# GLOBAL SOLVABILTY FOR NONLINEAR WAVE EQUATIONS WITH SINGULAR POTENTIAL 

VLADIMIR GEORGIEV AND HIDEO KUBO

#### Abstract

In this work we study the global existence for 3 d semilinear wave equation with non-negative potential satisfying generic decay assumptions. In the supercritical case $p>1+\sqrt{2}$ we establish the small data global existence result. The approach is based on appropriate conformal energy estimate in combination with Hardy inequality for conformal energy on space - like surfaces.

## 1. Introduction

In this article we study global solvabilty for the Cauchy problem to the power-type nonlinear wave equations with the potential:

$$
\begin{align*}
& \left(\partial_{t}^{2}-\Delta+V(|x|)\right) u=b|u|^{p-1} u, \quad \text { for } \quad(t, x) \in[0, T) \times \mathbb{R}^{3}, \\
& u(0, x)=f(x),\left(\partial_{t} u\right)(0, x)=g(x) \quad \text { for } x \in \mathbb{R}^{3} \tag{1.1}
\end{align*}
$$

Here we shall assume that the potential $V$ is of the form

$$
\begin{equation*}
V(r)=\frac{\chi(r)}{r^{2}} \tag{1.2}
\end{equation*}
$$

where $\chi(r) \in C([0, \infty)) \cap C^{1}((0, \infty))$ is a non - increasing bounded function satisfying

$$
\begin{equation*}
\chi(r) \geq c>\frac{3}{4} . \tag{1.3}
\end{equation*}
$$

[^0]The assumption (1.3) guarantees that the operator

$$
A=-\Delta+V
$$

can be extended as an essentially self - adjoint operator (using the result of Simon in [18]). It is easy to see that $V(r) \in C^{1}(0, \infty)$ and satisfies the property

$$
\begin{equation*}
r V^{\prime}(r)+2 V(r) \leq 0, \quad \forall r>0 \tag{1.4}
\end{equation*}
$$

The potentials satisfying (1.4) satisfy also

$$
\begin{equation*}
V(r) \geq \frac{c}{r^{2}}, r \in(0, \infty) \tag{1.5}
\end{equation*}
$$

In particular $V(r)=a / r^{2}$, i.e. inverse square potential with $a>0$ satisfies (1.4) with equality in the place of inequality.

In this work we shall assume $b \in \mathbb{R}, p>1$, and $u(t, x)$ is a real-valued unknown function. If we use the Friedrich's extension of the operator $-\Delta$ restricted to $C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right)$, then it is well known that we have the following property of the domain $\mathcal{D}\left(\sqrt{A_{F}}\right)$, where $A_{F}$ is the Friedrichs extension of $-\Delta$ restricted to $C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right)$

$$
\begin{equation*}
\mathcal{D}\left(\sqrt{A_{F}}\right) \subset H^{1}\left(\mathbb{R}^{3}\right) \tag{1.6}
\end{equation*}
$$

In fact, introducing the quadratic form

$$
q(u, v):=(\sqrt{-\Delta} u, \sqrt{-\Delta} v)_{L^{2}\left(\mathbb{R}^{3}\right)}+(V u, v)_{L^{2}\left(\mathbb{R}^{3}\right)}
$$

on $C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right)$ and using the Hardy inequality

$$
\begin{equation*}
\left(r^{-2} u, u\right)_{L^{2}\left(\mathbb{R}^{3}\right)} \leq 4(-\Delta u, u)_{L^{2}\left(\mathbb{R}^{3}\right)} \tag{1.7}
\end{equation*}
$$

one can see that any Cauchy sequence $u_{j}$ (with respect to $q$ ) of functions in $C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right)$ is a Cauchy sequence in $H^{1}$ so we have (1.6).

$$
q(u, v):=(\sqrt{-\Delta} u, \sqrt{-\Delta} v)_{L^{2}\left(\mathbb{R}^{3}\right)}+(V u, v)_{L^{2}\left(\mathbb{R}^{3}\right)}
$$

is well defined on $H^{1}\left(\mathbb{R}^{3}\right)$ and this space coincides with the closure of $C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right)$ functions with respect to the norm generated by $q$.

We are interestead in the existence of strong solutions for (1.1), that is, we look for a solution of (1.1) in the class

$$
u \in C^{2}\left([0, T): L^{2}\left(\mathbb{R}^{3}\right)\right) \cap C([0, T): \mathcal{D}(A))
$$

with $T>0$.
Then we may associate (1.1) with the following integral equation:

$$
\begin{equation*}
u(t)=(\cos t \sqrt{A}) f+\frac{\sin t \sqrt{A}}{\sqrt{A}} g+\int_{0}^{t} \frac{\sin (t-\tau) \sqrt{A}}{\sqrt{A}} F(u(\tau)) d \tau \tag{1.8}
\end{equation*}
$$

with $F(u(t))=b|u(t)|^{p-1} u(t)$.

When $V \equiv 0$, the problem (1.1) has been well studied. It was shown in [6] that if $p>1+\sqrt{2}$, then the problem admits a unique global solution for sufficiently small initial data, and that if $1<p<1+\sqrt{2}$, then the classical solution blows up in finite time, even though we have small initial data. In the critical case $p=1+\sqrt{2}$, the latter blow up behavior occur due to [16]. The blow up result for subcritical case in higher dimensional case is due to Sideris [17]. The critical case is studied in [22], where blow up result is obtained (see [23], [10], [13]). The global existence for supercritical case in the case of dimension $n \geq 3$ is obtained in [5] (see also [8, [9], [20, [3] ).

On the other hand, the case of $V \not \equiv 0$ is less studied. When $V$ is non - negative and satisfies $|V(x)| \lesssim(1+|x|)^{-2-\delta}$ for large values of $x$ with some $\delta>0$, the blow-up result was obtained by [21] provided $1<p<1+\sqrt{2}$ (see also [19] for the case of negative potential). In the case of smooth compactly supported potential the supercritical case was studied in [4], for the case of sign - changing potential related results can be found in [7]. In [1] it was shown among other things that if $p \geq 3, V(x)=a|x|^{-2}, a>-1 / 4$, then the small amplitude solution exists globally in time (see also [15]). Recently, this result is extended by [2] to the case $p>1+\sqrt{2}$, provided that the solution has rotational invariance (see also [14). We note that in these works the higher space dimensional case are also handled.

The global existence result is complementary to the blow - up and life - span results obtained in [12]. In order to reach the critical exponent $1+\sqrt{2}$, we need to obtain suitable decay away from the light cone. However, we have no good representation formula, because we deal with the potential which is not exactly the inverse-square potential. For this reason, we make use of the framework given by Lai [11.

We denote $B(k):=\left\{x \in \mathbb{R}^{3}| | x \mid \leq k\right\}$.

Theorem 1.1. Assume $(f, g) \in \mathcal{D}(A) \times \mathcal{D}\left(A^{\frac{1}{2}}\right)$ satisfy supp $f$, supp $g \subset$ $B(1)$. Suppose that $V$ is a non-negative function that satisfies (1.4) and (1.5). Set

$$
\begin{equation*}
\eta:=\sum_{j=0}^{2}\left\|A^{\frac{2-j}{2}} f\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\sum_{j=1}^{2}\left\|A^{\frac{2-j}{2}} g\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} . \tag{1.9}
\end{equation*}
$$

If $1+\sqrt{2}<p<3$, then there exists $\eta_{0}>0$ such that for any $\eta \in$ $\left(0, \eta_{0}\right)$ there exists a unique strong solution of (1.1) in $[0, \infty)$ satisfing
$\operatorname{supp} u(t, \cdot) \subset B(1+t)$ and

$$
\sum_{j=0}^{2}\left\|A^{\frac{2-j}{2}} u(t)\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\sum_{j=1}^{2}\left\|A^{\frac{2-j}{2}} \partial_{t} u(t)\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} \lesssim \eta
$$

for $t \in[0, \infty)$.
In the section 2, we prepare a couple of inequalities which are valid for general functions. Those estimates are simple generalization of [11] for any dimensions larger than 3 . We give a new characterization of the domain of the Friedrics extension, especially (3.9) in the section 3. This estimate is crucial in proving the local existence result (see Theorem 5.1 below). In the section 4 , we derive a weighted $L^{2}$-estimate for strong solutions to the wave equation with the singular potential by using the same multiplier as in [11]. In the section 5, we give a proof of Theorem 1.1, by showing a blowup criterion and a suitable apriori estimate.

## 2. Preliminaries

First of all, we prepare the following estimate, in order to prove Proposition 2.2.

Lemma 2.1. Let $n \geq 2$, $s \neq 1$ and $k>0$. If $\phi \in C^{1}\left(\mathbb{R}^{n}\right)$ satisfies $\operatorname{supp} \phi \subset B(k)$, then we have

$$
\begin{aligned}
& \left\|(1+k-r)^{(s-2) / 2} \phi\right\|_{L^{2}\left(\mathbb{R}^{n}\right)} \\
\lesssim & \left\|(1+k-r)^{s / 2} \partial_{r} \phi\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}+\left\|(1+k-r)^{s / 2} \frac{\phi}{r}\right\|_{L^{2}\left(\mathbb{R}^{n}\right)},
\end{aligned}
$$

as long as the right hand side is finite. Here the implicit constant is independent of $k$.

