# A NOTE ON LARGE INDUCED SUBGRAPHS WITH PRESCRIBED RESIDUES IN BIPARTITE GRAPHS 

ZACH HUNTER

#### Abstract

It was proved by Scott that for every $k \geq 2$, there exists a constant $c(k)>0$ such that for every bipartite $n$-vertex graph $G$ without isolated vertices, there exists an induced subgraph $H$ of order at least $c(k) n$ such that $\operatorname{deg}_{H}(v) \equiv 1$ $(\bmod k)$ for each $v \in H$. Scott conjectured that $c(k)=\Omega(1 / k)$, which would be tight up to the multiplicative constant. We confirm this conjecture.

## 1. Introduction

Given a graph $G$ and integers $q>r \geq 0$, we define $f(G, r, q)$ to be the maximum order of an induced subgraph $H$ of $G$ where $\operatorname{deg}_{H}(v) \equiv r(\bmod q)$ for all $v \in H$ (or if no such $H$ exists, we set $f(G, r, q)=0)$.

There are many questions and conjectures concerning the behavior of $f(G, r, q)$ for various $G, r, q$. An old unpublished result of Gallai in this area is that ${ }^{1} f(G, 0,2) \geq n / 2$ for every $n$-vertex graph (see [7, Excercise 5.17] for a proof). Further questions about the behavior of $f$ received attention around 20-30 years ago (see e.g., [2, 3, 8, 9]). And more recently, this topic has had a minor renaissance (see e.g., $[1,5,6]$ ).

This note will focus on an old result of Scott. For positive integer $k$, we define $c(k)$ to be $\inf _{G}\{f(G, 1, k) /|G|\}$ where $G$ ranges over all bipartite graphs with $\delta(G) \geq 1$. The following was proved by Scott:

Theorem 1. [9, Lemma 8] Let $k \geq 2$. Then

$$
1 /\left(2^{k}+k+1\right) \leq c(k) \leq 1 / k
$$

Scott observed that a slightly more careful argument could further show that $c(k)=$ $\Omega\left(\frac{1}{k^{2} \log k}\right)$.

[^0]In this note we give an improved lower bound to $c(k)$ which is optimal up to the (implied) multiplicative constant.

Theorem 2. Let $k \geq 2$. Then $c(k)=\Omega(1 / k)$.

This is done by taking the improved argument suggested by Scott, and then applying a dyadic pigeonhole argument which was previously overlooked.

## 2. Proof of Theorem 2

We will need the following result on the mixing time of random walks modulo $k$.
Proposition 2.1. Let $X_{i}$ be i.i.d. random variables that sample $\{0,1\}$ uniformly at random. If $n \geq k^{3}$, then $\mathbb{P}\left(\sum_{i=1}^{n} X_{i} \equiv 1(\bmod k)\right) \geq\left(1-o_{k}(1)\right) / k$.

Proposition 2.1 is a mild variant of several known results, and $k^{3}$ could replaced with $k^{2} \log k$ (or any function which is $\omega\left(k^{2}\right)$ ). We omit its proof, to keep our paper short and our methods elementary.

In [9], when Scott outlined how to prove $c(k) \geq \Omega\left(\frac{1}{k^{2} \log k}\right)$, he noted that Proposition 2.1 (the key to the improvement) can be derived by slightly modifying the argument in [4, Theorem 2 of Chapter 3]. These appropriate modifications now appear in [5]. Namely, the interested reader can confirm that Proposition 2.1 follows from the proof ${ }^{2}$ of [5, Lemma 2.3]. Both of these proofs rely on discrete Fourier Analysis.

We now proceed to the main proof.
Proof of Theorem 2. Let $G$ be an $n$-vertex bipartite graph with $\delta(G) \geq 1$, and let $V_{1}, V_{2}$ bipartition $G$ with $\left|V_{1}\right| \geq\left|V_{2}\right|$. We shall write $c_{1}, c_{2}$ to denote small positive quantities which will be determined later (it would suffice to take $c_{1}=1 / 4, c_{2}=1 / 2$, but for clarity and a slightly better constant we will only consider their values at the end of the proof and shall have them depend slightly on $k$ ). Our proof splits into three cases.

