalent
i) $P: \mathcal{C}^{o p} \longrightarrow$ ISL is of the form $\widehat{P_{0}}: Q_{P^{0}}^{o p} \longrightarrow$ InfSL, i.e. an elementary quotient completion, for some elementary doctrine $P_{0}: \mathcal{C}_{0}^{o p} \longrightarrow$ ISL with comprehensive diagonals and full comprehensions.
ii) $P: C^{o p} \longrightarrow$ ISL has enough $P$-projectives and these are closed under finite limits.

When one of the conditions holds, then $P$ is the intensional elementary quotient completion of its restriction to the full subcategory of $\mathcal{C}$ made of $P$-projectives.

Proof. Analogous to the proof of Theorem 5.5. Just observe that for the direction i $\Rightarrow$ ii) $P$-projectives are closed under pullbacks, and hence finite limits by Proposition 2.30 applied to $P_{0}$ which has full comprehensions and comprehensive diagonals.

In a similar way we obtain a characterization of intensional quotient completions:
5.7 Theorem. Suppose $P: \mathcal{C}^{o p} \longrightarrow \mathbf{I S L}$ is an elementary doctrine with effective descent quotients. The following are equivalent
i) $P: \mathcal{C}^{o p} \longrightarrow \mathbf{I S L}$ is the intensional elementary quotient of some elementary doctrine $P_{0}: \mathcal{C}_{0}^{o p} \longrightarrow$ ISL.
ii) $P: \mathcal{C}^{o p} \longrightarrow$ ISL has enough $P$-projectives and these are closed under binary products.
When one of the conditions holds, then $P$ is the intensional elementary quotient completion of its restriction to the full subcategory of $\mathcal{C}$ made of $P$-projectives.

We now show how Theorem 5.5 is a generalization of Carboni-Vitale's characterization of exact completions of a lex category. To this purpose, we need some lemmas:
5.8 Lemma. In a category $C$ with finite limits an object is projective with respect to the subobject doctrine $\mathrm{Sub}_{\mathcal{C}}$ of $\mathcal{C}$ if and only if it is a regular projective.

Proof. The notion of $\mathrm{Sub}_{\mathcal{C}}$-effective quotient coincide with that of categorical effective quotient.
5.9 Lemma. Let $\mathcal{C}$ be an exact category. Denote by $\mathcal{C}_{0}$ the full subcategory of $\mathcal{C}$ on its regular projectives. If $\mathcal{C}$ has enough projectives closed under finite limits then the subobject doctrine $\mathrm{Sub}_{\mathcal{C}}$ restricted to $\mathcal{C}_{0}$ is isomorphic to the doctrines of variations $\Psi_{\mathcal{C}_{0}}: \mathcal{C}_{0}^{O P} \longrightarrow$ ISL.

Proof. The doctrine of variations can be fully and faithfully embedded in $\mathrm{Sub}_{C}$ as follows: to any map $f: A \longrightarrow B$ in $\mathcal{C}_{0}$ we associate the subobject $i_{f}: \operatorname{Im}(f) \longrightarrow$ $B$ given by the image factorization of $f$ in an exact category.

Conversely, given any subobject $i: C \longrightarrow B$ in $C$ over a projective $B$, by hypothesis there exists a projective cover $q_{C}: X_{C} \rightarrow C$ of $C$ which gives rise to map $i q_{C}: X_{C} \rightarrow B$ which is in $\mathcal{C}_{0}$. The correspondence is bijective since the weak subobject given by $i_{f} q_{I m f}$ is the same as that of $f$ due to the projectivity of $X_{I m f}$ and $A$, and the image of $i q_{C}$ is the suboject of $i$ by the uniqueness of the image factorization in an exact category.
5.10 Corollary. Let $\mathcal{C}$ be an exact category. The following are equivalent:
i) $\mathcal{C}$ is an ex/lex completion.
ii) $\mathcal{C}$ has enough regular projectives closed under finite limits.

When one of the conditions holds, then $\mathcal{C}$ is the ex/lex completion of its full subcategory of regular projectives.

Proof. First, recall that the exact completion of a category with binary products and weak pullbacks is an instance of the elementary quotient completion (see Example $2.53-(\mathrm{d})$ ) and that the subobject doctrine of an exact category has effective descent quotients by Lemma 2.51. Then, the claim is an instance of Theorem 5.6 by Lemma 5.8 and 5.9 .

## 6 Structural properties in the elementary quotient completion

In this section and in the next ones we generalize well known facts concerning the categorical structure of the ex/lex completion to the elementary quotient completion.

It is well known that the ex/lex completion brings weak structures of $\mathcal{C}$ to strong structures in $\mathcal{C}_{\mathrm{ex} / \text { lex }}$ and this holds for elementary quotient completions in an analogous way. In this section we shall focus on local cartesian closure, disjoint stable coproducts and predicate classifier from a given variational elementary doctrine $P$. First note the following.
6.1 Proposition. $P$ is a first order doctrine if and only if $\widehat{P}$ is a first order doctrine.

Proof. Immediate, see also Pas16.
A $J$-diagrams in $\mathcal{C}$ is a functor of the form $J \rightarrow \mathcal{C}$. We say that $\mathcal{C}$ has $J$-indexed limits if every $J$-diagram has a limits and that $C$ has $J$-weak indexed
limits if every $J$-diagram has the existence property of a limit but not the uniqueness condition. Accordingly we say that $\mathcal{C}$ has $J$-indexed colimits if every $J$-diagram has a colimits.

Recall that for a variational doctrine $P$ on $\mathcal{C}$ the $\nabla_{P}: \mathcal{C} \rightarrow Q_{P}$ (i.e. the functor that maps $f: A \rightarrow B$ to $\left.[f]:\left(A, \delta_{A}\right) \longrightarrow\left(B, \delta_{B}\right)\right)$ is full and faithfull.
6.2 Proposition. If $P: \mathcal{C}^{o p} \longrightarrow$ ISL is a variational doctrine, then for every $J \rightarrow C$ it holds

1. if $Q_{P}$ has $J$-indexed limits, then $\mathcal{C}$ has $J$-indexed weak limits;
2. if $Q_{P}$ has $J$-indexed colimits of the form $\left(W, \delta_{W}\right)$, then $C$ has $J$-indexed colimits.

Proof. 1. Let $F$ be a $J$-diagram in $\mathcal{C}$. If $(W, \omega)$ is the limit of $\nabla_{P} F$ in $Q_{P}$, then $\left(W, \delta_{W}\right)$ is a weak limit of $\nabla_{P} F$ in the image of $\nabla_{P}$ within $Q_{P}$, and hence $W$ is a weak limit of $F$ in $\mathcal{C}$. 2. Consider a diagram $F: J \longrightarrow \mathcal{C}$ and suppose $\left(W, \delta_{W}\right)$ is the colimit for $\nabla_{P} F$. $W$ is easily seen to be a weak colimit for $F$ in $\mathcal{C}$. Suppose $X$ is a cocone and let arrows $q, p: W \rightarrow X$ be such that they make commute all the relevant triangles. So do $[q],[p]:\left(W, \delta_{W}\right) \longrightarrow\left(X, \delta_{X}\right)$ in $Q_{P}$. Universality of $\left(W, \delta_{W}\right)$ ensures that $[q]=[p]$, i.e. $\top_{W} \leq P_{\langle q, p\rangle}\left(\delta_{X}\right)$, whence $q=p$ in $\mathcal{C}$ as diagonals are comprehensive.
6.3 Proposition. Suppose $P$ is a variational doctrine and $f: X \longrightarrow A, g: Y \longrightarrow A$ are arrows of $\mathcal{C}$. Suppose also that $\rho$ and $\sigma$ are $P$-equivalence relations over $X$ and $Y$ respectively such that $\rho \leq P_{f \times f}\left(\delta_{A}\right)$ and $\sigma \leq P_{g \times g}\left(\delta_{A}\right)$. Consider two arrows $k: P \longrightarrow X$ and $h: P \longrightarrow Y$ and the following two squares

If the left square is a weak pullback in $\mathcal{C}$, the right square is a pullback in $Q_{P}$.
Proof. Take any two arrows $[a]:(C, \gamma) \rightarrow(X, \rho)$ and $[b]:(C, \gamma) \rightarrow(Y, \sigma)$ with $[f][a]=[g][b]$. That is to say $T_{C}=P_{f a \times g b}\left(\delta_{A}\right)$. Since diagonals are comprehensive we have $f a=g b$. Hence there is $u: C \longrightarrow S$ with $k u=a$ and $h u=b$. Since $\gamma \leq P_{a \times a}(\rho)=P_{u \times u} P_{k \times k}(\rho)$ and $\gamma \leq P_{b \times b}(\rho)=P_{u \times u} P_{h \times h}(\sigma)$ one has $\gamma \leq P_{u \times u}\left(P_{h \times h}(\sigma) \wedge P_{k \times k}(\rho)\right)$, showing that $[u]$ is an arrow in $Q_{P}$, thus also $[k][u]=[a]$ and $[h][u]=[b]$. If $\left[u^{\prime}\right]$ is such that $[k]\left[u^{\prime}\right]=[a]$ and $[h]\left[u^{\prime}\right]=[b]$, then also $[k]\left[u^{\prime}\right]=[k][u]$ and $[h]\left[u^{\prime}\right]=[h][u]$, i.e.

$$
\top_{C} \leq P_{u \times u^{\prime}} P_{k \times k}(\rho) \quad \top_{C} \leq P_{u \times u^{\prime}} P_{h \times h}(\sigma)
$$

whence $\top_{C} \leq P_{u \times u^{\prime}}\left(P_{h \times h}(\sigma) \wedge P_{k \times k}(\rho)\right)$ showing that $[u]=\left[u^{\prime}\right]$.
6.4 Proposition. Suppose $P: \mathcal{C}^{o p} \longrightarrow \mathbf{I S L}$ is a variational doctrine and consider two squares of the form

If the right square is a pullback in $Q_{P}$, the left square is a weak pullback in $\mathcal{C}$
Proof. Suppose $a: C \rightarrow X$ and $b: C \rightarrow Y$ are such that $f a=g b$. Then $[a]:\left(C, \delta_{C}\right) \rightarrow\left(X, \delta_{A}\right)$ and $[b]:\left(C, \delta_{A}\right) \rightarrow\left(Y, \delta_{Y}\right)$ are such that $[f][a]=[g][b]$. So there is $[u]$ with $[k][u]=[a]$ and $[h][u]=[b]$, i.e.

$$
\top_{C}=P_{\langle k u, a\rangle}\left(\delta_{X}\right) \quad \top_{C}=P_{\langle h u, b\rangle}\left(\delta_{Y}\right)
$$

Since diagonals are comprehensive, $u$ is such that $k u=a$ and $h u=b$ in $\mathcal{C}$.

### 6.1 Local cartesian closure

In this section we characterize sufficient and necessary conditions that an elementary doctrine $P$ must satisfy to guarantee that the base of its elementary quotient completion is locally cartesian closed.

