Abstract. The Catalan Language Understanding Benchmark (CLUB) encompasses various datasets representative of different NLU tasks that enable accurate evaluations of language models, following the General Language Understanding Evaluation (GLUE) example. It is part of AINA and PlanTL, two public funding initiatives to empower the Catalan language in the Artificial Intelligence era.

Keywords: Benchmark · NLU · Catalan

1 Introduction

Two public funding initiatives in Spain, PlanTL and AINA, aim at providing Catalan with the tooling and resources that modern Artificial Intelligence (AI) models can bring to industry, commerce and society in general. These initiatives are enabling high-quality corpora and datasets which, along with extensive Transformer and Spacy¹ language models, are being made available through various open platforms in order to enable Natural Language Understanding (NLU) capabilities for any institution, organization, company or individual, and not only for big corporations with deep pockets. These efforts have incorporated corpus annotation best practices, and at the same time strive to foster local companies that can deal with the complex tasks needed for Data Science and modern AI.

The Catalan Language Understanding Benchmark (CLUB) is a set of test corpora to drive accurate evaluations of language models and downstream applications for real, practical use. As such, they are not modelled after usual linguistic academic research corpus, but are designed for training and evaluating Transformer models, powerful neural network embeddings in widespread use for Artificial Intelligence applications.

2 Datasets

We have compiled a new benchmark dataset suite for evaluating NLU capabilities for Catalan, the Catalan Language Understanding Benchmark (CLUB).² To build it, we bootstrap from existing resources (such as the AnCora corpus³) and create new high quality ones from scratch, adopting (and in some cases improving on) existing guidelines. These datasets have permissive licences, and are made publicly available through the Zenodo platform, under the Catalan AI language resources community,⁴ and through HuggingFace.⁵

2.1 Data statements

In general, we provide as much curation information as possible following (Bender and Friedman, 2018), [3] when relevant. For example, gender and socioeconomic status are considered not as relevant for the kind of semantic annotations created. However, the fact that all commissioned annotators (1) were native speakers of Catalan, (2) were translators, editors, philologists or linguists, and (3) had previous experience in language-related tasks, *is* considered to be important. The curation rationale we follow was to make these datasets both representative of contemporary Catalan language use, as well as directly comparable to similar reference datasets from the General Language Understanding Evaluation [6] (GLUE) benchmark.⁶ Since our datasets are geared towards Machine Learning and Language Modelling, we have provided training, evaluation and tests splits at HuggingFace. In what follows, we describe some of these datasets.

2.2 POS and NERC from AnCora

For **Part-of-Speech Tagging (POS)** and **Named Entity Recognition and Classification (NERC)** evaluations, we use annotations from the of the well-known AnCora corpus, projected on the Universal Dependencies treebank⁷. We extracted Named Entities from the original AnCora⁸ version, filtering out some unconventional ones, like book titles, and transcribe them into a standard CONLL-IOB format.

The AnCora corpus has been released recently under CC-BY licence, and we published our derivative version under the same licence.⁹

2.3 TECa: Textual Entailment for Catalan

Textual entailment (TE) is the directional relation between two sentences, a *premise* and an *hypothesis*. For every *premise* the relation with an *hypothesis* can be Neutral, Inference or Contradiction. Textual Entailment is considered an important evaluation of the ability of a model to incorporate some measure of inferential capabilities, as opposed to make do with a prodigious memory of what it has actually seen before. TECa¹⁰ contains more than 20 000 pairs of sentences annotated with their relation label, that can be 0 (neutral), 1 (inference) or 2 (contradiction).

Table 1: Example of a premise and a neutral, inference and contradiction hypothesis.

Premise:	El Port de Barcelona ha guanyat un 30% el primer semestre del 2016
Inference:	El Port de Barcelona augmenta la seva activitat
Neutral:	El segon semestre de 2016 no ha estat tan bo
Contradiction:	L'inici del 2016 ha estat un mal any pel Port de Barcelona

Source sentences are extracted from the Catalan Textual Corpus¹¹ and from Vilaweb newswire.¹²

We randomly chose 18 000 sentences from those sources, and filtered them by different criteria, such as length and stand-alone intelligibility. From the remaining text sentences, we commissioned 3 hypotheses (one for each entailment category) to be written by a team of annotators. We obtained more than 20 000 annotated sentence pairs, which are published under CC-by licence. From 600 randomly selected samples we cross-annotated for Quality Assurance, and obtained an inter-annotator agreement of 83,57%.

