# Asymptotic behaviour of penalized robust estimators in logistic regression when dimension increases 

Ana M. Bianco ${ }^{a}$, Graciela Boente ${ }^{a}$ and Gonzalo Chebi ${ }^{a}$<br>${ }^{a}$ Facultad de Ciencias Exactas y Naturales, Universidad de Buenos Aires and CONICET, Argentina

#### Abstract

Penalized $M$-estimators for logistic regression models have been previously study for fixed dimension in order to obtain sparse statistical models and automatic variable selection. In this paper, we derive asymptotic results for penalized $M$-estimators when the dimension $p$ grows to infinity with the sample size $n$. Specifically, we obtain consistency and rates of convergence results, for a variety of penalties. Moreover, we prove that these estimators consistently select variables with probability tending to 1 and derive their asymptotic distribution.

## 1 Introduction

A common practice to reduce the complexity of a regression model, is to bet on sparsity. In this situation, it is assumed that the number of actually relevant predictors, $k$, is lower than the number of measured covariates. Sparse models have been extensively studied in linear regression, but they are not limited to them. In particular, in high-dimensional logistic regression, practitioners usually have to face the challenge of robustly estimating sparse models, which is the topic of this paper.

Logistic regression is a widely studied problem in statistics and has been useful to classify data. In the non-sparse scenario the maximum likelihood estimator (MLE) of the regression coefficients is very sensitive to outliers, meaning that we cannot accurately classify a new observation based on these estimators, neither identify those covariates with important information for assignation. Robust methods for logistic regression have been introduced and discussed in Bianco and Yohai (1996), Croux and Haesbroeck (2003), Cantoni and Ronchetti (2001) and Bondell (2005, 2008), among others. The minimum divergence proposal due to Basu et al. (2017) may be seen as a particular case of the Bianco and Yohai (1996) estimator with a properly defined loss function. However, these methods are not reliable under collinearity and they do not allow for automatic variable selection when only a few number of covariates are relevant. These topics become more challenging when the number of covariates is close to the sample size or even larger.

Some robust estimators for logistic regression in the sparse regressors framework have already been recently proposed in the literature. Among others, we can mention Chi and Scott (2014) who considered a least squares estimator with a Ridge and Elastic Net penalty and Kurnaz et al. (2018) who
proposed estimators based on a trimmed sum of the deviances with an Elastic Net penalty. It is worth noticing that the least squares estimator in Chi and Scott (2014) corresponds to a particular choice of the loss function bounding the deviance considered in Bianco and Yohai (1996). Finally, Tibshirani and Manning (2013) introduced a real-valued shift factor to protect against the possibility of mislabelling, while Park and Konishi (2016) considered a weighted deviance approach with weights based on the Mahalanobis distance computed over a lower-dimensional principal component space and includes an Elastic Net penalty. In these situations, the statistical challenge is to obtain sparse and robust estimators for logistic regression that provide variable selection and to derive their asymptotic properties. More recently, Guo et al. (2017) and Avella-Medina and Ronchetti (2018) treated the situation of penalized $M$-estimators in generalized linear models by bounding the quasi-likelihood. In this setting, Avella-Medina and Ronchetti (2018) considered penalties that are a deterministic sum of univariate functions, while Guo et al. (2017) proposed a penalty related to the ADALASSO one. They both studied the asymptotic behaviour of penalized robust quasi-likelihood type estimators, when the dimension $p$ increases with the sample size $n$. Basu et al. (2021) considered robust estimators based on the density power divergence using an adaptively weighted LASSO penalty. Finally, Bianco et al. (2021) proposed a general family of penalized estimators based on bounding the deviance with a general penalty term, possible random, to produce sparse estimators and studied their asymptotic behaviour for fixed $p$. In this sense, our aim is to fill the gap by studying the asymptotic behaviour of the penalized robust estimators defined in Bianco et al. (2021) when the dimension increases with the sample size. Unlike Guo et al. (2017), according to a natural point of view in robustness, we do not assume that the parameter space is a compact subset of $\mathbb{R}^{p}$, where $p$ is the covariates dimension and weaker assumptions on the penalty are required. Besides, our results are not restricted to the LASSO or ADALASSO penalties as in Avella-Medina and Ronchetti (2018) or Guo et al. (2017). Indeed, they are stated in a general penalty framework that allows to include not only the two penalties already mentioned but also SCAD and MCP penalties.
The rest of this paper is organized as follows. In Section 2, we briefly review the robust penalized logistic regression estimators defined in Bianco et al. (2021). Sections 3 and 4 summarize the asymptotic properties of the proposal. Proofs are relegated to the Appendix.

## 2 Preliminaries: Robust penalized estimators

Throughout this paper, we consider a sequence logistic regression models, where the number of covariates $p=p_{n}$ diverges to infinity. To be more precise, we consider a triangular array of independent Bernoulli random variables $\left\{y_{n, i}: 1 \leq i \leq n, n \geq 1\right\}$ and the corresponding triangular array of explanatory variables $\left\{\mathbf{x}_{n, i}: 1 \leq i \leq n, n \geq 1\right\}$ where $\mathbf{x}_{n, i} \in \mathbb{R}^{p}$ and $y_{n, i} \mid \mathbf{x}_{n, i} \sim B i\left(1, \pi_{0, n, i}\right)$ with $\pi_{0, n, i}=\mathbb{P}\left(y_{n, i}=1 \mid \mathbf{x}_{n, i}\right)=F\left(\mathbf{x}_{n, i}^{\mathrm{T}}, \boldsymbol{\beta}_{0, n}\right)$ and

$$
F(t)=\frac{\exp (t)}{1+\exp (t)}
$$

and $\left\{\boldsymbol{\beta}_{0, n}: n \geq 1\right\}$ is the sequence of true regression coefficient vectors. We will assume that for each $n$, $\left(y_{n, i}, \mathbf{x}_{n, i}\right), 1 \leq i \leq n$, are independent and identically distributed.

Denote $\operatorname{DEv}(y, t)=-\log (F(t)) y-\log (1-F(t))(1-y)$ the deviance and let $\rho: \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}$ be a bounded, differentiable and nondecreasing function with derivative $\psi=\rho^{\prime}$. For sparse models and fixed dimension, Bianco et al. (2021) defined a family of robust estimators which include a regularization term allowing to penalize candidates without few non-zero components as

$$
\begin{equation*}
\widehat{\boldsymbol{\beta}}_{n}=\underset{\boldsymbol{\beta} \in \mathbb{R}^{p}}{\operatorname{argmin}} \frac{1}{n} \sum_{i=1}^{n} \phi\left(y_{n, i}, \mathbf{x}_{n, i}^{\mathrm{T}} \boldsymbol{\beta}\right)+I_{\lambda_{n}}(\boldsymbol{\beta}), \tag{1}
\end{equation*}
$$

where $I_{\lambda_{n}}(\boldsymbol{\beta})$ is a penalty function, chosen by the user, depending on a tuning parameter $\lambda_{n}$ which measures the estimated logistic regression model complexity,

$$
\begin{align*}
\phi(y, t) & =\rho(\operatorname{DEv}(y, t))+G(F(t))+G(1-F(t)) \\
& =y \rho(-\log [F(t)])+(1-y) \rho(-\log [1-F(t)])+G(F(t))+G(1-F(t)), \tag{2}
\end{align*}
$$

and $G(t)=\int_{0}^{t} \psi(-\log u) d u$ is the correction factor needed to guarantee Fisher-consistency. When the model contains an intercept, it is not usually penalized. For that reason and for the sake of simplicity, when deriving the asymptotic properties of the estimators, we will assume that the model has no intercept. If the penalty function is properly chosen, the penalized $M$-estimator defined in (1) will be well-defined even when $p>n$ and will lead to sparse models.
As mentioned in Bianco et al. (2021), the estimates defined through (11) defines a wide family that includes, beyond the classical penalized estimator, the penalized least squares estimator defined in Chi and Scott (2014), since it corresponds to the bounded function $\rho(t)=1-\exp (-t)$ and the Elastic Net penalty $I_{\lambda}(\boldsymbol{\beta})=\lambda\left(\theta\|\boldsymbol{\beta}\|_{1}+[(1-\theta) / 2]\|\boldsymbol{\beta}\|_{2}^{2}\right)$. It also includes a penalized version of the minimum divergence estimators defined in Basu et al. (2017) taking $\rho(t)=\rho_{\text {Div }}(t)=(1+1 / c)\{1-\exp (-c t)\}$ as loss function in (22). When $I_{\lambda}(\boldsymbol{\beta}) \equiv 0$, Croux and Haesbroeck (2003) suggested a loss function which ensures the existence of the estimators under the same conditions than those required to the maximum likelihood estimators.

As it is well known, LASSO penalty tends to over-penalize large coefficients, resulting in a larger and biased model. In contrast, the choice of an appropriate non-convex penalty function can overcome this drawback. Among other non-convex penalties, we can mention the Bridge penalty introduced in Frank and Friedman (1993) and defined as $I_{\lambda}(\boldsymbol{\beta})=\lambda\|\boldsymbol{\beta}\|_{q}^{q}$ which is non-convex for $0<q<1$, the smoothly clipped absolute deviation (SCAD) penalty defined in Fan and Li (2001) and the minimax concave penalty (MCP) proposed by Zhang (2010). Both SCAD and MCP penalties can be written as $I_{\lambda}(\boldsymbol{\beta})=\sum_{j=1}^{p} J_{\lambda}\left(\left|\beta_{j}\right|\right)$, where $J_{\lambda_{n}}(\cdot)$ is a non negative, twice differentiable function in $(0, \infty)$. More precisely, for any positive real number $b$, the function $J_{\lambda}(b)$ equals $\operatorname{SCAD}_{\lambda, a}(b)$, in the first case and $\mathrm{MCP}_{\lambda, a}(b)$ in the latter, where

$$
\begin{align*}
\operatorname{SCAD}_{\lambda, a}(b) & =\lambda b \mathbf{1}_{\{b \leq \lambda\}}+\frac{1}{a-1}\left(a \lambda b-\frac{b^{2}+\lambda^{2}}{2}\right) \mathbf{1}_{\{\lambda<b \leq a \lambda\}}+\frac{\lambda^{2}\left(a^{2}-1\right)}{2(a-1)} \mathbf{1}_{\{b>a \lambda\}}  \tag{3}\\
\operatorname{MCP}_{\lambda, a}(b) & =\left(\lambda b-\frac{b^{2}}{2 a}\right) \mathbf{1}_{\{b \leq a \lambda\}}+\frac{a \lambda^{2}}{2} \mathbf{1}_{\{b>a \lambda\}} \tag{4}
\end{align*}
$$

with $\mathbf{1}_{A}$ the indicator of the set $A$. For both penalties, the positive constant $a$, which is larger than 2 for SCAD, is selected by the user.

Since the loss functions and penalties in this paper are non-convex, we will also consider the following restricted estimator:

$$
\begin{equation*}
\widehat{\boldsymbol{\beta}}_{n, R}=\underset{\|\boldsymbol{\beta}\|_{1} \leq R}{\operatorname{argmin}} \frac{1}{n} \sum_{i=1}^{n} \phi\left(y_{i}, \mathbf{x}_{i}^{\mathrm{T}} \boldsymbol{\beta}\right)+I_{\lambda}(\boldsymbol{\beta}), \tag{5}
\end{equation*}
$$

where $R>0$ is a fixed constant and $\phi$ is the function given in (2). Loh (2017) and Elsener and van de Geer (2018)) used this type of restrictions when the minimization problem involves a non-convex function. As it will be shown, consistency properties are easier to obtain for this restricted estimators. However, in this paper we also give consistency results for the unrestricted estimator defined in (1).

### 2.1 Assumptions

In order to derive the asymptotic results in this paper, the following assumptions on the function $\rho$ used in (2), will be needed.
$\mathbf{R 1} \rho: \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}$ is a bounded, continuously differentiable function with bounded derivative $\psi$ and $\rho(0)=0$.

R2 $\psi(t) \geq 0$ and there exists some $c \geq \log 2$ such that $\psi(t)>0$ for all $0<t<c$.
$\mathbf{R 3} \rho$ is is bounded, twice continuously differentiable with bounded derivatives, i.e., $\psi$ and $\psi^{\prime}=\rho^{\prime \prime}$ are bounded. Moreover, $\rho(0)=0$.

R4 $\psi(t) \geq 0$ and there exist values $c \geq \log 2$ and $\tau>0$ such that $\psi(t)>\tau$ for every $0<t<c$.
R5 $\rho$ is bounded, three times continuously differentiable, with bounded derivatives $\psi, \psi^{\prime}$ and $\psi^{\prime \prime}$ and $\rho(0)=0$.

Remark 2.1. Assumption R5 entails that the function $\phi(y, t)$ defined in (2) is three times differentiable with respect to $t$ and that the related derivatives are bounded for $y \in\{0,1\}$. On the other hand, if $\psi(0) \neq 0$ and assumptions R1 and R2 hold for some constant $c>\log (2)$, then condition R4 holds. This happens, for example, with the loss function introduced by Croux and Haesbroeck (2003).

For the sake of simplicity and to avoid burden notation, we will omit the subscript $n$ unless necessary. For instance, we will write $\boldsymbol{\beta}_{0}$ instead of $\boldsymbol{\beta}_{0, n}$.

We assume, without loss of generality, that only the first $k$ covariates are relevant for prediction purposes, i.e., $\boldsymbol{\beta}_{0}=\left(\boldsymbol{\beta}_{0, \mathrm{~A}}^{\mathrm{T}}, \mathbf{0}_{p-k}^{\mathrm{T}}\right)^{\mathrm{T}}$ where $\boldsymbol{\beta}_{0, \mathrm{~A}} \in \mathbb{R}^{k}$ corresponds to the active components, that is, it has all its coordinates different from zero. It is worth mentioning that the number $k=k_{n}$ of non-zero components may depend on $n$, eventually growing with the sample size. For that reason, in order to obtain results regarding the asymptotic distribution of our estimators, conditions on $m_{0, n}$ defined as

$$
\begin{equation*}
m_{0, n}=\min \left\{\left|\beta_{0, j}\right|: \beta_{0, j} \neq 0\right\} . \tag{6}
\end{equation*}
$$

will be required, Note that $m_{0, n}$ involves only the coefficients in $\boldsymbol{\beta}_{0, \mathrm{~A}}$. As mentioned in Bühlmann and van de Geer (2011), variable selection properties depend on the fact that the minimum signal $m_{0, n}$ does not tend to zero too fast.

We will also consider below some hypothesis regarding the distribution of the covariates. To be consistent with the notation used for $\boldsymbol{\beta}_{0}$, we will partition a vector of covariates $\mathbf{x}$ as $\mathbf{x}=\left(\mathbf{x}_{A}^{\mathrm{T}}, \mathbf{x}_{\mathrm{NA}}^{\mathrm{T}}\right)^{\mathrm{T}}$ where $\mathbf{x}_{\mathrm{A}} \in \mathbb{R}^{k}$ and $\mathbf{x}_{\mathrm{NA}} \in \mathbb{R}^{p-k}$. Besides, as done for the covariates, we will also write the estimator of $\boldsymbol{\beta}_{0}$ as $\widehat{\boldsymbol{\beta}}_{n}=\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}^{\mathrm{T}}, \widehat{\boldsymbol{\beta}}_{n, \mathrm{NA}}^{\mathrm{T}}\right)^{\mathrm{T}}$ where $\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}} \in \mathbb{R}^{k}$ correspond to the active components of $\boldsymbol{\beta}_{0}$ and $\widehat{\boldsymbol{\beta}}_{n, \mathrm{NA}} \in \mathbb{R}^{p-k}$ to the null ones.

Given a symmetric and positive semi-definite matrix $\mathbf{C} \in \mathbb{R}^{p \times p}$, the smallest and largest eigenvalues of $\mathbf{C}$ will be denoted as $\iota_{1}(\mathbf{C})$ and $\iota_{p}(\mathbf{C})$, respectively. From now on, we denote as $\Psi(y, t)=\partial \phi(y, t) / \partial t$ and $\chi(y, t)=\partial \Psi(y, t) / \partial t$. Note that $\Psi(y, t)=-[y-F(t)] \nu(t)$, while $\chi(y, t)=F(t)(1-F(t)) \nu(t)-$ $(y-F(t)) \nu^{\prime}(t)$, with $\nu(t)=\psi(-\log F(t))[1-F(t)]+\psi(-\log [1-F(t)]) F(t)$. The function $\chi(y, t)$ always exists for the minimum divergence estimators, while for other choices of the loss function $\rho$, it is well defined when $\rho$ is twice continuously differentiable. We also have that $\chi(0, s)=\chi(1,-s)$. To lighten the notation in the next assumptions, let $\left(y_{n}, \mathbf{x}_{n}\right)$ be such that $\left(y_{n}, \mathbf{x}_{n}\right) \sim\left(y_{n, 1}, \mathbf{x}_{n, 1}\right)$ and denote

$$
\begin{equation*}
\mathbf{H}=\mathbf{H}_{n}=\mathbb{E}\left(\mathbf{x}_{n} \mathbf{x}_{n}^{\mathrm{T}}\right) . \tag{7}
\end{equation*}
$$

Z1 Let $x_{n, i j}$ be the $j$-th coordinate of the random vector $\mathbf{x}_{n, i}$. Then,

$$
\mathbb{E}\left(\max _{1 \leq j \leq p} \frac{1}{n} \sum_{i=1}^{n} x_{n, i j}^{2}\right)=O(1) .
$$

Z2 There exists a constant $K_{1}>0$ not depending on $n$ such that $\iota_{p}(\mathbf{H}) \leq K_{1}$.
Z3 There exists a constant $\tau_{1}>0$ not depending on $n$ such that $\iota_{1}(\mathbf{H}) \geq \tau_{1}$.
Z4 There exists a constant $K_{2}>0$ not depending on $n$ such that $\boldsymbol{\beta}_{0}^{\mathrm{T}} \mathbf{H} \boldsymbol{\beta}_{0} \leq K_{2}^{2}$.
Z5 $\mathbf{x}_{n}$ has a centered elliptical distribution with characteristic function

$$
\phi_{\mathbf{x}_{n}}(\mathbf{t})=\xi\left(\mathbf{t}^{\mathrm{T}} \boldsymbol{\Gamma}_{p} \mathbf{t}\right)
$$

for some semi-definite symmetric matrix $\boldsymbol{\Gamma}_{p} \in \mathbb{R}^{p \times p}$ and some function $\xi: \mathbb{R} \rightarrow \mathbb{R}$ that does not depend on $n$. From now on, to avoid burden notation, we will simply denote $\boldsymbol{\Gamma}$ the scatter matrix instead of $\boldsymbol{\Gamma}_{p}$ whose dimension increases with the sample size.