Recall from CR00 that:
6.5 Definition. a category $\mathcal{C}$ with finite products is weakly cartesian closed if for every $A$ and $B$ in $C$ there is an arrow $e: A \times W \longrightarrow B$ such that for every arrow $f: A \times C \rightarrow B$ there is $\bar{f}: C \rightarrow W$ with $e\left(\mathrm{id}_{A} \times \bar{f}\right)=f$.

This definition has a direct generalization in the context of categories with weak products, provided that one reads $A \times W$ and $A \times C$ as weak products and $\operatorname{id}_{A} \times \bar{f}$ as the map that derives from the weak universal property of $A \times W$ :
6.6 Definition. A category $\mathcal{C}$ is weakly cartesian weakly closed if for every $X$ and $Y$ there is $W$ and an arrow $e: S \longrightarrow Y$, where $S$ is a weak product of $X$ along $W$, such that for every $C$ and every $k: T \longrightarrow Y$, where $T$ is a weak product of $X$ and $C$, there is $\bar{k}: C \rightarrow W$ such that $e\left(\operatorname{id}_{X} \times \bar{k}\right)=k$, where $\mathrm{id}_{X} \times \bar{k}$ is any of the obvious arrows coming from the weak universal property of $W$.
6.7 Proposition. Suppose $\mathcal{C}$ is a category with finite weak products and weak pullbacks. If $C$ is weakly closed the for every $A$ in $C$ and every weak terminal object 1 the map $\Psi_{C}\left(!_{A}\right): \Psi_{C}(1) \longrightarrow \Psi_{C}(A)$ as a right adjoint.

Proof. For $f: X \rightarrow A$ define $\Pi_{!_{A}}[f]=\left[!_{A^{x}}\right]$ where $A^{X}$ is a weak exponential.
If a category $\mathcal{C}$ has weak pullbacks the definition above can be phrased in each slice. We say that a category $\mathcal{C}$ with weak pullbacks is slice-wise weakly cartesian closed, if for every $A$ in $\mathcal{C}$ the slice is weakly cartesian weakly closed.
6.8 Proposition. Suppose $\mathcal{C}$ is a category with finite products and weak pullbacks. If $\mathcal{C}$ is slice-wise weakly cartesian closed, then $\Psi_{C}$ is implicational and universal.

Proof. The weak cartesian closure of $\mathcal{C} / A$ implies that the inf-semilattice $\Psi_{C}(A)$ has the Heyting implication. To see that Heyting implications are preserved by $\Psi_{C}(f)$, observe that from the implication properties and conjunction preservation under change of base $\Psi_{\mathcal{C}}(f)(\alpha \Rightarrow \beta) \leq \Psi_{\mathcal{C}}(f) \alpha \Rightarrow \Psi_{\mathcal{C}}(f) \beta$ follows. Moreover, $\Psi_{\mathcal{C}}(f) \alpha \wedge\left(\Psi_{\mathcal{C}}(f) \alpha \Rightarrow \Psi_{\mathcal{C}}(f) \beta\right) \leq \Psi_{\mathcal{C}}(f) \beta$ also holds and hence by applying $\Sigma_{F}$ to each member by Frobenius condition we get $\alpha \wedge \Sigma_{f}\left(\Psi_{C}(f) \alpha \Rightarrow\right.$ $\left.\Psi_{C}(f) \beta\right) \leq \beta$ and hence $\Psi_{\mathcal{C}}(f) \alpha \Rightarrow \Psi_{\mathcal{C}} \leq \Psi_{\mathcal{C}}(f)(\alpha \Rightarrow \beta)$, whence $\Psi_{\mathcal{C}}$ is implicational.

For every $A$ and every projection $\pi_{A}: A \times B \rightarrow A$, the known equivalence of categories between $C /(A \times B)$ and $(C / A) / \pi_{A}$ leads to the following commutative diagram

Since $\mathcal{C} / A$ is weakly cartesian closed, by 6.7 the map $\Psi_{C / A}\left(!_{\pi_{A}}\right)$ has a right adjoint, so also $\Psi_{C}\left(\pi_{A}\right)$ has a right adjoint. The doctrine $\Psi_{C}$ is such that for every $f$ the map $\Psi_{C}(f)$ has a left adjoint $\Sigma_{f}$ satisfying the Frobenius Reciprocity and the Beck-Chevalley condition on all pullbacks. So, by adjoint counits, for every $f: Z \rightarrow Y$ and every $\alpha$ in $\Psi_{C}(X \times Y)$ we get $\Sigma_{\operatorname{id}_{X} \times f} \Psi_{C}\left(\pi_{Z}\right) \Pi_{\pi_{Z}} \Psi_{C}\left(\mathrm{id}_{X} \times f\right)(\alpha) \leq$ $\alpha$. By the Beck-Chevalley on left adjoints this implies $\Psi_{C}\left(\pi_{Y}\right) \Sigma_{f} \Pi_{\pi_{Z}} \Psi_{C}\left(\mathrm{id}_{X} \times\right.$ $f)(\alpha) \leq \alpha$, whence $\Pi_{\pi_{Z}} \Psi_{C}\left(\mathrm{id}_{X} \times f\right)(\alpha) \leq \Psi_{\mathcal{C}}(f) \Pi_{\pi_{Y}}(\alpha)$. Since $\Psi_{C}(f) \Pi_{\pi_{Y}}(\alpha) \leq$ $\Pi_{\pi_{Z}} \Psi_{C}\left(\operatorname{id}_{X} \times f\right)(\alpha)$ follows easily as well by adjoint counit, we conclude that $\Psi_{C}$ preserves universal quantifiers and hence is universal.
6.9 Lemma. Suppose $P: C^{o p} \longrightarrow$ ISL is a variational doctrine. If $Q_{P}$ is locally cartesian closed, then $\mathcal{C}$ is slice-wise weakly cartesian closed.

Proof. Immediate after 6.4.
We now aim at proving the converse of 6.9
To this purpose, we give the following definition:
6.10 Definition. Let $C$ be slice-wise weakly cartesian closed. Let $P$ be a universal implicational doctrine on $C$ and consider $[f]:(B, \sigma) \longrightarrow\left(A, \delta_{A}\right)$ and $[g]:\left(B^{\prime}, \sigma^{\prime}\right) \longrightarrow\left(A, \delta_{A}\right)$. The fact that $\mathcal{C}$ is slice-wise weakly cartesian closed
ensures that the left diagram below is commutative

where the square $(A)$ is a weak pullback and $t^{\prime}: W^{\prime} \rightarrow A$ is a weak exponential of $g$ to the power of $f$ in $C / A$ with weak evaluation $e^{\prime}$. Now consider the element $\xi$ of $P\left(W^{\prime}\right)$ defined as
$V_{\operatorname{pr}_{3}}\left(P_{\left\langle p_{W^{\prime}} \operatorname{pr}_{1}, \operatorname{pr}_{3}\right\rangle}\left(\delta_{W^{\prime}}\right) \wedge P_{\left\langle p_{W^{\prime}} \operatorname{pr}_{2}, \operatorname{pr}_{3}\right\rangle}\left(\delta_{W^{\prime}}\right) \wedge P_{\left\langle p_{B} \operatorname{pr}_{1}, p_{B} \operatorname{pr}_{2}\right\rangle}(\sigma) \rightarrow P_{\left\langle e^{\prime} \operatorname{pr}_{1}, e^{\prime} \operatorname{pr}_{2}\right\rangle}\left(\sigma^{\prime}\right)\right)$
where $\mathrm{pr}_{1}, \mathrm{pr}_{2}$ and $\mathrm{pr}_{3}$ are projections from $S \times S \times W^{\prime}$. The composition $t^{\prime}$ with $\{\xi\}: W \rightarrow W^{\prime}$ determines $t=t^{\prime}\{\xi\}: W \rightarrow A$ in the right diagram above. The square $(B)$ is the weak pullback of $t$ along $f$. Since $f \pi_{B}=t \pi_{W}=t^{\prime}\{\xi\} \pi_{W}$, there is an arrow $\operatorname{id}_{f} \times_{A}\{\xi\}: Z \longrightarrow S$ and we denoted by $e$ the composition $e^{\prime}\left(\operatorname{id}_{f} \times_{A}\right.$ $\{\xi\}): Z \rightarrow B^{\prime}$. This shows that also the right diagram above is commutative.

Define the $P$-equivalence relation $\theta$ on $W$ as $P_{t \times t}\left(\delta_{A}\right) \wedge \omega$ where $\omega$ is
$V_{\left\langle\operatorname{pr}_{2}, \mathrm{pr}_{3}\right\rangle}\left(P_{\left\langle\pi_{W} \operatorname{pr}_{1}, \mathrm{pr}_{2}\right\rangle}\left(\delta_{W}\right) \wedge P_{\left\langle\pi_{W} \operatorname{pr}_{3}, \mathrm{pr}_{4}\right\rangle}\left(\delta_{W}\right) \wedge P_{\left\langle\pi_{B} \operatorname{pr}_{1}, \pi_{B} \operatorname{pr}_{3}\right\rangle}(\sigma) \rightarrow P_{\left\langle\mathrm{epr}_{2}, e \mathrm{er}_{4}\right\rangle}\left(\sigma^{\prime}\right)\right)$
where projections are from $Z \times W \times Z \times W$. We leave as an exercise to verify that

$$
P_{\pi_{B} \times \pi_{B}}(\sigma) \wedge P_{\pi_{W} \times \pi_{W}}(\theta) \leq P_{e \times e}\left(\sigma^{\prime}\right)
$$

establishing $e$ as a legitimate representative of the following arrow in $Q_{P}$

$$
[e]:\left(Z, P_{\pi_{B} \times \pi_{B}}(\sigma) \wedge P_{\pi_{W} \times \pi_{W}}(\theta)\right) \longrightarrow\left(B^{\prime}, \sigma^{\prime}\right)
$$

6.11 Lemma. Suppose $P$ on $\mathcal{C}$ is a variational f.o.d. If $\mathcal{C}$ is slice-wise weakly cartesian closed, then for every $A$ the slice $Q_{P} /\left(A, \delta_{A}\right)$ is cartesian closed.

Proof. For $[f]:(B, \sigma) \longrightarrow\left(A, \delta_{A}\right)$ and $[g]:\left(B^{\prime}, \sigma^{\prime}\right) \longrightarrow\left(A, \delta_{A}\right)$ consider the diagram

where $(C)$ is a pullback by 6.3. Take any $[h]:(C, \gamma) \longrightarrow\left(A, \delta_{A}\right)$ and $[m]:[f] \times{ }_{\left(A, \delta_{A}\right)}$ $[h] \rightarrow[g]$. Thanks to 6.3 we know that $[m]:\left[f \times_{A} h\right] \rightarrow[g]$. Thus there is $m^{\prime}: C \rightarrow W^{\prime}$ with $e^{\prime}\left(\mathrm{id}_{f} \times_{A} m^{\prime}\right)=m$ which is easily seen to be such that $m^{\prime}=\{\xi\} \bar{m}$ for some $\bar{m}: C \rightarrow W$. Moreover

$$
m=e^{\prime}\left(\mathrm{id}_{f} \times_{A} m^{\prime}\right)=e^{\prime}\left(\mathrm{id}_{f} \times\{\xi\}\right)\left(\mathrm{id}_{f} \times_{A} \bar{m}\right)=e\left(\mathrm{id}_{f} \times_{A} \bar{m}\right)
$$

showing that $[e]$ is a weak evaluation in $Q_{P} /\left(A, \delta_{A}\right)$. It is now an exercise to show that if $[l]:(C, \gamma) \rightarrow(W, \theta)$ is such that $[e]\left(\left[\mathrm{id}_{f}\right] \times_{(A, \rho)}[l]\right)=[m]$ then $\top_{C} \leq P_{\langle l, \bar{m}\rangle}(\theta)$ proving uniqueness of exponential transposes.

