ABSTRACT

An analysis of steady-state electron trajectories by simultaneous solution of the equation of motion and the dispersion relation (DR) for electromagnetic wave wiggler in free-electron laser (FEL) with axial magnetic field is presented. The effects of the normalized axial magnetic field and the normalized angular frequency of electromagnetic wave wiggler on axial and transverse velocity for group I and II orbits are investigated. A fluid model is used to obtain the DR for electrostatic wave and the right and the left circularly polarized electromagnetic waves with all relativistic effects included. This dispersion relation is solved numerically to investigation the unstable coupling among all waves. When the transverse velocity is small, only the FEL instability is found. In group II orbits, with large transverse velocity, new coupling between the negative and positive energy space charge waves as well as between the left circular wave and positive energy space charge wave are found.

Keywords: Free-electron laser, Dispersion relation, Instability, Growth rate, electromagnetic wiggler

1. INTRODUCTION

The free electron laser (FEL) has been shown to be a promising source of radiation over a broad range of frequencies. The physical mechanism in FEL depends upon the propagation of an electron beam through a periodic magnetic field (wiggler). There are several types of wigglers

called electrostatic, magnetostatic and electromagnetic wigglers. The wavelength of the output radiation for an electromagnetic wave wiggler (EWW) scales as $\lambda \approx \lambda_w/4\gamma_0^2$ while for a magnetostatic wiggler it scales as $\lambda \approx \lambda_w/2\gamma_0^2$ [1]. λ_w is the wiggler wavelength (period) and $\gamma_0 = (1 - v_0^2/c^2)^{-1/2}$. As a result, in equal conditions, the EWW will generate radiation with shorter wavelengths. Therefore, for a given electron beam energy, EWW is advantageous over the magnetostatic wiggler for the production of short wavelengths. It needs to be mentioned that for a given wavelength of the radiation, EWW requires smaller electron beam energy compared to a magnetostatic wiggler [1-4]. Theoretical and numerical studies of a FEL with a magnetostatic wiggler have been studied by a number of researchers[5-14]. The FEL with electromagnetic wave wiggler was first analyzed by Sprangle, and Granatstein [15]. There are also many studies on the electromagnetic wave wiggler FEL[16-24] and longitudinal electrostatic wiggler FEL[25-31].

In many papers, electrons dynamic behavior and chaos has been investigated [32,33]. In Ref. 34 the gain equation describing the interaction between an electron and the radiation field derived in the low-gain-per-pass limit. A theoretical study of electron trajectories, harmonic generation, and gain in a FEL with a linearly polarized electromagnetic-wave wiggler by Mehdian et al. [35] investigated for axial injection of electron beam. Olumi et al.[24] investigated the propagation of electromagnetic traveling wave in a FEL with an electromagnetic wiggler using the relativistic fluid Maxwell formulation. In Ref. 36 an analysis of equilibrium orbits for electromagnetic wave wiggler in a FEL with ion-channel guiding has been presented. Theoretical studies of electron trajectories and dispersion relations in a combined ion electrostatic field as well as large-amplitude backward-propagating electromagnetic waves analyzed by Mehdian and Jafari[37]. In Ref. 38 the dispersion relation for EWW ion channel free electron laser in the absence of left circular wave was derived.

In this manuscript, we derive the electron equilibrium orbits in FEL with an EWW and an axial magnetic field and investigate the equilibrium trajectories. We will also derive a general DR for the interaction of all the waves, in which all possible wave modes can have unstable couplings with each other. Contrary to the usual investigations, relativistic terms to all orders of the wiggler amplitude are retained in the linearized equations. This DR is solved numerically to find the unstable coupling between electrostatic and electromagnetic waves. The layout of the present work is as follows: In Sec. II, equilibrium orbits for the electron beam are calculated. In Sec. III, the equilibrium orbits are studied. In Sec. IV, a DR for FEL with EWW is obtained. In Sec. V, a

numerical analysis is carried out to investigate the unstable couplings between waves. In Sec. VI, concluding remarks are made.