We take $W_{1} \subset V_{2}$ to be a minimal set satisfying $\left|N(v) \cap W_{1}\right|>0$ for all $v \in V_{1}$ (i.e., $W_{1}$ is a minimal dominating set of $V_{1}$ ). By minimality of $W_{1}$, for each $w \in W_{1}$ there must exist $v_{w} \in V_{1}$ where $N\left(v_{w}\right) \cap W_{1}=\{w\}$. Let $S_{1}=\left\{v_{w}: w \in W_{1}\right\}$. We conclude that $W_{1} \cup S_{1}$ induces a matching in $G$, proving that $f(G, 1, k) \geq 2\left|W_{1}\right|$.

Hence, we will be done if $\left|W_{1}\right| \geq c_{1}\left|V_{1}\right| / k$ (this is "Case 1"). So we continue assuming $\left|W_{1}\right|<c_{1}\left|V_{1}\right| / k$.

[^1]For $2 \leq i \leq k-1$, we inductively create sets $W_{i}, S_{i}$. We take $W_{i} \subset W_{i-1}$ to be a minimal dominating set of $V_{1} \backslash\left(\bigcup_{j=1}^{i-1} S_{j}\right)$. And like in the above, we take $S_{i} \subset$ $V_{1} \backslash\left(\bigcup_{j=1}^{i-1} S_{j}\right)$ so that $W_{i} \cup S_{i}$ induces a matching in $G$.

Let $T=V_{1} \backslash\left(\bigcup_{i=1}^{k-1} S_{i}\right)$. We have

$$
\begin{aligned}
|T| & =\left|V_{1}\right|-\sum_{i=1}^{k-1}\left|S_{i}\right| \\
& =\left|V_{1}\right|-\sum_{i=1}^{k-1}\left|W_{i}\right| \\
& \geq\left|V_{1}\right|-(k-1)\left|W_{1}\right| \\
& \geq\left(1-c_{1}\right)\left|V_{1}\right| .
\end{aligned}
$$

Next, let $T^{*}=\left\{v \in T:\left|N(v) \cap W_{k-1}\right| \geq k^{3}\right\}$. Supposing that $\left|T^{*}\right| \geq c_{2}\left|V_{1}\right|$ (this is "Case 2"), we will deduce that $f(G, 1, k) \geq\left(c_{2}-o_{k}(1)\right)\left|V_{1}\right| / k$.

Indeed, let $U \subset W_{k-1}$ be a random subset where each element is included (independently) with probability $1 / 2$. We set $T_{U}=\{v \in T:|N(v) \cap U| \equiv 1(\bmod k)\}$. By Proposition 2.1, we have that $\mathbb{P}\left(v \in T_{U}\right) \geq\left(1-o_{k}(1)\right) / k$ for each $v \in T^{*}$. Thus by linearity of expectation we may fix some $U \subset W_{k-1}$ where $\left|T_{U}\right| \geq\left|T^{*}\right|\left(1-o_{k}(1)\right) / k \geq$ $\left(c_{2}-o_{k}(1)\right)\left|V_{1}\right| / k$. Next choosing $S \subset \bigcup_{i=1}^{k-1} S_{i}$ so that $\left|N(u) \cap\left(T_{U} \cup S\right)\right| \equiv 1(\bmod k)$ for each $u \in U$, we have that $S \cup U \cup T_{U}$ induces a subgraph in $G$ demonstrating that $f(G, 1, k) \geq\left|S \cup U \cup T_{U}\right| \geq\left|T_{U}\right| \geq\left(c_{2}-o_{k}(1)\right)\left|V_{1}\right| / k$.