After 6.11 it remains to prove that every slice of $Q_{P}$ is cartesian closed. Proposition 6.11 says that for every $\left(A, \delta_{A}\right)$ and every $[f]$ in $Q_{P} /\left(A, \delta_{A}\right)$ there is a right adjoint to the functor $-\times_{\left(A, \delta_{A}\right)}[f]: Q_{P} /\left(A, \delta_{A}\right) \rightarrow Q_{P} /\left(A, \delta_{A}\right)$. We aim at proving that these right adjoints exist for all $(A, \rho)$.

To this purpose we follow the line of the proof in Emm20 by relying on the existence of right adjoints as a consequence of one of Barr's tripability theorems in BW84.

We first need some instrumental propositions.
6.12 Proposition. In a m-variational doctrine $P: C^{o p} \longrightarrow$ ISL with stable effective quotients each quotient arrow is the coequalizer of its kernel pairs and hence it is a regular epimorphism. Moreover $\mathcal{C}$ is regular.

Proof. In MR13b it is proved that the kernel pairs of each map in $\mathcal{C}$ has a coequalizer which is an effective quotient arrow and hence $\mathcal{C}$ is regular.
6.13 Corollary. In a m-variational doctrine $P: \mathcal{C}^{o p} \longrightarrow$ ISL with stable effective quotients each coequalizer is a quotient arrow and it is stable under pullback.

Proof. Every coequalizer $e: A \rightarrow B$ is isomorphic to $q: A \rightarrow A / P_{\text {exe }}\left(\delta_{B}\right)$.
6.14 Proposition. Let $P: C^{o p} \longrightarrow$ ISL be an existential variational doctrine and $\widehat{P}: Q_{P}^{o p} \longrightarrow$ ISL be its elementary quotient completion. Then, for every quotient arrow $q:\left(A, \delta_{A}\right) \longrightarrow(A, \rho)$ in $Q_{P}$ the functor $q^{*}: Q_{P} /(A / \rho) \longrightarrow Q_{P} /\left(A, \delta_{A}\right)$ is monadic.

Proof. The proof is the same as that for exact categories given in JM95. Alternatively, just observe that $Q_{P}$ is regular and that any quotient map is a regular epimorphism by Lemma 6.12. Therefore it is well known that $q^{*}$ is of descent type in the sense of BW84].

Moreover, any map $f:(B, \tau) \longrightarrow(A, \rho)$ is isomorphic over $(A, \rho)$ to $\operatorname{pr}_{1}$. $\left\{P_{\langle i d, f\rangle}(\rho)\right\}:\left(X, P_{\left\langle\operatorname{pr}_{1}, \mathrm{pr}_{3}\right\rangle}(\rho) \wedge P_{\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{3}\right\rangle}(\tau)\right) \longrightarrow(A, \rho)$ which comes from a descent datum represented by $\mathrm{pr}_{1} \cdot\left\{P_{\langle i d, f\rangle}(\rho)\right\}:\left(X, \delta_{X}\right) \longrightarrow\left(A, \delta_{A}\right)$ with the obvious action.

Theorem 6.14 actually holds even in the more general situation of a generic existential variational doctrine with effective stable quotients with the same proof.

We recall from Theorem 3.7.2 in BW84.
6.15 Proposition. In a situation like the following

where $F \dashv U$ and $F^{\prime} \dashv U^{\prime}$, if furthermore

1. $W F$ is naturally isomorphic to $F^{\prime}$;
2. $U$ is monadic;
3. $W$ preserves co-equalizers of $U$-contractible pairs;
then $W$ has a right adjoint.
We apply this theorem to our context as follows:
6.16 Proposition. If an m-variational elementary $P: \mathcal{D}^{o p} \longrightarrow$ ISL has stable effective quotients, then for every quotient arrow $q: A \rightarrow A / \rho$, if the slice $\mathcal{D} / A$ is cartesian closed also the slice $\mathcal{D} /(A / \rho)$ is cartesian closed.

Proof. The cartesian closure of $\mathcal{D} / A$ ensures that for every $\alpha$ in $\mathcal{D} /(A / \rho)$ the functor $-\times_{A} q^{*} \alpha: \mathcal{D} / A \rightarrow \mathcal{D} / A$ has a right adjoint $R_{\alpha}$. Consider the diagram

Since $\Sigma_{q} \dashv q^{*}$ and $\Sigma_{q}\left(-\times_{A} q^{*} \alpha\right) \dashv R_{\alpha} q^{*}$ (by composition of adjoints), the claim is proved if we show that this situation meets the three conditions in proposition 6.15,
Condition 1 holds since, for any $\beta$ in $\mathcal{C} / A$, Frobenius reciprocity precisely says that $\Sigma_{q}(\beta) \times_{(A / \rho)} \alpha$ is isomorphic to $\Sigma_{q}\left(\beta \times_{A} q^{*} \alpha\right)$.
Condition 2 holds since every quotient arrow $q: A \rightarrow A / \rho$ induces a monadic functor $q^{*}$ by 6.14
Condition 3 is fullfiled as well, since in $C /(A / \rho)$ coequalizers of $q^{*}$-contractible pairs are preserved by $-\times_{A} q^{*} \alpha$ thanks to stability of coequalizers in Corollary 6.13

Now we are ready to prove the main theorem of the section.
6.17 Theorem. Suppose $P: \mathcal{C}^{o p} \longrightarrow$ ISL is a variational implicational and universal doctrine. Then $\mathcal{C}$ is slice-wise weakly cartesian closed if and only if $Q_{P}$ is locally cartesian closed.

Proof. The necessary condition is Lemma 6.9, For the converse note that every slice $Q_{P} /\left(A, \delta_{A}\right)$ is cartesian closed by Lemma 6.11. For every $(A, \rho)$ the arrow $\left[\operatorname{id}_{A}\right]:\left(A, \delta_{A}\right) \longrightarrow(A, \rho)$ is a quotient arrow. The claim follows by 6.16 when $\mathcal{D}$ there is $Q_{P}$.

Recall that the exact completion of a category with binary products and weak pullbacks is an instance of the elementary quotient completion. More specifically $\widehat{\Psi_{C}} \simeq \operatorname{Sub}_{C_{\text {ex/lex }}}$, which has as corollary $Q_{\Psi_{C}} \equiv \mathcal{C}_{\mathrm{ex} / \mathrm{lex}}$.

Therefore Proposition 6.17 shows that $\mathcal{C}$ is slice-wise weakly cartesian closed if and only if $C_{\text {ex/lex }}$ is locally cartesian. Hence we recover the characterization in CR00 and Emm20.
6.18 Corollary. Suppose $\mathcal{C}$ a category with finite products and weak pullbacks. Then $\mathcal{C}$ is slice-wise weakly cartesian closed if and only if $\mathcal{C}_{\text {ex/lex }}$ is locally cartesian closed.

Proof. It follows from 6.17 when applied to the doctrine functor of variations $\Psi_{C}: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL. Just note that the doctrine of variations is implicational with universal quantifications by Proposition 6.8.
6.19 Remark. The proof of Theorem 6.17 can be considered a generalization of Carboni-Rosolini characterization of locally cartesian closed exact completions $\mathcal{C}_{\text {ex/lex }}$ in CR00 only in the case the category has finite products. Related proofs of locally cartesian closure for the elementary quotient completion of a syntactic category out of specific type theories are in [Pal19] and in Mai09 and in Cio22.

### 6.2 Finite disjoint coproducts

In this section we establish the necessary and sufficient conditions under which an elementary quotient completion has stable finite coproducts.

We are interested in studying those elementary doctrines with comprehensive diagonals whose elementary quotient completion has coproducts. After 6.2 we know that if $Q_{P}$ has coproducts then $P: \mathcal{C}^{\mathrm{op}} \longrightarrow \mathbf{I S L}$ must have coproducts.

For the rest of the section, unless specified otherwise, $P$ is a variational f.o.d. on a category $\mathcal{C}$ with binary distributive coproducts.
6.20 Proposition. Canonical injections are $P$-injective, i.e. $P_{i_{A} \times i_{A}}\left(\delta_{A+B}\right)=$ $\delta_{A}$ and $P_{i_{B} \times i_{B}}\left(\delta_{A+B}\right)=\delta_{B}$.

Proof. The idea of the proof is simple when formulate in the internal language of doctrines. Given an element $a$ : $A$ then we can define a projection $\bar{p}: A+B \rightarrow A$ as follows

$$
\overline{p_{a}}(z) \equiv\left\{\begin{array}{l}
w \text { if } z=i_{A}(w) \\
a \text { if } z=i_{B}\left(w^{\prime}\right)
\end{array}\right.
$$

Hence if $i_{A}(x)={ }_{A+B} i_{A}(y)$ then $x={ }_{A} \overline{p_{x}}\left(i_{A}(x)\right)={ }_{A} \overline{p_{x}}\left(i_{A}(y)\right)={ }_{A} y$.
We, now, give its algebraic version, whose calculations are more involved.

