## Abstract

In this study, we identify variations in target time fulfilment as a new key performance indicator (KPI) candidate for predicting employee job performance. KPIs represent a well-established, measurable benchmark of an organisation's critical success metrics, so, with this work, we try to find a new comprehensible and definable way utilizing the RSD variations method to identify employees who are experiencing a transition in their RSD towards a higher percentual deviation as an indicator for emerging suboptimal working settings.

We determine an employee's deviation from the average of all employees over a period using relative standard deviation (RSD). RSD variations, we believe, can be used as an additional assessment factor, particularly in profiling.

The study's limitations stem from the study's small sample size; the long observation period tries to make up for this shortcoming in part.

## 1 Introduction

Variation in target time achievements is a straightforward metric to calculate and yet is critical for determining an optimal work environment. The target time of the indicator is a quantifiable feature, and KPIs are a quantifiable representation of an organization's critical success factors. Thus, KPIs should be selected based on the context of the organisation, and each KPI should be aligned with and quantified against business objectives. KPIs aid in the definition of critical roles and the development of departmental performance indicators. As a result, the performance of an organisation can be quantified. Performance management requires the establishment of specific and attainable key performance indicators (KPIs).

### Benefits of this research

Along with establishing a baseline the findings from this study can be used as a guide for future research. This study's results indicate that when evaluating employees' working conditions and role guidelines, organisations should consider RSD variations in target time fulfilments as an intervening variable to consider.

### Profiling of employees

As a component of workforce planning, profiling focuses on matching individuals to workloads and ensuring enough workforce to account for cyclical activity levels variations (Thain et al., 2002<sup>i</sup>). When quantifiable work volumes can be determined and anticipated correctly, profiling methods are applied. We assume that RSD variations can be seen as a supplemental assessment factor, specifically in the context of profiling, especially in conjunction with other KPI factors.

A similar study that provided support for our method thus used logistic regression to analyse the turnover of approximately 4,000 workers over a one-year period to determine how to reduce it. (Setiawan et al., 2020<sup>ii</sup>).

### Daily Fluctuations in Relation to Monthly Fluctuations

In the studies available, the focus was primarily on short-term, daily influences - we see that it is particularly in our RSD model overriding influences are uncovered. While overall work engagement levels are generally stable (e.g., Mauno et al., 2007<sup>iii</sup>), daily levels vary significantly (Sonnentag et al., 2010<sup>iv</sup>). At times, a highly motivated individual is disengaged from work, whereas an impartiality individual under certain circumstances can account for daily shifts in work commitment (Bledow et al., 2011<sup>v</sup>). A historical study of 1989 identified employees with low employee reliability scores more hostile, impulsive, insensitive, self-absorbed, and unhappy, according to other standard inventories<sup>vi</sup>. But these approaches are very much related to individual surveys and therefore cannot be used neutrally as a KPI like the proposed RSD variations KPI.

## 2 Research Methodology

### Target Hours vs Achieved Hours

As a data source we used daily performance assessment measurements from an internal Enterprise Resource Planning (ERP) system: the productivity of individual employees (actual working times) and target working times (target times) are recorded. Our study is based on the extracted data of 19 employees and their actual and target working hours in the period between January 2016 and October 2021.

### RSD Anomalies in Target Time Fulfilment

Following that, the collected data is processed to determine the relative standard deviation. In our study, we define RSD as a factor in which the response time value serves as a proxy for greater analysis depth. A low RSD indicates that the data points are typically implying more stable or consistent performance throughout the system. A large RSD, on the other hand, indicates that the data span a wide range of values and that the target time fulfilment is more unpredictable and unstable when compared to the total quantity. With the help of the RSD variations method, we can identify the employees depicted in the chart below who are experiencing a transition in their RSD towards a higher percentual deviation. This is in line with the findings of the team around Nada (Nada et al., 2020<sup>vii</sup>) especially regarding the performance effects from the change in the individual work environment

Chart no. 1 – Sample Data Distribution: Working time and duration of employment

## 3 Results

The proposed RSD variation method allows for the identification of an indication of a decrease in the hourly target achievement rate for an individual employee by visualising a shift in the RSD value to a larger deviation value when using the hourly target achievement rate. The fact that the total number of employees on a team or in a company is taken into consideration in the equation means that parameters that affect the entire group are effectively filtered out, and the predictive accuracy of disturbing influences that affect individual employees increases.

The differences between actual and target time were as follows: Each worker's target time and actual reported time are shown on the Y-axis, on the X-axis are the differences between the first target time and the previous target time per worker.

Using the above example, worker W 010 has a Fend result of 373.75 for actual time differences and -416 for target time differences. That is, he reduced his target time for 2017-2021 but increased his efforts. Enclosed is the graph of the evaluation of sample data extraction. One can see a substantial fluctuation in the target fulfilment rate of test persons (WO03 to WO24) in relation to the entire team over several years of observation.