Proof. It follows that

$$
\begin{aligned}
& \left\|(1+k-r)^{(s-2) / 2} \phi\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}^{2} \\
= & \frac{1}{s-1} \int_{S^{n-1}} d S_{\omega} \int_{0}^{k}(1+k-r)^{s-1} \partial_{r}\left((\phi(r \omega))^{2} r^{n-1}\right) d r \\
\leq & \frac{2}{s-1}\left\|(1+k-r)^{s / 2} \partial_{r} \phi\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}\left\|(1+k-r)^{(s-2) / 2} \phi\right\|_{L^{2}\left(\mathbb{R}^{n}\right)} \\
& +\frac{n-1}{s-1}\left\|(1+k-r)^{s / 2} \frac{\phi}{r}\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}\left\|(1+k-r)^{(s-2) / 2} \phi\right\|_{L^{2}\left(\mathbb{R}^{n}\right)},
\end{aligned}
$$

which leads to the conclusion.

Proposition 2.1. Let $n \geq 2, s \neq 1$ and $k \geq 1$. If $\phi \in C^{1}\left(\mathbb{R}^{n}\right)$ satisfies $\operatorname{supp} \phi \subset B(k)$, then we have

$$
\begin{aligned}
& \left\|r^{(n-2) / 2}(1+k+r)^{1 / 2}(1+k-r)^{(s-1) / 2} \phi(r \omega)\right\|_{L_{r}^{\infty} L^{2}\left(S^{n-1}\right)} \\
\lesssim & \left\|(1+k-r)^{s / 2} \partial_{r} \phi\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}+\left\|(1+k-r)^{s / 2} \frac{\phi}{r}\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}
\end{aligned}
$$

Here the implicit constant is independent of $k$.
Proof. Let $x \in \mathbb{R}^{n}$. First, suppose $0 \leq 2 r \leq 1+k$, so that $1+k+r$ is equivalent to $1+k-r$. Then, it suffices to show

$$
\begin{aligned}
& r^{n-2}(1+k-r)^{s}\|\phi(r \omega)\|_{L^{2}\left(S^{n-1}\right)}^{2} \\
\lesssim & \left\|(1+k-r)^{s / 2} \partial_{r} \phi\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}^{2}+\left\|(1+k-r)^{s / 2} \frac{\phi}{r}\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}^{2}
\end{aligned}
$$

Rewriting the left hand side, we see that it equals to

$$
\begin{aligned}
& -\int_{r}^{k} \partial_{\lambda}\left(\lambda^{n-2}(1+k-\lambda)^{s}\|\phi(\lambda \omega)\|_{L^{2}\left(S^{n-1}\right)}^{2}\right) d \lambda \\
\leq & s \int_{0}^{\infty} \lambda^{n-2}(1+k-\lambda)^{s-1}\|\phi(\lambda \omega)\|_{L^{2}\left(S^{n-1}\right)}^{2} d \lambda \\
& +2 \int_{0}^{\infty} \lambda^{n-2}(1+k-\lambda)^{s}\left(\int_{S^{n-1}} \phi(\lambda \omega) \partial_{r} \phi(\lambda \omega) d S_{\omega}\right) d \lambda \\
\lesssim & \left\|(1+k-r)^{s / 2} \frac{\phi}{r}\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}\left\|(1+k-r)^{(s-2) / 2} \phi\right\|_{L^{2}\left(\mathbb{R}^{n}\right)} \\
& +\left\|(1+k-r)^{s / 2} \frac{\phi}{r}\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}\left\|(1+k-r)^{s / 2} \partial_{r} \phi\right\|_{L^{2}\left(\mathbb{R}^{n}\right)} .
\end{aligned}
$$

Using Lemma 2.1]in order to bound the first term, we obtain the desired estimate.

Next, suppose $1+k \leq 2 r$, so that $1+k+r$ is equivalent to $r$. Similarly to the previous case, we have

$$
\begin{aligned}
& r^{n-1}(1+k-r)^{s-1}\|\phi(r \omega)\|_{L^{2}\left(S^{n-1}\right)}^{2} \\
= & -\int_{r}^{k} \partial_{\lambda}\left(\lambda^{n-1}(1+k-\lambda)^{s-1}\|\phi(\lambda \omega)\|_{L^{2}\left(S^{n-1}\right)}^{2}\right) d \lambda \\
\leq & (s-1)\left\|(1+k-r)^{(s-2) / 2} \phi\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}^{2} \\
& +2\left\|(1+k-r)^{s / 2} \partial_{r} \phi\right\|_{L^{2}\left(\mathbb{R}^{n}\right)}\left\|(1+k-r)^{(s-2) / 2} \phi\right\|_{L^{2}\left(\mathbb{R}^{n}\right)},
\end{aligned}
$$

which yields the desire estimate.
Next we introduce the following analogous estimate to the Hardy inequality.

Lemma 2.2. Let $s \geq 0$ and $k \geq 1$. If $\phi \in C^{1}\left(\mathbb{R}^{3}\right)$ satisfies $\operatorname{supp} \phi \subset$ $B(k)$, then we have

$$
\begin{align*}
& \left\|(1+k-r)^{s / 2} \frac{\phi}{r}\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} \leq 2\left\|(1+k-r)^{s / 2}\left(\partial_{r} \phi+\frac{\phi}{r}\right)\right\|_{L^{2}\left(\mathbb{R}^{3}\right)},  \tag{2.1}\\
& \left\|(1+k-r)^{s / 2} \partial_{r} \phi\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} \leq\left\|(1+k-r)^{s / 2}\left(\partial_{r} \phi+\frac{\phi}{r}\right)\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} . \tag{2.2}
\end{align*}
$$

Proof. First we prove (2.1). It follows that

$$
\begin{aligned}
& \int_{0}^{\infty}(1+k-r)^{s} \phi^{2} d r \\
= & s \int_{0}^{\infty}(1+k-r)^{s-1} \phi^{2} r d r-2 \int_{0}^{\infty}(1+k-r)^{s} \phi \partial_{r} \phi r d r \\
\geq & -2 \int_{0}^{\infty}(1+k-r)^{s} \phi\left(\partial_{r} \phi+\frac{\phi}{r}\right) r d r+2 \int_{0}^{\infty}(1+k-r)^{s} \phi^{2} d r,
\end{aligned}
$$

since $s \geq 0$. Therefore, we have

$$
\int_{0}^{\infty} \int_{s^{2}}(1+k-r)^{s} \phi^{2} d S_{\omega} d r \leq 2 \int_{0}^{\infty} \int_{S^{2}}(1+k-r)^{s} \phi\left(\partial_{r} \phi+\frac{\phi}{r}\right) r d S_{\omega} d r
$$

which leads to (2.1) by the Schwarz inequality.
Next we prove (2.2) It follows that

$$
\begin{aligned}
& \int_{0}^{\infty} \int_{S^{2}}(1+k-r)^{s}\left(\partial_{r} \phi+\frac{\phi}{r}\right)^{2} r^{2} d S_{\omega} d r \\
= & \int_{0}^{\infty} \int_{S^{2}}(1+k-r)^{s}\left(\partial_{r} \phi\right)^{2} r^{2} d S_{\omega} d r \\
& +\int_{0}^{\infty} \int_{S^{2}}(1+k-r)^{s} \partial_{r}\left(\phi^{2}\right) r d S_{\omega} d r+\int_{0}^{\infty} \int_{S^{2}}(1+k-r)^{s} \phi^{2} d S_{\omega} d r \\
= & \int_{0}^{\infty} \int_{S^{2}}(1+k-r)^{s}\left(\partial_{r} \phi\right)^{2} r^{2} d S_{\omega} d r \\
& +s \int_{S^{2}}\left(\int_{0}^{\infty}(1+k-r)^{s-1} \phi^{2} r d r\right) d S_{\omega},
\end{aligned}
$$

which implies the desired estimate, because $s \geq 0$.

## 3. Representation of the domain of the Friedrichs EXTENSION

Our starting point is to introduce the operator $A_{0}=-\Delta+\frac{\chi(r)}{r^{2}}$ with domain $\mathcal{D}\left(A_{0}\right)=C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right)$. In the case when the assumption (1.3) is satisfied, i.e.

$$
\begin{equation*}
\chi(r) \geq c>\frac{3}{4} \tag{3.1}
\end{equation*}
$$

the important result of Simon in [18] states that $A_{0}$ is essentially self-adjoint. As (unique) self - adjoint extension we can choose the Friedrichs extension $A_{F}$ of $A_{0}$.