Suppose $i_{A}: A \rightarrow A+B$ is a canonical injection and consider the commutative diagram

where $j$ is the isomorphism that comes from distributivity. Denote by $\mathrm{pr}_{i}(i=$ $1,2,3,4$, ) the projections from $Z=A \times(A+B) \times A \times(A+B)$. By Beck-Chevalley conditions on equality (see MR13b) one has both

$$
\begin{gathered}
\delta_{Z}=P_{\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{3}\right\rangle}\left(\delta_{A}\right) \wedge P_{\left\langle\mathrm{pr}_{2}, \mathrm{pr}_{4}\right\rangle}\left(\delta_{A+B}\right) \\
\delta_{Z} \leq P_{j \times j} P_{\left[\mathrm{pr}_{2}, \mathrm{pr}_{1}\right] \times\left[\mathrm{pr}_{2}, \mathrm{pr}_{1}\right]}\left(\delta_{A}\right)
\end{gathered}
$$

Evaluating both sides on $P_{e}$ for

$$
e=\left\langle\mathrm{pr}_{1}, i_{A} \mathrm{pr}_{1}, \mathrm{pr}_{1}, i_{A} \mathrm{pr}_{2}\right\rangle: A \times A \longrightarrow Z
$$

where $\mathrm{pr}_{1}, \mathrm{pr}_{2}: A \times A \rightarrow A$ are projections, we obtain

$$
\begin{aligned}
P_{e}\left(\delta_{Z}\right)= & P_{\left\langle\operatorname{pr}_{1}, \mathrm{pr}_{1}\right\rangle}\left(\delta_{A}\right) \wedge P_{i_{A} \times i_{A}}\left(\delta_{A+B}\right)=P_{i_{A} \times i_{A}}\left(\delta_{A+B}\right) \\
& P_{e}\left(\delta_{Z}\right) \leq P_{e} P_{j \times j} P_{\left[\mathrm{pr}_{2}, \mathrm{pr}_{1}\right] \times\left[\mathrm{pr}_{2}, \mathrm{pr}_{1}\right]}\left(\delta_{A}\right)
\end{aligned}
$$

Note that $e$ can be obtained by the following composition

Therefore $\left(\left[\mathrm{pr}_{2}, \mathrm{pr}_{1}\right] \times\left[\mathrm{pr}_{2}, \mathrm{pr}_{1}\right]\right)(j \times j) e$ is equal to

$$
\left(\left[\mathrm{pr}_{2}, \mathrm{pr}_{1}\right] j\left\langle\mathrm{id}_{A}, i_{A}\right\rangle \times\left[\mathrm{pr}_{2}, \mathrm{pr}_{1}\right] j\left(\mathrm{id}_{A} \times i_{A}\right)\right)\left(\Delta_{A} \times \mathrm{id}_{A}\right)
$$

since $\left[\mathrm{pr}_{2}, \mathrm{pr}_{1}\right] j\left(\mathrm{id}_{A} \times i_{A}\right)=\mathrm{pr}_{2}: A \times A \longrightarrow A$ one has

$$
\left(\left[\mathrm{pr}_{2}, \operatorname{pr}_{1}\right] j\left\langle\operatorname{id}_{A}, i_{A}\right\rangle \times\left[\mathrm{pr}_{2}, \operatorname{pr}_{1}\right] j\left(\operatorname{id}_{A} \times i_{A}\right)\right)\left(\Delta_{A} \times \operatorname{id}_{A}\right)=\operatorname{id}_{A \times A}
$$

whence $P_{i_{A} \times i_{A}}\left(\delta_{A+B}\right)=P_{e}\left(\delta_{Z}\right) \leq \delta_{A}$.
We now aim at proving that the equality on a coproduct is given by the formula

$$
\delta_{A+B}=\mathcal{G}_{i_{A} \times i_{A}}\left(\delta_{A}\right) \vee \mathcal{B}_{i_{B} \times i_{B}}\left(\delta_{B}\right)
$$

To this purpose we define the following:
6.21 Definition. Let $P$ is a variational f.o.d. on a category $C$ with binary distributive coproducts. Two arrows $h: A \longrightarrow Y$ and $k: X \longrightarrow Y$ are jointly $P$-surjective if

$$
\top_{Y}=\mathcal{G}_{h}\left(\top_{A}\right) \vee \mathcal{G}_{k}\left(\top_{X}\right)
$$

6.22 Proposition. Canonical injections are jointly $P$-surjective.

Proof. Suppose $A$ and $B$ are objects of $C$ and consider their coproduct with canonical injections $i_{A}: A \longrightarrow A+B$ and $i_{B}: B \rightarrow A+B$. Abbreviate by $k: X \longrightarrow$ $A+B$ the weak comprehension

$$
\left\{\mathcal{H}_{i_{A}}\left(\top_{A}\right) \vee \mathcal{H}_{i_{B}}\left(\top_{B}\right)\right\}: X \rightarrow A+B
$$

Clearly

$$
\top_{A} \leq P_{i_{A}}\left(\mathcal{H}_{i_{A}}\left(\top_{A}\right)\right) \leq P_{i_{A}}\left(\mathcal{H}_{i_{A}}\left(\top_{A}\right) \vee \mathcal{B}_{i_{B}}\left(\top_{B}\right)\right)
$$

and analogously for $i_{B}$. By the universal property of comprehensions there are arrows $t_{A}: A \rightarrow X$ and $t_{B}: B \rightarrow X$ with $k t_{A}=i_{A}$ and $k t_{B}=i_{B}$. These induce an arrow $\left[t_{A}, t_{B}\right]: A+B \rightarrow X$ which is a section of $k$. Thus $\left\{\top_{A+B}\right\}=\mathrm{id}_{A+B}$ factors through $\left\{\mathcal{G}_{i_{A}}\left(\top_{A}\right) \vee \mathcal{G}_{i_{B}}\left(\top_{B}\right)\right\}$. Fullness of comprehensions completes the proof.
6.23 Proposition. For every pair of $P$-injective arrows $h: A \longrightarrow Y$ and $k: X \longrightarrow$ $Y$, for every reflexive relation $\rho$ over $A$ and every reflexive relation $\theta$ over $X$, the following relation over $Y$

$$
\mathcal{G}_{h \times h}(\rho) \vee \mathcal{G}_{k \times k}(\theta)
$$

is reflexive if and only if $h$ and $k$ are jointly surjective.
Proof. Suppose $h$ and $k$ are jointly surjective and consider the relation $\mathcal{G}_{h \times h}(\rho)$. By Beck-Chevalley conditions it is

$$
P_{\Delta_{Y}}\left(\mathcal{G}_{h \times h}(\rho)\right)=\mathcal{G}_{h}\left(P_{\Delta_{A}}(\rho)\right)=\mathcal{H}_{h}\left(\top_{A}\right)
$$

Analogously $\left.P_{\Delta_{Y}}\left(\mathcal{G}_{k \times k}(\theta)\right)=\mathcal{G}_{k}\left(\top_{X}\right)\right)$ whence

$$
P_{\Delta_{Y}}\left(\mathcal{H}_{h \times h}(\rho) \vee \mathcal{G}_{k \times k}(\theta)\right)=\mathcal{G}_{h}\left(\top_{A}\right) \vee \mathcal{G}_{k}\left(\top_{X}\right)
$$

Therefore, reflexitivity holds, i.e. $\top_{Y}=P_{\Delta_{Y}}\left(\mathcal{G}_{h \times h}(\rho) \vee \mathcal{G}_{k \times k}(\theta)\right)$ if and only if $h$ and $k$ are jointly surjective, i.e. $\top_{Y}=\mathcal{G}_{h}\left(\top_{A}\right) \vee \mathcal{G}_{k}\left(\top_{X}\right)$.
6.24 Proposition. For every $A$ and $B$ in $C$ it is

$$
\delta_{A+B}=\mathcal{G}_{i_{A} \times i_{A}} \delta_{A} \vee \mathcal{H}_{i_{B} \times i_{B}} \delta_{B}
$$

where $i_{A}: A \longrightarrow A+B$ and $i_{B}: B \longrightarrow A+B$ are canonical injections.
Proof. From $\delta_{A} \leq P_{i_{A} \times i_{A}}\left(\delta_{A+B}\right)$ and $\delta_{B} \leq P_{i_{B} \times i_{B}}\left(\delta_{A+B}\right)$ one obtains a canonical inequality

$$
\mathcal{G}_{i_{A} \times i_{A}} \delta_{A} \vee \mathcal{H}_{i_{B} \times i_{B}} \delta_{B} \leq \delta_{A+B}
$$

This is actually an equality, since injections are $P$-injective (6.20) and jointly surjective (6.22) hence $\mathcal{G}_{i_{A} \times i_{A}} \delta_{A} \vee \mathcal{G}_{i_{B} \times i_{B}} \delta_{B}$ is reflexive by 6.23

We leave to the readers the proof of the following instrumental lemma before the main statement of the section.
6.25 Proposition. If $\rho$ in $P(A \times A)$ is transitive and if $h: A \rightarrow B$ is $P$-injective, then $\mathcal{G}_{h \times h}(\rho)$ is transitive.

Proof. Immediate.
We can finally focus on the elementary quotient completion of a doctrine whose base has distributive binary coproducts. First recall the following:
6.26 Definition. Suppose $\mathcal{C}$ has finite coproducts. Coproducts are said distributive if the canonical arrow $(A \times B)+(A \times C) \rightarrow A \times(B+C)$ is an isomorphism.
6.27 Theorem. Suppose $P: \mathcal{C}^{o p} \longrightarrow$ ISL is a variational first order doctrine. $\mathcal{C}$ has distributive binary coproducts if and only if $Q_{P}$ has distributive binary coproducts.
Proof. Suppose $C$ has binary distributive coproducts. Consider $(A, \rho)$ and $(B, \sigma)$ in $Q_{P}$ and the coproduct $A+B$ with canonical injections $i_{A}$ and $i_{B}$. Define

$$
\rho \boxplus \sigma=\mathcal{G}_{i_{A} \times i_{A}} \rho \vee \mathcal{B}_{i_{B} \times i_{B}} \sigma
$$

by Lemma 6.23 and 6.22 the relation $\rho \boxplus \sigma$ is reflexive. It is trivially symmetric. Transitivity follows from 6.25 and 6.20. Thus

$$
(A, \rho) \xrightarrow{\left[i_{A}\right]}(A+B, \rho \boxplus \sigma) \stackrel{\left[i_{B}\right]}{\longleftrightarrow}(B, \sigma)
$$

is a diagram in $Q_{P}$. We claim that it is a coproduct diagram of $(A, \rho)$ and $(B, \sigma)$. It is immediate to see that it is a weak coproduct. We now prove that it is a strong coproduct. Suppose that $f: A \rightarrow T$ and $g: B \rightarrow T$ represent two arrows $[f]:(A, \rho) \rightarrow(T, \theta)$ and $[g]:(B, \sigma) \longrightarrow(T, \theta)$. If $k$ and $l$ represents two arrows $[k],[l]:(A+B, \rho \boxplus \sigma) \longrightarrow(T, \theta)$ with

$$
\begin{array}{lll}
{[k]\left[i_{A}\right]=[f]} & \text { and } & {[k]\left[i_{B}\right]=[g]} \\
{[l]\left[i_{A}\right]=[f]} & \text { and } & {[l]\left[i_{B}\right]=[g]}
\end{array}
$$

i.e. $k$ and $l$ are such that

$$
\begin{array}{ll}
\top_{A} \leq P_{\left\langle k i_{A}, f\right\rangle}(\theta) & \text { and } \quad \top_{B} \leq P_{\left\langle k i_{B}, g\right\rangle}(\theta) \\
\top_{A} \leq P_{\left\langle l i_{A}, f\right\rangle}(\theta) & \text { and } \quad \top_{B} \leq P_{\left\langle l i_{B}, g\right\rangle}(\theta)
\end{array}
$$

then we have also $\rho \leq P_{k i_{A} \times f}(\theta) \wedge P_{l i_{A} \times f}(\theta) \leq P_{i_{A} \times i_{A}} P_{k \times l}(\theta)$ and similarly $\sigma \leq P_{i_{B} \times i_{B}} P_{k \times l}(\theta)$. Therefore

$$
\exists_{i_{A} \times i_{A}} \rho \leq P_{k \times l}(\theta) \quad \text { and } \quad \exists_{i_{B} \times i_{B}} \sigma \leq P_{k \times l}(\theta)
$$

from which $\rho \boxplus \sigma \leq P_{k \times l}(\theta)$, i.e. $[k]=[l]$.
For the converse, consider $A$ and $B$ in $C$. The coproduct in $Q_{P}$ of $\left(A, \delta_{A}\right)$ and $\left(B, \delta_{B}\right)$ is $\left(A+B, \delta_{A} \boxplus \delta_{B}\right)$. By 6.27 this is $\left(A+B, \delta_{A+B}\right)$. The claim follows by 6.2-2.
6.28 Definition. Suppose $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL is a variational first order doctrine whose base has finite coprroducts. For objects $A$ and $B$ in the base, we say that $A+B$ is $P$-disjoint if

$$
P_{i_{A} \times i_{B}}\left(\delta_{A+B}\right)=\perp_{A \times B}
$$

6.29 Proposition. $C$ has $P$-disjoint distributive binary coproducts if and only if $Q_{P}$ has $\widehat{P}$-disjoint distributive binary coproducts.