Z6 There exists a constant $K_{3}>0$ not depending on $n$ such that $\mathbb{E}\left\|\mathbf{x}_{n, \mathrm{~A}}\right\|_{2}^{6} \leq K_{3}$.
Z7 There exists a constant $\tau_{2}>0$ not depending on $n$ such that $\iota_{1}\left(\mathbf{B}_{\mathrm{A}}\right) \geq \tau_{2}$, where

$$
\mathbf{B}_{\mathrm{A}}=\mathbf{B}_{n, \mathrm{~A}}=\mathbb{E}\left[\Psi^{2}\left(y_{n}, \mathbf{x}_{n, \mathrm{~A}}^{\mathrm{T}} \boldsymbol{\beta}_{0, \mathrm{~A}}\right) \mathbf{x}_{n, \mathrm{~A}} \mathbf{x}_{n, \mathrm{~A}}^{\mathrm{T}}\right] .
$$

Remark 2.2. Assumption Z1 is needed to obtain rates of convergence with order $(p \log p / n)^{1 / 2}$ without requiring additional bounding conditions on the eigenvalues of $\mathbf{H}$. This assumption holds, for example, if $\mathbf{x}_{n} \sim N\left(\mathbf{0}_{p}, \mathbf{I}_{p}\right)$ and $a_{n}=\log p / n \rightarrow 0$. Indeed, let $V_{j}=\sum_{i=1}^{n} x_{n, i j}^{2}, V_{1}, \ldots, V_{p}$ are independent $V_{j} \sim \chi_{n}^{2}$. Then, inequality (7) in Dasarathy (2011) allows to obtain the bound

$$
\mathbb{E}\left(\max _{1 \leq j \leq p} \frac{1}{n} \sum_{i=1}^{n} x_{n, i j}^{2}\right)=\frac{1}{n} \mathbb{E}\left(\max _{1 \leq j \leq p} V_{n}\right) \leq \frac{4 a_{n}}{1-\exp \left(-2 a_{n}\right)} .
$$

Using the fact that $1-x \geq \exp (-2 x)$ for $0<x \leq 1 / 2$, we get that Z1 holds if $a_{n}=\log p / n \rightarrow 0$.
Assumptions $\mathbf{Z 3}, \mathbf{Z 4}$ and $\mathbf{Z 5}$ will be used to derive consistency results for the unrestricted estimator defined in (1). It is worth mentioning that, under Z3, the matrix $\boldsymbol{\Gamma}$ in $\mathbf{Z 5}$ is nonsingular.

Note that $\mathbf{Z 3}$ and $\mathbf{Z 4}$ imply that $\tau_{1}\left\|\boldsymbol{\beta}_{0}\right\|^{2} \leq \operatorname{VAR}\left(\mathbf{x}_{n}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right) \leq K_{2}^{2}$ which together with the fact that $\left\|\boldsymbol{\beta}_{0}\right\|^{2}=\left\|\boldsymbol{\beta}_{0, \mathrm{~A}}\right\|^{2}$, leads to $\sum_{j=1}^{k} \beta_{0, j}^{2} \leq K_{2}^{2} / \tau_{1}$ for all $n$ (even if $k$ grows with the sample size). In particular, $\max \left\{\left|\beta_{0, j}\right|: \beta_{0, j} \neq 0\right\}$ is bounded and $m_{0, n}=O(1 / \sqrt{k})$, with $m_{0, n}$ defined in (6). Then, if $k \rightarrow \infty$, as the sample size increases, and assumptions Z3 and Z4 hold, we have that $m_{0, n} \rightarrow 0$.

Assumption $\overline{\mathbf{Z 2}}$ is required to obtain rates of convergence with order $\sqrt{n / p}$ (see Theorem 3.2b)). Finally, Z6 and $\mathbf{Z 7}$ will be used to derive the asymptotic normality of the estimators when using the SCAD or MCP penalties.

Remark 2.3. It is worth mentioning that assumption $\mathbf{Z 5}$ holds if $\mathbf{x}_{n}$ is a scale mixture of normal distributions of the form $\mathbf{x}_{n} \sim S_{n} \mathbf{z}_{n}$ where $S_{n}$ and $\mathbf{z}_{n}$ are independent, $\mathbb{P}\left(S_{n}>0\right)=1, \mathbf{z}_{n} \sim N\left(\mathbf{0}_{p}, \boldsymbol{\Gamma}_{p}\right)$ and, in addition, $S_{n}$ has a distribution that does not depend on $n$, i.e., for all $n, S_{n} \sim S$, for some positive random variable $S$. Among others, assumption Z5 includes the contaminated normal and the multivariate Student's $T_{m}$ with degrees of freedom $m$ not depending on $n$.

In the sequel, for clarity, we strength the dependence of the dimension $p$ on $n$. Analogous arguments to those considered in Remark 2.1 in Boente et al. (2014) allow to show that if assumption Z5 holds and $\boldsymbol{\Gamma}_{p_{n}}>0$ which arises if $\mathbf{Z 3}$ also holds, then $\mathbf{x}_{n}$ is a scale mixture of normals as described above. Effectively, let $\mathbf{w}_{p_{n}}=\boldsymbol{\Gamma}_{p_{n}}^{-1 / 2} \mathbf{x}_{n}$. It is enough to show that $\mathbf{w}_{p_{n}} \sim S \mathbf{z}_{p_{n}}$ for some positive random variable $S$ whose distribution does not depend on $n$ and some $p_{n}$-dimensional random vector $\mathbf{z}_{p_{n}}$ which is independent of $S$ and such that $\mathbf{z}_{p_{n}} \sim N\left(\mathbf{0}_{p_{n}}, \mathbf{I}_{p_{n}}\right)$
Using that the random vector $\mathbf{w}_{p_{n}}=\left(w_{n, 1}, \ldots, w_{n, p_{n}}\right)^{\mathrm{T}}=\boldsymbol{\Gamma}_{p_{n}}^{-1 / 2} \mathbf{x}_{n}$, we get that $\mathbf{w}_{p_{n}}$ has a spherical distribution in $\mathbb{R}^{p_{n}}$ with characteristic function given by $\phi_{\mathbf{w}_{p_{n}}}(\mathbf{t})=\xi\left(\|\mathbf{t}\|^{2}\right), \mathbf{t} \in \mathbb{R}^{p_{n}}$. As it is well known, the function $\xi$ is the characteristic function of $w_{n, 1}$. The fact that $\mathbf{w}_{p_{n}}$ has a spherical distribution entails that $\mathbf{w}_{p_{n}}=T_{p_{n}} \mathbf{u}_{p_{n}}$, where $\mathbf{u}_{p_{n}}=\mathbf{w}_{p_{n}} /\left\|\mathbf{w}_{p_{n}}\right\|$ has a uniform distribution on the $p_{n}$-dimensional unit sphere, and $T_{p_{n}}=\left\|\mathbf{w}_{p_{n}}\right\|$ is a non-negative random variable independent from $\mathbf{u}_{p_{n}}$. The distribution of $\mathbf{u}_{p_{n}}$ may be represented as $\mathbf{u}_{p_{n}} \sim \mathbf{z}_{p_{n}} /\left\|\mathbf{z}_{p_{n}}\right\|$ where $\mathbf{z}_{p_{n}} \sim N\left(\mathbf{0}_{p_{n}}, \mathbf{I}_{p_{n}}\right)$ and is independent of $T_{n}$. Hence, we have that $\mathbf{w}_{p_{n}} \sim D_{n} S_{n} \mathbf{z}_{p_{n}}$, where $D_{n}=\sqrt{p_{n}} /\left\|\mathbf{z}_{p_{n}}\right\|, S_{n}=T_{n} / \sqrt{p_{n}}$ and $\mathbf{z}_{p_{n}}=\left(z_{1}, \ldots, z_{p_{n}}\right)^{\mathrm{T}} \sim$ $N\left(\mathbf{0}_{p_{n}}, \mathbf{I}_{p_{n}}\right)$ independent of $S_{n}$. Hence, $w_{n, 1} \sim D_{n} S_{n} z_{1}$, with $z_{1} \sim N(0,1)$ independent of $S_{n}$. The weak law of large numbers and the fact that $p_{n} \rightarrow \infty$ as $n \rightarrow \infty$, entails that $D_{n} \xrightarrow{p} 1$. Since the distributions of $w_{n, 1}$ and $z_{1}$ do not depend on $n, S_{n}$ must converge in distribution to a random variable
$S$, with $S$ being independent of $z_{1}$. Thus, $w_{n, 1} \sim S z_{1}$ and the fact that $\mathbf{w}_{p_{n}}$ is spherically distributed allows to conclude that $\mathbf{w}_{p_{n}} \sim S \mathbf{z}_{p_{n}}$ which is a scale mixture of normals where the distribution of $S$ does not depend on $n$, which concludes the proof.

As mentioned in Kingman (1972), the spherical symmetry of $\mathbf{w}_{p_{n}}$ entails that $\xi$ is a radial characteristic function of dimension $p_{n}$, which is only possible if $\xi(t)=\int_{0}^{\infty} \exp \left(-u t^{2}\right) d G(u)$ for some distribution function $G$, which also leads to the desired result.

Let $\boldsymbol{\beta}_{0}=\left(\beta_{0,1}, \ldots, \beta_{0, p}\right)^{\mathrm{T}}$. To obtain the asymptotic distribution of the estimators of $\boldsymbol{\beta}_{0, \mathrm{~A}}$ and the oracle property of the penalized estimators, we consider the following assumptions regarding the growth of $n$, $k, \lambda_{n}$ and the coefficients in $\boldsymbol{\beta}_{0, \mathrm{~A}}$.
$\mathbf{N} 1 m_{0, n} \sqrt{n / k} \rightarrow \infty$.
N2 $m_{0, n} / \lambda_{n} \rightarrow \infty$.
N3 $k / n=O\left(\lambda_{n}^{2}\right)$.
Remark 2.4. It is worth mentioning that, if $k$ and $\boldsymbol{\beta}_{0, \mathrm{~A}}$ are fixed, $\mathbf{N} 1$ holds, whereas $\mathbf{N} 2$ is equivalent to $\lambda_{n} \rightarrow 0$. On the other hand, if there exists $m_{0}>0$ (independent of $n$ ) such that $m_{0, n}>m_{0}$, then $k / n \rightarrow 0$ and $\lambda_{n} \rightarrow 0$ imply N1 and N2, respectively. If additionally $m_{0, n}$ has a finite upper bound these conditions are equivalent. Finally, if $m_{0, n}=O(1 / \sqrt{k})$, as it is the case when Z3 and Z4 hold, then N1 and N2 imply $k^{2} / n \rightarrow 0$ and $k \lambda_{n}^{2} \rightarrow 0$. Note that the two latter conditions are the same when $\lambda_{n}=O(1 / \sqrt{n})$. For other convergence rates of the penalty parameter, N1 and N2 give a relationship between the penalty parameter and the growth rate of the number of non-zero coordinates.

## 3 Consistency and rates of convergence

Recall that $\left(y_{n}, \mathbf{x}_{n}\right) \sim\left(y_{n, 1}, \mathbf{x}_{n, 1}\right)$. From now on, $\mathbb{L}(\boldsymbol{\beta})$ and $L_{n}(\boldsymbol{\beta})$ stand for

$$
\begin{equation*}
\mathbb{L}(\boldsymbol{\beta})=\mathbb{E} \phi\left(y_{n}, \mathbf{x}_{n}^{\mathrm{T}} \boldsymbol{\beta}\right) \quad \text { and } \quad L_{n}(\boldsymbol{\beta})=\frac{1}{n} \sum_{i=1}^{n} \phi\left(y_{n, i}, \mathbf{x}_{n, i}^{\mathrm{T}} \boldsymbol{\beta}\right) . \tag{8}
\end{equation*}
$$

Note that $L_{n}(\boldsymbol{\beta})$ is the empirical counterpart of $\mathbb{L}(\boldsymbol{\beta})$. It is worth mentioning that, since the distribution of $\mathbf{x}_{n}$ and the dimension of $\mathbf{x}_{n}$ and $\boldsymbol{\beta}_{0}$ depend on $n$ through $p=p(n)$, the function $\mathbb{L}(\cdot)$ also depends on $n$. However, to avoid burden notation, we omit the dependence on $n$ and write $\mathbb{L}(\boldsymbol{\beta})$ instead of $\mathbb{L}_{n}(\boldsymbol{\beta})$, unless clarification is needed. In order to give a measure of closeness between the predicted probabilities, we define

$$
\begin{equation*}
d_{n}^{2}\left(\boldsymbol{\beta}, \boldsymbol{\beta}_{0}\right)=\mathbb{E}\left[F\left(\mathbf{x}_{n}^{\mathrm{T}} \boldsymbol{\beta}\right)-F\left(\mathbf{x}_{n}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right]^{2}, \tag{9}
\end{equation*}
$$

where the index $n$ is used to make explicit the dependence on the sample size. Note that $d_{n}^{2}\left(\widehat{\boldsymbol{\beta}}_{n}, \boldsymbol{\beta}_{0}\right)$ can be written as $d_{n}^{2}\left(\widehat{\boldsymbol{\beta}}_{n}, \boldsymbol{\beta}_{0}\right)=\mathbb{E}\left\{\left[F\left(\mathbf{x}_{n}^{\mathrm{T}} \widehat{\boldsymbol{\beta}}_{n}\right)-F\left(\mathbf{x}_{n}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right]^{2} \mid\left(y_{n, 1}, \mathbf{x}_{n, 1}\right), \ldots\left(y_{n, n}, \mathbf{x}_{n, n}\right)\right\}$.

The following result shows that the estimators defined in (11) and (5) lead to consistent predictions. The weak consistency of the unrestricted estimator defined through (1), in the sense that $\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2} \xrightarrow{p} 0$, is also derived under additional assumptions.

Theorem 3.1. Suppose that $\boldsymbol{R 1}$ and $\boldsymbol{R} 4$ hold. Let $\widehat{\boldsymbol{\beta}}_{n}$ and $\widehat{\boldsymbol{\beta}}_{n, R}$ be the estimators defined through (1) and (5), respectively. Then,
(a) $d_{n}^{2}\left(\widehat{\boldsymbol{\beta}}_{n}, \boldsymbol{\beta}_{0}\right)=O_{\mathbb{P}}\left(\sqrt{p / n}+I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right)\right)$.
(b) If, in addition, $\iota_{1}(\mathbf{H})>0$, where $\mathbf{H}$ is defined in (7), $\left\|\boldsymbol{\beta}_{0}\right\|_{1} \leq R$ and there exists a constant $M>0$ such that $P\left(\|\mathbf{x}\|_{\infty} \leq M\right)=1$, for all $n \geq 1$, then

$$
\left\|\widehat{\boldsymbol{\beta}}_{n, R}-\boldsymbol{\beta}_{0}\right\|_{2}^{2}=O_{\mathbb{P}}\left(\left(\sqrt{\frac{p}{n}}+I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right)\right) \frac{1}{\iota_{1}(\mathbf{H})}\right) .
$$

Therefore, if ZЗ holds, $\left\|\widehat{\boldsymbol{\beta}}_{n, R}-\boldsymbol{\beta}_{0}\right\|_{2}^{2}=O_{\mathbb{P}}\left(\sqrt{p / n}+I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right)\right)$.
(c) When Z3, Z4 and Z5 also hold, $p / n \rightarrow 0$ and $I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right) \rightarrow 0$, then $\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2} \xrightarrow{p} 0$.

Remark 3.1. Note that Theorem 3.1(a) implies that $F\left(\mathbf{x}^{\mathrm{T}} \widehat{\boldsymbol{\beta}}_{n}\right)$ is consistent in the $L_{2}-$ norm if $p / n \rightarrow 0$ and $I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right) \rightarrow 0$. However, in contrast to the linear regression setting, this convergence does not necessarily imply the consistency of $\widehat{\boldsymbol{\beta}}_{n}$, since the link function $F$ is bounded. For that reason, some additional assumptions such as Z3 are needed. Note that, in fact, this last assumption is also required when considering the linear regression model. The convergence stated in (a) also holds for the restricted estimator defined through (5). The result given in Theorem 3.1(b) provides a preliminary rate of convergence for the restricted estimator that will be improved in Theorem 3.2, under suitable conditions. Note that Theorem 3.1(c) shows that the consistency of $F\left(\mathbf{x}^{\mathrm{T}} \widehat{\boldsymbol{\beta}}_{n}\right)$ leads to the consistency of the unrestricted estimator defined in (1) when $\mathbf{x}$ is a scale mixture of normals.

From now on, $\mathcal{B}_{s}(\boldsymbol{\theta}, \delta)$ stands for the closed $s$-dimensional ball, with respect to the usual $\|\cdot\|_{2}$, centred at $\boldsymbol{\theta}$ with radius $\delta$, that is, $\mathcal{B}_{s}(\boldsymbol{\theta}, \delta)=\left\{\mathbf{z} \in \mathbb{R}^{s}:\|\mathbf{z}-\boldsymbol{\theta}\|_{2}<\delta\right\}$. Moreover, when $\delta=1$, we will write $\mathcal{B}_{s}(\boldsymbol{\theta})$ instead of $\mathcal{B}_{s}(\boldsymbol{\theta}, 1)$.

In order to obtain rates of convergence for Lipschitz penalites such as LASSO or, under weaker conditions for $\lambda_{n}$, for bounded differentiable ones such as SCAD or MCP, we will need the following additional assumptions.

P1 There exists $\epsilon>0$ and a constant $K$ which does not depend on $\lambda$ nor on $n$, such that, for any $\boldsymbol{\beta}_{1}, \boldsymbol{\beta}_{2} \in \mathcal{B}_{p}\left(\boldsymbol{\beta}_{0}, \epsilon\right)$, we have $\left|I_{\lambda}\left(\boldsymbol{\beta}_{1}\right)-I_{\lambda}\left(\boldsymbol{\beta}_{2}\right)\right| \leq \lambda K\left\|\boldsymbol{\beta}_{1}-\boldsymbol{\beta}_{2}\right\|_{1}$.

P2 TThere exist a positive constant value $\widetilde{\delta}$ and non-negative sequences $\left\{a_{n}\right\}_{n \in \mathbb{N}}$ and $\left\{b_{n}\right\}_{n \in \mathbb{N}}$, such that, for any $\boldsymbol{\beta}$ with $\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2} \leq \widetilde{\delta}$, the penalty $I_{\lambda_{n}}$ satisfies

$$
\begin{equation*}
I_{\lambda_{n}}(\boldsymbol{\beta})-I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right) \geq-a_{n} \sqrt{k}\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}-b_{n}\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2} . \tag{10}
\end{equation*}
$$

Remark 3.2. As mentioned in Remark 4 in Bianco et al. (2021), Ridge, Elastic Net, SCAD and MCP penalties satisfy $\mathbf{P 1}$, while LASSO, SCAD or MCP penalizations satisfy $\mathbf{P 2}$, Indeed, for the LASSO penalty this assumption holds taking $a_{n}=\lambda_{n}$ and $b_{n}=0$. SCAD or MCP penalties can be written as $I_{\lambda_{n}}(\boldsymbol{\beta})=\sum_{j=1}^{p} J_{\lambda_{n}}\left(\left|\beta_{j}\right|\right)$ where $J_{\lambda_{n}}(\cdot)$ is a non negative, twice differentiable function in $(0, \infty)$, $J_{\lambda_{n}}^{\prime}\left(\left|\beta_{0, \ell}\right|\right) \geq 0$ and $J_{\lambda_{n}}(0)=0$. Given $\delta_{0}>0$, define

$$
\begin{aligned}
a_{n} & =\max \left\{J_{\lambda_{n}}^{\prime}\left(\left|\beta_{0, \ell}\right|\right): 1 \leq \ell \leq p \mathrm{y} \beta_{0, \ell} \neq 0\right\}=\max \left\{J_{\lambda_{n}}^{\prime}\left(\left|\beta_{0, \ell}\right|\right): 1 \leq \ell \leq k\right\} \\
b_{n} & =b_{n}\left(\delta_{0}\right)=\sup \left\{\left|J_{\lambda_{n}}^{\prime \prime}\left(\left|\beta_{0, \ell}\right|+\tau \delta_{0}\right)\right|: \tau \in[-1,1], 1 \leq \ell \leq p \text { y } \beta_{0, \ell} \neq 0\right\} \\
& =\sup \left\{\left|J_{\lambda_{n}}^{\prime \prime}\left(\left|\beta_{0, \ell}\right|+\tau \delta_{0}\right)\right|: \tau \in[-1,1], 1 \leq \ell \leq k\right\} .
\end{aligned}
$$

Using same arguments as those considered in the proof of Theorem 2(b) in Bianco et al. (2021), it may be shown that (10) holds.