2. BASIC ASSUMPTIONS

In order to understand the FEL interaction it is first necessary to understand the individual electron motion in the presence of EWW as governed by the Lorentz force equation

$$\frac{d\mathbf{P}}{dt} = -e \left[\mathbf{E}_{w} + \frac{1}{c} \mathbf{v} \times \left(\mathbf{B}_{w} + \mathbf{B}_{0} \right) \right],\tag{1}$$

and

$$\frac{d\gamma}{dt} = -\frac{e}{m_0 c^2} \mathbf{v} \cdot \mathbf{E}_w$$
(2)

where \mathbf{E}_{w} and \mathbf{B}_{w} are electric and magnetic fields of circularly polarized EWW, which are described by

$$\begin{cases} \mathbf{B}_{w}(z,t) = B_{w} \left[\hat{\mathbf{e}}_{x} \cos(k_{w}z + \omega_{w}t) + \hat{\mathbf{e}}_{y} \sin(k_{w}z + \omega_{w}t) \right], \\ \mathbf{E}_{w}(z,t) = -\frac{\omega_{w}}{ck_{w}} B_{w} \left[\hat{\mathbf{e}}_{x} \sin(k_{w}z + \omega_{w}t) - \hat{\mathbf{e}}_{y} \cos(k_{w}z + \omega_{w}t) \right], \end{cases}$$
(3)

 B_w denotes the amplitude of the EWW magnetic field and (ω_w, k_w) describe the frequency and wave number. For generality, a uniform axial magnetic field $\mathbf{B}_0 = B_0 \hat{\mathbf{z}}$ is also assumed to be present. Note that in the limit of $\omega_w \to 0$ EWW reduces to that of the static, one dimensional magnetostatic wiggler. Steady-state solutions are obtained by requiring that $\gamma = \text{constant}$. In this manner, the electron velocity can be obtained as

$$\mathbf{v} = v_w \left[\hat{\mathbf{e}}_x \cos(k_w z + \omega_w t) + \hat{\mathbf{e}}_y \sin(k_w z + \omega_w t) \right] + v_{\parallel} \hat{\mathbf{e}}_z,$$
(4)

where V_w and $V_{||}$ are constants given by

$$v_{w} = \frac{\Omega_{w} (v_{p} + v_{\parallel})}{\Omega_{0} - (\omega_{w} + k_{w} v_{\parallel})},$$
(5)

$$\frac{1}{\gamma_0^2} = 1 - \frac{v_w^2}{c^2} - \frac{v_{\parallel}^2}{c^2},\tag{6}$$

and $\Omega_{0,w} \equiv eB_{0,w}/\gamma_0 m_0 c$, and $v_p = \omega_w/k_w$.

3. EQUILIBRIUM AND STEADY-STATE ELECTRON TRAJECTORIES

To analyze the electron trajectories, we will use the Maxwell's equations for a cold beam with uniform density to obtain ω_w and k_w satisfying a dispersion relation of the form

$$\omega_{w}^{2} - c^{2}k_{w}^{2} + \frac{\omega_{b}^{2}(\omega_{w} + k_{w}v_{\parallel})}{\Omega_{0} - \omega_{w} - k_{w}v_{\parallel}} = 0,$$
(7)

where $\omega_b = 4\pi n_b e^2 / \gamma_0 m_0$ is the beam plasma frequency (n_b is beam density).

To show the dependency of the orbital velocities, requires the simultaneous solution of Eqs. (5), (6), and (7). Figure 1 shows the wave modes described by DR (7). Solid lines represent relevant wave modes for stable orbits with $v_{\parallel} > 0$ that are physically accepted solutions.

Fig.1 Normalized angular frequency ω_w/c as a function of wave number k_w for group I and group II orbits. Dotted line shows the unstable orbits

In this figure the parameters are $\Omega_0/c = 5.0263$, $\Omega_w/c = 0.1885$, $\gamma_0 = 2$, and $\omega_b/c = 1.3315$. The DR (7) contains two modes, i.e., escape mode and cyclotron mode. The solution corresponding to the escape mode is group I orbits with $\Omega_0 < k_w v_{\parallel} + \omega_w$ and the solution corresponding to the cyclotron mode is group II orbits with $\Omega_0 > k_w v_{\parallel} + \omega_w$. It should be noted that for escape mode, the phase velocity is larger than light velocity and for cyclotron

mode, the phase velocity is smaller than light velocity. Figure 2 shows the variation of v_{\parallel}/c as a function of the normalized cyclotron frequency $\Omega_0/k_w c$ for group I and group II orbits.