Proof. After 6.27 we only have to prove that coproducts in $\mathcal{C}$ are $P$-disjoint if and only if coproduct in $Q_{P}$ are $\widehat{P}$-disjoint. The necessary condition is immediate after 6.24 Consider the coproduct diagram in $Q_{P}$

$$
(A, \rho) \xrightarrow{\left[i_{A}\right]}(A+B, \rho \boxplus \sigma) \stackrel{\left[i_{B}\right]}{\longleftrightarrow}(B, \sigma)
$$

it holds

$$
P_{i_{A} \times i_{B}}(\rho \boxplus \sigma)=P_{i_{A} \times i_{B}}\left(\mathcal{H}_{i_{A} \times i_{A}} \rho \vee \mathcal{H}_{i_{B} \times i_{B}} \sigma\right)
$$

but, denoting by $\mathrm{pr}_{i}$ the projections from $A \times B \times(A+B) \times(A+B), P_{i_{A} \times i_{B}}\left(\mathcal{H}_{i_{A} \times i_{A}} \rho\right)$ is equal to

$$
G_{\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{2}\right\rangle}\left[P_{\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{3}\right\rangle}\left(P_{i_{A} \times i_{A}}\left(\delta_{A+B}\right)\right) \wedge P_{\left\langle\mathrm{pr}_{2}, \mathrm{pr}_{4}\right\rangle}\left(P_{i_{A} \times i_{B}}\left(\delta_{A+B}\right)\right) \wedge P_{\left\langle\mathrm{pr}_{3}, \mathrm{pr}_{4}\right\rangle}(\rho)\right]
$$

which is equal to $\perp_{A \times B}$ under the assumption that $P_{i_{A} \times i_{B}}\left(\delta_{A+B}\right)$ is so. Analogously $P_{i_{A} \times i_{B}}\left(\mathcal{G}_{i_{B} \times i_{B}} \sigma\right)=\perp_{A \times B}$ whence the claim.
6.30 Corollary. Suppose $\mathcal{C}$ is such that for every $A$ the domain of $\left\{\perp_{A}\right\}$ is an initial object. Then $\mathcal{C}$ has disjoint distributive binary coproducts if and only if $Q_{P}$ has disjoint distributive binary coproducts.

### 6.3 Classifiers

In this section we show how the elementary quotient completion of a suitable doctrine $P$ inherits a predicate classifier for the doctrine of strong monomorphisms which coincides with the doctrine $\widehat{P}$.

We first need to establish the following characterisation of epimorphisms as $P$-surjective arrows.
6.31 Lemma. Suppose $P$ is an existential variational doctrine with a strong predicate classifier as in Definition 2.19, An arrow $e: X \rightarrow A$ is epic if and only if it is $P$-surjective.

Proof. We have already observed that $P$-surjective arrows are epimorphism. So let $e: X \rightarrow A$ be epic. Consider the arrows $\chi_{\exists_{e}\left(T_{X}\right)}, \chi_{\top_{A}}: A \rightarrow \Omega$. Then

$$
P_{e}\left(P_{\chi_{\Xi_{e}\left(\top_{X}\right)}}(\epsilon)\right)=P_{e}\left(\mathcal{G}_{e}\left(\top_{X}\right)\right)=\top_{X}=P_{e}\left(\top_{A}\right)=P_{e}\left(P_{\chi_{A}}(\epsilon)\right)
$$

Since the classifier is strong $\chi_{T_{A}} e=\chi_{\mathcal{B}_{e}\left(T_{X}\right)} e$ and then $\chi_{T_{A}}=\chi_{\mathcal{B}_{e}\left(T_{X}\right)}$ as $e$ is epic, whence $\top_{A}=P_{\chi_{\top_{A}}}(\epsilon)=P_{\chi_{\Xi_{e}\left(\top_{X}\right)}}(\epsilon)=\mathcal{G}_{e}\left(\top_{X}\right)$.

Recall that given two factorization systems $(E, M)$ and $\left(E^{\prime}, M^{\prime}\right)$ on the same category $\mathcal{C}$, we have that $E=E^{\prime}$ if and only if $M=M^{\prime}$. Thus, the following is an immediate corollary of 6.31 and 2.40.

## riferimento?

6.32 Proposition. In every m-variational existential doctrine with a strong predicate classifier comprehension arrows are the strong monomorphisms of the base.

Proof. By 2.40 comprehension arrows are the class of arrows which are right orthogonal to $P$-surjective arrows, but these coincide with epimorphisms by 6.31 whence the claim.
6.33 Proposition. In every m-variational existential doctrine with a strong predicate classifier the domain $T$ of $\{\in\}: T \rightarrow \Omega$ is a terminal object.
Proof. Let 1 be terminal. The arrow $\chi_{T_{1}}: 1 \rightarrow \Omega$ is such that $P_{\chi_{T_{1}}}(\in)=T_{1}$. The universal property of $\{\in\}$ produces an arrow $k: 1 \rightarrow T$ with $\{\in\} k=\chi_{T_{1}}$. The universal property of 1 ensures that $!_{T} k=\mathrm{id}_{1}$. Moreover from

$$
\{\in\}(\in)=\top_{T}=P_{!_{T}}\left(\top_{1}\right)=P_{!_{T}} P_{\chi T!}(\in)
$$

we have $\chi_{T_{1}}!_{T}=\{\in\}$, so $\{\in\} k!_{T}=\{\in\}$, whence $k!_{T}=\operatorname{id}_{T}$ as $\{\in\}$ is monic.
6.34 Corollary. If $P: C^{o p} \longrightarrow$ ISL is a $m$-variational existential doctrine, then $P$ has a strong predicate classifier if and only if $C$ has a classifier of strong monomorphism.

Proof. Suppose $\Omega$ is a strong predicate classifier in $P$. After 6.32 it suffices to show that $\Omega$ is a classifier for the class of comprehension arrows. Note that every $\alpha$ in $P(A)$ the following is a pullback

where $!: X \rightarrow T$ is the arrow produced by the universal property of $\{\in\}$ as $\top_{X}=P_{\{\alpha\}}(\alpha)=P_{\{\alpha\}} P_{\chi_{\alpha}}(\in)=P_{\chi_{\alpha}\{\alpha\}}(\in)$. The object $T$ is a terminal (6.33). If $f: A \longrightarrow \Omega$ makes the square $\{\in\}!=f\{\alpha\}$ a pullback, then $\{\alpha\}$ is isomorphic to $\left\{P_{f}(\in)\right\}$ by Lemma 2.33, By fullness of comprehension $P_{f}(\in)=\alpha=P_{\chi_{\alpha}}(\in)$, hence $f=\chi_{\alpha}$.

Conversely suppose $t: 1 \rightarrow \Omega$ is a strong monomorphism classifier. Define $\epsilon=\mathcal{G}_{t}\left(\top_{1}\right)$. For $\alpha$ in $P(A)$ the arrow $\{\alpha\}: X \rightarrow A$ is a strong monic by 6.32 Thus there is a unique $\chi_{\alpha}: A \longrightarrow \Omega$ that makes the following

a pullback. By 2.32 and 2.31 it is $P_{\chi_{\alpha}}(\in)=P_{\chi_{\alpha}} \mathcal{G}_{t}\left(\top_{1}\right)=\mathcal{G}_{\{\alpha\}} P_{!_{X}}\left(\top_{1}\right)=$ $\mathcal{G}_{\{\alpha\}}\left(\top_{X}\right)=\alpha$. Suppose $f: A \rightarrow \Omega$ is such that $P_{f}(\in)=\alpha$. Since $t: 1 \longrightarrow$ $\Omega$ is a strong monomorphism classifier its pullback along $f$ classifies a strong monomorphism. By 6.32 this is of the form $\{\beta\}: X^{\prime} \rightarrow A$. Moreover, by 2.32 $\alpha=P_{f}(\in) \equiv P_{f}\left(\mathcal{H}_{t}\left(\top_{1}\right)\right)=\mathcal{H}_{\{\beta\}}\left(\top_{X}\right)=\beta$. So $\{\alpha\}=\{\beta\}$ and hence $\chi_{\alpha}$ and $f$ classifies the same strong monomorphisms showing that $f=\chi_{\alpha}$.
6.35 Proposition. Let $P$ be a variational first order doctrine on $\mathcal{C}$. The following are equivalent

1. $P$ has a weak predicate classifier
2. $\widehat{P}$ has a strong predicate classifier
3. $Q_{P}$ has a classifier for strong monomorphisms.

Proof. $1 \Leftrightarrow 2$. The necessary condition is immediate, while if $\Omega$ is a predicate weak classifier in $\mathcal{C}$, then $(\Omega, \lambda)$ is a predicate classifier in $Q_{P}$ where

$$
\lambda=P_{\mathrm{pr}_{1}}(\epsilon) \leftrightarrow P_{\mathrm{pr}_{2}}(\epsilon)
$$

$2 \Leftrightarrow 3$. By 3.13 the doctrine $\widehat{P}$ is m -variational. Then apply Corollary 6.34,

## 7 The quasitopos construction from a hyper-tripos

In this section we are going to show how the elementary quotient completion of a suitable tripos gives rise to a quasitopos completion.

We start by recalling the definition of quasitopos which is a generalisation of that of topos:
7.1 Definition. A quasitopos is a category $\mathcal{C}$
(i) with finite limits
(ii) with finite co-limits
(iii) locally cartesian closed
(iv) there is a classifier for strong monomorphisms

Then recall from Wyl91 that every quasitopos has effective quotients of strong equivalence relations, namely a $\mathrm{Sub}_{\mathcal{C}}$-equivalence relation represented by a strong monomorphism. Therefore it makes sense to try to characterise those quasitoposes which arise as elementary quotient completions.

In the following when we refer to an equivalence relation in a category $\mathcal{C}$ we mean a $\operatorname{Sub}_{\mathcal{C}}$-equivalence relation, while for a strong equivalence relation we mean a $\mathrm{Sub}_{\mathcal{C}}$-equivalence relation represented by a strong monomorphism.