When considering the SCAD or MCP penalizations, $J_{\lambda_{n}}^{\prime}(t)$ and $J_{\lambda_{n}}^{\prime \prime}(t)$ are equal to zero if $t>a \lambda_{n}$ where $a$ is the second tuning parameter of this penalty functions (which is assumed to be fixed). Hence, if $m_{0, n}>a \lambda_{n}$ for $n \geq n_{0}$ where $m_{0, n}$ is defined in (6), we have that $a_{n}=0$ and $b_{n}=0$ for a sufficiently large $n$. In particular, this holds if there exists $m_{0}>0$ such that it does not depend on $n, m_{0, n}>m_{0}$ and $\lambda_{n} \rightarrow 0$ or if N2 holds. Moreover, observe that, since $m_{0, n}=O(1 / \sqrt{k})$, if $\mathbf{Z 3}$ and $\mathbf{Z 4}$ hold, there exists a value $M$ such that if $\sqrt{k} m_{0, n} \leq M$ for all $n$, so the condition $m_{0, n}>a \lambda_{n}$ for $n \geq n_{0}$ implies that $\lambda_{n}=O(1 / \sqrt{k})$.

Theorem 3.2 gives convergence rates for our estimators. Its proof is based on bounds for the increments of empirical processes given in Bühlmann and van de Geer (2011) and Theorem 3.2.5 from van der Vaart and Wellner (2012), which uses the so called "peeling device".

Theorem 3.2. Assume that $\boldsymbol{R 1}$ holds and that there exist constants $\eta>0$ and $\tau>0$ such that if $\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2} \leq \eta$, then $\mathbb{L}(\boldsymbol{\beta})-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right) \geq \tau\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2}$ for all $n \geq 1$. Let $\widehat{\boldsymbol{\beta}}_{n}$ be the estimator defined in (1) or (5) and assume that $\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2} \xrightarrow{p} 0$.
(a) If 피 and Z1 hold and $\lambda_{n}=O(\sqrt{\log p / n})$, then

$$
\begin{equation*}
\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}=O_{\mathbb{P}}\left(\sqrt{\frac{p \log p}{n}}\right) . \tag{11}
\end{equation*}
$$

(b) Under P1 and Z2, if $\lambda_{n}=O(\sqrt{1 / n})$, then

$$
\begin{equation*}
\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}=O_{\mathbb{P}}\left(\sqrt{\frac{p}{n}}\right) . \tag{12}
\end{equation*}
$$

(c) Assume that $\mathbf{P 2}$ is satisfied and $b_{n} \rightarrow 0$, then
(i) if Z1 holds and $a_{n} \sqrt{k}=O(\sqrt{p \log p / n})$, (11) is verified.
(ii) if Z2 holds and $a_{n} \sqrt{k}=O(\sqrt{p / n})$, (12) is verified.

An important requirement in Theorem 3.2 is that there exist positive real numbers $\eta$ and $\tau$ such that $\mathbb{L}(\boldsymbol{\beta})-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right) \geq \tau\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2}$ whenever $\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2} \leq \eta$. Lemma 3.3 gives conditions ensuring that this assumption holds, under some of the assumptions we have stated above.

Lemma 3.3. Assume that Z2 to Z5 hold and that the function $\rho$ satisfies R1 and R4. Then, there exist positive constants $\eta$ and $\tau$ such that $\mathbb{L}(\boldsymbol{\beta})-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right) \geq \tau\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2}$ when $\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2} \leq \eta$.

Remark 3.3. From Remark 3.2, we get that items (a) and (b) from Theorem 3.2 may be applied to the Ridge, LASSO, Elastic Net, SCAD and MCP penalties. However, taking into account that LASSO, SCAD and MCP also verify P2, Theorem 3.2(c) allows to obtain the rates of convergence given in (a) and (b), but with milder assumptions for $\lambda_{n}$. In particular, for the LASSO penalty, to obtain the considered convergence rates, the parameter $\lambda_{n}$ must satisfy $\lambda_{n} \sqrt{n k / p}=O(1)$ instead of $\lambda_{n} \sqrt{n}=O(1)$, while for the SCAD and MCP the required rate for $\lambda_{n}$ is easily derived from Remark 3.2, As mentioned in Remark 5 from Bianco et al. (2021) who studied the situation where $p$ is fixed, the differences between uniformly Lipschitz penalties, that is, penalties satisfying P1 and those verifying P2 play an important role in the variable selection properties of the estimator.

## 4 Variable selection and asymptotic distribution

In this section, we derive the asymptotic distribution of the considered estimators. In particular, we show that for the SCAD and MCP penalties, the robust penalized estimator has the oracle property, that is, that the penalized $M$-estimator of the non-null components of $\boldsymbol{\beta}_{0}, \widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}$ has the same asymptotic distribution as that of the non-penalized estimator obtained assuming that the last components of $\boldsymbol{\beta}_{0}$ are equal to 0 and using this restriction in the logistic regression model. As in other settings, a key step is to derive variable selection properties, that is, to show that the procedure correctly identifies variables related to non-null coefficients. The variable selection property is obtained for penalties satisfying condition (15) below. This inequality trivially holds for the LASSO penalization, while Corollary 4.2 shows that it also holds for the SCAD and MCP penalties. For notation simplicity, given a vector $\mathbf{b}=\left(\mathbf{b}_{1}^{\mathrm{T}}, \mathbf{b}_{2}^{\mathrm{T}}\right)^{\mathrm{T}}$ where $\mathbf{b}_{1} \in \mathbb{R}^{k}$ and $\mathbf{b}_{2} \in \mathbb{R}^{p-k}$, we will denote $I_{\lambda}\left(\mathbf{b}_{1}, \mathbf{b}_{2}\right)=I_{\lambda}(\mathbf{b})$.
Theorem 4.1. Let $\widehat{\boldsymbol{\beta}}_{n}$ be the estimator defined in (11) or (5), where $\phi(y, t)$ is given in (2) and the function $\rho: \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}$ satisfies R3, Let $\left\{\ell_{n}\right\}_{n \in \mathbb{N}}$ be a sequence such that $\ell_{n}\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}=O_{\mathbb{P}}(1)$ and define

$$
\begin{align*}
& c_{n}=\frac{\sqrt{\iota_{p}(\mathbf{B})}}{\sqrt{n}}+\frac{\iota_{p}(\mathbf{H})}{\ell_{n}},  \tag{13}\\
& \mathbf{B}=\mathbb{E}\left\{\Psi^{2}\left(y, \mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right) \mathbf{x} \mathbf{x}^{\mathrm{T}}\right\}=\mathbb{E}\left\{F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\left[1-F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right] \nu^{2}\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right) \mathbf{x} \mathbf{x}^{\mathrm{T}}\right\}, \tag{14}
\end{align*}
$$

where $\nu(t)=\psi(-\log F(t))[1-F(t)]+\psi(-\log [1-F(t)]) F(t)$. Assume that for each $C>0$, there exist constants $K_{C}>0$ and $N_{C} \in \mathbb{N}$ such that for any $n \geq N_{C}$ and all vectors $\mathbf{u}_{1} \in \mathbb{R}^{k}$ and $\mathbf{u}_{2} \in \mathbb{R}^{p-k}$ satisfying $\left\|\mathbf{u}_{1}\right\|_{2}^{2}+\left\|\mathbf{u}_{2}\right\|_{2}^{2} \leq C^{2}$ the following inequality holds

$$
\begin{equation*}
I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}+\frac{\mathbf{u}_{1}}{\ell_{n}}, \frac{\mathbf{u}_{2}}{\ell_{n}}\right)-I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}+\frac{\mathbf{u}_{1}}{\ell_{n}}, \mathbf{o}_{p-k}\right) \geq K_{C} \frac{\lambda_{n}}{\ell_{n}}\left\|\mathbf{u}_{2}\right\|_{2} \tag{15}
\end{equation*}
$$

Then, if $\lambda_{n} c_{n}^{-1} \rightarrow \infty$, we have that $\mathbb{P}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{NA}}=\mathbf{0}_{p-k}\right) \rightarrow 1$.
Remark 4.1. It is worth mentioning that if $\ell_{n}=\sqrt{n / p}$ and there exists a constant $K>0$ not depending on $n$ such that $\left.\max \left\{\iota_{p}(\mathbf{H}), \iota_{p}(\mathbf{B})\right\} \leq K\right)$, then $c_{n}=O(\sqrt{p / n})$, so $\lambda_{n} c_{n}^{-1} \rightarrow \infty$ if $\lambda_{n} \sqrt{n / p} \rightarrow$ $\infty$. Recall that, to obtain estimators with rate of convergence $\sqrt{n / p}$, Theorem 3.2 (b) requires that the penalty parameter has order $\lambda_{n}=O(\sqrt{1 / n})$ which entails that $\lambda_{n} \sqrt{n / p} \rightarrow 0$ when the dimension increases with the sample size. Likewise, when considering LASSO, the required order for the penalty parameter in Theorem [3.2(c) is also incompatible with $\lambda_{n} \sqrt{n / p} \rightarrow \infty$. However, these rates coincide when $p$ is fixed leading to the same rates as in Bianco et al. (2021). On the other hand, if there exists a constant $K^{\star}>0$ such that $\min \left\{\iota_{p}(\mathbf{H}), \iota_{p}(\mathbf{B})\right\} \geq K^{\star}$, both conditions $\lambda_{n} c_{n}^{-1} \rightarrow \infty$ and $\lambda_{n} \sqrt{n / p} \rightarrow \infty$ are equivalent, which implies that, in this case, the required order of the penalty parameter in Theorem 4.1 is analogous to the one stated in Theorem 3 in Bianco et al. (2021).

Corollary 4.2 states that the variable selection property holds for the SCAD and MCP penalties.
Corollary 4.2. Let $\widehat{\boldsymbol{\beta}}_{n}$ be the estimator defined in (11) or (5), where $\phi(y, t)$ is given in (2) and the function $\rho: \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}$ satisfies $\boldsymbol{R 3}$. Let $\left\{\ell_{n}\right\}_{n \in \mathbb{N}}$ be a sequence such that $\ell_{n}\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}=O_{\mathbb{P}}(1)$ and define $c_{n}$ as in (13). Assume that $\lambda_{n} c_{n}^{-1} \rightarrow \infty, \lambda_{n} \ell_{n} \rightarrow \infty$ and that $I_{\lambda}(\boldsymbol{\beta})$ is the SCAD or MCP penalty. Then, $\mathbb{P}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{NA}}=\mathbf{0}_{p-k}\right) \rightarrow 1$.

Remark 4.2. As mentioned in Remark 4.1, when we only assume that $\mathbf{P 1}$ holds, the order of convergence required to $\lambda_{n}$ in Theorem 3.2(a) and (b) in order to derive convergence rates for the robust penalized estimators are incompatible with the condition $\lambda_{n} c_{n}^{-1} \rightarrow \infty$. However, according to Theorem [3.2, when using the SCAD or MCP penalization, convergence rates for $\widehat{\boldsymbol{\beta}}_{n}$ are obtained by just requiring $\lambda_{n} \rightarrow 0$ whenever $m_{0, n}=\min \left\{\left|\beta_{0, j}\right|: \beta_{0, j} \neq 0\right\}>m_{0}$ for every $n$. According to Remark 3.2, under Z3 and Z4, $m_{0, n}=O(1 / \sqrt{k})$, so $\lambda_{n}=O(1 / \sqrt{k})$, which is not contradictory with the order for $\lambda_{n}$ required in Corollary 4.2. In particular, if $\ell_{n}=\sqrt{n / p}$ and there exist constants $K>0$ and $K^{\star}>0$ such that $K^{\star} \leq \min \left\{\iota_{p}(\mathbf{H}), \iota_{p}(\mathbf{B})\right\} \leq \max \left\{\iota_{p}(\mathbf{H}), \iota_{p}(\mathbf{B})\right\} \leq K$, the condition $\lambda_{n} c_{n}^{-1} \rightarrow \infty$ is equivalent to $n /(k p) \rightarrow \infty$ when assumptions Z3 and Z4 hold, while, if N2 holds, the condition $\lambda_{n} c_{n}^{-1} \rightarrow \infty$ implies $m_{0, n} \sqrt{n / p} \rightarrow \infty$.

It is worth mentioning that if $\mathbf{Z 3}$ holds, then the condition $\lambda_{n} \ell_{n} \rightarrow \infty$ required in Corollary 4.2 is a consequence of $\lambda_{n} c_{n}^{-1} \rightarrow \infty$.

From Theorems 3.2 and 4.1, we can obtain the following corollary that allows to improve the convergence rate of the estimators defined in (1) or (5). First, observe that $I_{\lambda}(\cdot): \mathbb{R}^{p} \rightarrow \mathbb{R}$, so in all the previous results the penalizations constitute a sequence of functions, not only by their dependence on $\lambda_{n}$, but also because their domains depend on the sample size. However, to avoid the use of heavy notation, we will not make this distinction explicit, so $I_{\lambda}(\boldsymbol{\beta})$ for $\boldsymbol{\beta} \in \mathbb{R}^{p}$ or $I_{\lambda}(\mathbf{b})$ with $\mathbf{b} \in \mathbb{R}^{k}$ will refer to penalizations with different domains. For the sake of clarity, we will use the subindex $k$ to indicate vectors in $\mathbb{R}^{k}$. To state Corollary 4.3, define

$$
\widehat{\mathbf{b}}_{k}=\underset{\mathbf{b}_{k} \in \mathbb{R}^{k}}{\operatorname{argmin}} \frac{1}{n} \sum_{i=1}^{n} \phi\left(y_{i}, \mathbf{x}_{i, \mathrm{~A}}^{\mathrm{T}} \mathbf{b}_{k}\right)+I_{\lambda}\left(\mathbf{b}_{k}\right),
$$

and consider the following assumption on the penalty function
P3 If $\mathbf{b}_{k} \in \mathbb{R}^{k}$ is such that $\mathbf{b}_{k} \neq \mathbf{0}_{k}$, then $I_{\lambda}\left(\mathbf{b}_{k}\right)=I_{\lambda}\left(\mathbf{b}_{k}, \mathbf{0}_{p-k}\right)$.
Corollary 4.3. Let $\widehat{\boldsymbol{\beta}}_{n}$ be the estimator defined in (11) or in (5). Assume that $\mathbb{P}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{NA}}=\mathbf{0}_{p-k}\right) \rightarrow 1$ when $n \rightarrow \infty$. Assume that $\widehat{\boldsymbol{P} 3}$ holds and that $\left\|\widehat{\mathbf{b}}_{k}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right\|_{2}=O_{\mathbb{P}}(\sqrt{k / n})$, then $\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}=O_{\mathbb{P}}(\sqrt{k / n})$.

Remark 4.3. First, observe that assumption $\mathbf{P 3}$ holds for the LASSO, SCAD and MCP penalizations. More generally, it holds for every penalty function that can be written as $I_{\lambda}(\boldsymbol{\beta})=\sum_{j=1}^{p} J_{\lambda}\left(\left|\beta_{j}\right|\right)$ where $J_{\lambda}(0)=0$.

On the other hand, Theorem 3.2 gives conditions that guarantee $\left\|\widehat{\mathbf{b}}_{k}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right\|_{2}=O_{\mathbb{P}}(\sqrt{k / n})$. In fact, to obtain $\left\|\widehat{\mathbf{b}}_{k}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right\|_{2}=O_{\mathbb{P}}(\sqrt{k / n})$, assumptions Z1 to Z5 can be replaced by analogous versions in which only the first $k$ coordinates of $\mathbf{x}$ and $\boldsymbol{\beta}_{0}$ are considered. Moreover, denoting

$$
\mathbf{H}_{\mathrm{A}}=\mathbf{H}_{n, \mathrm{~A}}=\mathbb{E}\left(\mathbf{x}_{n, \mathrm{~A}} \mathbf{x}_{n, \mathrm{~A}}^{\mathrm{T}}\right),
$$

we get that Z4 is equivalent to $\boldsymbol{\beta}_{0, \mathrm{~A}}^{\mathrm{T}} \mathbf{H}_{\mathrm{A}} \boldsymbol{\beta}_{0, \mathrm{~A}} \leq K_{2}^{2}$, which already gives a condition for the first $k$ components of $\mathbf{x}_{n}$ and $\boldsymbol{\beta}_{0}$.

We now proceed to study the asymptotic distribution of the estimator $\widehat{\boldsymbol{\beta}}_{n}$ defined through (1). Theorem 4.4 states that, for certain penalties which include SCAD and MCP, the robust penalized $M$-estimator has the oracle property.

To emphasize the dependence on the sample size, given a vector $\mathbf{b}_{k} \in \mathbb{R}^{k}$, denote $\mathbf{A}_{\mathrm{A}}^{(k)}\left(\mathbf{b}_{k}\right) \in \mathbb{R}^{k \times k}$ and $\mathbf{B}_{\mathrm{A}}^{(k)}\left(\mathbf{b}_{k}\right) \in \mathbb{R}^{k \times k}$ the matrices

$$
\mathbf{A}_{\mathrm{A}}^{(k)}\left(\mathbf{b}_{k}\right)=\mathbb{E}\left[\chi\left(y_{n}, \mathbf{x}_{n, \mathrm{~A}}^{\mathrm{T}} \mathbf{b}_{k}\right) \mathbf{x}_{n, \mathrm{~A}} \mathbf{x}_{n, \mathrm{~A}}^{\mathrm{T}}\right] \quad \text { and } \quad \mathbf{B}_{\mathrm{A}}^{(k)}\left(\mathbf{b}_{k}\right)=\mathbb{E}\left[\Psi^{2}\left(y_{n}, \mathbf{x}_{n, \mathrm{~A}}^{\mathrm{T}} \mathbf{b}_{k}\right) \mathbf{x}_{n, \mathrm{~A}} \mathbf{x}_{n, \mathrm{~A}}^{\mathrm{T}}\right] .
$$

In addition, we define $\mathbf{A}_{\mathrm{A}}^{(k)}=\mathbf{A}_{\mathrm{A}}^{(k)}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}\right)$ and $\mathbf{B}_{\mathrm{A}}^{(k)}=\mathbf{B}_{\mathrm{A}}^{(k)}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}\right)$. Note that, in this case, given $\mathbf{v}_{k} \in \mathbb{R}^{k}$ with $\left\|\mathbf{v}_{k}\right\|_{2}=1$, the value $t^{2}=\mathbf{v}_{k}^{\mathrm{T}} \mathbf{B}_{\mathrm{A}}^{(k)} \mathbf{v}_{k}$ also depends on $n$. However, to simplify the notation in Theorem 4.4 and Corollary 4.5, we will write $t$ instead of $t_{n}$. Moreover, for $\mathbf{b}_{k}=\left(b_{1}, \ldots, b_{k}\right)^{\mathrm{T}} \in \mathbb{R}^{k}$ with $b_{j} \neq 0,1 \leq j \leq k$, we define $\nabla I_{\lambda}\left(\mathbf{b}_{k}\right)=\partial I_{\lambda}\left(\mathbf{b}_{k}, \mathbf{0}_{p-k}\right) / \partial \mathbf{b}_{k}$.
Theorem 4.4. Let $\mathbf{v}_{k} \in \mathbb{R}^{k}$ be a vector such that $\left\|\mathbf{v}_{k}\right\|_{2}=1$ and denote $t^{2}=\mathbf{v}_{k}^{\mathrm{T}} \mathbf{B}_{\mathrm{A}}^{(k)} \mathbf{v}_{k}$. Assume that $\lim _{n \rightarrow \infty} \mathbb{P}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{NA}}=\mathbf{0}_{p-k}\right)=1$ and that $\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}=O_{\mathbb{P}}(\sqrt{k / n})$. Moreover, assume that N1, R5, Z6 and Z7 hold. Then, if $k^{2} / n \rightarrow 0$ and

$$
\begin{equation*}
\sqrt{n}\left\|\nabla I_{\lambda_{n}}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}\right)\right\|_{2} \xrightarrow{p} 0, \tag{16}
\end{equation*}
$$

we have that $\sqrt{n} t^{-1} \mathbf{v}_{k}^{\mathrm{T}} \mathbf{A}_{\mathrm{A}}^{(k)}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right) \xrightarrow{D} N(0,1)$.
Finally, Corollary 4.5 shows that the conclusion of Theorem4.4 holds when considering SCAD or MCP.
Corollary 4.5. Let $\mathbf{v}_{k} \in \mathbb{R}^{k}$ be a vector such that $\left\|\mathbf{v}_{k}\right\|_{2}=1$ and $t^{2}=\mathbf{v}_{k}^{\mathrm{T}} \mathbf{B}_{\mathrm{A}}^{(k)} \mathbf{v}_{k}$. Assume that $\lim _{n \rightarrow \infty} \mathbb{P}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{NA}}=\mathbf{0}_{p-k}\right)=1$ and that $\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}=O_{\mathbb{P}}(\sqrt{k / n})$. Furthermore, assume that N1, N2, N3, R5, Z6 and Z7 hold. If $k^{2} / n \rightarrow 0$ and $I_{\lambda_{n}}$ is the SCAD or MCP penalization, then $\sqrt{n} t^{-1} \mathbf{v}_{k}^{\mathrm{T}} \mathbf{A}_{\mathrm{A}}^{(k)}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right) \xrightarrow{D} N(0,1)$.