Fig.2 Axial velocity v_{\parallel}/c as a function of the normalized axial magnetic field $\Omega_0/k_w c$ for group I and group II orbits

In this figure the parameters are $\Omega_w/k_w c = 0.0839$, $\gamma_0 = 2$, and $\omega_b/k_w c = 0.212$. In Fig. 3, the relation between the normalized axial velocity v_{\parallel}/c and the normalized angular frequency ω_w/c for both group I and group II orbits are shown. The range of the allowed values of ω_w for group II orbits are shown in Fig. 3.

Fig.3 Axial velocity v_{\parallel}/c as a function of the normalized angular frequency ω_w/c for group I and group II orbits

The variation of v_w/c with ω_w/c for group I and II orbits are shown in Fig. 4. In Figs. 3 and 4, the parameters are $\Omega_0/c = 5.0263$, $\Omega_w/c = 0.1885$, $\gamma_0 = 2$, and $\omega_b/c = 1.3315$.

Fig.4 Transverse velocity v_w/c as a function of the normalized angular frequency ω_w/c for group I and group II orbits

Figure 4 shows that the value of v_w increases with increasing the normalized cyclotron frequency for group I orbits while, it decreases for group II orbits. The variation of the wave number k_w as a function of the normalized cyclotron frequency Ω_0/ω_w for group I and group II orbits are shown in Fig. 5.

Fig.5 Wave number k_w as a function of the normalized axial magnetic field Ω_0/ω_w for group I and group II orbits. Dotted line shows the unstable orbits. electron beam energy

This Figure shows that for group I orbits, the wave number is smaller in comparison with group II orbits. In Fig. 5, the parameters are $\Omega_w/c = 0.1885$, $\gamma_0 = 2$, and $\omega_b/c = 1.3315$. The variation of the wave number k_w with the electron beam energy for group I and group II orbits is shown in Fig. 6.

Fig.6 Wave number k_w as a function of the electron beam energy γ_0 for group I and group II orbits. Dotted line shows the unstable orbits

This figure shows that for $\omega_w = \text{constant}$, there is an upper limit on the electron beam energy for group I and II orbits. In Fig. 6 the parameters are $\Omega_0/c = 5.0263$, $\Omega_w/c = 0.1885$, and $\omega_{\rm h}/c = 1.3315$.

4. DISPERSION RELATION

An analysis of the wave propagation in the FEL with an EWW and axial guiding magnetic field will be based on the electron continuity equation, the cold-electron relativistic momentum equation and the wave equation. The perturbed state can be considered as the unperturbed state $n_b = const., \mathbf{v}_0 = \mathbf{v}_w + v_{\parallel} \hat{\mathbf{z}}, \mathbf{B}_w + \mathbf{B}_0$, and \mathbf{E}_w plus small perturbations $\delta n, \delta \mathbf{v}, \delta \mathbf{E}$, and $\delta \mathbf{B}$. The unperturbed quantities are defined in the previous section. The perturbation quantities associated with the right and the left circularly polarized electromagnetic waves and the space charge wave are

$$\partial \mathbf{E}_{L}, \quad \partial \mathbf{B}_{L}, \quad \partial \mathbf{v}_{L} \sim (\hat{\mathbf{x}} \pm i\hat{\mathbf{y}}) \exp[i(k_{L}z - \omega t)], \quad (8)$$

$$\delta E_{z}, \delta v_{z}, \delta n_{b} \sim \exp[i(kz - \omega t)], \qquad (9)$$

where $k_R = k - k_w$, $k_L = k + k_w$, $\omega_R = \omega + \omega_w$, $\omega_L = \omega - \omega_w$. By Substituting the perturbed quantities into the linearized continuity, relativistic momentum, and wave equations, a system of linear homogenous algebraic equations for the wave amplitudes, \tilde{n}_b , \tilde{v}_z , \tilde{v}_R , \tilde{v}_L , \tilde{E}_z , \tilde{E}_R , \tilde{E}_L , \widetilde{B}_R , and \widetilde{B}_L are obtained. It is convenient to combine these equations to reduce the number of equations and unknowns versus components of the perturbed electric field. The necessary and sufficient condition for a nontrivial solution consists of the determinant of coefficients equated to zero. Imposing this condition yields