If $\mathcal{C}$ is a quasitopos, then both $\Psi_{C}$ and $\operatorname{Sub}_{\mathcal{C}}$ are first order doctrines. Another first order doctrine is the doctrine of strong subobjects of $\mathcal{C}$ denoted by $S t g_{\mathcal{C}}^{\mathrm{op}} \longrightarrow \mathbf{I S L}$.
7.2 Definition. A intensional hyper-tripos is an elementary existential doctrine $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL with a weak predicate classifier and full weak comprehensions such that $\mathcal{C}$ has weak pullbacks, is slice-wise weakly cartesian closed and has finite distributive coproducts. A hyper-tripos is a intensional hyper-tripos with comprehensive diagonals.
7.3 Proposition. A intensional hyper-tripos is a tripos.

Proof. Suppose $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL is a intensional hyper-tripos. Then it has full weak comprehensions. By Proposition 3.8 there is a topology $j$ on $\Psi_{\mathcal{C}}$ such that $P$ is $\Psi_{C j}$. Since $\mathcal{C}$ has weak pullbacks, is slice-wise weakly cartesian closed and has finite distributive coproducts, the doctrine $\Psi_{C}$ is first order, so is $P$ by Proposition 3.6, $C$ is weakly cartesian closed and $P$ has a weak classifier, so $P$ has weak power objects by Proposition 2.20 .
7.4 Proposition. A hyper-tripos has $P$-disjoint coproducts.

Proof. Take two objects $A, B$ and consider $\chi_{T_{A}}: A \rightarrow \Omega$ and $\chi_{\perp_{B}}: B \rightarrow \Omega$. Abbreviate with $d: A+B \rightarrow \Omega$ the arrow $\left[\chi_{\top_{A}}, \chi_{\perp_{B}}\right.$ ]. From $\delta_{A+B} \leq P_{d \times d}\left(\delta_{\Omega}\right)$ we get $P_{i_{A} \times i_{B}}\left(\delta_{A+B}\right) \leq P_{d i_{A} \times d i_{B}}\left(\delta_{\Omega}\right)=\chi_{\top_{A}} \times \chi_{\perp_{B}}\left(\delta_{\Omega}\right)$. Finally observe that $\delta_{\Omega} \leq P_{\mathrm{pr}_{1}}(\in) \leftrightarrow P_{\mathrm{pr}_{2}}(\in)$ from which we deduce $\chi_{\top_{A}} \times \chi_{\perp_{B}}\left(\delta_{\Omega}\right) \leq P_{\mathrm{pr}_{1}}\left(P_{\chi_{\top_{A}}}(\epsilon\right.$ $)) \leftrightarrow P_{\mathrm{pr}_{2}}\left(P_{\chi_{\top_{A}}}(\in)\right)=P_{\mathrm{pr}_{1}}\left(\top_{A}\right) \leftrightarrow P_{\mathrm{pr}_{2}}\left(\perp_{B}\right)=\top_{A \times B} \leftrightarrow \perp_{A \times B}=\perp_{A \times B}$. One concludes that $P_{i_{A} \times i_{B}}\left(\delta_{A+B}\right) \leq \perp_{A \times B}$.
7.5 Proposition. Let $P: C^{o p} \longrightarrow$ ISL be a tripos. For every $A$ and every $\rho$ in $P(A \times A)$ there is a $P$-equivalence relation $\bar{\rho}$ over $A$ such that $\rho \leq \bar{\rho}$ and for every $P$-equivalence relation $\mu$ over $A$, if $\rho \leq \sigma$ then $\mu \leq \bar{\rho}$.
Proof. We shall employ the language introduced in 2.25. Take $A$ in $\mathcal{C}$ and define the formulas in $U: \mathbb{P} A \times A$

$$
\begin{gathered}
\mathrm{r}(U):=\forall_{a: A}(a, a) \in_{A} U \\
\mathrm{~s}(U):=\forall_{a: A} \forall_{a^{\prime}: A}\left[\left(a, a^{\prime}\right) \in_{A} U \Rightarrow\left(a^{\prime}, a\right) \in_{A} U\right] \\
\mathrm{t}(U):=\forall_{a: A} \forall_{a^{\prime}: A} \forall_{a^{\prime \prime}: A}\left[\left(\left(a, a^{\prime}\right) \in_{A} U \wedge\left(a^{\prime}, a^{\prime \prime}\right) \in_{A} U\right) \Rightarrow\left(a^{\prime}, a^{\prime \prime}\right) \in_{A} U\right] \\
\mathrm{eq}(U):=\mathrm{r}(U) \wedge \mathrm{s}(U) \wedge \mathrm{t}(U)
\end{gathered}
$$

For every formula $\rho$ over $A \times A$ define $\bar{\rho}$ to be the following
$a: A, a^{\prime}: A \mid \forall_{U: \mathbb{P}(A \times A)}\left[\mathrm{eq}(U) \wedge \forall_{x: A} \forall_{x^{\prime}: A}\left(\rho\left(x, x^{\prime}\right) \Rightarrow\left(x, x^{\prime}\right) \in_{A} U\right) \Rightarrow\left(a, a^{\prime}\right) \in_{A} U\right]$
It is an easy exercise in first order logic to check that $\bar{\rho}$ is a $P$-equivalence relation over $A \times A$. Then, take any $\mu$ in $P(A \times A)$ and consider $\chi_{\mu}: 1 \rightarrow \mathbb{P}(A \times A)$. Recall that $\chi_{\mu}$ has the property that $\left(a, a^{\prime}\right) \in_{A} \chi_{\mu} \dashv \vdash \mu\left(a, a^{\prime}\right)$, so in $a: A, a^{\prime}: A$ it holds

$$
\bar{\rho}\left(a, a^{\prime}\right) \vdash \mathrm{eq}\left(\chi_{\mu}\right) \wedge \forall_{x: A} \forall_{x^{\prime}: A}\left(\rho\left(x, x^{\prime}\right) \Rightarrow \mu\left(x, x^{\prime}\right)\right) \Rightarrow \mu\left(a, a^{\prime}\right)
$$

If $\mu$ is a $P$-equivalence relation over $A$ then eq $\left(\chi_{\mu}\right)$ is a true sentence. If moreover $\rho \leq \mu$ also $\forall_{x: A} \forall_{x^{\prime}: A}\left(\rho\left(x, x^{\prime}\right) \Rightarrow \mu\left(x, x^{\prime}\right)\right)$ is a true sentence. Whence the sequent above reduces to $\bar{\rho}\left(a, a^{\prime}\right) \vdash \mu\left(a, a^{\prime}\right)$, which proves the claim.
7.6 Lemma. The base of a tripos with effective quotients and comprehensive diagonals has coequalizers.

Proof. Let $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL be a tripos with quotients. We shall employ the language introduced in 2.25. Take two arrows $f, g: Y \rightarrow A$ in $\mathcal{C}$ and define $\rho$ in $P(A \times A)$ to be

$$
a: A, a^{\prime}: A \mid \exists_{y: Y}\left(f(y)={ }_{A} a \wedge g(y)={ }_{A} a^{\prime}\right)
$$

By 7.5 there is the smallest $P$-equivalence relation $\bar{\rho}$ over $A$ that contains $\rho$. Consider the quotient $q: A \rightarrow A / \bar{\rho}$. It is clear that

$$
y^{\prime}: Y \mid \exists_{y: Y} f(y)==_{A} f\left(y^{\prime}\right) \wedge g(y)=_{A} g\left(y^{\prime}\right)
$$

is a true formula, that is to say $\top_{Y} \leq P_{\langle f, g\rangle}(\rho)$. So also $\top_{Y} \leq P_{\langle f, g\rangle}(\bar{\rho})$ and by effectiveness of quotient $\top_{Y} \leq P_{\langle q f, q g\rangle}\left(\delta_{A / \bar{\rho}}\right)$. So $q f=q g$ as $P$ has comprehensive diagonals.

Suppose now $k: A \rightarrow Z$ is such that $k f=k g$, then in $y: Y, a: A, a^{\prime}: A$ it holds

$$
f(y)={ }_{A} a \wedge g(y)={ }_{A} a^{\prime} \vdash k f(y)={ }_{A} k(a) \wedge k g(y)={ }_{A} k\left(a^{\prime}\right) \vdash k(a)={ }_{A} k\left(a^{\prime}\right)
$$

Therefore $\exists_{y: Y}\left(f(y)={ }_{A} a \wedge g(y)={ }_{A} a^{\prime} \vdash k(a)={ }_{A} k\left(a^{\prime}\right)\right.$. That is to say that $\rho \leq P_{k \times k}\left(\delta_{A}\right)$. By 7.5 also $\bar{\rho} \leq P_{k \times k}\left(\delta_{A}\right)$. By the universal property of quotients there is $h: A / \bar{\rho} \longrightarrow Z$ with $h q=k$.
7.7 Definition. Let $\mathcal{C}$ be a quasitopos. We denote with $S t g_{\mathcal{C}}: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL the doctrine of strong subobjects of $\mathcal{C}$, namely equivalence classes up to isomorphisms of those monic orthogonal to epimorphisms in $\mathcal{C}$.

From Wyl91 we can easily deduce that:
7.8 Lemma. The doctrine of strong subobjects $S t g_{\mathcal{C}}: \mathcal{C}^{o p} \longrightarrow$ ISL of a quasitopos $\mathcal{C}$ is a tripos.
7.9 Proposition. Let be $\mathcal{C}$ a quasitopos. The following are equivalent:

1. the quasitopos $\mathcal{C}$ is a topos;
2. the doctrine of strong subobjects Stg $_{\mathcal{C}}$ satisfies (RUC);
3. the doctrine strong subobjects Stg $_{\mathcal{C}}$ is the subobject doctrine Sub $_{\mathcal{C}}$.

Proof. A quasitopos $\mathcal{C}$ is a topos if and only if it is balanced. By Proposition 2.34 a monic arrow in $\mathcal{C}$ is $S t g_{\mathcal{C}}$-injective and by 6.31 epimorphisms are $S^{\prime} g_{\mathcal{C}^{-}}$-surjective. Then, the equivalences follow by Proposition 2.37 ,
7.10 Theorem. A doctrine $P: C^{o p} \longrightarrow$ ISL is a hyper-tripos if and only if $Q_{P}$ is a quasitopos and $\widehat{P}$ is the doctrine of strong subobjects.

Proof. In Definition 7.1 of quasitopos, point (i) comes from Proposition 3.14 point (ii) from Proposition 6.17, while point (iv) comes from Proposition 6.35 Finite coproducts come directly from Proposition 6.29 and the existence of coequalizers from Lemma 7.6. In particular the initial object in $Q_{P}$ is the initial object of $\mathcal{C}$ with the total relation. By Proposition 3.13 the doctrine $\widehat{P}: Q_{P}^{\text {op }} \longrightarrow$ ISL is m-variational. Hence $\widehat{P}$ is the doctrine of strong monomorphisms of $Q_{P}$ by Proposition 6.32

For the converse, if $Q_{P}$ is a quasitopos, by Lemma $7.8 S t g_{\mathcal{C}}$ is a tripos and it coincides with $\widehat{P}$ by Proposition 6.32 So by Proposition $6.1 P$ is first order on a slice-wise weakly cartesian closed category by Lemma 6.9 with a weak predicated classifier by Proposition 6.35. Whence $P$ is a tripos. Coproducts follows from Proposition 6.29
7.11 Corollary. If $P$ is a intensional hyper-tripos then $Q_{P}$ is a quasitopos and also $P_{\mathrm{x}}$ is a hyper-tripos.