Remark 4.4. It is worth mentioning that the asymptotic normality stated in Theorem 4.4 and Corollary 4.5 still hold if we require as convergence rate the rate derived in Theorem 3.2, that is, $\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}=O_{\mathbb{P}}(\sqrt{p / n})$ and we replace the condition $k^{2} / n \rightarrow 0$ by $p^{2} / n \rightarrow 0$ and assumptions $\mathbf{N} 1$ and N3 by the requirements $m_{0, n} \sqrt{n / p} \rightarrow \infty$ and $p / n=O\left(\lambda_{n}^{2}\right)$, respectively.

## A Appendix

In order to lighten the notation and when there is no confusion, we will omit the sub-index $n$ in $\left(y_{n, i}, \mathbf{x}_{n, i}\right), 1 \leq i \leq n$, as well as in $\left(y_{n}, \mathbf{x}_{n}\right)$ which has the same distribution as $\left(y_{n, 1}, \mathbf{x}_{n, 1}\right)$.

## A. 1 Proofs of the results in Section 3

To prove the consistency of the proposed estimators when $p \rightarrow \infty$, we will make use of Theorem 2.14.1 from van der Vaart and Wellner (2012). It is worth to remind that, since the dimension $p$ diverges to infinity, the usual limit theorems such as the law of large numbers or the central limit theorem are no longer useful. Instead, in this context we will need explicit bounds for the empirical process for a fixed $n$, as the one obtained in Lemma A. 1 for the family of functions $\mathcal{F}=\left\{f(y, \mathbf{x})=\phi\left(y, \mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}\right)\right.$ : $\left.\boldsymbol{\beta} \in \mathbb{R}^{p}\right\}$. Given a function $f: \mathbb{R}^{p+1} \rightarrow \mathbb{R}$, we use the usual empirical process notation, that is, $P_{n} f=(1 / n) \sum_{i=1}^{n} f\left(y_{i}, \mathbf{x}_{i}\right)$ and $P f=\mathbb{E}[f(y, \mathbf{x})]$.

Lemma A.1. Let $\phi$ be defined as in (2) and $\mathcal{F}=\left\{f(y, \mathbf{x})=\phi\left(y, \mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}\right): \boldsymbol{\beta} \in \mathbb{R}^{p}\right\}$. If R1 and R2 hold, then there exists a constant $C_{1}$ that does not depend on n nor $p$ such that

$$
\mathbb{E}\left[\sup _{f \in \mathcal{F}}\left|\left(P_{n}-P\right)(f)\right|\right] \leq C_{1} \sqrt{\frac{p}{n}}
$$

Proof. Since $\rho$ is bounded, there exists a constant $C=\|\phi\|_{\infty}>0$ such that $\left|\phi\left(y, \mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}\right)\right| \leq\|\phi\|_{\infty}$ for $y \in\{0,1\}, \mathbf{x} \in \mathbb{R}^{p}$ and $\boldsymbol{\beta} \in \mathbb{R}^{p}$. Hence, $\|\phi\|_{\infty}$ is an envelope for the class $\mathcal{F}$. Lemma S.2.2 in Bianco et al. (2021) entails that $\mathcal{F}$ is VC-subgraph with index $V(\mathcal{F}) \leq 2 p+4$.
Theorem 2.6.7 from van der Vaart and Wellner (2012) allows to conclude that, for some universal constant $K_{1}$,

$$
\begin{equation*}
N\left(\varepsilon\|\phi\|_{\infty}, \mathcal{F},\|\cdot\|_{2, \mathbb{Q}}\right) \leq K_{1} V(\mathcal{F})(16 e)^{V(\mathcal{F})}\left(\frac{1}{\varepsilon}\right)^{2(V(\mathcal{F})-1)} \leq K_{1}(2 p+4)(16 e)^{2 p+4}\left(\frac{2}{\varepsilon}\right)^{4 p+6} \tag{A.1}
\end{equation*}
$$

Moreover, Theorem 2.14 .1 from van der Vaart and Wellner (2012) implies that for some universal constant $M>0$

$$
\mathbb{E}\left[\sup _{f \in \mathcal{F}}\left|\sqrt{n}\left(P_{n}-P\right)(f)\right|\right] \leq M\|\phi\|_{\infty} \sup _{\mathbb{Q}} \int_{0}^{1} \sqrt{1+\log N\left(\varepsilon\|\phi\|_{\infty}, \mathcal{F},\|\cdot\|_{2, \mathbb{Q}}\right)} d \varepsilon
$$

where the supremum is taken over all discrete probability measures $\mathbb{Q}$. Using (A.1) and that $\log p \leq p$ for $p \geq 1$, we get that

$$
\sqrt{1+\log N\left(\varepsilon\|\phi\|_{\infty}, \mathcal{F},\|\cdot\|_{2, \mathbb{Q}}\right)} \leq \sqrt{1+16 C p+(4 p+6) \log \left(\frac{2}{\varepsilon}\right)}
$$

for some constant $C>0$ independent from $n$ and $p$. Thus, using that $4 p+6 \leq 16 p$ and denoting $C_{2}=4 M\|\phi\|_{\infty} C_{1}$ with $C_{1}=\max (C+\log (2), 1)$, we obtain that

$$
\mathbb{E}\left[\sup _{f \in \mathcal{F}}\left|\sqrt{n}\left(P_{n}-P\right)(f)\right|\right] \leq \sqrt{p} C_{2} \int_{0}^{1} \sqrt{1+\log \left(\frac{1}{\varepsilon}\right)} d \varepsilon
$$

which together with the fact that $\int_{0}^{1} \sqrt{1-\log (\varepsilon)} d \varepsilon<\infty$ concludes the proof.
Lemma A.2. Let $M\left(\pi, \pi_{0}\right)$ be defined as

$$
\begin{equation*}
M\left(\pi, \pi_{0}\right)=\pi_{0} \rho(-\log \pi)+\left(1-\pi_{0}\right) \rho(-\log (1-\pi))+G(\pi)+G(1-\pi) \tag{A.2}
\end{equation*}
$$

for $\left(\pi, \pi_{0}\right) \in(0,1) \times[0,1]$.
(a) If assumptions $\boldsymbol{R 1}$ and $\boldsymbol{R} \mathbf{2}$ hold, then the function $M\left(\pi, \pi_{0}\right)$ can be extended to a continuous function on $[0,1] \times[0,1]$.
(b) If assumptions $\boldsymbol{R 1}$ and $\boldsymbol{R 4}$ hold, then there exists a constant $\tau>0$ such that, for each $0<\pi<1$, $M\left(\pi, \pi_{0}\right)-M\left(\pi_{0}, \pi_{0}\right) \geq \tau\left(\pi-\pi_{0}\right)^{2}$.

Proof. (a) Note that assumptions R1 and R2 imply that there exists a finite constant $\rho_{\infty}$ which is equal to $\|\rho\|_{\infty}$ such that $\lim _{t \rightarrow \infty} \rho(t)=\rho_{\infty}$. Hence, if we define $M\left(0, \pi_{0}\right)=\pi_{0} \rho_{\infty}+G(1)$ and $M\left(1, \pi_{0}\right)=\left(1-\pi_{0}\right) \rho_{\infty}+G(1)$, standard arguments allow to see that the resulting extended function $M\left(\pi, \pi_{0}\right)$ is continuous in $[0,1] \times[0,1]$, which concludes the proof of (a).
(b) Assume that $0<\pi<1$. From the proof of Lemma 2.1 in Bianco and Yohai (1996), we get that

$$
\frac{\partial}{\partial \pi} M\left(\pi, \pi_{0}\right)=\left(\pi-\pi_{0}\right) g(\pi)
$$

where $g(\pi)$ is defined as

$$
g(\pi)=\left(\frac{\psi(-\log \pi)}{\pi}+\frac{\psi(-\log (1-\pi))}{1-\pi}\right)
$$

Note that $g$ is a function symmetric around $\pi=1 / 2$. Furthermore, if $\pi \in[1 / 2,1]$,

$$
\begin{equation*}
g(\pi) \geq \frac{\psi(-\log \pi)}{\pi} \geq \psi(-\log \pi) \geq \tau \tag{A.3}
\end{equation*}
$$

where $\tau$ is the constant given in R4 Hence, the result follows from (A.3) and the fact that

$$
M\left(\pi, \pi_{0}\right)-M\left(\pi_{0}, \pi_{0}\right)=\left.\int_{\pi_{0}}^{\pi} \frac{\partial M\left(s, \pi_{0}\right)}{\partial s}\right|_{s=u} d u
$$

Lemma A.3. Let $\mathbf{z}=\left(Z_{1}, Z_{2}\right)^{\mathrm{T}} \in \mathbb{R}^{2}$ be a random vector with a centered elliptical distribution and characteristic function $\phi_{\mathbf{z}}(\mathbf{u})=\xi\left(\mathbf{u}^{\mathrm{T}} \mathbf{\Upsilon} \mathbf{u}\right)$. Assume that $\mathbb{E}\left(Z_{j}^{2}\right)<\infty$, for $j=1,2$, and denote $\boldsymbol{\Sigma}=$ $\operatorname{Cov}(\mathbf{z})$, that is,

$$
\boldsymbol{\Sigma}=\left(\begin{array}{cc}
\sigma_{1}^{2} & \rho \sigma_{1} \sigma_{2} \\
\rho \sigma_{1} \sigma_{2} & \sigma_{2}^{2}
\end{array}\right)=-2 \xi^{\prime}(0) \mathbf{\Upsilon}
$$

with $|\rho| \leq 1$. Additionally, assume that $\sigma_{2}>0$ and that there exists a constant $K_{2}>0$ such that $\sigma_{2} \leq K_{2}$ and the distribution of $\mathbf{Z}$ verifies

$$
\begin{equation*}
\mathbb{E}\left\{\left[F\left(Z_{1}\right)-F\left(Z_{2}\right)\right]^{2}\right\}<\frac{\left[F\left(4 K_{2}\right)-F\left(2 K_{2}\right)\right]^{2}}{4} \tag{A.4}
\end{equation*}
$$

where $F(t)=\exp (t) /(1+\exp (t))$. Then,
(a) there exists a constant $C_{0}$ that only depends on $\xi$ such that $\sigma_{1} \leq C_{0} K_{2}$.
(b) there exists a constant $C_{2}$ that only depends on $K_{2}$ and $\xi$ such that

$$
\mathbb{E}\left[\left(Z_{1}-Z_{2}\right)^{2}\right] \leq C_{2} \mathbb{E}\left[\left(F\left(Z_{1}\right)-F\left(Z_{2}\right)\right)^{2}\right] .
$$

Proof. To prove (a), note that if $\sigma_{1}=0$, the inequality holds with $C_{0}=1$. Assume now that $\sigma_{1} \neq 0$. Tchebychev's inequality implies

$$
\begin{equation*}
\mathbb{P}\left(\left|Z_{2}\right| \leq 2 K_{2}\right) \geq 3 / 4 \tag{A.5}
\end{equation*}
$$

Let $c$ be a constant such that

$$
\begin{equation*}
\mathbb{E}\left\{\left[F\left(Z_{1}\right)-F\left(Z_{2}\right)\right]^{2}\right\}<c<\frac{\left[F\left(4 K_{2}\right)-F\left(2 K_{2}\right)\right]^{2}}{4} . \tag{A.6}
\end{equation*}
$$

Hence,

$$
\begin{aligned}
c & >\mathbb{E}\left\{\left[F\left(Z_{1}\right)-F\left(Z_{2}\right)\right]^{2}\right\} \geq \mathbb{E}\left\{\left[F\left(Z_{1}\right)-F\left(Z_{2}\right)\right]^{2} \mathbb{I}_{\left|Z_{2}\right| \leq 2 K_{2}} \mathbb{I}_{\left|Z_{1}\right|>4 K_{2}}\right\} \\
& \geq\left[F\left(4 K_{2}\right)-F\left(2 K_{2}\right)\right]^{2} \mathbb{P}\left(\left|Z_{2}\right| \leq 2 K_{2} \cap\left|Z_{1}\right|>4 K_{2}\right) \\
& \geq\left[F\left(4 K_{2}\right)-F\left(2 K_{2}\right)\right]^{2}\left\{\mathbb{P}\left(\left|Z_{2}\right| \leq 2 K_{2}\right)-\mathbb{P}\left(\left|Z_{1}\right| \leq 4 K_{2}\right)\right\},
\end{aligned}
$$

which together with (A.6) implies that

$$
\mathbb{P}\left(\left|Z_{2}\right| \leq 2 K_{2}\right)-\mathbb{P}\left(\left|Z_{1}\right| \leq 4 K_{2}\right)<\frac{1}{4}
$$

Therefore, using (A.5), we get that

$$
\begin{equation*}
\mathbb{P}\left(\left|Z_{1}\right| \leq 4 K_{2}\right) \geq 1 / 2 \tag{A.7}
\end{equation*}
$$

Let $V_{j}=Z_{j} / \sigma_{j}, j=1,2$. The characteristic function of $V_{1}=Z_{1} / \sigma_{1}$ equals

$$
\phi_{V_{1}}(s)=\phi_{\mathbf{z}}\left(\frac{s}{\sigma_{1}}, 0\right)=\xi\left(\frac{s^{2}}{-2 \xi^{\prime}(0)}\right),
$$

so its distribution only depends on $\xi$. Let $m$ be the median of $\left|V_{1}\right|$. Note that (A.7) implies $\mathbb{P}\left(\left|V_{1}\right| \leq\right.$ $\left.4 K_{2} / \sigma_{1}\right) \geq 1 / 2$, so $4 K_{2} / \sigma_{1} \geq m$ concluding the proof of (a).

We now prove (b). First, assume that $|\rho| \neq 1$ and $\sigma_{1} \neq 0$ meaning that the matrix $\boldsymbol{\Sigma}$ is non-singular. Define $\mathbf{w}=\boldsymbol{\Sigma}^{-1 / 2} \mathbf{z}$, so $\mathbf{w}$ has a spherical distribution with characteristic function

$$
\phi_{\mathbf{w}}(\mathbf{t})=\xi\left(\frac{\mathbf{t}^{\mathrm{T}} \mathbf{t}}{-2 \xi^{\prime}(0)}\right) .
$$

The eigenvalues of $\boldsymbol{\Sigma}$ may be bounded by its trace, $\operatorname{TR}(\boldsymbol{\Sigma})=\sigma_{1}^{2}+\sigma_{2}^{2} \leq\left(C_{0}^{2}+1\right) K_{2}^{2}$, where we used the inequality given in (a).

Besides, note that

$$
\mathbf{w}^{\mathrm{T}} \mathbf{w}=\mathbf{z}^{\mathrm{T}} \boldsymbol{\Sigma}^{-1} \mathbf{z} \geq \iota_{1}\left(\boldsymbol{\Sigma}^{-1}\right)\|\mathbf{z}\|_{2}^{2} \geq \frac{1}{\left(C_{0}^{2}+1\right) K_{2}^{2}}\|\mathbf{z}\|_{2}^{2} .
$$

Let $m_{1}$ be the median of $\|\mathbf{w}\|_{2}$, which only depends on $\xi$. Then, if $\|\mathbf{w}\|_{2}^{2} \leq m_{1}^{2}$, we have that $\max \left\{\left|Z_{1}\right|,\left|Z_{2}\right|\right\} \leq C_{1} K_{2}$, where $C_{1}=m_{1}\left(C_{0}^{2}+1\right)^{1 / 2}$ only depends on $\xi$. Hence, the mean value theorem implies that there exists a value $\theta$ such that $-C_{1} K_{2} \leq \theta \leq C_{1} K_{2}$ and $\left[F\left(Z_{1}\right)-F\left(Z_{2}\right)\right]^{2}=$ $\left[F^{\prime}(\theta)\right]^{2}\left(Z_{1}-Z_{2}\right)^{2}$. Using the fact that $F^{\prime}(t)=F(t)(1-F(t))$ is an even function, increasing in $(-\infty, 0]$ and decreasing in $[0, \infty)$, we conclude that $\left[F\left(Z_{1}\right)-F\left(Z_{2}\right)\right]^{2} \geq\left[F^{\prime}\left(C_{1} K_{2}\right)\right]^{2}\left(Z_{1}-Z_{2}\right)^{2}$, so

$$
\mathbb{E}\left\{\left[F\left(Z_{1}\right)-F\left(Z_{2}\right)\right]^{2}\right\} \geq \mathbb{E}\left\{\left[F\left(Z_{1}\right)-F\left(Z_{2}\right)\right]^{2} \mathbb{I}_{\|\mathbf{w}\|_{2} \leq m_{1}}\right\} \geq \mathbb{E}\left\{\left[F^{\prime}\left(C_{1} K_{2}\right)\right]^{2}\left(Z_{1}-Z_{2}\right)^{2} \mathbb{I}_{\|\mathbf{w}\|_{2} \leq m_{1}}\right\}
$$

Let $\mathbf{v}=(1,-1)^{\mathrm{T}}$. Taking into account that $\mathbf{w}=\boldsymbol{\Sigma}^{-1 / 2} \mathbf{z}$ and $\mathbf{w} /\|\mathbf{w}\|_{2}$ is independent from $\|\mathbf{w}\|_{2}$, we obtain

$$
\begin{aligned}
\mathbb{E}\left\{\left[F\left(Z_{1}\right)-F\left(Z_{2}\right)\right]^{2}\right\} & \geq\left[F^{\prime}\left(C_{1} K_{2}\right)\right]^{2} \mathbb{E}\left(\mathbf{v}^{\mathrm{T}} \mathbf{z \mathbf { z } ^ { \mathrm { T } } \mathbf { v } \mathbb { I } _ { \| \mathbf { w } \| _ { 2 } \leq m _ { 1 } } )}\right. \\
& =\left[F^{\prime}\left(C_{1} K_{2}\right)\right]^{2} \mathbb{E}\left(\mathbf{v}^{\mathrm{T}} \boldsymbol{\Sigma}^{1 / 2} \mathbf{w} \mathbf{w}^{\mathrm{T}} \boldsymbol{\Sigma}^{1 / 2} \mathbf{v} \mathbb{I}_{\|\mathbf{w}\|_{2} \leq m_{1}}\right) \\
& =\left[F^{\prime}\left(C_{1} K_{2}\right)\right]^{2} \mathbf{v}^{\mathrm{T}} \boldsymbol{\Sigma}^{1 / 2} \mathbb{E}\left(\frac{\mathbf{w} \mathbf{w}^{\mathrm{T}}}{\|\mathbf{w}\|_{2}^{2}}\right) \mathbb{E}\left(\|\mathbf{w}\|_{2}^{2} \mathbb{I}_{\|\mathbf{w}\|_{2} \leq m_{1}}\right) \boldsymbol{\Sigma}^{1 / 2} \mathbf{v} .
\end{aligned}
$$

Moreover, using that $\mathbb{E}\left(\mathbf{w w}^{\mathrm{T}} /\|\mathbf{w}\|_{2}^{2}\right)=(1 / 2) \mathbf{I}_{2}$ and $\mathbf{v}^{\mathrm{T}} \boldsymbol{\Sigma} \mathbf{v}=\mathbb{E}\left[\left(Z_{1}-Z_{2}\right)^{2}\right]$, we get

$$
\mathbb{E}\left\{\left[F\left(Z_{1}\right)-F\left(Z_{2}\right)\right]^{2}\right\} \geq \frac{\left[F^{\prime}\left(C_{1} K_{2}\right)\right]^{2}}{2} \mathbb{E}\left(\|\mathbf{w}\|_{2}^{2} \mathbb{I}_{\|\mathbf{w}\|_{2} \leq m_{1}}\right) \mathbb{E}\left[\left(Z_{1}-Z_{2}\right)^{2}\right]=C \mathbb{E}\left[\left(Z_{1}-Z_{2}\right)^{2}\right]
$$

The fact that $m_{1}$ is the median of $\|\mathbf{w}\|_{2}$ leads to $\mathbb{P}\left(\|\mathbf{w}\|_{2} \leq m_{1}\right) \geq 1 / 2$, so $\mathbb{E}\left(\|\mathbf{w}\|_{2}^{2} \mathbb{I}_{\| \mathbf{w}} \|_{2} \leq m_{1}\right) \neq 0$. Hence, $C>0$ and the proof of (b) is concluded if $\rho \neq 1$.