$$K_1(K_5K_9 - K_6K_8) + K_2(K_6K_7 - K_4K_9) + K_3(K_4K_8 - K_5K_7) = 0, \qquad (10)$$

where

where

$$K_{1} = A_{R} + \frac{A_{R}}{\omega_{R}} \left\{ -k_{R}v_{\parallel} - \Omega_{0} + A_{1} + A_{2} \right\} + \omega_{b}^{2} \left\{ 1 - \frac{v_{w}^{2}}{2c^{2}} - \frac{k_{R}v_{\parallel}}{\omega_{R}} \right\},$$
(11)

$$K_{2} = \frac{A_{L}}{\omega_{L}} \left(-A_{1} + A_{2} \right) - \omega_{b}^{2} \frac{v_{w}^{2}}{2c^{2}}, \qquad (12)$$

$$K_{3} = \frac{kv_{w}}{\sqrt{2}} \left\{ \omega_{R} - k_{R}v_{\parallel} - \Omega_{0} + 2A_{2} \right\} + A_{3} \left(kv_{\parallel} - \omega \right) - \omega_{b}^{2} \frac{v_{w}v_{\parallel}}{\sqrt{2}c^{2}}, \qquad (13)$$

$$K_{4} = \frac{A_{R}}{\omega_{R}} \left(A_{1} - A_{2} \right) - \omega_{b}^{2} \frac{v_{w}^{2}}{2c^{2}}, \qquad (14)$$

$$K_{5} = A_{L} + \frac{A_{L}}{\omega_{L}} \left\{ -k_{L}v_{\parallel} + \Omega_{0} - A_{1} - A_{2} \right\} + \omega_{b}^{2} \left\{ 1 - \frac{v_{w}^{2}}{2c^{2}} - \frac{k_{L}v_{\parallel}}{\omega_{L}} \right\},$$
(15)

$$K_{6} = \frac{kv_{w}}{\sqrt{2}} \left\{ \omega_{L} - k_{L}v_{\parallel} + \Omega_{0} - 2A_{2} \right\} - A_{3} \left(kv_{\parallel} - \omega \right) - \omega_{b}^{2} \frac{v_{w}v_{\parallel}}{\sqrt{2}c^{2}}, \qquad (16)$$

$$K_{7} = \frac{A_{R}}{\omega_{R}} \frac{\Omega_{w}}{\sqrt{2}} \left(1 + \frac{v_{p}v_{\parallel}}{c^{2}} \right) + \omega_{b}^{2} \left\{ -\frac{v_{\parallel}v_{w}}{c^{2}\sqrt{2}} + \frac{v_{w}}{\sqrt{2}} \frac{k_{R}}{\omega_{R}} \right\},\tag{17}$$

$$K_8 = -\frac{A_L}{\omega_L} \frac{\Omega_w}{\sqrt{2}} \left(1 + \frac{v_p v_{\parallel}}{c^2} \right) + \omega_b^2 \left\{ -\frac{v_{\parallel} v_w}{c^2 \sqrt{2}} + \frac{v_w}{\sqrt{2}} \frac{k_L}{\omega_L} \right\},\tag{18}$$

$$K_{9} = -(\omega - kv_{\parallel})^{2} + \omega_{b}^{2} \gamma_{\parallel}^{-2}, \qquad (19)$$

$$A_1 = \frac{v_p v_w}{2c^2} \Omega_w, \tag{20}$$

$$A_{2} = \frac{\gamma_{\circ}^{2} v_{w}^{2}}{2c^{2}} k_{w} \left(v_{p} + v_{\parallel} \right), \tag{21}$$

$$A_{3} = \frac{1}{\sqrt{2}} \left(k_{w} v_{w} + \Omega_{w} \right) + \frac{\gamma_{\circ}^{2}}{\sqrt{2}} \frac{v_{w} k_{w} v_{\parallel}}{c^{2}} \left(v_{p} + v_{\parallel} \right),$$
(22)

$$A_R = k_R^2 c^2 - \omega_R^2, \tag{23}$$

$$A_{L} = k_{L}^{2}c^{2} - \omega_{L}^{2}, \qquad (24)$$

$$\gamma_{\parallel} = \left(1 - \frac{v_{\parallel}^2}{c^2}\right)^{-1/2}.$$
(25)

Equation (10) is the DR for the coupled electrostatic and electromagnetic waves propagating along a relativistic electron beam in the presence of an EWW and an axial guide magnetic field. As expected, the DR (10) reduces to the well-known results¹² of the magnetostatic wiggler in the limit as $\omega_w \rightarrow 0$. This DR (10) will be solved numerically, in the next section, to investigate the instabilities associated with different couplings between the wave modes.