Chart no. 2 – Data Basis for the Movement through Years Analysis: Spread in Target Time Fulfilment for Sample Workers (WO03 to WO24)

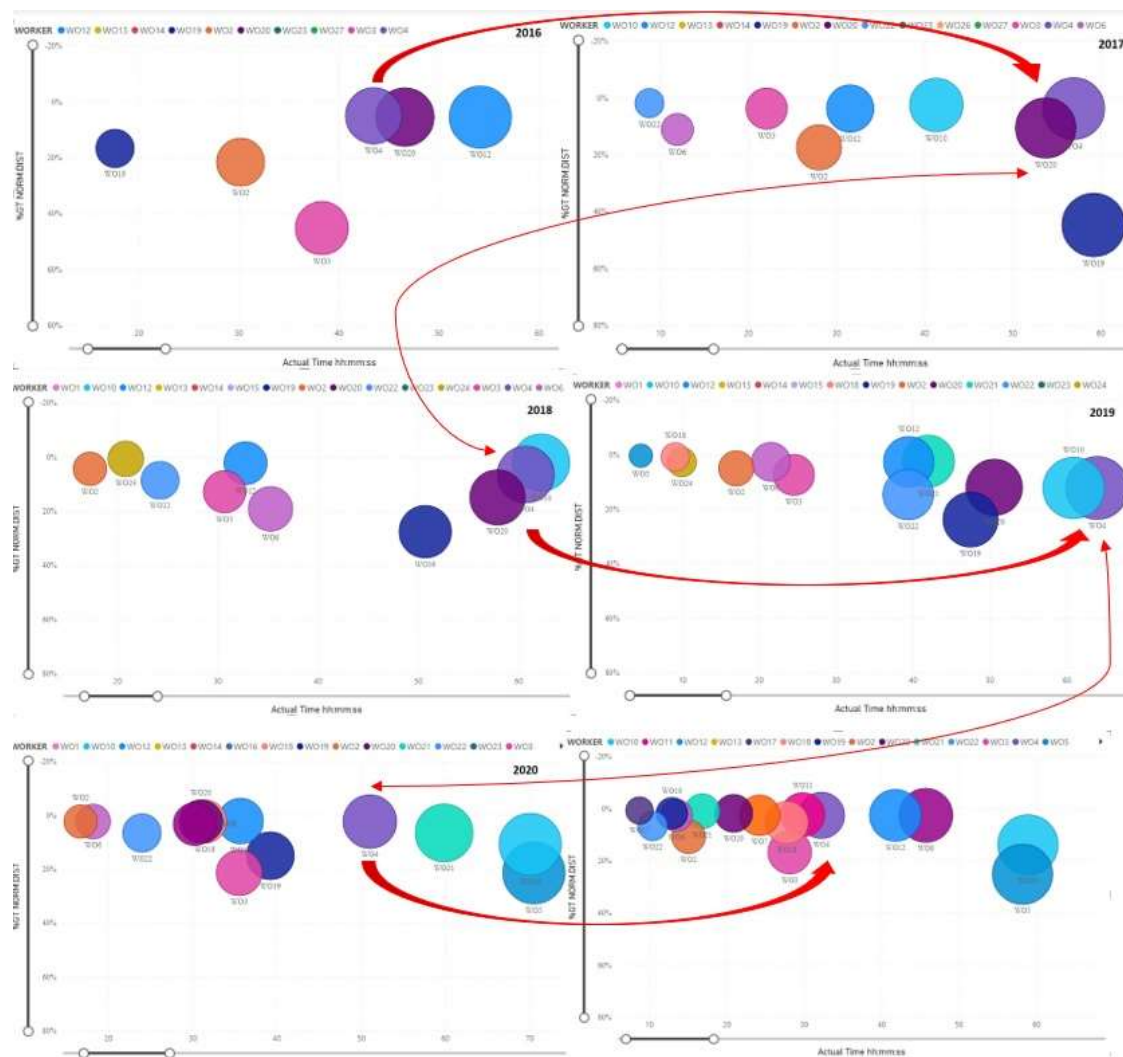

Chart no. 3 – RSD volatility of a sample person over a 6-year observation period

#### 4 Conclusion

Our study demonstrates that a straightforward variable such as the volatility of the target time fulfilment ratio, calculated as the relative standard deviation (RSD), can be incorporated into the KPI assessment of employee performance predictability. On the one hand, the addition of target agreements with employees and the usage and application of key performance indicators (KPIs) to evaluate the efficiency and predictability of employees' work performance are now made possible by using the RSD variation method. When the RSD variation increases, it can serve as an early warning system for potential vulnerabilities and emerging difficulties in an employee's work environment and function as an early trigger for implementing operational improvement measures.