Proof. $Q_{P}$ is a quasitopos with the same proof in 7.10 as comprehensive diagonals in $P$ play no role in the proof. Moreover, from Theorem 2.57 we know that $\widehat{P}$ is equivalent to $\widehat{P_{\mathrm{x}}}$, and hence we conclude that $P_{\mathrm{x}}$ is hyper-tripos and hence from Theorem 7.10

As a corollary we also get Menni's characterization of toposes as exact completions in Men03] as follows:
7.12 Corollary. For a finite product category $\mathcal{C}$ with weak pullbacks, $\mathcal{C}$ is slice-wise cartesian closed and has a weak proof classifier if and only if $\mathcal{C}_{\text {ex/lex }}$ is a topos.

Proof. It follows by Theorem 7.10 and Proposition 7.9 when $P=\Psi_{\mathcal{C}}$ after recalling that $\Psi_{C}$ is a hyper-tripos precisely when $\mathcal{C}$ is slice-wise cartesian closed and has a weak proof classifier as remarked in Example 2.23 (d) and that $\mathcal{C}_{\text {ex }} /$ lex is equivalent to $Q_{\Psi_{c}}$ as remarked in Example 2.53f(d).

Denote by $\mathcal{T}_{P}$ the topos that comes from the tripos $P$ under the tripos to topos construction. If $P: \mathcal{C}^{\mathrm{op}} \longrightarrow$ ISL is a hyper-tripos (intensional hypertripos), then $\mathcal{T}_{P} \equiv \mathcal{E} \mathcal{F}_{\widehat{P}}$ (this is Theorem 3.5 in [MPR17]). Thus for every hyper-tripos $P: \mathcal{C}^{\mathrm{op}} \longrightarrow \mathrm{ISL}$ the topos $\mathcal{T}_{P}$ is the topos of coarse objects of $Q_{P}$.

Note that from the proof of Theorem 7.10 that comprehensive diagonals are not necessary to get a quasitopos out of the elementary quotient completion.

Theorem 7.10 can be extended to produce arithmetic quasitoposes:
7.13 Definition. A quasitopos is arithmetic if it has a natural number object, and hence a parameterized natural numbers object.
7.14 Proposition. $P$ is a intensional hyper-tripos with a natural numbers object) if and only if $Q_{P}$ is a arithmetic quasitopos.

Proof. From Theorem 7.10 and Lemma 3.5. of [MPR19] stating we know that if $P$ has a parameterized natural number objects if and only if $Q_{P}$ has a parameterized natural number object.

Recall from Joh02 that
7.15 Definition. An object $A$ in a category $C$ is coarse if for every morphism $f: C \rightarrow B$ which is both monic and epic and every $g: C \rightarrow A$ there is a unique $t: B \rightarrow A$ such that $g=t f$.
7.16 Proposition. Every quasitopos $\mathcal{C}$ contains a full reflective subcategory $\mathrm{Crs}_{C}$ which is a topos.

Proof. The topos $\mathrm{Crs}_{C}$ is reflective and the reflector is build as follows. For any object $A$ note that the diagonal $\delta_{A}$ in $\operatorname{Stg}(A \times A)$ is represented by the diagonal (being the diagonal a strong monomorphism). Its classifying arrow $\chi_{\delta_{A}}$ factors as a strong monic followed by an epimorphism as

The object $S_{A}$ will be called object of $A$-singletons and we call $\eta_{A}: A \rightarrow S_{A}$ the singleton arrow of $A$. Note that $\chi_{\delta_{A}}$ is monic, whence the singleton arrow of $A$ is both epic and monic. Strong monic are strong comprehension arrows in $\operatorname{Stg}_{\mathcal{C}}$ so it is easy to see that every arrow $f: A \longrightarrow B$ determines a unique arrow $\mathcal{S}_{f}: \mathcal{S}_{A} \rightarrow \mathcal{S}_{B}$ with $\mathcal{S}_{f} i_{A}=i_{B} f$. This determines a functor $\mathcal{S}: \mathrm{Crs}_{C} \rightarrow \mathcal{C}$ where $\mathrm{Crs}_{C}$ is the full subcategory of $\mathcal{C}$ on coarse objects.

As shown in Joh02, Proposition 2.6.12] the functor $\mathcal{S}$ is left adjoint to the inclusion of $\mathrm{Crs}_{\mathcal{C}}$ into $\mathcal{C}$ with singleton arrows as unite. So in particular an object $A$ is coarse if and only if it is isomorphic to its own singletons, i.e. if $A \simeq S_{A}$.

Recall from Remark 2.56 that the construction that maps an existential elementary doctrine $P: C^{\mathrm{op}} \longrightarrow \mathbf{I S L}$ to the existential elementary doctrine $P_{F}: \mathcal{E} \mathcal{F}_{P}^{\mathrm{op}} \longrightarrow$ ISL satisfying (RUC). Then, we can show:
7.17 Proposition. Let $\mathcal{C}$ be a quasitopos. The doctrine of strong subobjects $S t g_{\mathcal{C}}: \mathcal{C}^{\text {op }} \longrightarrow$ ISL along the inclusion of the topos of coarse objects $\mathrm{Crs}_{\mathcal{C}}$ is equivalent to $\mathrm{Sub}_{\mathcal{C}}: \mathcal{E F}_{\text {Stg }_{\mathcal{C}}}^{o p} \longrightarrow \mathbf{I S L}$.
Proof. Any arrow $m$ in $\mathcal{C}$ can be written as the composite $m=s e$ where $s$ is strong monic and $e$ is epic. If $m$ is monic then $e$ is monic too. So if $m$ is monic in $\mathrm{Crs}_{C}$ then $e$ is an isomorphism. So every monic in $\mathrm{Crs}_{\mathcal{C}}$ so the change of base of $S t g_{\mathcal{C}}$ along the inclusion of $\mathrm{Crs}_{\mathcal{C}}$ into $\mathcal{C}$ is $\mathrm{Sub}_{\mathrm{Crs}_{C}}: \mathrm{Crs}_{C}^{\mathrm{op}} \longrightarrow \mathbf{I S L}$. So it suffices to show that $\mathrm{Crs}_{\mathcal{C}}$ is equivalent to $\mathfrak{E} \mathcal{F}$ Stg $_{C}$.

We want to find a functor $S^{\prime}: \mathcal{E F}_{\text {Stg }_{Q}} \rightarrow \mathrm{Crs}_{Q}$ naturally inverse to the composition

$$
\mathrm{Crs}_{\mathcal{C}} \longleftrightarrow \mathrm{C} \xrightarrow{\Gamma_{S t g_{C}}} \mathcal{E} \mathcal{F}_{S t g_{C}}
$$

where $\Gamma_{S t g_{C}}$ acts as the identity on objects and maps $f: A \rightarrow B$ to the formula $a: A, b: B \mid f(a)={ }_{B} b$ in $\operatorname{Stg}_{C}(A \times B)$. On the object we define $S^{\prime}$ as the action of the reflector $S: Q \rightarrow \operatorname{Crs}_{Q}$ in Lemma 7.17 i.e for any object $A$ we put $S^{\prime} A=S A$. To define the inverse on morphisms take a total and single-valued relation $F \in \operatorname{Stg}_{Q}(A \times B)$, this is a strong monic $F=\left\langle F_{1}, F_{2}\right\rangle: X \rightarrow A \times B$ in $Q$ where $F_{1}: X \rightarrow A$ is monic and epic. Thus $S F_{1}: S X \rightarrow S A$ is an isomorphism. Finally define $S^{\prime} F=S F_{2}\left(S F_{1}\right)^{-1}$.

Then, we can characterize when an hyper-tripos leads to an elementary quotient completion which is a topos:
7.18 Theorem. Let $P: C^{o p} \longrightarrow$ ISL be a hyper-tripos. Then the following are equivalent:

1. $P$ satisfies (RC).
2. $Q_{P}$ is a topos and coincides with the exact completion of the base of $P$ as a finite product category.

Proof. By Proposition $2.38 P$ is $\Psi_{C}$ if and only if (1) holds. Hence the equivalence follows by Corollary 7.12

Therefore, examples of toposes arising in this way are exactly those obtained as exact completions of a category $\mathcal{C}$ as in Men03 by taking $\Psi_{\mathcal{C}}$ for $P$.

Furthermore, we characterize those elementary quotient completions which arise as tripos-to-topos constructions originally introduced in HJP80.

To this purpose, recall from MPR17:
7.19 Definition. We say that an elementary existential doctrine $P: C^{o p} \longrightarrow$ ISL is equipped with $\epsilon$-operators if for any object $A$ in $C$ and any $\alpha$ in $P(A \times B)$ there exists an arrow $\epsilon_{\alpha}: A \rightarrow B$ such that

$$
\mathcal{H}_{\mathrm{pr}_{1}}(\alpha)=P_{\left\langle\mathrm{id}_{A}, \epsilon_{\alpha}\right\rangle}(\alpha)
$$

holds in $P(A)$, where $\mathrm{pr}_{1}: A \times B \rightarrow A$ is the first projection.
7.20 Definition. Given a tripos $P$, let us denote with $\tau_{P}$ the tripos-to-topos construction the category $\mathcal{T}_{P}$ consists of
objects: pairs $\langle A, \rho\rangle$ such that $\rho$ is in $P(A \times A)$ and satisfies symmetry and transitivity as in $(i i)$ and (iii) of Definition 2.41,
arrows: an arrow $\phi:\langle A, \rho\rangle \rightarrow\langle B, \sigma\rangle$ is an object $\phi$ in $P(A \times B)$ such that
(i) $\phi \leq P_{\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{1}\right\rangle}(\rho) \wedge P_{\left\langle\mathrm{pr}_{2}, \mathrm{pr}_{2}\right\rangle}(\sigma)$;
(ii) $P_{\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{2}\right\rangle}(\rho) \wedge P_{\left\langle\mathrm{pr}_{2}, \mathrm{pr}_{3}\right\rangle}(\phi) \leq P_{\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{3}\right\rangle}(\phi)$ in $P(A \times A \times B)$ where the $\mathrm{pr}_{i}$ 's are the projections from $A \times A \times B$;
(iii) $P_{\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{2}\right\rangle}(\phi) \wedge P_{\left\langle\mathrm{pr}_{2}, \mathrm{pr}_{3}\right\rangle}(\sigma) \leq P_{\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{3}\right\rangle}(\phi)$ in $P(A \times B \times B)$ where the $\mathrm{pr}_{i}$ 's are the projections from $A \times B \times B$;
(iv) $P_{\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{2}\right\rangle}(\phi) \wedge P_{\left\langle\mathrm{pr}_{1}, \mathrm{pr}_{3}\right\rangle}(\phi) \leq P_{\left\langle\mathrm{pr}_{2}, \mathrm{pr}_{3}\right\rangle}(\sigma)$ in $P(A \times B \times B)$ where the $\mathrm{pr}_{i}$ 's are as in (iii);
(v) $P_{\left\langle\operatorname{idd}_{A}, \operatorname{id}_{A}\right\rangle}(\rho) \leq \exists_{\mathrm{pr}_{1}}(\phi)$ in $P(A)$
where the $\mathrm{pr}_{i}$ 's are the projections from $A \times B$.
7.21 Theorem. Let $P: \mathcal{C}^{o p} \longrightarrow$ ISL be a tripos. Then the following are equivalent:

1. $P$ is equipped with $\epsilon$-operators.
2. $P_{c}$ satisfies (RC).
3. $Q_{P_{C}}$ is a topos and coincides with the tripos-to-topos construction $\tau_{P}$ of the tripos $P$.