In fact, introducing the quadratic form

$$
q(u, v):=(\sqrt{-\Delta} u, \sqrt{-\Delta} v)_{L^{2}\left(\mathbb{R}^{3}\right)}+(V u, v)_{L^{2}\left(\mathbb{R}^{3}\right)}
$$

on $C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right)$ and using the Hardy inequality

$$
\begin{equation*}
\left(r^{-2} u, u\right)_{L^{2}\left(\mathbb{R}^{3}\right)} \leq 4(-\Delta u, u)_{L^{2}\left(\mathbb{R}^{3}\right)} \tag{3.2}
\end{equation*}
$$

one can see that any Cauchy sequence $u_{j}$ (with respect to $q$ ) of functions in $C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right)$ is a Cauchy sequence in $H^{1}$ so we have

$$
\begin{equation*}
\mathcal{D}(q) \subset H^{1}\left(\mathbb{R}^{3}\right) \tag{3.3}
\end{equation*}
$$

where the domain $\mathcal{D}(q)$ is completion of $C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right)$ with respect to $q$. The domain $\mathcal{D}(q)$ is simply

$$
\begin{equation*}
\mathcal{D}(q)=H^{1}\left(\mathbb{R}^{3}\right) \tag{3.4}
\end{equation*}
$$

To verify this it is sufficient to show that any $C_{0}^{\infty}\left(\mathbb{R}^{3}\right)$ function $f(x)$ can be approximated in $H^{1}\left(\mathbb{R}^{3}\right)$ by functions in $C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right)$. For the purpose we define $\varphi \in C_{0}^{\infty}\left(\mathbb{R}^{3}\right)$ such that

$$
\varphi(x)= \begin{cases}1 & \text { if }|x| \leq 1 \\ 0 & \text { if }|x| \geq 2\end{cases}
$$

Now we can construct easily the needed approximating sequence

$$
f_{k}(x)=(1-\varphi(k x)) f(x) \in C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right), k \in \mathbb{N}
$$

Indeed, we have the pointwise estimates

$$
\left|f_{k}(x)-f(x)\right| \lesssim|\varphi(k x)|, \quad\left|\nabla f_{k}(x)-\nabla f(x)\right| \lesssim k|(\nabla \varphi)(k x)|+|\varphi(k x)|
$$

and use the fact that

$$
\|\varphi(k x)\|_{L^{2}\left(\mathbb{R}^{3}\right)}+k\|(\nabla \varphi)(k x)\|_{L^{2}\left(\mathbb{R}^{3}\right)} \rightarrow 0
$$

as $k \rightarrow \infty$.
Recall that the Friedrichs extension $A_{F}$ has domain

$$
\begin{equation*}
\mathcal{D}\left(A_{F}\right)=\left\{f \in \mathcal{D}(q), g \in \mathcal{D}(q) \rightarrow q(f, g) \text { is bounded in } L^{2}\right\} . \tag{3.5}
\end{equation*}
$$

More precisely, the $L^{2}$ boundedness means that for fixed $f \in \mathcal{D}(q)$ we have

$$
|g(f, g)| \leq C_{f}\|g\|_{L^{2}\left(\mathbb{R}^{3}\right)}
$$

Then the Riesz representation theorem implies that $A_{F} f$ is well defined, since

$$
q(f, g)=\left(A_{F} f, g\right)_{L^{2}}
$$

and the Friedrichs theorem guarantees that $A_{F}$ is non negative self adjoint operator with

$$
\mathcal{D}\left(\sqrt{A_{F}}\right)=\mathcal{D}(q) .
$$

The above observations lead to the following well -known conclusion.
Lemma 3.1. The operator $A_{0}=-\Delta+\frac{\chi(r)}{r^{2}}$ with $\chi(r) \geq c>-1 / 4$ and with domain $\mathcal{D}\left(A_{0}\right)=C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right)$ has a Friedrichs extension $A_{F}$, such that
i): we have

$$
\mathcal{D}\left(\sqrt{A_{F}}\right)=\mathcal{D}(q)=H^{1}\left(\mathbb{R}^{3}\right) ;
$$

ii): for $u \in \mathcal{D}\left(\sqrt{A_{F}}\right)$ we have

$$
\begin{equation*}
\left\|\sqrt{A_{F}} u\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} \sim\|\nabla u\|_{L^{2}\left(\mathbb{R}^{3}\right)} . \tag{3.6}
\end{equation*}
$$

Our next step is to give appropriate characterizations of the domains $\mathcal{D}\left(A_{F}\right)$ in the case when $c>3 / 4$. In this case, the result of Simon [18] guarantees that $A_{F}$ coincides with the graph closure $\overline{A_{0}}$ of $A_{0}$, i.e.

Definition 1. A function $u \in L^{2}$ belongs to $\mathcal{D}\left(\overline{A_{0}}\right)$ if and only if there exists a sequence $\left\{u_{k}\right\}_{k \in \mathbb{N}}$ in $C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right)$ and a function $g \in L^{2}$ so that

$$
\begin{array}{r}
\lim _{k \rightarrow \infty}\left\|u_{k}-u\right\|_{L^{2}}=0, \\
\lim _{k \rightarrow \infty}\left\|A_{0}\left(u_{k}\right)-g\right\|_{L^{2}}=0 . \tag{3.7}
\end{array}
$$

We shall give now simple characterization of the unique symmetric closure $\overline{A_{0}}$ of the operator $A_{0}=-\Delta+\frac{\chi(r)}{r^{2}}$ with domain $\mathcal{D}\left(A_{0}\right)=$ $C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right)$ in the case

$$
\begin{equation*}
\inf \chi=c>\frac{3}{4} \tag{3.8}
\end{equation*}
$$

Lemma 3.2. Assume (3.8) is fulfilled. Then we have
a):

$$
\mathcal{D}\left(\overline{A_{0}}\right)=\mathcal{D}\left(A_{F}\right)=\left\{u \in H^{2}\left(R^{3}\right) ; \quad u(0)=0\right\}
$$

b): for $u \in \mathcal{D}\left(\overline{A_{0}}\right)$ we have

$$
\begin{equation*}
\|\Delta u\|_{L^{2}\left(\mathbb{R}^{3}\right)} \lesssim\left\|A_{F} u\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} . \tag{3.9}
\end{equation*}
$$

Proof. Take sequence $\left\{u_{k}\right\}_{k \in \mathbb{N}}$ in $C_{0}^{\infty}\left(\mathbb{R}^{3} \backslash 0\right)$ and set

$$
g_{k}=-\Delta u_{k}+\frac{\chi(r) u_{k}}{r^{2}} .
$$

Using radial coordinates $r=|x|, \omega=x /|x|$ we rewrite the above relation as equation

$$
-r^{-2} \partial_{r}\left(r^{2} \partial_{r}\right) u_{k}-\frac{1}{r^{2}} \Delta_{\mathbb{S}^{2}} u_{k}+\frac{\chi(r) u_{k}}{r^{2}}=g_{k}
$$

We multiply this equation by $u_{k}(r \omega)$ and integrate over $r \in(0, \infty)$, $\omega \in \mathbb{S}^{2}$ using the measure $d r d \omega$

$$
\left\{\begin{array}{l}
\int_{0}^{\infty} \int_{\mathbb{S}^{2}}\left|\partial_{r} u_{k}(r \omega)\right|^{2} d \omega d r-\int_{0}^{\infty} \int_{\mathbb{S}^{2}} \frac{\left|u_{k}(r \omega)\right|^{2}}{r^{2}} d \omega d r+  \tag{3.10}\\
+\int_{0}^{\infty} \int_{\mathbb{S}^{2}} \frac{\left|\nabla_{\omega} u_{k}(r \omega)\right|^{2}}{r^{2}} d \omega d r+ \\
+\int_{0}^{\infty} \int_{\mathbb{S}^{2}} \frac{\chi(r)\left|u_{k}(r \omega)\right|^{2}}{r^{2}} d \omega d r=\int_{0}^{\infty} \int_{\mathbb{S}^{2}} g_{k}(r \omega) u_{k}(r \omega) d \omega d r
\end{array}\right.
$$

where in the integration by parts we have used the fact that $u(r \omega)=0$ for $r$ close to 0 . Using the Hardy inequality

$$
\int_{0}^{\infty}\left|\partial_{r} f(r)\right|^{2} d r \geq \frac{1}{4} \int_{0}^{\infty} \frac{|f(r)|^{2}}{r^{2}} d r
$$

valid when $f(r)$ is $C^{1}$ function on $(0, \infty)$ with compact support in $(0, \infty)$ we see that the left side of (3.10) can be estimated from below by

$$
\left(c-\frac{3}{4}\right) \int_{0}^{\infty} \int_{\mathbb{S}^{2}} \frac{\left|u_{k}(r \omega)\right|^{2}}{r^{2}} d \omega d r
$$

We can bound the right side (3.10) from above by using Cauchy inequality by

$$
\left\|g_{k}\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}\left(\int_{0}^{\infty} \int_{\mathbb{S}^{2}} \frac{\left|u_{k}(r \omega)\right|^{2}}{r^{2}} d \omega d r\right)^{1 / 2}
$$