Otherwise, we must have that $T \backslash T^{*}$, the set of $v \in T$ where $\left|N(v) \cap W_{k-1}\right|<k^{3}$, has $>\left(1-c_{1}-c_{2}\right)\left|V_{1}\right|$ elements (this is "Case 3"). By dyadic pigeonhole, there exists some $0 \leq p \leq \log \left(k^{3}\right)=O(\log k)$ so that

$$
\begin{aligned}
\left|\left\{v \in T: 2^{p} \leq\left|N(v) \cap W_{k-1}\right|<2^{p+1}\right\}\right| & \geq\left|T \backslash T^{*}\right| / O(\log k) \\
& \geq\left(1-c_{1}-c_{2}\right)\left|V_{1}\right| / O(\log k)
\end{aligned}
$$

Take $T^{\prime}=\left\{v \in T: 2^{p} \leq\left|N(v) \cap W_{k-1}\right|<2^{p+1}\right\}$ to be this large set.
We let $U \subset W_{k-1}$ be a random subset so that each element is included (independently) with probability $1 / 2^{p}$. Defining $T_{U}$ as before, some casework ${ }^{3}$ shows $\mathbb{P}(v \in$ $\left.T_{U}\right) \geq e^{-2}$ for each $v \in T^{\prime}$. Hence, by linearity of expectation, we may fix $U$ so that

[^2]$\left|T_{U}\right| \geq e^{-2}\left|T^{\prime}\right|$. As above we may find $S \subset \bigcup_{i=1}^{k-1} S_{i}$ so that $S \cup U \cup T_{U}$ demonstrates that $f(G, 1, k) \geq\left|S \cup U \cup T_{U}\right| \geq e^{-2}\left(1-c_{1}-c_{2}\right)\left|V_{1}\right| / O(\log k)$.

Now fix any sufficiently small $\epsilon>0$. Letting $c_{1}=1 / 3-\epsilon / 2, c_{2}=2 / 3-\epsilon$, we get that each of the first two cases imply that $f(G, 1, k) \geq\left(2 / 3-\epsilon-o_{k}(1)\right)\left|V_{1}\right| / k \geq$ $\left(1 / 3-\epsilon-o_{k}(1)\right) n / k$ (since $\left.\left|V_{1}\right| \geq\left|V_{2}\right|\right)$. Meanwhile with $\epsilon$ fixed, the third case implies $f(G, 1, k)=\Omega_{\epsilon}(n / \log k)$. Taking $\epsilon \downarrow 0$ as $k \rightarrow \infty$ we have that $f(G, 1, k) \geq(1 / 3-$ $\left.o_{k}(1)\right) n / k$.

As a closing remark, we note it is still open whether $c(k)=1 / k$ for all $k$ (as noted in [9], considering $K_{k, k}$ demonstrates that $\left.c(k) \leq 1 / k\right)$. Even for $k=2$, the best known bounds are $1 / 4 \leq c(2) \leq 1 / 2$, with the lower bound coming from [8, Theorem 2].

Acknowledgements. The author thanks Zachary Chase for spotting some typographical errors in a previous draft of this paper.

    ${ }^{1}$ Actually what Gallai proved was slightly stronger. He showed that for each graph $G$, we can partition $V(G)$ into two parts $A, B$ so that $\operatorname{deg}_{G[A]}(v) \equiv 0(\bmod 2)$ (respectively $\operatorname{deg}_{G[B]}(v) \equiv 0$ $(\bmod 2))$ for each $v \in A($ respectively $v \in B)$.

[^1]:    ${ }^{2}$ In [5], the statement of their lemma hides some constants which are necessary to verify Proposition 2.1.

[^2]:    ${ }^{3}$ If $p=0$, then $U=W_{k-1}$ and this probability is one. Otherwise this probability is $\left(\begin{array}{|c}\left|N(v) \cap W_{k-1}\right|\end{array}\right)(1-$ $\left.2^{-p}\right)^{\left|N(v) \cap W_{k-1}\right|} 2^{-p} \geq\left(1-2^{-p}\right)^{2^{p+1}-1} \geq e^{-2}$.