Proof. 1. and 2. are equivalent by Theorem 5.15 in MPR17] where the category of predicates $\operatorname{Prd} d_{P}$ denotes $X_{P_{\mathrm{c}}}$. To show that 2. implies 3 . observe that from Theorem 5.5 in MPR17] we know that $P_{\mathrm{c}}$ satisfies the rule of choice iff $P_{\mathrm{c}_{\mathrm{x}}}$ satisfies the rule of choice. By Theorem 7.18, we also know that $P_{\mathrm{c}_{\mathrm{x}}}$ satisfies the rule of choice iff $Q_{{\mathrm{c}_{\mathrm{x}}}}$ is a topos and coincides with the exact completion of the base of $P_{\mathrm{c}_{\mathrm{x}}}$. Moreover $Q_{{\mathrm{c}_{\mathrm{x}}}}$ is the exact completion of the base of $P_{\mathrm{c}_{\mathrm{x}}}$ iff $Q_{P_{\mathrm{c}_{\mathrm{x}}}}$ is equivalent to $\tau_{P}$ by corollary 6.3 in MPR17. From MR13a we know that $Q_{\mathrm{c}_{\mathrm{x}}}$ is equivalent to $Q_{P_{\mathrm{c}}}$ and this concludes the proof.
7.22 Theorem. Suppose $P: \mathcal{C}^{o p} \longrightarrow$ ISL is a intensional hyper-tripos. Its tripos-to-topos construction $\mathcal{I}_{P}$ is a reflective subcategory of the quasitopos $Q_{P}$ and coincides with the category of coarse objects of $Q_{P}$

$$
\begin{equation*}
Q_{P} \underset{\longleftrightarrow}{\rightleftarrows} \mathcal{T}_{P} \tag{3}
\end{equation*}
$$

Proof. It follows from Theorem 7.17, by Theorem 7.10 and Theorem 4.7 of MPR17.

## 8 Applications

Suppose $P: C^{\mathrm{op}} \longrightarrow$ ISL is a intensional hyper-tripos. The category $Q_{P}$ is a quasitopos by Corollary 7.11. Its reflective subcategory on coarse objects $\mathrm{Crs}_{Q_{P}}$ is the topos $\mathcal{T}_{P}$ obtained from $P$ via the tripos-to-topos construction by Theorem 7.17. Moreover, by Proposition 3.5 and Proposition 3.4, we know that the category $Q_{P}$ is also a full reflective subcategory of $Q_{\Psi_{c}}$ and that $Q_{\Psi_{c}}$ is equivalent to $C_{\mathrm{ex} / \text { lex }}$ as summarized in this picture

$$
\begin{equation*}
Q_{\Psi_{c}} \stackrel{\perp}{\longleftrightarrow} Q_{P} \stackrel{\perp}{\longleftrightarrow} \mathcal{I}_{P} \tag{4}
\end{equation*}
$$

By Proposition 3.5 the intensional hyper-tripos $P$ generates a topology $j_{P}$ on $\Psi_{C}$ whose extension $\widehat{j_{P}}$ is a topology on $\operatorname{Sub}_{C_{\text {ex } / \text { lex }}}$. Moreover, $Q$ is equivalent to $\operatorname{Sep}\left(\widehat{j_{P}}\right)$ by Proposition 3.16. So picture 4 can be equivalently described as follows:

We now instantiate this picture on differente choices of $P$.
Recall triposes of the form $\mathcal{P}_{\mathcal{H}}$ as Example 2.23ł(b). As observed in Proposition 3.5 these triposes have comprehensions but they are not full. We can then consider the completion $\mathcal{P}_{\mathcal{H}_{c}}: \operatorname{Set}_{c}^{\mathrm{op}} \longrightarrow$ ISL described in 3.5, Note that $\operatorname{Set}_{c}$ is Goguen's category $\operatorname{Fuz}(\mathcal{H})$ of $\mathcal{H}$-valued fuzzy sets Gog74 for a local $\mathcal{H}$. Whence $\operatorname{Set}_{c}$ is a quasitopos and therefore it is slice-wise cartesian closed with finite coproducts. It can be equivalently described as the category $\mathcal{H}_{+}$obtained by freely adding coproducts to $\mathcal{H}$ Men03. The ex/lex completion of $\mathcal{H}_{4}$ is the topos $\operatorname{PreShv}(\mathcal{H})$ of presheaves of $\mathcal{H}$, while the tripos-to-topos construction applied to $P_{c}$ gives the topos $\operatorname{Shv}(\mathcal{H})$ of sheaves over $\mathcal{H}$. Thus, when $P$ is $\mathcal{P}_{\mathcal{H}}$, picture 4 becomes

$$
\operatorname{PreShv}(\mathcal{H}) \rightleftarrows \mathrm{\perp} \operatorname{Sep}\left(\widehat{\mathcal{P}_{\mathscr{H} c}}\right) \stackrel{\perp}{\longleftrightarrow} \operatorname{Shv}(\mathcal{H})
$$

The change of base of triposes of the form $\mathcal{P}_{\mathcal{H}}$ along the forgetful functor Top $\rightarrow$ Set is again a tripos as it suffices to endow $\mathcal{H}^{A}$ with the indiscrete topology to have the power objects (see Pas18]). In the special case of $\mathcal{H}=$ $\{0,1\}$, the tripos $\mathcal{P}_{\mathcal{H}}$ reduces to the contravariant powerset functor $\mathcal{P}: \mathcal{S e t}^{\mathrm{op}} \longrightarrow$ ISL and its change of base along Top $\rightarrow$ Set is a tripos that we call $\mathcal{T}$. The tripos $\mathcal{T}$ has full strong comprehensions given by subspace topologies. Top has coproducts and is slice-wise weakly cartesian closed CR00. So $\mathcal{T}:$ Top $^{\text {op }} \longrightarrow$ ISL is a hyper-tripos. The category of generalised equilogical spaces Gequ is equivalent to the base $Q_{\mathcal{P}}$ of the elementary quotient completion of $\mathcal{P}$. Since $\mathcal{T}$ is boolean the topology $j_{\mathcal{T}}$ is the double negation topology of example 3.7 whence also $\widehat{j_{\mathcal{T}}}$. So picture 4 becomes.

$$
\mathbf{T o p}_{\text {ex } / \text { lex }} \longleftrightarrow \stackrel{\perp}{\longleftrightarrow} \text { Gequ } \underset{\longleftrightarrow}{\longleftrightarrow} \text { Set }
$$

As a byproduct we have that Gequ is the category of $\neg \neg$-separated objects of $\mathrm{Top}_{\text {ex/lex }}$ as shown in Ros00.

The category Asm of assemblies has as objects are pair $(A, \alpha)$ where $A$ is a set $\alpha: A \longrightarrow \mathbb{P N}$ is a function from a to non-empty subsets of natural numbers. An arrow $f:(A, \alpha) \longrightarrow(B, \beta)$ is a function $f: A \rightarrow B$ such that there is $n \in \mathrm{~N}$ such that for all $a$ in $A$ and all $p$ in $\alpha(a)$ the application $n . p$ is defined and it belongs to $\beta(f(a))$.The category Pasm of partitioned assemblies is the full subcategory of Asm on those $(A, \alpha)$ such that each $\alpha(a)$ is a singleton, i.e. $\alpha$ can be seen as a function from $A$ to N . The change of base of $\mathcal{P}$ along the forgetful functor Pasm $\longrightarrow$ Set is a tripos as it suffice to chose has weak power object of
$(A, \alpha)$ the partitioned assembly $\left(\mathcal{P} A, k_{0}\right)$ where $k_{0}$ is the constant map to 0 . We call such a tripos $\mathcal{R}:$ Pasm $^{\mathrm{op}} \longrightarrow \mathbf{I S L}$. It is easy to see that $\mathcal{R}$ has full strong comprehensions where for a partitioned assembly $(A, \alpha)$ and a subset $X \subseteq A$ the inclusion of of $X$ into $A$ determines a morphism of partitioned assembly $\{X\}:\left(X, \alpha_{\mid X}\right) \longrightarrow(A, \alpha)$ which is the desired comprehension arrow. Since Pasm is slice-wise cartesian closed, the tripos $\mathcal{R}$ is an hyper-tripos. Whence $Q_{\mathcal{R}}$ is a quasitopos by 7.10. Recall that $\mathrm{Pasm}_{\mathrm{ex} / \mathrm{lex}}$ is $\mathcal{E f f}$. And the quasitopos of $\neg \neg$-separated objects of Eff is Asm. So picture 4 becomes

As byproduct we have that $Q_{\mathcal{R}}$ is equivalent to Asm. A different proof of this is given in MPR19.

Another remarkable example is in type theory with the construction of the so called setoid models over Coquand-Huet's Calculus of Inductive Constructions CoC Coq90. The setoid model of functional relations over CoC is the tripos-to-topos construction $\mathcal{T}_{F \text { Coc }}$ with $F^{\mathrm{CoC}}$ the doctrine of propositions over CoC mentioned in MR13b. The topos $\mathcal{T}_{F}$ coc coincides with the topos of coarse objects within the quasitopos $Q_{F \text { Coc }}$ whic was one of the inspiring examples to the introduction of the elementary quotient completion in MR13b.

## 9 Conclusions

We have introduced the notion of quasitopos construction of an hypertripos by employing the machinery of the elementary quotient completion introduced in MR13b, MR13a.

In doing so we have generalized three theorems regarding exact completions by adopting the approach of elementary quotient completions: CarboniVitali's characterization of exact completions in terms of projectives in CV98, Carboni-Rosolini's characterization of locally cartesian closed exact completions of a category with finite products and weak pullbacks in CR00, and Menni's characterization of topoi as exact completions in Men03. These relevant examples of elementary quotient completions which are not exact completions like the category of assemblies of realizability topos.

In the future we intend to generalize the quasitopos construction to include examples like the syntactic models obtained from predicative theories such as the extensional level of the Minimalist Foundation in Mai09.