Hence we have the estimate

$$
\left(c-\frac{3}{4}\right)\left(\int_{0}^{\infty} \int_{\mathbb{S}^{2}} \frac{\left|u_{k}(r \omega)\right|^{2}}{r^{2}} d \omega d r\right)^{1 / 2} \leq\left\|g_{k}\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}
$$

Therefore, we get

$$
\begin{equation*}
\left(c-\frac{3}{4}\right)\left\|\frac{u_{k}}{|\cdot|^{2}}\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} \leq\left\|g_{k}\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} . \tag{3.11}
\end{equation*}
$$

This estimate is valid replacing $u_{k}$ by $u_{k}-u_{m}$ so using the fact that $g_{k}$ is a Cauchy sequence in $L^{2}\left(\mathbb{R}^{3}\right)$, we see that $u_{k}(x) /|x|^{2}$ is a Cauchy sequence in $L^{2}\left(\mathbb{R}^{3}\right)$ so $u /|x|^{2} \in L^{2}\left(\mathbb{R}^{3}\right)$ and from the equation

$$
\begin{equation*}
-\Delta u+\frac{\chi(r) u}{r^{2}}=g \tag{3.12}
\end{equation*}
$$

we deduce $u \in H^{2}\left(\mathbb{R}^{3}\right)$. In this case $u(0)$ is well defined and must be 0 since

$$
\left\|\frac{u}{|\cdot|^{2}}\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}<\infty
$$

In conclusion, we have established that

$$
\mathcal{D}\left(\overline{A_{0}}\right)=\mathcal{D}\left(A_{F}\right) \subseteq\left\{u \in H^{2}\left(R^{3}\right) ; \quad u(0)=0\right\}
$$

and (taking the limit $k \rightarrow \infty$ in (3.11))

$$
\begin{equation*}
\left(c-\frac{3}{4}\right)\left\|\frac{u}{|\cdot|^{2}}\right\|_{L^{2}\left(\mathbb{R}^{3}\right.} \leq\|g\|_{L^{2}\left(\mathbb{R}^{3}\right)} \tag{3.13}
\end{equation*}
$$

for any $u \in \mathcal{D}\left(\overline{A_{0}}\right)$.
The opposite inclusion easily follows from Hardy inequality. This completes the proof of a). The proof of b) follows directly from (3.13) and the equation (3.12).

This completes the proof.

## 4. Weighted energy estimates

We plan to prove a weighted $L^{2}$ - estimate of conformal type. In principle the conformal type estimate can be derived using appropriate multipliers for the linear wave equation

$$
\begin{equation*}
\partial_{t}^{2} u-\Delta u+V u=F \tag{4.1}
\end{equation*}
$$

assuming $F \in L^{1}\left((0, \infty) ; L^{2}\left(\mathbb{R}^{3}\right)\right)$ are supported in $\{|x| \leq t+1\}$ for any $t \geq 0$.

We use spherical harmonics $Y_{\ell}^{k}, k \in \mathbb{Z},|k| \leq \ell$ on the sphere $\mathbb{S}^{2}$ that are solutions to the equation

$$
-\Delta_{S^{2}} Y_{\ell}^{k}=\lambda_{\ell} Y_{\ell}^{k}, \quad \lambda_{\ell}=\ell(1+\ell), \quad \ell=0,1,2, \cdots
$$

Using radial coordinates $r=|x|, \omega=x / r$ and the expansions of $u, F$

$$
\left\{\begin{array}{l}
u(t, x)=\sum_{\ell=0}^{\infty} \sum_{k=-\ell}^{\ell} \frac{u_{\ell}^{k}(t, r)}{r} Y_{\ell}^{k}(\omega)  \tag{4.2}\\
F(t, x)=\sum_{\ell=0}^{\infty} \sum_{k=-\ell}^{\ell} \frac{F_{\ell}^{k}(t, r)}{r} Y_{\ell}^{k}(\omega)
\end{array}\right.
$$

one can extend $u_{\ell}^{k}(t, r), F_{\ell}^{k}(t, r)$ as odd functions on $r \in \mathbb{R}$ and rewrite (4.1) as

$$
\begin{equation*}
\left(\partial_{t}^{2}-\partial_{r}^{2}\right) u_{\ell}^{k}(t, r)+\left(V(r)+\frac{\lambda_{\ell}}{r^{2}}\right)\left(u_{\ell}^{k}\right)=F_{\ell}^{k}(t, r) \tag{4.3}
\end{equation*}
$$

It is clear that $r^{2} V(r)=\chi(r)$ can be extended as even function on $\mathbb{R}$.

## NONLINEAR WAVE EQUATIONS WITH SINGULAR POTENTIAL 11

To simplify the notations we shall omit the indices $k, \ell$ so we shall consider the 1D equation

$$
\begin{equation*}
\left(\partial_{t}^{2}-\partial_{r}^{2}\right) u(t, r)+\left(V(r)+\frac{\lambda}{r^{2}}\right) u(t, r)=F(t, r) . \tag{4.4}
\end{equation*}
$$

Using the notations

$$
\nabla_{ \pm}=\partial_{t} \pm \partial_{r}, \tau_{ \pm}=2+t \pm r
$$

we can rewrite (4.4) as

$$
\begin{equation*}
\nabla_{+} \nabla_{-} u(t, r)+\left(V(r)+\frac{\lambda}{r^{2}}\right) u(t, r)=F(t, r) \tag{4.5}
\end{equation*}
$$

We use as a multiplier

$$
M(u):=\tau_{+}^{s} \nabla_{+} u+\tau_{-}^{s} \nabla_{-} u
$$

Lemma 4.1. Let $s \geq 0$ and $T>0$. For $u \in C^{2}\left([0, T) \times\left(\mathbb{R}^{3} \backslash 0\right)\right)$, we have

$$
\begin{align*}
& M(u)\left[\partial_{t}^{2} u-\partial_{r}^{2} u+\left(V(r)+\frac{\lambda}{r^{2}}\right) u\right]=  \tag{4.6}\\
= & \frac{1}{2}\left(\partial_{t}+\partial_{r}\right) X_{+} u+\frac{1}{2}\left(\partial_{t}-\partial_{r}\right) X_{-} u+\mathfrak{R}|u|^{2}
\end{align*}
$$

where we put

$$
\begin{align*}
& X_{\mp}(u)=\frac{1}{2} \tau_{ \pm}^{s}\left|\nabla_{ \pm} u\right|^{2}+\frac{\tau_{\mp}^{s}}{2}\left(V(r)+\frac{\lambda}{r^{2}}\right)|u|^{2},  \tag{4.7}\\
& \Re(r, t)=-\frac{\left(\tau_{+}^{s}-\tau_{-}^{s}\right)}{2 r}\left(r V^{\prime}(r)+2 V(r)\right)+\frac{\rho V}{r}+\frac{\rho \lambda}{r^{3}},
\end{align*}
$$

with

$$
\begin{equation*}
\rho(t, r)=\tau_{+}^{s}-\tau_{-}^{s}-s\left(r \tau_{+}^{s-1}+r \tau_{-}^{s-1}\right) \tag{4.8}
\end{equation*}
$$

Proof. Using the commutator relations

$$
\left[\nabla_{+}, \nabla_{-}\right]=0,\left[\nabla_{-}, \tau_{+}\right]=\left[\nabla_{+}, \tau_{-}\right]=0
$$

as well as the relations

$$
\nabla_{+} \tau_{+}^{a}=2 a \tau_{+}^{a-1}, \nabla_{-} \tau_{-}^{a}=2 a \tau_{-}^{a-1}
$$

we arrive at

$$
\begin{aligned}
& M(u) F=\nabla_{+}\left(\frac{1}{2} \tau_{-}^{s}\left|\nabla_{-} u\right|^{2}\right)+\nabla_{-}\left(\frac{1}{2} \tau_{+}^{s}\left|\nabla_{+} u\right|^{2}\right)+ \\
& +\frac{\tau_{+}^{s}}{2}\left(V(r)+\frac{\lambda}{r^{2}}\right) \nabla_{+}|u|^{2}+\frac{\tau_{-}^{s}}{2}\left(V(r)+\frac{\lambda}{r^{2}}\right) \nabla_{-}|u|^{2}
\end{aligned}
$$

where $F$ represents the left-hand side of (4.5). Since

$$
X_{\mp}(u)=\frac{1}{2} \tau_{ \pm}^{s}\left|\nabla_{ \pm} u\right|^{2}+\frac{\tau_{\mp}^{s}}{2}\left(V(r)+\frac{\lambda}{r^{2}}\right)|u|^{2},
$$

we obtain

$$
M(u) F=\nabla_{+} X_{+}(u)+\nabla_{-} X_{-}(u)+\Re|u|^{2},
$$

where

$$
\begin{gathered}
\mathfrak{R}=-\nabla_{-}\left(\frac{\tau_{-}^{s}}{2}\left(V(r)+\frac{\lambda}{r^{2}}\right)\right)-\nabla_{+}\left(\frac{\tau_{+}^{s}}{2}\left(V(r)+\frac{\lambda}{r^{2}}\right)\right) \\
=-\left(s \tau_{-}^{s-1}+s \tau_{+}^{s-1}\right)\left(V(r)+\frac{\lambda}{r^{2}}\right)+\frac{\left(\tau_{-}^{s}-\tau_{+}^{s}\right)}{2}\left(V^{\prime}(r)-\frac{2 \lambda}{r^{3}}\right)= \\
=-\frac{\left(\tau_{+}^{s}-\tau_{-}^{s}\right)}{2 r}\left(r V^{\prime}(r)+2 V(r)\right)+\frac{\rho V}{r}+\frac{\rho \lambda}{r^{3}} .
\end{gathered}
$$