2.4 Text Classification: TeCla

TeCla¹³ (Textual Classification for Catalan) is a Catalan News corpus for thematic Text Classification tasks. It contains 153 265 articles classified under 30 different categories, albeit editorially-oriented ones rather than truly encyclopedic labels.

We crawled 219 586 articles from the Catalan News Agency (ACN)¹⁴ newswire archive, the latest from October 11, 2020. We used the *subsection* category as

¹⁰ <https://doi.org/10.5281/zenodo.4761458>

¹¹ <https://doi.org/10.5281/zenodo.4519349>

¹² <http://www.vilaweb.cat>

¹³ <https://doi.org/10.5281/zenodo.4627197>

¹⁴ <http://www.acn.cat>

a classification label, after excluding territorial labels and labels with less than 2 000 occurrences. With this criteria we compiled a total of 153 265 articles for this text classification dataset.

Fig. 1: Label distribution of the Text Classification dataset. Here, we show the distribution of the filtered dataset of labels with at least 2,000 instances.

2.5 Extractive Question Answering

For Extractive Question Answering we translated or created from scratch three different datasets: XQuAD-Ca, VilaQuAD and ViquiQuad.

XQuAD-Ca The Cross-lingual Question Answering Dataset¹⁵ is a multilingual benchmark for evaluating question answering performance. The dataset consists of a subset of 240 paragraphs from the Wikipedia and 1 190 question-answer pairs from the development set of SQuAD v1.1 (Rajpurkar et al., 2016) together with their professional translations into ten languages: Spanish, German, Greek, Russian, Turkish, Arabic, Vietnamese, Thai, Chinese, and Hindi. Rumanian was added later. We created a Catalan version using professional translators.

¹⁵ <https://github.com/deepmind/xquad>

ViquiQuAD Is an extractive Question Answering dataset¹⁶ using content from the Catalan Wikipedia (Viquipèdia).¹⁷ From a set of high quality, non-translation, articles in the Catalan Wikipedia, 597 were randomly chosen, and from them 5-8 sentence contexts were extracted. We commissioned the creation of between 1 and 5 questions for each context, following an adaptation of the guidelines from SQUAD 1.0 [4]. Annotators were native language speakers. In total, 15 153 pairs of a question and an extracted fragment that contained the answer were created.

VilaQuAD Following the same guidelines as in 2.5, we developed VilaQuAD,¹⁸ an extractive QA dataset from newswire. From a the online edition of the catalan newspaper Vilaweb,¹⁹ 2 095 article headlines were randomly selected. These headlines were also used to create the Textual Entailment dataset (TECa). For the extractive QA dataset, creation of between 1 and 5 questions for each news context was commissioned to a team of native speakers. In total, 6 282 pairs of a question and an extracted fragment that contains the answer were created.

Table 2: Statistics on the number of tokens in contexts, questions, and answers in our QA datasets

	XQuAD-ca	ViquiQuAD	VilaQuAD
Paragraph	48	597	2 095
Context	240	3 111	2 095
Total sentences	1 167	14 966	11 462
Sentences/context	4.9	4.81	5.5
Questions	1 189	15 153	6 282
Questions/context	4.9	4.9	3.0
Tokens in context	39 981	468 250	421 595
Tokens in questions	15 391	145 124	65 819
Tokens in questions/questions	12.96	9.58	10.48
Tokens in answers	4 424	63 157	27 676
Tokens in answers/answers	3.72	4.17	4.41

2.6 Semantic Textual Similarity: STS-ca

For Semantic Textual Similarity (STS) [1], we create a new dataset from scratch, STS-ca²⁰. It contains more than 3,000 sentence pairs, annotated with their semantic similarity using a scale from 0 (no similarity at all) to 5 (semantic equivalence).

Table 3: Question-answer reasoning typology. We sampled 100 random question-answer pairs and classified them manually. We add SQuAD and FQuAD for completeness.

	XQuAD-ca	ViquiQuAD	VilaQuAD	SQuAD	FQuAD
Lexical variation	33.0%	7.0%	32.0%	33.3%	35.2%
World knowledge	16.0%	17.0%	16.0%	9.1%	11.1%
Syntactic variation	35.0%	43.0%	22.0%	64.1%	57.4%
Multiple sentence	17.0%	9.0%	16.0%	13.6%	17.6%

Table 4: Question type frequencies. Differences between XQuAD-ca and XQuAD-en are explained because there are not unambiguous translations for some pronouns.