The DR for the right wave alone, in the absence of the other two waves, is $K_1 = 0$ and the DR for the left wave alone, in the absence of the other two waves, is $K_5 = 0$ which indicate that the wiggler has direct effect on the right and left waves. Each DR consists of two modes, i.e., right-cyclotron (R_c) and right-escape (R_e) modes for the right wave; and left-cyclotron (L_c) and left-escape (L_e) modes for the left circularly polarized electromagnetic wave. $K_9 = 0$ is the DR for the space-charge wave when the right and left waves are absent. This shows that the space-charge wave is not directly affected by the wiggler. This because that the transverse motion of electrons, caused by the wiggler does not have any effect on the longitudinal oscillations of the space-charge wave. The DR for space-charge wave consists of two modes, i.e., positive-energy space-charge wave (Sc_+) with $\omega = kv_{\parallel} + \omega_b \gamma_{\parallel}^{-1}$, and negative-energy space-charge wave (Sc_-) with $\omega = kv_{\parallel} - \omega_b \gamma_{\parallel}^{-1}$.

5. NUMERICAL STUDIES

In order to find unstable couplings between the electrostatic and electromagnetic waves, the DR (10) will be solved numerically. Analyzing steady-state behavior on specific geometries with complex boundary conditions on electric or magnetic potential (Dirichlet) or their derivatives (Neumann) requires more advanced numerical methods such as the Finite Element Method, which has been applied in various fields of study to solve partial differential equations [39-48]. The parameters are $\Omega_w/k_wc = 0.0839$, $\gamma_0 = 3$, and $\omega_b = 0.212$. The roots of the DR (10) are found numerically for group I orbits. The normalized imaginary part of the coupling between the negative-energy space charge (Sc_-) and the escape branch of the right circular wave R_e as a function of the normalized k/k_w for group I orbits with $\Omega_0/k_wc = 0.2$ is shown in Fig. 7.

Fig7 Im $\omega/k_w c$ versus k/k_w for group I orbits. Dotted line shows the FEL instability in limit $\omega_w \to 0$

This coupling is called the FEL instability. In Fig. 7, the FEL instability in the limit $\omega_w \to 0$ (the FEL with magnetostatic wiggler) is shown with a dotted line for comparison. The FEL instability starts at $k/k_w \approx 30.3$ and ends at $k/k_w \approx 33.3$. The maximum growth rate of the FEL instability occurs at $k/k_w \approx 31.7$ with $\text{Im}(\omega/k_w c)_{\text{max}} = 0.043$ while, it occurs at $k/k_w \approx 14.8$ with $\text{Im}(\omega/k_w c)_{\text{max}} = 0.042$ for magnetostatic wiggler. Figure 7 shows that the FEL instability in EWW occurs at the shorter wavelength in comparison with the case of magnetostatic wiggler. The results of numerical solution of the DR (10) for group II orbits have been shown in Fig. 8 for $\Omega_0/k_w c = 4$, 3, and 2.65. It should be noted that, for group II orbits, with decreasing normalized cyclotron frequency, $\Omega_0/k_w c$ increases the transverse wiggler velocity, e. g., v_w is 0.0773, 0.1434, and 0.1998 in Figs. 8 (a), 8(b), and 8(c), respectively.