This completes the proof.
Remark 4.1. It is easy to show that

$$
\begin{equation*}
\rho(r, t) \geq 0, \quad \forall r \in[0, t+1], \forall s \in[1,2] . \tag{4.9}
\end{equation*}
$$

Indeed, we have the relation

$$
\rho(r, t)=(2+t)^{s} f\left(\frac{r}{2+t}\right),
$$

where

$$
f(x):=\underbrace{(1+x)^{s}-s x(1+x)^{s-1}}_{=\phi(x)}-\underbrace{\left((1-x)^{s}+s x(1-x)^{s-1}\right)}_{\phi(-x)} .
$$

Note that the derivative of $f$ is

$$
s(1-s) x\left((1+x)^{s-2}-(1-x)^{s-2}\right)
$$

and it is positive for $x \in(0,1)$. Hence $f(x) \geq f(0)=0$.
Proposition 4.1. Suppose that $V$ is a non-negative function that satisfies (1.4) and (1.5). Let $1<s<2$ and $0<\delta<s-1$. We assume that $F \in C\left([0, T): L^{2}\left(\mathbb{R}^{3}\right)\right)$ satisfies supp $F(t, \cdot) \subset B(1+t)$ and that $u$ is the strong solution to

$$
\begin{align*}
& \left(\partial_{t}^{2}+A\right) u=F(t, x) \quad \text { for } \quad(t, x) \in[0, T) \times \mathbb{R}^{3}, \\
& u(0, x)=f(x), \quad\left(\partial_{t} u\right)(0, x)=g(x) \quad \text { for } x \in \mathbb{R}^{3} \tag{4.10}
\end{align*}
$$

satisfying $\operatorname{supp} u(t, \cdot) \subset B(1+t)$. Then, for $t \in[0, T)$, we have

$$
\begin{align*}
& \left\|(2+t-r)^{s / 2} \nabla_{t, r} u(t)\right\|_{L^{2}(\mathbb{R})} \\
& +\sum_{j=1}^{3}\left\|(2+t-r)^{s / 2} \frac{\left|R_{j} u(t)\right|}{r}\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}  \tag{4.11}\\
& +\left\|(2+t-r)^{s / 2} \frac{u(t)}{r}\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} \leq C_{\delta}\left(\|g\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\|\nabla f\|_{L^{2}\left(\mathbb{R}^{3}\right)}\right. \\
& \left.+\left\|(2+t+r)^{s / 2}(2+t-r)^{(1+\delta) / 2} F\right\|_{L^{2}\left((0, T) \times \mathbb{R}^{3}\right)}\right)
\end{align*}
$$

Proof. Using radial coordinates $r=|x|, \omega=x / r$ and the expansions (4.2) of $u, F, f, g$ in spherical harmonics, we reduce the proof to the following estimate for $u_{\ell}^{k}$

$$
\left\{\begin{array}{l}
\left\|(2+t-r)^{s / 2} \nabla_{t, r} u_{\ell}^{k}(t)\right\|_{L^{2}(\mathbb{R})}+  \tag{4.12}\\
+\ell\left\|(2+t-r)^{s / 2} \frac{u_{\ell}^{k}(t)}{r}\right\|_{L^{2}(\mathbb{R})} \leq \\
\leq C_{\delta}\left(\left\|g_{\ell}^{k}\right\|_{L^{2}(\mathbb{R})}+\left\|\nabla f_{\ell}^{k}\right\|_{L^{2}(\mathbb{R})}\right. \\
\left.+\left\|(2+t+r)^{s / 2}(2+t-r)^{(1+\delta) / 2} F_{\ell}^{k}\right\|_{L^{2}([0, T) \times \mathbb{R})}\right)
\end{array}\right.
$$

Here and below $u_{\ell}^{k}$ are solutions to the $1 D$ semilinear wave equation of type (4.5), i.e.

$$
\begin{equation*}
\left(\partial_{t}^{2}-\partial_{r}^{2}\right) u_{\ell}^{k}(t, r)+\left(V(r)+\frac{\lambda_{\ell}}{r^{2}}\right) u_{\ell}^{k}(t, r)=F_{\ell}^{k}(t, r) \tag{4.13}
\end{equation*}
$$

with initial data $f_{\ell}^{k}, g_{\ell}^{k}$.
To arrive at (4.11) it is sufficient to take into account the Hardy type estimates (2.1) and see that (4.12) implies (4.11).

Then the identity (4.6) suggests to integrate the expression

$$
\frac{1}{2}\left(\partial_{t}+\partial_{r}\right) X_{+} u_{\ell}^{k}+\frac{1}{2}\left(\partial_{t}-\partial_{r}\right) X_{-} u_{\ell}^{k}+\Re\left|u_{\ell}^{k}\right|^{2}
$$

in the right side of (4.6) over appropriate space time domain. To explain more clearly the domain of integration we take $T>1$ and then choose two positive parameters $\alpha, \beta$ satisfying the relations

$$
\begin{equation*}
2 T+1>\alpha, \alpha>\beta>-1, \quad \frac{\alpha+\beta}{2}>T \tag{4.14}
\end{equation*}
$$

First, we consider the case

$$
\begin{equation*}
2 T+1>\alpha, \alpha>\beta>1, \quad \frac{\alpha+\beta}{2}>T \tag{4.15}
\end{equation*}
$$

In this case the domain for $(\alpha, \beta)$ is represented by the hexagon hex $(\alpha, \beta, T)=$ $A B C D E F$ on Figure 1 .

Applying the Gauss - Green formula for the integral of (4.6) over the hexagon, we find

$$
\begin{gathered}
\iint_{\operatorname{hex}(\alpha, \beta, T)} M\left(u_{\ell}^{k}\right) F_{\ell}^{k}=E_{-}(\beta, T)+ \\
E_{+}(\alpha, T)+E_{0}(\alpha, \beta, T)+\iint_{\operatorname{hex}(\alpha, \beta, T)} \Re\left|u_{\ell}^{k}\right|^{2}-\frac{1}{2} \int_{E F} X_{+} u_{\ell}^{k}+X_{-} u_{\ell}^{k}
\end{gathered}
$$

where

$$
\begin{gathered}
E_{-}(\beta, T)=\frac{1}{\sqrt{2}} \int_{A B(\beta, T)} X_{-} u_{\ell}^{k}, E_{+}(\alpha, T)=\frac{1}{\sqrt{2}} \int_{C D(\beta, T)} X_{+} u_{\ell}^{k} \\
E_{0}(\alpha, \beta, T)=\frac{1}{2} \int_{B C(\alpha, \beta, T)} X_{+} u_{\ell}^{k}+X_{-} u_{\ell}^{k}
\end{gathered}
$$

Of special interests are the segments $A B, B C, C D$ parameterized as follows:

$$
\begin{gathered}
A B(\beta): r=\rho, t=\rho+\beta, \quad \rho \in\left[-\frac{\beta+1}{2}, T-\beta\right], \\
B C(\alpha, \beta): r=\rho, t=T, \quad \rho \in[T-\beta, \alpha-T] \\
C D(\alpha): r=\rho, t=\alpha-\rho, \quad \rho \in\left[\alpha-T, \frac{\alpha+1}{2}\right]
\end{gathered}
$$

We have the following estimates

Figure 1. Domain of integration for $\beta>1$.

$$
\left|\int_{E F} X_{+} u_{\ell}^{k}+X_{-} u_{\ell}^{k}\right| \lesssim\left\|g_{\ell}^{k}\right\|_{L^{2}(\mathbb{R})}^{2}+\left\|\nabla f_{\ell}^{k}\right\|_{L^{2}(\mathbb{R})}^{2}
$$

and

$$
\left|\iint_{\operatorname{hex}(\alpha, \beta, T)} M\left(u_{\ell}^{k}\right) F_{\ell}^{k}\right| \leq \int_{0}^{T} \int_{\mathbb{R}}\left|M\left(u_{\ell}^{k}\right) F_{\ell}^{k}\right| d r d t
$$