We now consider the case where $|\rho|=1$ and $\sigma_{1} \neq 0$. In this setting, there exists a constant $a \neq 0$ such that $Z_{1}=a Z_{2}$, so $\sigma_{1}^{2}=a^{2} \sigma_{2}^{2}$ and $V_{2}=Z_{2} / \sigma_{2}=Z_{1} / \sigma_{1}=V_{1}$. Recall that $m$ is the median of $\left|V_{1}\right|=\left|V_{2}\right|$, which implies $\mathbb{P}\left(\left|V_{2}\right| \leq m\right) \geq 1 / 2$. Then, if $\left|V_{2}\right| \leq m$, from (a) we obtain that $\left|Z_{1}\right| \leq m \sigma_{1} \leq m C_{0} K_{2}$ and $\left|Z_{2}\right| \leq m \sigma_{2} \leq m K_{2}$, i.e. $\max \left\{\left|Z_{1}\right|,\left|Z_{2}\right|\right\} \leq C_{2} K_{2}$ where $C_{2}=m \max \left\{C_{0}, 1\right\}$. Hence, using that $\mathbb{E}\left[\left(Z_{1}-Z_{2}\right)^{2}\right]=(a-1)^{2} \sigma_{2}^{2}$ and the mean value theorem, we obtain

$$
\begin{aligned}
\mathbb{E}\left\{\left[F\left(Z_{1}\right)-F\left(Z_{2}\right)\right]^{2}\right\} & \geq \mathbb{E}\left\{\left[F\left(Z_{1}\right)-F\left(Z_{2}\right)\right]^{2} \mathbb{I}_{\left|V_{2}\right| \leq m}\right\} \geq\left[F^{\prime}\left(C_{2} K_{2}\right)\right]^{2} \mathbb{E}\left[\left(Z_{1}-Z_{2}\right)^{2} \mathbb{I}_{\left|V_{2}\right| \leq m}\right] \\
& \geq\left[F^{\prime}\left(C_{2} K_{2}\right)\right]^{2}(a-1)^{2} \sigma_{2}^{2} \mathbb{E}\left[\frac{Z_{2}^{2}}{\sigma_{2}^{2}} \mathbb{I}_{\left|V_{2}\right| \leq m}\right] \\
& \geq\left[F^{\prime}\left(C_{2} K_{2}\right)\right]^{2} \mathbb{E}\left[\left(Z_{1}-Z_{2}\right)^{2}\right] \mathbb{E}\left(V_{2}^{2} \mathbb{I}_{\left|V_{2}\right| \leq m}\right)
\end{aligned}
$$

Since the distribution of $V_{2}$ only depends on $\xi, \mathbb{E}\left[V_{2}^{2} \mathbb{I}_{\left|V_{2}\right| \leq m}\right]$ only depends on $\xi$ and is positive since $\mathbb{P}\left(\left|V_{2}\right| \leq m\right) \geq 1 / 2$, which concludes the proof.

Finally, we analyse the case where $\sigma_{1}=0$, which is equivalent to $\mathbb{P}\left(Z_{1}=0\right)=1$. Thus, we must show that $\mathbb{E}\left\{\left[F\left(Z_{1}\right)-F\left(Z_{2}\right)\right]^{2}\right\} \geq C \sigma_{2}^{2}$ for some constant $C$ that only depends on $\xi$ and $K_{2}$. In this case, let $m_{2}$ be the median of $V_{2}$. As in the case where $|\rho|=1$ and $\sigma_{1} \neq 0$, the mean value theorem implies that, if $\left|Z_{2}\right| \leq m \sigma_{2} \leq m K_{2}$, then $\left[F(0)-F\left(Z_{2}\right)\right]^{2} \geq\left[F^{\prime}\left(m K_{2}\right)\right]^{2} Z_{2}^{2}$. Then, the conclusion follows easily from

$$
\mathbb{E}\left\{\left[F\left(Z_{1}\right)-F\left(Z_{2}\right)\right]^{2}\right\} \geq \mathbb{E}\left\{\left[F(0)-F\left(Z_{2}\right)\right]^{2} \mathbb{I}_{\left|V_{2}\right| \leq m}\right\} \geq\left[F^{\prime}\left(m K_{2}\right)\right]^{2} \sigma_{2}^{2} \mathbb{E}\left(V_{2}^{2} \mathbb{I}_{\left|V_{2}\right| \leq m}\right)
$$

Proof of Theorem 3.1. We will first prove (a). Using the definition of $\widehat{\boldsymbol{\beta}}_{n}$, we have that

$$
L_{n}\left(\widehat{\boldsymbol{\beta}}_{n}\right) \leq L_{n}\left(\widehat{\boldsymbol{\beta}}_{n}\right)+I_{\lambda_{n}}\left(\widehat{\boldsymbol{\beta}}_{n}\right) \leq L_{n}\left(\boldsymbol{\beta}_{0}\right)+I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right),
$$

which implies $\mathbb{L}\left(\widehat{\boldsymbol{\beta}}_{n}\right)-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right) \leq\left[L_{n}\left(\boldsymbol{\beta}_{0}\right)-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right)\right]-\left[L_{n}\left(\widehat{\boldsymbol{\beta}}_{n}\right)-\mathbb{L}\left(\widehat{\boldsymbol{\beta}}_{n}\right)\right]+I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right)$. Let $C_{1}$ be the constant from Lemma A.1, which we will assume, without loss of generality, to be greater than one. Consider the event

$$
\mathcal{A}_{n, T}=\left\{\sup _{\boldsymbol{\beta}}\left|L_{n}(\boldsymbol{\beta})-\mathbb{L}(\boldsymbol{\beta})\right| \leq C_{1} T \sqrt{\frac{p}{n}}\right\} .
$$

From Lemma A. 1 and Markov's inequality, we get that $\mathbb{P}\left(\mathcal{A}_{n, T}\right) \geq 1-1 / T$ for $T>1$. Thus, restricting to the event $\mathcal{A}_{n, T}$, we obtain

$$
\begin{equation*}
\mathbb{L}\left(\widehat{\boldsymbol{\beta}}_{n}\right)-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right) \leq 2 C_{1} T \sqrt{\frac{p}{n}}+I_{\lambda}\left(\boldsymbol{\beta}_{0}\right) \leq 2 C_{1} T\left\{\sqrt{\frac{p}{n}}+I_{\lambda}\left(\boldsymbol{\beta}_{0}\right)\right\} . \tag{A.8}
\end{equation*}
$$

Straightforward calculations show that

$$
\mathbb{L}\left(\widehat{\boldsymbol{\beta}}_{n}\right)-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right)=\mathbb{E}\left\{M\left(F\left(\mathbf{x}^{\mathrm{T}} \widehat{\boldsymbol{\beta}}_{n}\right), F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right)-M\left(F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right), F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right) \mid\left(y_{1}, \mathbf{x}_{1}\right), \ldots\left(y_{n}, \mathbf{x}_{n}\right)\right\},
$$

with $M$ defined in (A.2). Then, using Lemma A.2 we obtain that there exists a constant $\tau>0$ independent from $n$ such that

$$
\mathbb{L}\left(\widehat{\boldsymbol{\beta}}_{n}\right)-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right) \geq \tau \mathbb{E}\left\{\left[F\left(\mathbf{x}^{\mathrm{T}} \widehat{\boldsymbol{\beta}}_{n}\right)-F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right]^{2} \mid\left(y_{1}, \mathbf{x}_{1}\right), \ldots\left(y_{n}, \mathbf{x}_{n}\right)\right\}=\tau d_{n}^{2}\left(\widehat{\boldsymbol{\beta}}_{n}, \boldsymbol{\beta}_{0}\right),
$$

which together with (A.8) concludes the proof for (a).
To prove (b), observe that if $\max \left\{\left\|\widehat{\boldsymbol{\beta}}_{n}\right\|_{1},\left\|\boldsymbol{\beta}_{0}\right\|_{1}\right\} \leq R$ and $\|\mathbf{x}\|_{\infty} \leq A$, then the Hölder inequality implies $\max \left\{\left|\mathbf{x}^{\mathrm{T}} \widehat{\boldsymbol{\beta}}_{n}\right|,\left|\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right|\right\} \leq A R$. Using the fact that $F^{\prime}(t)$ is an even function, increasing in $(-\infty, 0]$ and decreasing in $[0, \infty)$, we obtain that

$$
\begin{aligned}
\mathbb{E}\left[\left(F\left(\mathbf{x}^{\mathrm{T}} \widehat{\boldsymbol{\beta}}_{n}\right)-F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right)^{2}\right] & \geq\left(F^{\prime}(A R)\right)^{2} \mathbb{E}\left[\left(\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right)^{\mathrm{T}} \mathbf{x x}^{\mathrm{T}}\left(\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right)\right] \\
& \geq\left(F^{\prime}(A R)\right)^{2} \iota_{1}(\mathbf{H})\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}^{2} .
\end{aligned}
$$

In particular, when (Z3) holds, $\mathbb{E}\left[\left(F\left(\mathbf{x}^{\mathrm{T}} \widehat{\boldsymbol{\beta}}_{n}\right)-F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right)^{2}\right] \geq \tau_{1}\left(F^{\prime}(A R)\right)^{2}\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}^{2}$. Then, the desired result follows from (a).

Finally, we prove (c). It suffices to show that given $\varepsilon>0$ and $\delta>0$, there exists $n_{0}$ such that if $n \geq n_{0}$, then

$$
\begin{equation*}
\mathbb{P}\left(\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}^{2} \leq \varepsilon\right)>1-\delta . \tag{A.9}
\end{equation*}
$$

Assumption Z5 implies that, for every $\boldsymbol{\beta} \in \mathbb{R}^{p}, \mathbf{z}_{\boldsymbol{\beta}}=\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}, \mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)^{\mathrm{T}}$ has a centered elliptical distribution with finite second moments and generating function $\xi$. From assumption [Z3, we obtain that $\operatorname{Var}\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right) \neq 0$. On the other hand, since $\mathbf{Z 4}$ holds, $\operatorname{VAR}\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right) \leq K_{2}$, where $K_{2}$ does not depend on $n$.

Using that $p / n \rightarrow 0$ and $I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right) \rightarrow 0$, from (a) we conclude that $d_{n}\left(\widehat{\boldsymbol{\beta}}_{n}, \boldsymbol{\beta}_{0}\right) \xrightarrow{p} 0$. Define the event

$$
\mathcal{B}_{n}=\left\{d_{n}^{2}\left(\widehat{\boldsymbol{\beta}}_{n}, \boldsymbol{\beta}_{0}\right) \leq \frac{\left[F\left(4 K_{2}\right)-F\left(2 K_{2}\right)\right]^{2}}{8}\right\}
$$

If $\omega \in \mathcal{B}_{n}$, then $\mathbf{z}_{\widehat{\boldsymbol{\beta}}_{n}(\omega)}=\left(\mathbf{x}^{\mathrm{T}} \widehat{\boldsymbol{\beta}}_{n}(\omega), \mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)^{\mathrm{T}}$ satisfies the conditions of Lemma A.3. Hence, from item (b) of that Lemma, there exists $C_{2}$ that only depends on $\xi$ and $K_{2}$ (and is independent from $\omega$ and $n$ ) such that

$$
D_{n}^{2}\left(\widehat{\boldsymbol{\beta}}_{n}, \boldsymbol{\beta}_{0}\right) \leq C_{2} d_{n}^{2}\left(\widehat{\boldsymbol{\beta}}_{n}, \boldsymbol{\beta}_{0}\right),
$$

where $D_{n}^{2}\left(\boldsymbol{\beta}, \boldsymbol{\beta}_{0}\right)=\mathbb{E}\left[\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}-\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)^{2}\right]$. Moreover, define the event $\mathcal{A}_{\varepsilon, n}=\left\{d_{n}^{2}\left(\widehat{\boldsymbol{\beta}}_{n}, \boldsymbol{\beta}_{0}\right) \leq \varepsilon \tau_{1} / C_{2}\right\}$, where $\tau_{1}$ is given in Z3.
The fact that $d_{n}\left(\widehat{\boldsymbol{\beta}}_{n}, \boldsymbol{\beta}_{0}\right) \xrightarrow{p} 0$ implies that $\lim _{n} \mathbb{P}\left(\mathcal{A}_{\varepsilon, n}\right)=\lim _{n} \mathbb{P}\left(\mathcal{B}_{n}\right)=1$, so $\lim _{n} \mathbb{P}\left(\mathcal{A}_{\varepsilon, n} \cap \mathcal{B}_{n}\right)=1$ and there exists $n_{0}$ such that if $n \geq n_{0}, \mathbb{P}\left(\mathcal{A}_{\varepsilon, n} \cap \mathcal{B}_{n}\right)>1-\delta$. Note that for any $\omega \in \mathcal{A}_{\varepsilon, n} \cap \mathcal{B}_{n}$, we have that $D_{n}^{2}\left(\widehat{\boldsymbol{\beta}}_{n}, \boldsymbol{\beta}_{0}\right) \leq C_{2} d_{n}^{2}\left(\widehat{\boldsymbol{\beta}}_{n}, \boldsymbol{\beta}_{0}\right) \leq \varepsilon \tau_{1}$. Besides,

$$
D_{n}^{2}\left(\widehat{\boldsymbol{\beta}}_{n}, \boldsymbol{\beta}_{0}\right)=\left(\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right)^{\mathrm{T}} \mathbf{H}\left(\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right) \geq\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}^{2} \iota_{1}(\mathbf{H}) \geq \tau_{1}\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}^{2},
$$

which implies $\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}^{2}<\varepsilon$. Thus, (A.9) holds, concluding the proof.
Proof of Theorem 3.2. We will only prove the result for the estimator $\widehat{\boldsymbol{\beta}}_{n}$ defined in (11), since the proof for the restricted estimator given in (5) is analogous. It is worth mentioning that R1 implies $\mathbb{L}(\boldsymbol{\beta})<\infty$ for all $\boldsymbol{\beta}$.

Let us show (a). Define $v_{n}(\boldsymbol{\beta})=L_{n}(\boldsymbol{\beta})-\mathbb{L}(\boldsymbol{\beta})$ and $\ell_{n}=\sqrt{n /(p \log p)}$. We will begin by bounding the increments of the empirical process $v_{n}$ and for that aim define $\gamma(y, s)=\phi(y, s)$ and $y \in\{0,1\}$. Observe that $\gamma(y, s)$ is differentiable with respect to its second argument with derivative $\gamma^{\prime}(y, s)=\Psi(y, s)$ where $\Psi(y, t)=\partial \phi(y, t) / \partial t=-[y-F(t)] \nu(t)$, so $\left\|\gamma^{\prime}\right\|_{\infty} \leq 4\|\psi\|_{\infty}<\infty$. The mean value theorem implies that $|\gamma(y, s)-\gamma(y, \widetilde{s})| \leq C_{\gamma}|s-\widetilde{s}|$, for any $s, \widetilde{s} \in \mathbb{R}$ with $C_{\gamma}=4\|\psi\|_{\infty}$. Thus, Lemma 14.20 from Bühlmann and van de Geer (2011) allow to conclude that for every $M>0$,

$$
\mathbb{E}\left(\sup _{\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{1} \leq M}\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right|\right) \leq 4 M C_{\gamma} \sqrt{\frac{2 \log (2 p)}{n}} \mathbb{E}\left(\max _{1 \leq j \leq p} \frac{1}{n} \sum_{i=1}^{n} X_{i j}^{2}\right) \leq M C_{1} \sqrt{\frac{\log p}{n}}
$$

where the last inequality follows from $\mathbf{Z 1}$ and the constant $C_{1}$ does not depend neither on $n$ nor $p$. Using that $\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2} \leq \delta$ implies $\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{1} \leq \sqrt{p} \delta$, we obtain

$$
\mathbb{E}\left(\sup _{\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2} \leq \delta}\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right|\right) \leq \mathbb{E}\left(\sup _{\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{1} \leq \sqrt{p} \delta}\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right|\right) \leq \frac{C_{1} \delta}{\ell_{n}} .
$$

Thus, from Markov's inequality, we conclude that for each $C>0$,

$$
\begin{equation*}
\mathbb{P}\left(\sup _{\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2} \leq \delta}\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right|>C\right) \leq \frac{C_{1} \delta}{\ell_{n} C} . \tag{A.10}
\end{equation*}
$$

The proof follows using the same arguments as those considered in the proof of Theorem 3.2.5 in van der Vaart and Wellner (2012) and is based on the so called peeling device. More precisely, let $c_{n}=\mathbb{P}\left(\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2} \geq \eta\right)$, where $\eta>0$ is such that $\mathbb{L}(\boldsymbol{\beta})-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right) \geq \tau\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2}$ for each $n \geq 1$ and $\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\| \leq \eta$. Since $\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2} \xrightarrow{p} 0$, we have that $c_{n} \rightarrow 0$. For $j \in \mathbb{N}$, define the sets

$$
A_{n, j}=\left\{\boldsymbol{\beta} \in \mathbb{R}^{p}: 2^{j-1} \leq \ell_{n}\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2} \leq 2^{j}\right\} .
$$