Fig.8 Im $\omega/k_w c$ versus k/k_w for group II orbits. Dotted line in Figs. (a) and (b) show the FEL instability in limit $\omega_w \to 0$

 v_w plays important roles in the unstable coupling between waves. It is interesting to note that with increasing V_w , new unstable couplings are found, e.g., in Figs. 8(b) and 8(c). In Fig. 8(a), the normalized imaginary part of $\omega/k_w c$ versus k/k_w for coupling between R_c mode and Sc_{-} mode is shown. This coupling starts from $k/k_{w} = 30.58$ and ends at $k/k_{w} = 33.06$ with $\text{Im}(\omega/k_w c)_{\text{max}} = 0.0345 \text{ at } k/k_w = 31.78$. In Fig. 8(a), the FEL instability in limit $\omega_w \to 0$ is shown with a dotted line for comparison. In Fig. 8(b), in addition to the FEL instability, a new coupling between the R_c mode and the R_e mode is found. Coupling between the R_c and the R_e modes starts from $k/k_w = 13.74$ and ends at $k/k_w = 14.35$. For the group II orbits with $\Omega_0/k_w c = 2.65$, the wiggler induced velocity v_w is large enough to cause additional couplings between positive and negative-energy space-charge waves and between the L_e and Sc_+ modes. The coupling, in Fig. 8(c), between the negative and positive-energy space-charge waves starts from $k/k_w \approx 0.41$ and ends at $k/k_w \approx 24.89$ that have been shown with solid lines. Coupling between the R_c and the R_e modes starts from $k/k_w = 16.19$ and ends at $k/k_w = 17.96$ with $\text{Im}(\omega/k_w c)_{\text{max}} = 0.0344$ at $k/k_w = 17.08$ that have been shown with Circle line. Coupling between the R_c and the Sc_{-} modes starts from $k/k_w = 28.63$ and ends around $k/k_w \approx 79$ that have been shown with a dotted line. Coupling between the L_c and the Sc_+ modes starts from $k/k_w = 32.06$ and ends at $k/k_w = 32.54$ with $\text{Im}(\omega/k_w c)_{\text{max}} = 0.093$ at $k/k_w = 32.31$. This coupling is shown with triangle line in Fig. 8 (c).

6. CONCLUSION

In this analysis equilibrium steady-state orbits are found for a electromagnetic wave wiggler FEL with axial magnetic field. The DR for EWW is derived in order to investigate the steady-state orbits. Steady-state orbits show that there is a minimum value of the normalized cyclotron frequency Ω_0/ω_w for group I while, there is maximum value of Ω_0/ω_w for group II, when angular frequency ω_w is a constant. The investigation of the effect of the variation of equilibrium orbits shows that in collective or Raman regime there exist an upper limit for the electron beam

density when ω_w is a constant. Our numerical study shows that $\Omega_w < 0$ is also acceptable, this does not indicate a change in the direction of the wiggler field, rather, it indicates a phase shift of 180° in EWW. In this case, v_w is in the opposite direction of the previous state. Variation of k_w versus γ_0 with ω_w = constant shows that there exist a maximum value of γ_0 for group II orbits. In the continuation, a general DR (10) is derived for a FEL with a EWW and an axial magnetic field, with all of the relativistic terms related to the transverse velocity included. This DR is solved numerically to study many unstable couplings among all possible modes. In order to analyze the couplings, we introduce the role of the transverse velocity v_w and find that when v_w is zero each wave propagate along the axial magnetic field without interaction with other waves. In the presence of wiggler, transverse velocity causes interaction between modes. Increasing transverse velocity causes the appearance of new couplings between modes. It should be noted that DR (10) is to sixth order in transverse velocity. In DR (10), higher order terms in v_w are from $d\gamma/dt$ and the expansion of the relativistic factor about its equilibrium value γ_0 .

In the group I orbits, the transverse velocity v_w is low, therefore, on the well know FEL coupling between the right wave and the negative-energy space-charge wave is possible. Also, in the group II with strong axial magnetic field only the FEL coupling occurs. For lower values of the normalized cyclotron frequency, in group II orbits, v_w is large and the relativistic terms play important roles, therefore, there exists the FEL coupling with additional coupling between the negative and positive-energy space charge waves and between the L_e and Sc_+ modes.

Hassan Ehsani Amri :Recived his PhD from the science and research branch of Islamic Azad University in Fabruary 2011.He was group leader of physics and photonic department of Islamic Azad University of Nour branch from 2011-2016.Now he is with the physics department of Islamic Azad university as an assistant professor and his research area are laser spectroscopy, photonics and free electron laser.

Taghi Mohsenpour: Recived his PhD degree from the Amirkabir University of Technology in February 2010.He is now with the physics department of University of Mazandaran as an associated professor and group leader .His research area are free electron laser and quantum plasmas.