Hence, we have the estimate

$$
\left\{\begin{array}{c}
E_{-}(\beta, T)+E_{+}(\alpha, T)+E_{0}(\alpha, \beta, T)+\iint_{\operatorname{hex}(\alpha, \beta, T)} \mathfrak{R}\left|u_{\ell}^{k}\right|^{2} \lesssim  \tag{4.16}\\
\lesssim\left\|g_{\ell}^{k}\right\|_{L^{2}(\mathbb{R})}^{2}+\left\|\nabla f_{\ell}^{k}\right\|_{L^{2}(\mathbb{R})}^{2}+\int_{0}^{T} \int_{\mathbb{R}}\left|M\left(u_{\ell}^{k}\right) F_{\ell}^{k}\right| d r d t
\end{array}\right.
$$

Using (4.7), we deduce the following estimates

$$
\left\{\begin{array}{l}
E_{-}(\beta, T) \geq \int_{A B(\beta, T)}(2+t+r)^{s}\left(\partial_{t} u+\partial_{r} u\right)^{2},  \tag{4.17}\\
E_{+}(\alpha, T) \geq \int_{C D(\alpha, T)}(2+t-r)^{s}\left(\partial_{t} u-\partial_{r} u\right)^{2} \\
E_{0}(\alpha, \beta, T) \geq \int_{B C(\alpha, \beta, T)}(2+t-r)^{s}\left(\left(\nabla_{t, r} u\right)^{2}+\ell^{2} \frac{|u|^{2}}{r^{2}}\right)
\end{array}\right.
$$

The multiplier

$$
M(u):=\tau_{+}^{s} \nabla_{+} u+\tau_{-}^{s} \nabla_{-} u
$$

can be substituted in the right side of (4.16) so we get

$$
\begin{gathered}
\int_{0}^{T} \int_{\mathbb{R}}\left|\tau_{+}^{s / 2} \nabla_{+} u_{\ell}^{k} \tau_{+}^{s / 2} F_{\ell}^{k}\right| d r d t=\int_{-1}^{2 T+1} d \beta \int_{A B(\beta, T)}\left|\tau_{+}^{s / 2} \nabla_{+} u_{\ell}^{k} \tau_{+}^{s / 2} F_{\ell}^{k}\right| \lesssim \\
\lesssim \int_{-1}^{2 T+1} d \beta E_{-}(\beta, T)^{1 / 2}\left(\int_{A B(\beta, T)} \tau_{+}^{s}\left|F_{\ell}^{k}\right|^{2}\right)^{1 / 2} \lesssim \\
\lesssim \sup _{-1<\beta<2 T+1} E_{-}(\beta, T)^{1 / 2}\left(\int_{-1}^{2 T+1} d \beta \int_{A B(\beta, T)}(1+\beta)^{s} \tau_{-}^{s}\left|F_{\ell}^{k}\right|^{2}\right)^{1 / 2}= \\
=\sup _{-1<\beta<2 T+1} E_{+}(\beta, T)^{1 / 2}\left\|\tau_{+}^{s / 2} \tau_{-}^{s / 2} F_{\ell}^{k}\right\|_{L^{2}((0, T) \times \mathbb{R})}
\end{gathered}
$$

In a similar way we get

$$
\begin{gathered}
\int_{0}^{T} \int_{\mathbb{R}}\left|\tau_{-}^{s / 2} \nabla_{-} u_{\ell}^{k} \tau_{-}^{s / 2} F_{\ell}^{k}\right| d r d t \lesssim \\
\lesssim \sup _{-1<\alpha<2 T+1} E_{-}(\alpha, T)^{1 / 2}\left\|\tau_{+}^{s / 2} \tau_{-}^{s / 2} F_{\ell}^{k}\right\|_{L^{2}((0, T) \times \mathbb{R})} .
\end{gathered}
$$

Turning back to (4.16) we get

$$
\left\{\begin{array}{c}
E_{-}(\beta, T)+E_{+}(\alpha, T)+E_{0}(\alpha, \beta, T)+\iint_{\operatorname{hex}(\alpha, \beta, T)} \mathfrak{R}\left|u_{\ell}^{k}\right|^{2} \lesssim  \tag{4.18}\\
\lesssim\left\|g_{\ell}^{k}\right\|_{L^{2}(\mathbb{R})}^{2}+\left\|\nabla f_{\ell}^{k}\right\|_{L^{2}(\mathbb{R})}^{2}+\left\|\tau_{+}^{s / 2} \tau_{-}^{s / 2} F_{\ell}^{k}\right\|_{L^{2}((0, T) \times \mathbb{R})}^{2}
\end{array}\right.
$$

This estimate and the lower bounds (4.17) imply (4.12) and complete the proof.

In the case $-1<\beta<1$ we have pentagon $\operatorname{pen}(\alpha, \beta, T)=A B C D E$ on Figure 2 and we follow the same argument and deduce

$$
\left\{\begin{array}{l}
E_{-}(\beta, T)+E_{+}(\alpha, T)+E_{0}(\alpha, \beta, T)+\iint_{\operatorname{pen}(\alpha, \beta, T)} \mathfrak{R}\left|u_{\ell}^{k}\right|^{2} \lesssim  \tag{4.19}\\
\lesssim\left\|g_{\ell}^{k}\right\|_{L^{2}(\mathbb{R})}^{2}+\left\|\nabla f_{\ell}^{k}\right\|_{L^{2}(\mathbb{R})}^{2}+\left\|\tau_{+}^{s / 2} \tau_{-}^{s / 2} F_{\ell}^{k}\right\|_{L^{2}((0, T) \times \mathbb{R})}^{2} \\
\hline
\end{array}\right.
$$

Figure 2. Domain of integration for $\beta \in(-1,1)$

Corollary 4.2. Let $s \in(1,2), \theta \in[0,1]$ and $q \in[2, \infty]$. Define $\sigma \in$ $[2, \infty], \kappa \in[2, q]$ by

$$
\frac{1}{\sigma}=\frac{\theta}{2}+\frac{1-\theta}{\infty}, \quad \frac{1}{\kappa}=\frac{\theta}{q}+\frac{1-\theta}{2} .
$$

Then, under the assumptions of Proposition 3.2, we have

$$
\begin{align*}
& \quad\left\|r^{(1-3 \theta) / 2}(2+t+r)^{(1-\theta) / 2}(2+t-r)^{(s-1+\theta) / 2} u(t, r \omega)\right\|_{L_{r}^{\sigma} L^{k}\left(S^{2}\right)}  \tag{4.20}\\
& \lesssim\|g\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\|\nabla f\|_{L^{2}\left(\mathbb{R}^{3}\right)} \\
& \quad+\left\|(2+t+r)^{s / 2}(2+t-r)^{(1+\delta) / 2} F\right\|_{L^{2}\left([0, T] \times \mathbb{R}^{3}\right)}
\end{align*}
$$

for $t \in[0, T)$. Here and in what follows, for $\sigma \in[1, \infty), q \in[1, \infty]$, we denote

$$
\|f\|_{L_{r}^{\sigma} L^{q}\left(S^{2}\right)}:=\left(\int_{0}^{\infty}\|f(r \omega)\|_{L^{q}\left(S^{2}\right)}^{\sigma} r^{2} d r\right)^{1 / \sigma}
$$

Proof. For $q \in[2, \infty)$ and $\phi \in H^{1}\left(S^{2}\right)$, we have

$$
\|\phi\|_{L^{q}\left(S^{2}\right)} \lesssim\|\phi\|_{H^{1}\left(S^{2}\right)} \sim \sum_{|\alpha| \leq 1}\left\|R^{\alpha} \phi\right\|_{L^{2}\left(S^{2}\right)}
$$

by the Sobolev embedding theorem. Therefore, (4.11) implies

$$
\begin{align*}
&\left\|r^{-1}(2+t-r)^{s / 2} u(t, r \omega)\right\|_{L_{r}^{2} L^{q}\left(S^{2}\right)} \\
& \lesssim\|g\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\|\nabla f\|_{L^{2}\left(\mathbb{R}^{3}\right)}  \tag{4.21}\\
& \quad+\left\|(2+t+r)^{s / 2}(2+t-r)^{(1+\delta) / 2} F\right\|_{L^{2}\left([0, T] \times \mathbb{R}^{3}\right)}
\end{align*}
$$

for $t \in[0, T)$. Combining (4.11) and Proposition 2.1] with $n=3$, we get

$$
\begin{align*}
& \quad\left\|r^{1 / 2}(2+t+r)^{1 / 2}(2+t-r)^{(s-1) / 2} u(t, r \omega)\right\|_{L_{r}^{\infty} L^{2}\left(S^{2}\right)} \\
& \lesssim\|g\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\|\nabla f\|_{L^{2}\left(\mathbb{R}^{3}\right)}  \tag{4.22}\\
& \quad+\left\|(2+t+r)^{s / 2}(2+t-r)^{(1+\delta) / 2} F\right\|_{L^{2}\left([0, T] \times \mathbb{R}^{3}\right)}
\end{align*}
$$

for $t \in[0, T)$. The interpolation between (4.21) and (4.22) yields the desired estimate.