Let $M \in \mathbb{N}$. Using that $\widehat{\boldsymbol{\beta}}_{n}$ minimizes $L_{n}(\boldsymbol{\beta})+I_{\lambda_{n}}(\boldsymbol{\beta})$, we obtain $L_{n}\left(\widehat{\boldsymbol{\beta}}_{n}\right)+I_{\lambda_{n}}\left(\widehat{\boldsymbol{\beta}}_{n}\right) \leq L_{n}\left(\boldsymbol{\beta}_{0}\right)+I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right)$. Thus,

$$
\begin{aligned}
\mathbb{P}\left(\ell_{n}\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}\right. & \left.\geq 2^{M}\right) \leq c_{n}+\sum_{\substack{j \geq M+1 \\
2^{j} \leq \ell_{n} \eta}} \mathbb{P}\left(\widehat{\boldsymbol{\beta}}_{n} \in A_{n, j}\right) \\
& \leq c_{n}+\sum_{\substack{j \geq M+1 \\
2^{j} \leq \ell_{n} \eta}} \mathbb{P}\left(\inf _{\boldsymbol{\beta} \in A_{n, j}} L_{n}(\boldsymbol{\beta})+I_{\lambda_{n}}(\boldsymbol{\beta})-L_{n}\left(\boldsymbol{\beta}_{0}\right)-I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right) \leq 0\right) \\
& \leq c_{n}+\sum_{\substack{j \geq M+1 \\
2^{j} \leq \ell_{n} \eta}} \mathbb{P}\left(\inf _{\boldsymbol{\beta} \in A_{n, j}} v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)+I_{\lambda_{n}}(\boldsymbol{\beta})-I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right)+\mathbb{L}(\boldsymbol{\beta})-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right) \leq 0\right) .
\end{aligned}
$$

Note that $\mathbf{P 1}$ implies $I_{\lambda_{n}}(\boldsymbol{\beta})-I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right) \geq-\left|I_{\lambda_{n}}(\boldsymbol{\beta})-I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right)\right| \geq-\lambda_{n} K\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{1}$. Besides, given $\boldsymbol{\beta} \in A_{n, j},\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\| \leq \eta$ if $2^{j} \leq \ell_{n} \eta$, so $\mathbb{L}(\boldsymbol{\beta})-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right) \geq \tau\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2}$. Then, if $\boldsymbol{\beta} \in A_{n, j}$, $v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)+I_{\lambda_{n}}(\boldsymbol{\beta})-I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right)+\mathbb{L}(\boldsymbol{\beta})-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right) \geq-\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right|-\lambda_{n} K\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{1}+\tau\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2}$,
which allows to conclude that $\mathbb{P}\left(\ell_{n}\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2} \geq 2^{M}\right) \leq c_{n}+d_{n}$, where $d_{n}=\sum_{j \geq M+1,2^{j} \leq \ell_{n} \eta} d_{n, j}$ with

$$
d_{n, j}=\mathbb{P}\left(-\sup _{\boldsymbol{\beta} \in A_{n, j}}\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right|-K \lambda_{n} \sup _{\boldsymbol{\beta} \in A_{n, j}}\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{1}+\tau \inf _{\boldsymbol{\beta} \in A_{n, j}}\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2} \leq 0\right) .
$$

Observe that if $\boldsymbol{\beta} \in A_{n, j}$,

$$
\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2} \geq \frac{2^{2 j-2}}{\ell_{n}^{2}} \quad \text { and } \quad\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{1} \leq \sqrt{p}\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2} \leq \frac{\sqrt{p} 2^{j}}{\ell_{n}}
$$

then,

$$
-K \lambda_{n} \sup _{\boldsymbol{\beta} \in A_{n, j}}\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{1}+\tau \inf _{\boldsymbol{\beta} \in A_{n, j}}\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2} \geq-K \lambda_{n} \frac{\sqrt{p} 2^{j}}{\ell_{n}}+\frac{\tau 2^{2 j-2}}{\ell_{n}^{2}}=\alpha_{n}
$$

from which we obtain

$$
d_{n, j} \leq \mathbb{P}\left(\sup _{\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2} \leq \frac{2 j}{\ell_{n}}}\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right| \geq \alpha_{n}\right)
$$

Using that $\lambda_{n}=O(\sqrt{\log p / n})$, we get that there exists a constant $D>0$ such that $\lambda_{n} \leq D \sqrt{\log p / n}$ for all $n$, so choosing

$$
M \geq \frac{\log \left(\frac{8 K D}{\tau}\right)}{\log 2}+1=M_{0}
$$

we have that $\alpha_{n}>0$. Using (A.10) we obtain that for all $j \geq M+1$,

$$
d_{n, j} \leq C_{1} \frac{2^{j}}{\ell_{n}^{2} \alpha_{n}}
$$

From $\lambda_{n} \leq D \sqrt{\log p / n}$ for all $n$, we conclude $\lambda_{n} \sqrt{p} \leq D / \ell_{n}$ which implies that $\ell_{n}^{2} \alpha_{n} \geq 2^{j}\left(\tau 2^{j-2}-K D\right)>$ $\tau 2^{2 j} / 8$ if $j \geq M+1$, so $d_{n, j} \leq 2^{-j}\left(8 C_{1}\right) / \tau$. Given $\varepsilon>0$, let $N_{\varepsilon} \in \mathbb{N}$ be such that if $n \geq N_{\varepsilon}, c_{n} \leq \varepsilon / 2$. Besides, let $M_{\varepsilon} \in \mathbb{N}$, be such that $M_{\varepsilon} \geq M_{0}$ and $\sum_{j \geq M_{\varepsilon}} 2^{-j}<\tau \varepsilon /\left(16 C_{1}\right)$. Hence, for any $n \geq N_{\varepsilon}$, we have $\mathbb{P}\left(\ell_{n}\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2} \geq 2^{M_{\varepsilon}}\right) \leq \varepsilon$, which concludes the proof of (a).
To derive (b), define $\ell_{n}=\sqrt{n / p}$ and denote $\iota_{p}$ the maximum eigenvalue of $\mathbf{H}$. Note that for any $\boldsymbol{\beta}$ such that $\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2} \leq \delta$, we have that $\mathbb{E}\left[\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}-\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)^{2}\right] \leq \delta^{2} \iota_{p}$. Lemma 14.19 in Bühlmann and van de Geer (2011) implies that

$$
\mathbb{E}\left(\sup _{\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2} \leq \delta}\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right|\right) \leq \mathbb{E}\left(\sup _{\mathbb{E}\left[\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}-\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)^{2}\right] \leq \delta^{2} \iota_{p}}\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right|\right) \leq 4 C_{\gamma} \delta \sqrt{\iota_{p}} \sqrt{\frac{p}{n}} .
$$

Assumption Z2 ensures that $\iota_{p}(\mathbf{H}) \leq K_{1}$ for all $n$, hence

$$
\mathbb{E}\left(\sup _{\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2} \leq \delta}\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right|\right) \leq 4 C_{\gamma} \sqrt{K_{1}} \delta \sqrt{\frac{p}{n}}=\frac{4 C \sqrt{K_{1}} \delta}{\ell_{n}} .
$$

The proof follows now using the same arguments considered above in the proof of (a).
To prove (c)(i), consider $\ell_{n}=\sqrt{n /(p \log p)}$. Following the inequality chain used in (a), when bounding (A.11) but considering the bound (10) stated in (P2, we obtain that $V_{n}(\boldsymbol{\beta})=v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)+I_{\lambda_{n}}(\boldsymbol{\beta})-$ $I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0}\right)+\mathbb{L}(\boldsymbol{\beta})-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right)$ can be bounded by

$$
V_{n}(\boldsymbol{\beta}) \geq-\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right|-a_{n} \sqrt{k}\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}-b_{n}\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2}+\tau\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2} .
$$

Hence, if $\boldsymbol{\beta} \in A_{n, j}$ we have that

$$
V_{n}(\boldsymbol{\beta}) \geq-\sup _{\boldsymbol{\beta} \in A_{n, j}}\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right|-a_{n} \sqrt{k} \frac{2^{j}}{\ell_{n}}-b_{n} \frac{2^{2 j}}{\ell_{n}^{2}}+\tau \frac{2^{2 j-2}}{\ell_{n}^{2}},
$$

which implies that $\mathbb{P}\left(\ell_{n}\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2} \geq 2^{M}\right) \leq c_{n}+d_{n}$, where $c_{n}=\mathbb{P}\left(\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2} \geq \widetilde{\eta}\right), \widetilde{\eta}=\min (\eta, \widetilde{\delta})$ and $d_{n}=\sum_{j \geq M+1,2^{j} \leq \ell_{n} \tilde{\eta}} d_{n, j}$ with

$$
d_{n, j}=\mathbb{P}\left(\inf _{\boldsymbol{\beta} \in A_{n, j}} V_{n}(\boldsymbol{\beta}) \leq 0\right) \leq \mathbb{P}\left(\sup _{\boldsymbol{\beta} \in A_{n, j}}\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right| \geq \frac{\tau 2^{2 j-2}}{\ell_{n}^{2}}-a_{n} \sqrt{k} \frac{2^{j}}{\ell_{n}}-b_{n} \frac{2^{2 j}}{\ell_{n}^{2}}\right)
$$

The fact that $a_{n} \sqrt{k}=O\left(1 / \ell_{n}\right)$ entails that there exists $D>0$ such that $a_{n} \sqrt{k} \leq D / \ell_{n}$ for all $n$. Let $n_{0} \in \mathbb{N}$ be such that for any $n \geq n_{0}, b_{n} \leq \tau / 8$ and let

$$
M \geq \frac{\log \left(\frac{16 D}{\tau}\right)}{\log 2}+1=M_{0} .
$$

Then, if $n \geq n_{0}$ and $M \geq M_{0}$, we get that

$$
\alpha_{n}=\frac{\tau 2^{2 j-2}}{\ell_{n}^{2}}-a_{n} \sqrt{k} \frac{2^{j}}{\ell_{n}}-b_{n} \frac{2^{2 j}}{\ell_{n}^{2}} \geq \frac{2^{2 j}}{\ell_{n}^{2}}\left(\frac{\tau}{4}-\frac{D}{2^{j}}-b_{n}\right) \geq \frac{2^{2 j}}{\ell_{n}^{2}} \frac{\tau}{16} .
$$

Therefore, we obtain

$$
d_{n, j} \leq \mathbb{P}\left(\sup _{\boldsymbol{\beta} \in A_{n, j}}\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right| \geq \alpha_{n}\right) \leq \mathbb{P}\left(\sup _{\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2} \leq 2^{j} / \ell_{n}}\left|v_{n}(\boldsymbol{\beta})-v_{n}\left(\boldsymbol{\beta}_{0}\right)\right| \geq \frac{2^{2 j}}{\ell_{n}^{2}} \frac{\tau}{16}\right)
$$

which together with (A.10) allow to conclude that $d_{n, j} \leq\left(16 C_{1}\right) /\left(\tau 2^{j}\right)$ and the result follows as in (a). The proof of (c)(ii) is completely analogous, taking $\ell_{n}=\sqrt{n / p}$.

Proof of Lemma 3.3. First, note that $\mathbb{L}(\boldsymbol{\beta})=\mathbb{E} \phi\left(F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right), \mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}\right)$, thus

$$
\mathbb{L}(\boldsymbol{\beta})-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right)=\mathbb{E}\left[\phi\left(F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right), \mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}\right)-\phi\left(F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right), \mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right] .
$$

Using Lemma A. 2 we get that there exists a constant $\tau_{0}>0$ independent of $n$ such that

$$
\begin{equation*}
\mathbb{L}(\boldsymbol{\beta})-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right)=\mathbb{E}\left[\phi\left(F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right), \mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}\right)-\phi\left(F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right), \mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right] \geq \tau_{0} \mathbb{E}\left[F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}\right)-F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right]^{2} \tag{A.12}
\end{equation*}
$$

On the other hand, we have that $\mathbb{E}\left[F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}\right)-F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right]^{2} \leq \iota_{p}(\mathbf{H})\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2}$. Assumption $\mathbf{Z 5}$ implies $\mathbf{z}=\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}, \mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)^{\mathrm{T}}$ has a centered elliptical distribution with finite second moments, whereas from $\mathbf{Z} 3$ we get that $\operatorname{VAR}\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right) \neq 0$. Moreover, $\mathbf{Z 4}$ implies $\operatorname{VAR}\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right) \leq K_{2}^{2}$, where $K_{2}$ does not depend on $n$. Hence, we can choose a sufficiently small value $\eta>0$ such that, for $\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}<\eta$, condition (A.4) from Lemma A. 3 holds, where $\sigma_{2}^{2}=\operatorname{VAR}\left(\mathrm{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)$ and $K_{2}$ is the constant from assumption Z4. Using Lemma A.3(b), we conclude that there exists a constant $C_{1}>0$ independent of the sample size $n$ such that

$$
\begin{equation*}
\mathbb{E}\left[\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}-\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right]^{2} \leq C_{1} \mathbb{E}\left[F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}\right)-F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right]^{2} \tag{A.13}
\end{equation*}
$$

Inequalities (A.12) and (A.13) lead to

$$
\mathbb{L}(\boldsymbol{\beta})-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right) \geq \tau_{0} \mathbb{E}\left[F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}\right)-F\left(\mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right]^{2} \geq \tau_{0} C_{1}^{-1} \mathbb{E}\left[\mathbf{x}^{\mathrm{T}}\left(\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right)\right]^{2} \geq \tau_{0} C_{1}^{-1} \iota_{1}\left(\mathbb{E}\left[\mathbf{x x}^{\mathrm{T}}\right]\right)\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2}
$$

which allows to conclude that for any $\boldsymbol{\beta}$ such that $\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}<\eta$, we have that $\mathbb{L}(\boldsymbol{\beta})-\mathbb{L}\left(\boldsymbol{\beta}_{0}\right) \geq$ $\tau\left\|\boldsymbol{\beta}-\boldsymbol{\beta}_{0}\right\|_{2}^{2}$, where $\tau=\tau_{0} \tau_{1} C_{1}^{-1}$ with $\tau_{1}$ given in Z3.

## A. 2 Proofs of the results in Section 4

Proof of Theorem 4.1. The proof follows similar arguments to those considered in the proof of Theorem 3 in Bianco et al. (2021), but adapted to the present situation in which the dimension increases with the sample size.

Given $\tau>0$, we will show that $\mathbb{P}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{NA}}=\mathbf{0}_{p-k}\right)>1-\tau$ for $n$ large enough. Define $V_{n}: \mathbb{R}^{k} \times \mathbb{R}^{p-k} \rightarrow \mathbb{R}$ as

$$
V_{n}\left(\mathbf{u}_{1}, \mathbf{u}_{2}\right)=L_{n}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}+\frac{\mathbf{u}_{1}}{\ell_{n}}, \frac{\mathbf{u}_{2}}{\ell_{n}}\right)+I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}+\frac{\mathbf{u}_{1}}{\ell_{n}}, \frac{\mathbf{u}_{2}}{\ell_{n}}\right)
$$

where $L_{n}(\boldsymbol{\beta})$ is given in (8). Let $C>0$ be a constant such that $\mathbb{P}\left(\mathcal{B}_{n}\right) \geq 1-\tau / 2$, where $\mathcal{B}_{n}=$ $\left\{\ell_{n}\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2} \leq C\right\}$. Then, for each $\omega \in \mathcal{B}_{n}$, we can write

$$
\widehat{\boldsymbol{\beta}}_{n}=\left(\boldsymbol{\beta}_{0, \mathrm{~A}}^{\mathrm{T}}+\frac{\mathbf{u}_{1, n}^{\mathrm{T}}}{\ell_{n}}, \frac{\mathbf{u}_{2, n}^{\mathrm{T}}}{\ell_{n}}\right)^{\mathrm{T}}
$$

where $\left\|\mathbf{u}_{n}\right\|_{2} \leq C$ and $\mathbf{u}_{n}=\left(\mathbf{u}_{1, n}^{\mathrm{T}}, \mathbf{u}_{2, n}^{\mathrm{T}}\right)^{\mathrm{T}}, \mathbf{u}_{1, n} \in \mathbb{R}^{k}, \mathbf{u}_{2, n} \in \mathbb{R}^{p-k}$. Observe that

$$
\begin{equation*}
\left(\mathbf{u}_{1, n}^{\mathrm{T}}, \mathbf{u}_{2, n}^{\mathrm{T}}\right)^{\mathrm{T}}=\underset{\left\|\mathbf{u}_{1}\right\|_{2}^{2}+\left\|\mathbf{u}_{2}\right\|_{2}^{2} \leq C^{2}}{\operatorname{argmin}} V_{n}\left(\mathbf{u}_{1}, \mathbf{u}_{2}\right) . \tag{A.14}
\end{equation*}
$$

Our goal is to prove that, with high probability, $V_{n}\left(\mathbf{u}_{1}, \mathbf{u}_{2}\right)-V_{n}\left(\mathbf{u}_{1}, \mathbf{0}_{p-k}\right)>0$ for all $\left\|\mathbf{u}_{1}\right\|_{2}^{2}+\left\|\mathbf{u}_{2}\right\|_{2}^{2} \leq C^{2}$ with $\mathbf{u}_{2} \neq \mathbf{0}_{p-k}$.