	XQuAD-ca	ViquiQuAD	VilaQuAD	XQuAD-en
Quin/-s/-a/-es? (Which?)	44.41%	22.42%	20.87 %	7.06%
Què? (What?)	16.32%	25.51%	22.59 %	57.31%
Qui? (Who?)	10.18%	14.75%	18.45 %	10.00%
Quant/-s/-a/-es? (How many?)	8.16%	6.1%	9.57 %	6.55%
Com? (How?)	7.82%	12.13%	8.21 %	5.13%
Quan? (When?)	6.48%	6.5%	7.18 %	7.14%
Per què? (Why?)	1.26%	2.29%	4.36 %	1.26%
On? (Where?)	3.2%	10.16 %	8.77 %	3.86%
Other	2.19%	0.14%	0%	1.93%

To develop STS-ca, we pre-selected potential sentence pairs from the CaText corpus²¹ by using different similarity measures (Jaccard, Doc2Vec and DistilBERT [5] embedding cosine similarity). We did a final manual review to ensure that the selection represented superficial and deep similarities in subject matter and lexicon. Following the guidelines set in the SemEval challenges,²² we commissioned 4 native speaker annotators from 2 independent companies to assess the similarity of the sentence pairs on a scale between 0 (*completely dissimilar*) to 5 (*completely equivalent*), with other possible values, such as 3 (*roughly equivalent, but some important information differs*). Then, for each sentence pair, we computed the mean of the four annotations, and we discarded single annotations that deviate by more than 1 from the mean. After this filtering process, we used the mean of the remaining annotations as a final score. Finally, in order to assess the quality of the dataset, we measured the correlation of each annotator’s labels with the average of the rest of the annotators, and averaged all the individual correlations, resulting in a Pearson correlation of 0.739.

²¹ <https://doi.org/10.5281/zenodo.4519349>

²² <http://ixa2.si.ehu.es/stswiki>

Table 5: Example from STS-ca

Sentence 1	Sentence 2	STS
Els manifestants ocupen l’Imperial Tarraco durant una hora fent jocs de taula	Els manifestants ocupen l’Imperial Tarraco i fan jocs de taula	4
Aleshores hi posarem un got de vi i continuarem amb la cocció fins que s’hagi evaporat el vi i ho salpebrarem.	Mentre, hi posarem el vi al sofregit i deixarem coure uns 7/8, fins que el vi s’evapori.	3

3 Evaluating Transformer models using CLUB

CLUB was created originally to evaluate the biggest embeddings yet deployed for the Catalan language, using huge crawlings of the .cat domains, along with specific ones of catalan government websites, resulting in a RoBERTa-base model (BERTa)²³ introduced in [2]. This model was created with more than 1 700 million word tokens, and outperforms in these tasks all other mono or multilingual models available for this Iberian language.

For our model, we leverage the Huggingface Transformers library [7]. For each task, we attach a linear layer to the models and fine tuned with the training set of the specific dataset. We trained each specific model under the same settings across tasks consisting of 10 training epochs, with an effective batch size of 32 instances, a learning rate of $5e^{-5}$ and a maximum input length of 512 tokens for all the datasets but TECA, where we used 128 tokens. The rest of the hyperparameters are set to the default values in Huggingface Transformers. We select the best checkpoint as per the task-specific metric in the corresponding validation set, and then evaluate it on the test set. We report the results and metrics used in Table 6.²⁴

Table 6: Results of BERTa Catalan model using CLUB.

QA viquiquad		STS	NERC	POS	TE
F1	EM	Pe/Sp	F1	F1	Acc
86.99	73.24	81.56	89.63	98.94	79.12

4 Further work

Project AINA will ensure that Catalan has the resources and models needed to claim its rightful place in a global digital AI ecosystem. We are also designing and commissioning other datasets, such as realistic chatbot conversations for

²³ <https://huggingface.co/PlanTL-GOB-ES/roberta-base-ca>

²⁴ We use F1 for POS and NERC, accuracy for TC, an average of Pearson and Spearman (Pe/Sp) coefficient for STS and F1/Exact Match for QA (ViquiQuAD).

customer support, Winograd tests, Sentiment Analysis corpora, etc. Also forthcoming are Speech corpus, like the recently published ParliamentParla²⁵ (more than 600 hours of speech from Catalan Parliament sessions) and contributions to the Catalan Commonvoice campaigns.²⁶ You can follow AINA through its official website.²⁷

5 Acknowledgments

This work was partially funded by the Generalitat de Catalunya through the project PDAD14/20/00001, the State Secretariat for Digitalization and Artificial Intelligence (SEDIA) within the framework of the Plan TL,²⁸ and the MT4All CEF project.