## 5. Proof of Theorem 1.1

We introduce the following function space $X_{T}$ in which we shall look for the solution to (1.1):
$X_{T}:=\left\{\left.v \in \bigcap_{j=0}^{1} C^{j}\left([0, T]: \mathcal{D}\left(A^{\frac{2-j}{2}}\right)\right) \right\rvert\,\|v\|_{X_{T}}<\infty, \operatorname{supp} v(t, \cdot) \subset B(1+t)\right\}$,
where we set

$$
\begin{equation*}
\|v\|_{X_{T}}:=\sup _{t \in[0, T]}\left\{\sum_{j=0}^{2}\left\|A^{\frac{2-j}{2}} v(t)\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\sum_{j=1}^{2}\left\|A^{\frac{2-j}{2}} \partial_{t} v(t)\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}\right\} \tag{5.1}
\end{equation*}
$$

In order to handle the nonlinear term $F(u(t))=b|u(t)|^{p-1} u(t)$, we prepare the following estimates.

Lemma 5.1. Let $1<p<3$. For $u, v \in X_{T}$ and $t \in[0, T]$, we have

$$
\begin{gather*}
\|F(u(t))-F(v(t))\|_{L^{2}\left(\mathbb{R}^{3}\right)} \lesssim\left(\|u\|_{X_{T}}^{p-1}+\|v\|_{X_{T}}^{p-1}\right)\|u-v\|_{X_{T}},  \tag{5.2}\\
\left\|A^{\frac{1}{2}}(F(u(t))-F(v(t)))\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} \lesssim\left(\|u\|_{X_{T}}^{p-1}+\|v\|_{X_{T}}^{p-1}\right)\|u-v\|_{X_{T}} . \tag{5.3}
\end{gather*}
$$

Proof. It follows that

$$
\begin{aligned}
&\|F(u(t))-F(v(t))\|_{L^{2}\left(\mathbb{R}^{3}\right)} \\
& \lesssim\left(\|u(t)\|_{L^{2 p}\left(\mathbb{R}^{3}\right)}^{p-1}+\|v(t)\|_{L^{2 p}\left(\mathbb{R}^{3}\right)}^{p-1}\right)\|(u-v)(t)\|_{L^{2 p}\left(\mathbb{R}^{3}\right)}
\end{aligned}
$$

By the Gagliardo-Nirenberg inequality, we have

$$
\|\varphi\|_{L^{2 p}\left(\mathbb{R}^{3}\right)} \lesssim\|\varphi\|_{L^{2}\left(\mathbb{R}^{3}\right)}^{1-\gamma}\|\nabla \varphi\|_{L^{2}\left(\mathbb{R}^{3}\right)}^{\gamma} \lesssim\|\varphi\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\|\nabla \varphi\|_{L^{2}\left(\mathbb{R}^{3}\right)}
$$

where we put $\gamma=3(p-1) /(2 p) \in(0,1)$ for $1<p<3$. Therefore, we get (5.2) by (3.6).

Noting that

$$
\begin{aligned}
&\|\nabla(F(u(t))-F(v(t)))\|_{L^{2}\left(\mathbb{R}^{3}\right)} \\
& \lesssim\|u(t)\|_{L^{2 p}\left(\mathbb{R}^{3}\right)}^{p-1}\|\nabla(u-v)(t)\|_{L^{2 p}\left(\mathbb{R}^{3}\right)} \\
& \quad+\|\nabla v(t)\|_{L^{2 p}\left(\mathbb{R}^{3}\right)}\left(\|u(t)\|_{L^{2 p}\left(\mathbb{R}^{3}\right)}^{p-2}+\|v(t)\|_{L^{2 p}\left(\mathbb{R}^{3}\right)}^{p-2}\right)\|(u-v)(t)\|_{L^{2 p}\left(\mathbb{R}^{3}\right)}
\end{aligned}
$$

and

$$
\begin{aligned}
\|\nabla \varphi\|_{L^{2 p}\left(\mathbb{R}^{3}\right)} & \lesssim \sum_{j=1}^{3}\left\|\partial_{j} \varphi\right\|_{L^{2 p}\left(\mathbb{R}^{3}\right)} \lesssim \sum_{j=1}^{3}\left(\left\|\partial_{j} \varphi\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\left\|\nabla \partial_{j} \varphi\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}\right) \\
& \lesssim\|\nabla \varphi\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\|\Delta \varphi\|_{L^{2}\left(\mathbb{R}^{3}\right)} \lesssim\left\|A^{\frac{1}{2}} \varphi\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\|A \varphi\|_{L^{2}\left(\mathbb{R}^{3}\right)}
\end{aligned}
$$

we obtain (5.3) by (3.6) and (3.9). This completes the proof.
For a given $(f, g) \in \mathcal{D}(A) \times \mathcal{D}\left(A^{\frac{1}{2}}\right)$ satisfying supp $f, \operatorname{supp} g \subset B(1)$, we define a sequence by

$$
\begin{align*}
u_{m+1}(t) & =u_{0}(t)+\int_{0}^{t} \frac{\sin (t-\tau) \sqrt{A}}{\sqrt{A}} F\left(u_{m}(\tau)\right) d \tau(m=0,1, \ldots) \\
u_{0} & =(\cos t \sqrt{A}) f+\frac{\sin t \sqrt{A}}{\sqrt{A}} g \tag{5.4}
\end{align*}
$$

Theorem 5.1. Let $1<p<3$. Assume $(f, g) \in \mathcal{D}(A) \times \mathcal{D}\left(A^{\frac{1}{2}}\right)$ satisfies supp $f$, supp $g \subset B(1)$. Set

$$
\begin{equation*}
\eta:=\sum_{j=0}^{2}\left\|A^{\frac{2-j}{2}} f\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\sum_{j=1}^{2}\left\|A^{\frac{2-j}{2}} g\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} . \tag{5.5}
\end{equation*}
$$

Then there exists $T=T(\eta)>0$ such that (1.1) admits a unique strong solution $u(t)$ in $X_{T}$.

Moreover, if $T_{*}$ is the supremum over all such $T$, then $T_{*}=\infty$ or $\|u(t)\|_{L^{2 p}\left(\mathbb{R}^{3}\right)} \notin L^{\infty}\left(\left[0, T_{*}\right)\right)$.

Proof. Due to (5.2) and (5.3), the existence and uniqueness follow from the standard argument.

In order to prove the blow-up criterion, by assuming $T_{*}<\infty$ and there exists a constant $M$ such that $\sup _{t \in\left[0, T_{*}\right)}\|u(t)\|_{L^{2 p}\left(\mathbb{R}^{3}\right)} \leq M$, we shall derive a contradiction. In the following, we always assume $t \in$ $\left[0, T_{*}\right)$. In view of the proof of (5.2) and (5.3) as $v=0$, we get

$$
\|F(u(t))\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\left\|A^{\frac{1}{2}} F(u(t))\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} \lesssim\|u(t)\|_{L^{2 p}\left(\mathbb{R}^{3}\right)}^{p-1} E(t),
$$

where we set

$$
E(t):=\sum_{j=0}^{2}\left\|A^{\frac{2-j}{2}} u(t)\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\sum_{j=1}^{2}\left\|A^{\frac{2-j}{2}} \partial_{t} u(t)\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} .
$$

Thus, using the integral equation for the solution:

$$
u(t)=u_{0}(t)+\int_{0}^{t} \frac{\sin (t-\tau) \sqrt{A}}{\sqrt{A}} F(u(\tau)) d \tau
$$

we obatin

$$
E(t) \leq C_{0}\left(1+T_{*}\right) \eta+C_{1}\left(1+T_{*}\right) \int_{0}^{t} M^{p-1} E(\tau) d \tau
$$

with some universal constants $C_{0}, C_{1}$. By the Gronwall inequality, we get

$$
E(t) \leq C_{0}\left(1+T_{*}\right) \eta \exp \left(C_{1} M^{p-1}\left(1+T_{*}\right) T_{*}\right)
$$

which implies $\sup _{t \in\left[0, T_{*}\right)} E(t)<\infty$. Therefore, we can extend $u(t)$ at $t=T_{*}$ so that $\left(u\left(T_{*}\right),\left(\partial_{t} u\right)\left(T_{*}\right)\right) \in \mathcal{D}(A) \times \mathcal{D}\left(A^{\frac{1}{2}}\right)$. But this means that the local solution $u(t)$ can be extended as a solution of (1.1) beyond $T_{*}$. This contradcts the definition of $T_{*}$ and finishes the proof.