Take $\mathbf{u}_{1} \in \mathbb{R}^{k}$ and $\mathbf{u}_{2} \neq \mathbf{0}_{p-k}$ such that $\left\|\mathbf{u}_{1}\right\|_{2}^{2}+\left\|\mathbf{u}_{2}\right\|_{2}^{2} \leq C^{2}$. Note that $V_{n}\left(\mathbf{u}_{1}, \mathbf{u}_{2}\right)-V_{n}\left(\mathbf{u}_{1}, \mathbf{0}_{p-k}\right)=$ $S_{1, n}(\mathbf{u})+S_{2, n}(\mathbf{u})$, where $\mathbf{u}=\left(\mathbf{u}_{1}, \mathbf{u}_{2}\right)$ and

$$
\begin{aligned}
& S_{1, n}(\mathbf{u})=L_{n}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}+\frac{\mathbf{u}_{1}}{\ell_{n}}, \frac{\mathbf{u}_{2}}{\ell_{n}}\right)-L_{n}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}+\frac{\mathbf{u}_{1}}{\ell_{n}}, \mathbf{o}_{p-k}\right) \\
& S_{2, n}(\mathbf{u})=I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}+\frac{\mathbf{u}_{1}}{\ell_{n}}, \frac{\mathbf{u}_{2}}{\ell_{n}}\right)-I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}+\frac{\mathbf{u}_{1}}{\ell_{n}}, \mathbf{0}_{p-k}\right) .
\end{aligned}
$$

First, we will bound $S_{1, n}(\mathbf{u})$. The mean value theorem entails that

$$
S_{1, n}(\mathbf{u})=(1 / n) \sum_{i=1}^{n} \Psi\left(y_{i}, \mathbf{x}_{i}^{\mathrm{T}} \boldsymbol{\beta}_{n}^{*}\right) \mathbf{x}_{i}^{\mathrm{T}} \mathbf{u}_{n}^{(0)}
$$

where $\mathbf{u}_{n}^{(0)}=\left(\mathbf{0}_{k}^{\mathrm{T}}, \mathbf{u}_{2}^{\mathrm{T}} / \ell_{n}\right)^{\mathrm{T}}$ and

$$
\boldsymbol{\beta}_{n}^{*}=\binom{\boldsymbol{\beta}_{0, \mathrm{~A}}+\frac{\mathbf{u}_{1}}{\ell_{n}}}{\alpha_{n, 1} \frac{\mathbf{u}_{2}}{\ell_{n}}}
$$

for some $\alpha_{n, 1} \in[0,1]$. In addition, using again the mean value theorem, we obtain

$$
\begin{aligned}
\frac{1}{n} \sum_{i=1}^{n}\left[\Psi\left(y_{i}, \mathbf{x}_{i}^{\mathrm{T}} \boldsymbol{\beta}_{n}^{*}\right)-\Psi\left(y_{i}, \mathbf{x}_{i}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right] \mathbf{x}_{i}^{\mathrm{T}} \mathbf{u}_{n}^{(0)} & =\frac{1}{n} \sum_{i=1}^{n} \chi\left(y_{i}, \mathbf{x}_{i}^{\mathrm{T}} \boldsymbol{\beta}_{n}^{* *}\right)\left(\boldsymbol{\beta}_{n}^{*}-\boldsymbol{\beta}_{0}\right)^{\mathrm{T}} \mathbf{x}_{i} \mathbf{x}_{i}^{\mathrm{T}} \mathbf{u}_{n}^{(0)} \\
& =\left(\boldsymbol{\beta}_{n}^{*}-\boldsymbol{\beta}_{0}\right)^{\mathrm{T}} \mathbf{A}_{n}\left(\boldsymbol{\beta}_{n}^{* *}\right) \mathbf{u}_{n}^{(0)},
\end{aligned}
$$

where $\mathbf{A}_{n}(\boldsymbol{\beta})$ and $\boldsymbol{\beta}_{n}^{* *}$ are defined as

$$
\mathbf{A}_{n}(\boldsymbol{\beta})=\frac{1}{n} \sum_{i=1}^{n} \chi\left(y_{i}, \mathbf{x}_{i}^{\mathrm{T}} \boldsymbol{\beta}\right) \mathbf{x}_{i} \mathbf{x}_{i}^{\mathrm{T}} \quad \text { and } \quad \boldsymbol{\beta}_{n}^{* *}=\binom{\boldsymbol{\beta}_{0, \mathrm{~A}}+\alpha_{n, 2} \frac{\mathbf{u}_{1}}{\ell_{n}}}{\alpha_{n, 2} \alpha_{n, 1} \frac{\mathbf{u}_{2}}{\ell_{n}}}
$$

with $\alpha_{n, 2} \in[0,1]$. Note that

$$
S_{1, n}(\mathbf{u})=\left\{\frac{1}{n} \sum_{i=1}^{n} \Psi\left(y_{i}, \mathbf{x}_{i}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right) \mathbf{x}_{i}^{\mathrm{T}}+\frac{1}{n} \sum_{i=1}^{n}\left[\Psi\left(y_{i}, \mathbf{x}_{i}^{\mathrm{T}} \boldsymbol{\beta}_{n}^{*}\right)-\Psi\left(y_{i}, \mathbf{x}_{i}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right)\right] \mathbf{x}_{i}^{\mathrm{T}}\right\} \mathbf{u}_{n}^{(0)},
$$

so $S_{1, n}(\mathbf{u})=S_{11, n}+S_{12, n}$ where

$$
\begin{aligned}
& S_{11, n}=\frac{1}{n} \sum_{i=1}^{n} \Psi\left(y_{i}, \mathbf{x}_{i}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right) \mathbf{x}_{i}^{\mathrm{T}} \mathbf{u}_{n}^{(0)}=\frac{1}{n} \frac{1}{\ell_{n}} \sum_{i=1}^{n} \Psi\left(y_{i}, \mathbf{x}_{i}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right) \mathbf{x}_{i}^{\mathrm{T}}\left(\mathbf{0}_{k}^{\mathrm{T}}, \mathbf{u}_{2}^{\mathrm{T}}\right)^{\mathrm{T}} \\
& S_{12, n}=\left(\boldsymbol{\beta}_{n}^{*}-\boldsymbol{\beta}_{0}\right)^{\mathrm{T}} \mathbf{A}_{n}\left(\boldsymbol{\beta}_{n}^{* *}\right) \mathbf{u}_{n}^{(0)}=\frac{1}{\ell_{n}^{2}}\left(\mathbf{u}_{1}^{\mathrm{T}}, \alpha_{n, 1} \mathbf{u}_{2}^{\mathrm{T}}\right) \mathbf{A}_{n}\left(\boldsymbol{\beta}_{n}^{* *}\right)\left(\mathbf{0}_{k}^{\mathrm{T}}, \mathbf{u}_{2}^{\mathrm{T}}\right)^{\mathrm{T}}
\end{aligned}
$$

Let us bound $S_{11, n}$. Using that $\mathbb{E}\left[\Psi\left(y, \mathbf{x}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right) \mathbf{x}\right]=0$ and Tchebychev's inequality, we get that

$$
\sqrt{\frac{1}{n \iota_{p}(\mathbf{B})}} \sum_{i=1}^{n} \Psi\left(y_{i}, \mathbf{x}_{i}^{\mathrm{T}} \boldsymbol{\beta}_{0}\right) \mathbf{x}_{i}^{\mathrm{T}}\left(\mathbf{0}_{k}^{\mathrm{T}}, \frac{\mathbf{u}_{2}^{\mathrm{T}}}{\left\|\mathbf{u}_{2}\right\|_{2}}\right)^{\mathrm{T}}=O_{\mathbb{P}}(1)
$$

where the matrix $\mathbf{B}$ is defined in (14). Hence,

$$
\begin{equation*}
S_{11, n}=\frac{\sqrt{\iota_{p}(\mathbf{B})}}{\ell_{n} \sqrt{n}}\left\|\mathbf{u}_{2}\right\|_{2} O_{\mathbb{P}}(1) \tag{A.15}
\end{equation*}
$$

On the other hand, using that $\chi$ is bounded and applying the Markov's inequality, we obtain

$$
\begin{equation*}
S_{12, n}=\frac{C \iota_{p}(\mathbf{H})}{\ell_{n}^{2}}\left\|\mathbf{u}_{2}\right\|_{2} O_{\mathbb{P}}(1) \tag{A.16}
\end{equation*}
$$

Thus, from (A.15) and (A.16) we conclude that $S_{1, n}(\mathbf{u})=C\left(c_{n} / \ell_{n}\right)\left\|\mathbf{u}_{2}\right\|_{2} O_{\mathbb{P}}(1)$.
Let $M_{C}>0$ be such that $\mathbb{P}\left(\left|S_{1, n}\right|>M_{C}\left(c_{n} / \ell_{n}\right)\left\|\mathbf{u}_{2}\right\|_{2}\right)<\tau / 2$. Hence,

$$
\mathbb{P}\left(S_{1, n}(\mathbf{u})>-M_{C}\left(c_{n} / \ell_{n}\right)\left\|\mathbf{u}_{2}\right\|_{2}\right) \geq 1-\tau / 2
$$

Using (15), we obtain that there exist constants $N_{C}$ and $K_{C}$ such that for any $n \geq N_{C}$, we have that $S_{2, n}(\mathbf{u}) \geq K_{C}\left(\lambda_{n} / \ell_{n}\right)\left\|\mathbf{u}_{2}\right\|_{2}$. Therefore, for any $n \geq N_{C}$,

$$
\mathbb{P}\left(S_{1, n}(\mathbf{u})+S_{2, n}(\mathbf{u}) \geq\left\|\mathbf{u}_{2}\right\|_{2} \frac{c_{n}}{\ell_{n}}\left(K_{C} \lambda_{n} c_{n}^{-1}-M_{C}\right)\right) \geq 1-\frac{\tau}{2}
$$

Taking into account that $\lambda_{n} c_{n}^{-1} \rightarrow \infty$, we obtain that there exists $n_{1}>N_{C}$ such that $K_{C} \lambda_{n} c_{n}^{-1}-M_{C}>1$ for all $n \geq n_{1}$. Hence, for any $n \geq n_{1}$ and for all $\left\|\mathbf{u}_{1}\right\|_{2}^{2}+\left\|\mathbf{u}_{2}\right\|_{2}^{2} \leq C^{2}$ such that $\mathbf{u}_{2} \neq \mathbf{0}_{p-k}$, we have that $\mathbb{P}\left(V_{n}\left(\mathbf{u}_{1}, \mathbf{u}_{2}\right)>V_{n}\left(\mathbf{u}_{1}, \mathbf{0}_{p-k}\right)\right)>1-\tau / 2$, which together with the fact that $\mathbb{P}\left(\mathcal{B}_{n}\right) \geq 1-\tau / 2$, leads to $\mathbb{P}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{NA}}=\mathbf{0}_{p-k}\right) \geq 1-\tau$ for each $n \geq n_{1}$, concluding the proof.

Proof of Corollary 4.2, It is enough to show that condition (15) holds. Note that, for the SCAD penalization,

$$
I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}+\frac{\mathbf{u}_{1}}{\ell_{n}}, \frac{\mathbf{u}_{2}}{\ell_{n}}\right)-I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}+\frac{\mathbf{u}_{1}}{\ell_{n}}, \mathbf{0}_{p-k}\right)=\sum_{j=1}^{p-k} \operatorname{SCAD}_{\lambda_{n}, a}\left(\frac{\left|u_{2, j}\right|}{\ell_{n}}\right),
$$

where $u_{2, j}$ is the $j$-th component of $\mathbf{u}_{2}$ and $\operatorname{SCAD}_{\lambda_{n}, a}$ is defined in (3)).
Using that $\lambda_{n} \ell_{n} \rightarrow \infty$, we get that there exists $N_{C} \in \mathbb{N}$ such that, for any $n \geq N_{C}$, we have that $\lambda_{n} \ell_{n}>C \geq u_{2, j}$ for $j=1, \ldots, p-k$. Thus, taking into account that $\sum_{j=1}^{p-k} u_{j}^{2} \leq\left(\sum_{j=1}^{p-k}\left|u_{j}\right|\right)^{2}$, we have that, if $n \geq N_{C}$,

$$
I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}+\frac{\mathbf{u}_{1}}{\ell_{n}}, \frac{\mathbf{u}_{2}}{\ell_{n}}\right)-I_{\lambda_{n}}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}+\frac{\mathbf{u}_{1}}{\ell_{n}}, \mathbf{o}_{p-k}\right)=\sum_{j=1}^{p-k} \frac{\lambda_{n}}{\ell_{n}}\left|u_{2, j}\right| \geq \frac{\lambda_{n}}{\ell_{n}}\left\|\mathbf{u}_{2}\right\|_{2}
$$

so condition (15) holds with $K_{C}=1$. The proof for the MCP penalty is completely analogous, using the function $\mathrm{MCP}_{\lambda_{n}, a}$ defined in (44).

Proof of Corollary 4.3. We will show that given $\delta>0$ there exist some $C>0$ and $n_{0} \in \mathbb{N}$ such that, for any $n \geq n_{0}, \mathbb{P}\left(\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}<C \sqrt{k / n}\right)>1-\delta$. Let $\mathcal{A}_{n}=\left\{\widehat{\boldsymbol{\beta}}_{n, \mathrm{NA}}=\mathbf{0}_{p-k}\right\}$. Using that $\mathbb{P}\left(\mathcal{A}_{n}\right) \rightarrow 1$, we get that there exists $n_{0} \in \mathbb{N}$ such that $\mathbb{P}\left(\mathcal{A}_{n}\right)>1-\delta / 2$ for all $n \geq n_{0}$. In addition, the fact that $\left\|\widehat{\mathbf{b}}_{k}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right\|_{2}=O_{\mathbb{P}}(\sqrt{k / n})$, entails that there exists $C>0$ such that $\mathbb{P}\left(\mathcal{C}_{n}\right)>1-\delta / 2$, where $\mathcal{C}_{n}=\left\{\left\|\widehat{\mathbf{b}}_{k}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right\|_{2}<C \sqrt{k / n}\right\}$. Thus, for any $n \geq n_{0}, \mathbb{P}\left(\mathcal{A}_{n} \cap \mathcal{C}_{n}\right)>1-\delta$.
Using assumption P3, it is easy to show that, for any $\omega \in \mathcal{A}_{n}$, we have that $\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}=\widehat{\mathbf{b}}_{k}$. Hence, in $\mathcal{A}_{n} \cap \mathcal{C}_{n},\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}=\left\|\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right\|_{2}=\left\|\widehat{\mathbf{b}}_{k}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right\| \leq C \sqrt{k / n}$, which concludes the proof.

To prove Theorem 4.4 we will need the following two lemmas. The first one is a direct extension of Hölder's inequality to the case of the product of three random variables. We include its proof for the sake of completeness. The second result is analogous to Lemma A. 1 , but now the family of functions is indexed over a compact set in $\mathbb{R}^{3 k}$.

Lemma A.4. Let $p, q$ and $r$ be real positive values such that $(1 / p)+(1 / q)+(1 / r)=1$. Let $U, V$ and $W$ be random variables that satisfy $\mathbb{E}|U|^{p}<\infty, \mathbb{E}|V|^{q}<\infty$ and $\mathbb{E}|W|^{r}<\infty$. Then,

$$
\mathbb{E}|U V W| \leq\left(\mathbb{E}|U|^{p}\right)^{1 / p}\left(\mathbb{E}|V|^{q}\right)^{1 / q}\left(\mathbb{E}|W|^{r}\right)^{1 / r}
$$

Proof. Define $1 / p^{\star}=(1 / p)+(1 / q)$. Thus, $\left(1 / p^{\star}\right)+(1 / r)=1$. Using Hölder's inequality, we get

$$
\begin{equation*}
\mathbb{E}|U V W| \leq\left(\mathbb{E}|U V|^{p^{\star}}\right)^{1 / p^{\star}}\left(\mathbb{E}|W|^{r}\right)^{1 / r} \tag{A.17}
\end{equation*}
$$

If $p_{1}=p / p^{\star}$ and $q_{1}=q / p^{\star}$, then $\left(1 / p_{1}\right)+\left(1 / q_{1}\right)=1$. Hence, applying again Hölder's inequality to the random variables $U_{1}=|U|^{p^{\star}}$ and $V_{1}=|V|^{p^{\star}}$, we obtain

$$
\begin{equation*}
\mathbb{E}|U V|^{p^{\star}}=\mathbb{E}\left|U_{1} V_{1}\right| \leq\left(\mathbb{E}\left|U_{1}\right|^{p_{1}}\right)^{1 / p_{1}}\left(\mathbb{E}\left|V_{1}\right|^{q_{1}}\right)^{1 / q_{1}}=\left(\mathbb{E}|U|^{p}\right)^{\frac{p^{\star}}{p}}\left(\mathbb{E}|V|^{q}\right)^{\frac{p^{\star}}{q}} . \tag{A.18}
\end{equation*}
$$

The result follows now from (A.17) and (A.18).

Recall that $\mathcal{B}_{k}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}\right)$ stands for the unit ball in $\mathbb{R}^{k}$ (with respect to the usual $\|\cdot\|_{2}$ norm) centred at $\boldsymbol{\beta}_{0, \mathrm{~A}}$ and denote as $\mathcal{S}^{k-1}=\left\{\mathbf{b} \in \mathbb{R}^{k}:\|\mathbf{b}\|_{2}=1\right\}$ the unit sphere centred in $\mathbf{0}_{k}$. To avoid the use of heavy notation, the vectors $\mathbf{b}_{k}, \mathbf{v}_{k}, \mathbf{w}_{k} \in \mathbb{R}^{k}$ will be denoted as $\mathbf{b}, \mathbf{v}$ and $\mathbf{w}$, respectively.

Lemma A.5. Let $h_{\mathbf{w}, \mathbf{b}, \mathbf{u}}:\{0,1\} \times \mathbb{R}^{k} \rightarrow \mathbb{R}$ be defined as $h_{\mathbf{w}, \mathbf{b}, \mathbf{u}}(y, \mathbf{z})=\chi\left(y, \mathbf{z}^{\mathrm{T}} \mathbf{b}\right) \mathbf{w}^{\mathrm{T}} \mathbf{z z}^{\mathrm{T}} \mathbf{u}$ and consider the family of functions

$$
\begin{equation*}
\mathcal{H}=\left\{h_{\mathbf{w}, \mathbf{b}, \mathbf{u}}, \quad \mathbf{b} \in \mathcal{B}_{k}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}\right), \mathbf{w}, \mathbf{u} \in \mathcal{S}^{k-1}\right\} . \tag{A.19}
\end{equation*}
$$

Then, under $\boldsymbol{R 5}$ and Z6, there exists a constant $C$ independent of $n$ and $p$ such that

$$
\mathbb{E}\left[\sup _{h \in \mathcal{H}}\left|\left(P_{n}-P\right)(h)\right|\right] \leq C \sqrt{\frac{k}{n}} .
$$

Proof. Note that a natural envelope for the class $\mathcal{H}$ is $H(\mathbf{z})=\|\chi\|_{\infty}\|\mathbf{z}\|_{2}^{2}$ and $\|H\|_{2, P}=\left[\mathbb{E} H^{2}\left(\mathbf{x}_{\mathrm{A}}\right)\right]^{1 / 2} \leq$ $\|\chi\|_{\infty}\left[\mathbb{E}\left\|\mathbf{x}_{\mathrm{A}}\right\|_{2}^{4}\right]^{1 / 2} \leq\|\chi\|_{\infty}\left[\mathbb{E}\left\|\mathbf{x}_{\mathrm{A}}\right\|_{2}^{6}\right]^{1 / 3} \leq\|\chi\|_{\infty} K_{3}^{1 / 3}<\infty$ where $K_{3}$ is the constant given in assumption Z6 which does not depend on $n$.

As it is well known, $N\left(\varepsilon / 2, \mathcal{H},\|\cdot\|_{r, \mathbb{Q}}\right) \leq N_{[]}\left(\varepsilon, \mathcal{H},\|\cdot\|_{r, Q}\right)$ for any probability measure $\mathbb{Q}$ and $r \geq$ 1. To apply Theorem 2.14 .1 in van der Vaart and Wellner (2012) it will be enough to give a proper bound for the bracketing number $N_{[]}\left(\varepsilon, \mathcal{H},\|\cdot\|_{r, \mathbb{Q}}\right)$ which will be handle through Theorem 2.7.11 in van der Vaart and Wellner (2012).