In order to prove the global existence, we assume $p>1+\sqrt{2}$, Then, since $p^{2}-2 p-1>0$ for $p>1+\sqrt{2}$, we can choose $\delta>0$ so small that $p^{2}-2 p-1>p \delta / 2$. For such $\delta$, we shall take $\theta \in(0,1)$ so that $p^{2} \theta<(p+1)(p-2)$ and $2 p \theta<\delta$. We define $\sigma=2 / \theta$ and take $\kappa \in(2, \infty)$. Now, we introduce the following quanity:

$$
\|v v\|_{X_{T}}=\sup _{t \in[0, T]}\left\{\|w(t) v(t)\|_{L_{r}^{\sigma} L^{\kappa}\left(S^{2}\right)}+\sum_{j=1}^{3}\left\|w(t) R_{j} v(t)\right\|_{L_{r}^{\sigma} L^{\kappa}\left(S^{2}\right)}\right\} .
$$

where the weight function $w=w(t, r)$ is defined by

$$
w(t, r):=r^{(1-3 \theta) / 2} \tau_{+}^{(1-\theta) / 2} \tau_{-}^{(s-1+\theta) / 2}, \quad s=1+(2 / p)
$$

In order to make use of the estimate of conformal type, we prepare the following lemma.

Lemma 5.2. Assume $1+\sqrt{2}<p<3$. Let $\delta, \theta, \sigma, \kappa$ and $s$ be as in the above. Then, for $u \in X_{T}$ satisfying $\left\|\|v\|_{X_{T}}<\infty\right.$, we have

$$
\begin{align*}
& \left\|\tau_{+}^{s / 2} \tau_{-}^{(1+\delta) / 2} F(u)\right\|_{L_{T}^{2} L^{2}\left(\mathbb{R}^{3}\right)}+\sum_{j=1}^{3}\left\|\tau_{+}^{s / 2} \tau_{-}^{(1+\delta) / 2} R_{j} F(u)\right\|_{L_{T}^{2} L^{2}\left(\mathbb{R}^{3}\right)}  \tag{5.6}\\
& \lesssim\|v\|_{X_{T}}^{p} .
\end{align*}
$$

Proof. Since $\kappa>2$, we have

$$
\|\phi\|_{L^{\infty}\left(S^{2}\right)} \lesssim\|\phi\|_{W^{1, \kappa}\left(S^{2}\right)} \sim\|\phi\|_{L^{\kappa}\left(S^{2}\right)}+\sum_{j=1}^{3}\left\|R_{j} \phi\right\|_{L^{\kappa}\left(S^{2}\right)}
$$

by the Sobolev inequality. Therefore, we can deduce

$$
\|F(u(t, r))\|_{L^{2}\left(S^{2}\right)}+\sum_{j=1}^{3}\left\|R_{j} F(u(t, r))\right\|_{L^{2}\left(S^{2}\right)} \lesssim\|u(t, r)\|_{W^{1, \kappa}\left(S^{2}\right)}^{p}
$$

Thus, noting that $(\sigma / 2 p)^{-1}+(1 /(1-p \theta))^{-1}=1$, we get

$$
\begin{align*}
& \left\|\tau_{+}^{s / 2} \tau_{-}^{(1+\delta) / 2} F(u(t))\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\sum_{j=1}^{3}\left\|\tau_{+}^{s / 2} \tau_{-}^{(1+\delta) / 2} R_{j} F(u(t))\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}  \tag{5.7}\\
& \lesssim\|w(t) u(t)\|_{L_{r}^{\sigma} W^{1, \kappa}\left(S^{2}\right)}^{p}(J(t))^{(1-p \theta) / 2}
\end{align*}
$$

where we set

$$
\begin{aligned}
J(t) & :=\int_{0}^{t+1}\left(\tau_{+}^{s} \tau_{-}^{1+\delta}(w(t, r))^{-2 p}\right)^{\frac{1}{1-p \theta}} r^{2} d r \\
& =\int_{0}^{t+1} r^{2-\frac{p(1-3 \theta)}{1-p \theta}} \tau_{+}^{\frac{s-p(1-\theta)}{1-p \theta}} \tau_{-}^{\frac{1+\delta-p(s-1+\theta)}{1-p \theta}} d r
\end{aligned}
$$

Since

$$
\begin{aligned}
& s-p(1-\theta)=1+(2 / p)-p+p \theta=\left(-(p+1)(p-2)+p^{2} \theta\right) / p<0 \\
& 1+\delta-p(s-1+\theta)=-1+\delta-p \theta
\end{aligned}
$$

we have

$$
J(t) \lesssim(2+t)^{\frac{1+(2 / p)-p+p \theta}{1-p \theta}} \int_{0}^{t+1} r^{2-\frac{p(1-3 \theta)}{1-p \theta}}(2+t-r)^{-\frac{1-\delta+p \theta}{1-p \theta}} d r .
$$

Noting that

$$
3-\frac{p(1-3 \theta)}{1-p \theta}>0 \text { if } p<3 \text { and } 1-\frac{1-\delta+p \theta}{1-p \theta}>0 \text { if } 2 p \theta<\delta
$$

we see that the above $r$-integral is bounded by

$$
\begin{aligned}
& (2+t)^{-\frac{1-\delta+p \theta}{1-p \theta}} \int_{0}^{(t / 2)+1} r^{2-\frac{p(1-3 \theta)}{1-p \theta}} d r \\
& \quad+(2+t)^{2-\frac{p(1-3 \theta)}{1-p \theta}} \int_{(t / 2)+1}^{t+1}(2+t-r)^{-\frac{1-\delta+p \theta}{1-p \theta}} d r \lesssim(2+t)^{\frac{2+\delta-p \theta-p}{1-p \theta}}
\end{aligned}
$$

Thus we get $(J(t))^{1-p \theta} \lesssim(2+t)^{3+(2 / p)-2 p+\delta}$. Now, it follows from (5.7) that

$$
\begin{aligned}
& \left\|\tau_{+}^{s / 2} \tau_{-}^{(1+\delta) / 2} F(u)\right\|_{L_{T}^{2} L^{2}\left(\mathbb{R}^{3}\right)}+\sum_{j=1}^{3}\left\|\tau_{+}^{s / 2} \tau_{-}^{(1+\delta) / 2} R_{j} F(u)\right\|_{L_{T}^{2} L^{2}\left(\mathbb{R}^{3}\right)} \\
& \lesssim\|v\|_{X_{T}}^{p}\left(\int_{0}^{T}(2+t)^{3+(2 / p)-2 p+\delta} d t\right)^{1 / 2} \lesssim\|v\|_{X_{T}}^{p},
\end{aligned}
$$

because $4+(2 / p)-2 p+\delta<0$ by the choice of $\delta$ under the assumption $p>1+\sqrt{2}$. Hence (5.6) holds. This completes the proof.

End of the proof of Theorem 1.1: By the blow-up criterion given in Theorem 5.1, we only need to derive a uniform bound of $\|u(t)\|_{L^{2 p}\left(\mathbb{R}^{3}\right)}$ with respect to $t \in\left[0, T_{*}\right)$.

Let $0<T<T_{*}$. Seeing the proof of (5.6), we find

$$
\begin{aligned}
& \|u(t)\|_{L^{2 p}\left(\mathbb{R}^{3}\right)} \leq\left\|\tau_{+}^{s / 2} \tau_{-}^{(1+\delta) / 2}|u(t)|^{p}\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}^{1 / p} \\
& \lesssim\|w(t) u(t)\|_{L_{r}^{\sigma} W^{1, \kappa}\left(S^{2}\right)}(J(t))^{(1-p \theta) /(2 p)} \lesssim\|u\|_{X_{T}}^{p}, t \in[0, T] .
\end{aligned}
$$

Therefore, it suffices to get a uniform bound of $\left\|\|u\|_{X_{T}}\right.$ with respect to $T \in\left[0, T_{*}\right)$. Since $u$ satisfies (4.10) with $F=F(u)$, applying the rotational vector fields $R_{j}$ to the equation, and using (4.20) and (5.6), we obtain

$$
\|w(t) u(t)\|_{L_{r}^{\sigma} L^{\kappa}\left(S^{2}\right)}+\sum_{j=1}^{3}\left\|w(t) R_{j} u(t)\right\|_{L_{r}^{\sigma} L^{\kappa}\left(S^{2}\right)} \leq C_{0} \eta+C_{1}\|u\|_{X_{T}}^{p}
$$

for $t \in[0, T)$, because $\left\|R_{j} g\right\|_{L^{2}\left(\mathbb{R}^{3}\right)}+\left\|\nabla R_{j} f\right\|_{L^{2}\left(\mathbb{R}^{3}\right)} \lesssim \eta$ by the assumption that the supports of $f$ and $g$ are compactly supported. Thus we get

$$
\|v v\|_{X_{T}} \leq C_{0} \eta+C_{1}\|u\|_{X_{T}}^{p}
$$

for any $T \in\left[0, T_{*}\right)$. This means that there exists $\eta_{0}>0$ such that if $0<\eta<\eta_{0}$, then $\|u\|_{X_{T}} \leq 2 C_{0} \eta$ holds for $T \in\left[0, T_{*}\right)$, because $p>1$. Hence the proof of Theorem 1.1 is completed.