Let us show that the family $\mathcal{H}$ is Lipschitz with respect to the parameters indexing it. Let $\mathbf{w}_{1}, \mathbf{w}_{2}, \mathbf{u}_{1}, \mathbf{u}_{2} \in$ $\mathcal{S}^{k-1}$ and $\mathbf{b}_{1}, \mathbf{b}_{2} \in \mathcal{B}_{k}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}\right)$. To simplify the notation, we denote $\boldsymbol{\theta}_{j}=\left(\mathbf{w}_{j}^{\mathrm{T}}, \mathbf{b}_{j}^{\mathrm{T}}, \mathbf{u}_{j}^{\mathrm{T}}\right), j=1,2$, and $h_{\boldsymbol{\theta}_{j}}=h_{\mathbf{w}_{j}, \mathbf{b}_{j}, \mathbf{u}_{j}}$. Moreover, let $d\left(\boldsymbol{\theta}_{1}, \boldsymbol{\theta}_{2}\right)=\left\|\boldsymbol{\theta}_{1}-\boldsymbol{\theta}_{2}\right\|_{2}$ be the Euclidean distance in $\mathbb{R}^{3 k}$, i.e., $d^{2}\left(\boldsymbol{\theta}_{1}, \boldsymbol{\theta}_{2}\right)=\left\|\mathbf{w}_{1}-\mathbf{w}_{2}\right\|_{2}^{2}+\left\|\mathbf{b}_{1}-\mathbf{b}_{2}\right\|_{2}^{2}+\left\|\mathbf{u}_{1}-\mathbf{u}_{2}\right\|_{2}^{2}$ and denote as $\chi_{1}(y, s)=(\partial / \partial s) \chi(y, s)$. Assumption R5 entails that $\chi_{1}$ is bounded. Hence, using that

$$
\begin{aligned}
\left|h_{\boldsymbol{\theta}_{1}}(y, \mathbf{z})-h_{\boldsymbol{\theta}_{2}}(y, \mathbf{z})\right| \leq & \left|h_{\boldsymbol{\theta}_{1}}(y, \mathbf{z})-h_{\mathbf{w}_{1}, \mathbf{b}_{1}, \mathbf{u}_{2}}(y, \mathbf{z})\right|+\left|h_{\mathbf{w}_{1}, \mathbf{b}_{1}, \mathbf{u}_{2}}(y, \mathbf{z})-h_{\mathbf{w}_{1}, \mathbf{b}_{2}, \mathbf{u}_{2}}(y, \mathbf{z})\right| \\
& +\left|h_{\mathbf{w}_{1}, \mathbf{b}_{2}, \mathbf{u}_{2}}(y, \mathbf{z})-h_{\boldsymbol{\theta}_{2}}(y, \mathbf{z})\right|,
\end{aligned}
$$

the mean value theorem and the Cauchy-Schwartz's inequality, we obtain

$$
\begin{aligned}
\left|h_{\boldsymbol{\theta}_{1}}(y, \mathbf{z})-h_{\boldsymbol{\theta}_{2}}(y, \mathbf{z})\right| & \leq\|\chi\|_{\infty}\|\mathbf{z}\|_{2}^{2}\left(\left\|\mathbf{u}_{1}-\mathbf{u}_{2}\right\|_{2}+\left\|\mathbf{w}_{1}-\mathbf{w}_{2}\right\|_{2}\right)+\left\|\chi_{1}\right\|_{\infty}\|\mathbf{z}\|_{2}^{3}\left\|\mathbf{b}_{1}-\mathbf{b}_{2}\right\|_{2} \\
& \leq\left(2\|\chi\|_{\infty}\|\mathbf{z}\|_{2}^{2}+\left\|\chi_{1}\right\|_{\infty}\|\mathbf{z}\|_{2}^{3}\right)\left\|\boldsymbol{\theta}_{1}-\boldsymbol{\theta}_{2}\right\|_{2},
\end{aligned}
$$

which implies that $\left|h_{\boldsymbol{\theta}_{1}}(y, \mathbf{z})-h_{\boldsymbol{\theta}_{2}}(y, \mathbf{z})\right| \leq H_{1}(\mathbf{z}) d\left(\boldsymbol{\theta}_{1}, \boldsymbol{\theta}_{2}\right)$, with $H_{1}(\mathbf{z})=\left(2\|\chi\|_{\infty}+\left\|\chi_{1}\right\|_{\infty}\right)\left(\|\mathbf{z}\|_{2}^{2}+\|\mathbf{z}\|_{2}^{3}\right)$. If we denote as $\mathcal{V}=\mathcal{S}^{k-1} \times \mathcal{B}_{k}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}\right) \times \mathcal{S}^{k-1}$, Theorem 2.7.11 from van der Vaart and Wellner (2012) allows to conlcude that, for any probability measure $\mathbb{Q}$ and $r \geq 1$ such that $\left\|H_{1}\right\|_{r, \mathbb{Q}}<\infty$,

$$
N\left(\varepsilon\left\|H_{1}\right\|_{r, \mathbb{Q}}, \mathcal{H},\|\cdot\|_{r, \mathbb{Q}}\right) \leq N_{[]}\left(2 \varepsilon\left\|H_{1}\right\|_{r, \mathbb{Q}}, \mathcal{H},\|\cdot\|_{r, \mathbb{Q}}\right) \leq N(\varepsilon, \mathcal{V}, d) .
$$

Note that $\mathcal{V}=\mathcal{S}^{k-1} \times \mathcal{B}_{k}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}\right) \times \mathcal{S}^{k-1} \subset \mathcal{B}_{3 k}\left(\boldsymbol{\theta}_{0}, 3\right)$ where $\boldsymbol{\theta}_{0}=\left(\mathbf{0}_{k}^{\mathrm{T}}, \boldsymbol{\beta}_{0, \mathrm{~A}}^{\mathrm{T}}, \mathbf{0}_{k}^{\mathrm{T}}\right)^{\mathrm{T}}$ and $\mathcal{B}_{3 k}(\boldsymbol{\theta}, \delta)$ is the ball in $\mathbb{R}^{3 k}$ with center $\boldsymbol{\theta}$ and radius $\delta$, as defined above. Hence, Lemma 2.5 from van de Geer (2000) implies that

$$
\begin{equation*}
N(\varepsilon, \mathcal{V}, d) \leq N\left(\varepsilon, \mathcal{B}_{3 k}\left(\boldsymbol{\theta}_{0}, 3\right), d\right) \leq\left(\frac{12+\varepsilon}{\varepsilon}\right)^{3 k} \tag{A.20}
\end{equation*}
$$

On the other hand, since $H(\mathbf{z}) \leq H_{1}(\mathbf{z}), H_{1}$ is also an envelope of the function class $\mathcal{H}$ and will be used in the rest of the proof. Moreover, if $g\left(\mathbf{x}_{\mathrm{A}}\right)=\left\|\mathbf{x}_{\mathrm{A}}\right\|_{2}^{2}+\left\|\mathbf{x}_{\mathrm{A}}\right\|_{2}^{3}$

$$
\left\|H_{1}\right\|_{2, P}=\left[\mathbb{E} H_{1}^{2}\left(\mathbf{x}_{\mathrm{A}}\right)\right]^{1 / 2} \leq\left(2\|\chi\|_{\infty}+\left\|\chi_{1}\right\|_{\infty}\right)\|g\|_{2, P} \leq A
$$

with $A=\left(2\|\chi\|_{\infty}+\left\|\chi_{1}\right\|_{\infty}\right)\left(K_{3}^{1 / 3}+K_{3}^{1 / 2}\right)$. Hence, from Theorem 2.14.1 from van der Vaart and Wellner (2012) we have that there exists a constant $M>0$ that does not depend on $n$ such that

$$
\begin{equation*}
\mathbb{E}\left[\sqrt{n} \sup _{h \in \mathcal{H}}\left|\left(P_{n}-P\right)(h)\right|\right] \leq M\left\|H_{1}\right\|_{2, P} J(1, \mathcal{H}) \leq M A J(1, \mathcal{H}) \tag{A.21}
\end{equation*}
$$

where $J(\delta, \mathcal{H})=\sup _{\mathbb{Q}} \int_{0}^{\delta} \sqrt{1+\log N\left(\epsilon\left\|H_{1}\right\|_{2, \mathbb{Q}}, \mathcal{H},\|\cdot\|_{2, \mathbb{Q}}\right)} d \epsilon$ with $\mathbb{Q}$ any discrete probability measure with $\left\|H_{1}\right\|_{2, \mathbb{Q}}>0$. Let $B=\sqrt{3}(1+\log (13))^{1 / 2}$. Using (A.20), we get that

$$
J(\delta, \mathcal{H}) \leq \int_{0}^{\delta} \sqrt{1+3 k \log \left(\frac{12+\varepsilon}{\varepsilon}\right)} d \epsilon \leq B \sqrt{k} \int_{0}^{1} \sqrt{1-\log (\varepsilon)} d \varepsilon
$$

where $\int_{0}^{1} \sqrt{1-\log (\varepsilon)} d \varepsilon<\infty$. Hence, the desired result follows from (A.21).

Proof of Theorem 4.4. Recall that $m_{0, n}=\min \left\{\left|\beta_{0, j}\right|: \beta_{0, j} \neq 0\right\}$ and let $\widehat{\boldsymbol{\beta}}_{n}=\left(\widehat{\beta}_{n, 1}, \ldots, \widehat{\beta}_{n, p}\right)$. First, note that

$$
\mathbb{P}\left(\widehat{\beta}_{n, j}=0 \text { for some } 1 \leq j \leq k\right) \leq \mathbb{P}\left(\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}>m_{0, n}\right)=\mathbb{P}\left(\sqrt{\frac{n}{k}}\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}>\sqrt{\frac{n}{k}} m_{0, n}\right)
$$

Let $\mathcal{A}_{n}=\left\{\widehat{\beta}_{n, j} \neq 0\right.$ for all $\left.1 \leq j \leq k\right\}$ and $\mathcal{B}_{n}=\left\{\widehat{\boldsymbol{\beta}}_{n, \mathrm{NA}}=\mathbf{0}_{p-k}\right\}$. Using that $\sqrt{n / k}\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}=O_{\mathbb{P}}(1)$ and assumption N1, we obtain that $\mathbb{P}\left(\mathcal{A}_{n}^{c}\right)=\mathbb{P}\left(\widehat{\beta}_{n, j}=0\right.$ for some $\left.1 \leq j \leq k\right) \rightarrow 0$. On the other hand, as $\mathbb{P}\left(\mathcal{B}_{n}\right)=\mathbb{P}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{NA}}=\mathbf{0}_{p-k}\right) \rightarrow 1$, we get that $\mathbb{P}\left(\mathcal{B}_{n} \cap \mathcal{A}_{n}\right) \rightarrow 1$ and for any $\omega \in \mathcal{B}_{n} \cap \mathcal{A}_{n}$, every component of $\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}$ is different from zero. Then, using that $\widehat{\boldsymbol{\beta}}_{n}=\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}^{\mathrm{T}}, \mathbf{0}_{p-k}^{\mathrm{T}}\right)^{\mathrm{T}}$ is the minimizer of $L_{n}(\boldsymbol{\beta})+I_{\lambda_{n}}(\boldsymbol{\beta}), \widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}$ minimizes $L_{n}\left(\mathbf{b}, \mathbf{0}_{p-k}\right)+I_{\lambda_{n}}\left(\mathbf{b}, \mathbf{0}_{p-k}\right)$ over $\mathbf{b} \in \mathbb{R}^{k}$, where we used for $L_{n}$ the same notation introduced in Section 4 for $I_{\lambda}$. Therefore, we get that

$$
\mathbf{0}_{k}=\nabla\left(\frac{1}{n} \sum_{i=1}^{n} \phi\left(y_{i}, \mathbf{x}_{i, \mathrm{~A}}^{\mathrm{T}} \widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}\right)\right)+\nabla\left(I_{\lambda_{n}}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}\right)\right)+\mathbf{r}_{n}
$$

where $\mathbb{P}\left(\mathbf{r}_{n}=0\right) \rightarrow 1$, which entails that for any $\mathbf{v} \in \mathbb{R}^{k}$ with $\|\mathbf{v}\|_{2}=1$, we have

$$
0=\frac{1}{n} \sum_{i=1}^{n} \Psi\left(y_{i}, \mathbf{x}_{i, \mathrm{~A}}^{\mathrm{T}} \widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}\right) \mathbf{v}^{\mathrm{T}} \mathbf{x}_{i, \mathrm{~A}}+\mathbf{v}^{\mathrm{T}} \nabla I_{\lambda_{n}}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}\right)+\mathbf{v}^{\mathrm{T}} \mathbf{r}_{n} .
$$

Given $\mathbf{b} \in \mathbb{R}^{k}$, define

$$
\mathbf{A}_{n, \mathrm{~A}}(\mathbf{b})=\frac{1}{n} \sum_{i=1}^{n} \chi\left(y_{i}, \mathbf{x}_{i, \mathrm{~A}}^{\mathrm{T}} \mathbf{b}\right) \mathbf{x}_{i, \mathrm{~A}} \mathbf{x}_{i, \mathrm{~A}}^{\mathrm{T}},
$$

and denote

$$
M_{n}(\theta)=\frac{1}{n} \sum_{i=1}^{n} \Psi\left(y_{i}, \mathbf{x}_{i, \mathrm{~A}}^{\mathrm{T}}\left[\theta \widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}+(1-\theta) \boldsymbol{\beta}_{0, \mathrm{~A}}\right]\right) \mathbf{v}^{\mathrm{T}} \mathbf{x}_{i, \mathrm{~A}} .
$$

Using the mean value theorem, we have that $M_{n}(1)=M_{n}(0)+M_{n}^{\prime}(\alpha)$ for some $\alpha \in[0,1]$. Hence,

$$
\begin{align*}
0 & =\frac{1}{n} \sum_{i=1}^{n} \Psi\left(y_{i}, \mathbf{x}_{i, \mathrm{~A}}^{\mathrm{T}} \boldsymbol{\beta}_{0, \mathrm{~A}}\right) \mathbf{v}^{\mathrm{T}} \mathbf{x}_{i, \mathrm{~A}}+\frac{1}{n} \sum_{i=1}^{n} \chi\left(y_{i}, \mathbf{x}_{i, \mathrm{~A}}^{\mathrm{T}} \boldsymbol{\beta}_{\mathrm{A}}^{*}\right) \mathbf{v}^{\mathrm{T}} \mathbf{x}_{i, \mathrm{~A}} \mathbf{x}_{i, \mathrm{~A}}^{\mathrm{T}}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right)+\mathbf{v}^{\mathrm{T}} \nabla I_{\lambda_{n}}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}\right)+\mathbf{v}^{\mathrm{T}} \mathbf{r}_{n} \\
& =\frac{1}{n} \sum_{i=1}^{n} \Psi\left(y_{i}, \mathbf{x}_{i, \mathrm{~A}}^{\mathrm{T}} \boldsymbol{\beta}_{0, \mathrm{~A}}\right) \mathbf{v}^{\mathrm{T}} \mathbf{x}_{i, \mathrm{~A}}+\mathbf{v}^{\mathrm{T}} \mathbf{A}_{n, \mathrm{~A}}\left(\boldsymbol{\beta}_{\mathrm{A}}^{*}\right)\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right)+\mathbf{v}^{\mathrm{T}} \nabla I_{\lambda_{n}}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}\right)+\mathbf{v}^{\mathrm{T}} \mathbf{r}_{n}, \tag{A.22}
\end{align*}
$$

where $\boldsymbol{\beta}_{\mathrm{A}}^{*}=\alpha \widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}+(1-\alpha) \boldsymbol{\beta}_{0, \mathrm{~A}}$ for some $\alpha \in[0,1]$. Observe that $\sqrt{n} t_{n}^{-1} \mathbf{v}^{\mathrm{T}} \mathbf{A}_{\mathrm{A}}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right)=$ $S_{1, n}+S_{2, n}+S_{3, n}$ where, to make the dependence on $n$ explicit, we wrote $t_{n}$ instead of $t=\left(\mathbf{v}^{\mathrm{T}} \mathbf{B}_{\mathrm{A}}^{(k)} \mathbf{v}\right)^{1 / 2}$, and $S_{1, n}=\sqrt{n} t_{n}^{-1} \mathbf{v}^{\mathrm{T}}\left(\mathbf{A}_{\mathrm{A}}-\mathbf{A}_{\mathrm{A}}\left(\boldsymbol{\beta}_{\mathrm{A}}^{*}\right)\right)\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right), S_{2, n}=\sqrt{n} t_{n}^{-1} \mathbf{v}^{\mathrm{T}}\left(\mathbf{A}_{\mathrm{A}}\left(\boldsymbol{\beta}_{\mathrm{A}}^{*}\right)-\mathbf{A}_{n, \mathrm{~A}}\left(\boldsymbol{\beta}_{\mathrm{A}}^{*}\right)\right)\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right)$ and $S_{3, n}=\sqrt{n} t_{n}^{-1} \mathbf{v}^{\mathrm{T}} \mathbf{A}_{n, \mathrm{~A}}\left(\boldsymbol{\beta}_{\mathrm{A}}^{*}\right)\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right)$. We will show that

$$
\begin{array}{lll}
S_{1, n} & \xrightarrow{p} 0, \\
S_{2, n} & \xrightarrow{p} & 0, \\
S_{3, n} & \xrightarrow{D} & N(0,1) . \tag{A.25}
\end{array}
$$

We will start by proving (A.23). Given positive real numbers $\varepsilon, \delta>0$ we need to show that $\mathbb{P}\left(\left|S_{1, n}\right|<\right.$ $\varepsilon)>1-\delta$ for $n$ large enough. The fact that $\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}=O_{\mathbb{P}}(\sqrt{k / n})$ implies that, for any $\delta>0$, there exists $C_{1}>0$ such that $\mathbb{P}\left(\mathcal{D}_{n}\right)>1-\delta / 4$ for all $n$, where

$$
\begin{equation*}
\mathcal{D}_{n}=\left\{\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2} \leq C_{1} \sqrt{k / n}\right\} . \tag{A.26}
\end{equation*}
$$

Note that from R5, $\chi_{1}(y, s)=(\partial / \partial s) \chi(y, s)$ is bounded. Then,

$$
\begin{aligned}
\left|S_{1, n}\right| & =\left|\sqrt{n} t_{n}^{-1} \mathbf{v}^{\mathrm{T}} \mathbb{E}\left[\left(\chi\left(y, \mathbf{x}_{\mathrm{A}}^{\mathrm{T}} \boldsymbol{\beta}_{0, \mathrm{~A}}\right)-\chi\left(y, \mathbf{x}_{\mathrm{A}}^{\mathrm{T}} \boldsymbol{\beta}_{\mathrm{A}}^{*}\right)\right) \mathbf{x}_{\mathrm{A}} \mathbf{x}_{\mathrm{A}}^{\mathrm{T}}\right]\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right)\right| \\
& \leq \sqrt{n} t_{n}^{-1} \mathbb{E}\left|\chi_{1}\left(y, \mathbf{x}_{\mathrm{A}}^{\mathrm{T}} \boldsymbol{\beta}_{\mathrm{A}}^{* *}\right) \mathbf{x}_{\mathrm{A}}^{\mathrm{T}}\left(\boldsymbol{\beta}_{0, \mathrm{~A}}-\boldsymbol{\beta}_{\mathrm{A}}^{*}\right) \mathbf{v}^{\mathrm{T}} \mathbf{x}_{\mathrm{A}} \mathbf{x}_{\mathrm{A}}^{\mathrm{T}}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right)\right|
\end{aligned}
$$

where $\boldsymbol{\beta}_{\mathrm{A}}^{* *}=\alpha_{1} \boldsymbol{\beta}_{\mathrm{A}}^{*}+\left(1-\alpha_{1}\right) \boldsymbol{\beta}_{0, \mathrm{~A}}$ for some $\alpha_{1} \in[0,1]$ and the expected value in the last equality is taken only with respect to $y$ and $\mathbf{x}_{\mathrm{A}}$. Hence, using the fact that $\chi_{1}$ is bounded and applying Lemma A. 4 to the random variables $U=\left(\boldsymbol{\beta}_{0, \mathrm{~A}}-\boldsymbol{\beta}_{\mathrm{A}}^{*}\right)^{\mathrm{T}} \mathbf{x}_{\mathrm{A}}, V=\mathbf{v}^{\mathrm{T}} \mathbf{x}_{\mathrm{A}}$ and $W=\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right)^{\mathrm{T}} \mathbf{x}_{\mathrm{A}}$ (taking $p=q=r=3$ ), we obtain

$$
\begin{aligned}
\left|S_{1, n}\right| & \leq\left\|\chi_{1}\right\|_{\infty} \sqrt{n} t_{n}^{-1} \mathbb{E}\left|\left(\boldsymbol{\beta}_{0, \mathrm{~A}}-\boldsymbol{\beta}_{\mathrm{A}}^{*}\right)^{\mathrm{T}} \mathbf{x}_{\mathrm{A}} \mathbf{v}^{\mathrm{T}} \mathbf{x}_{\mathrm{A}}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right)^{\mathrm{T}} \mathbf{x}_{\mathrm{A}}\right| \\
& \leq\left\|\chi_{1}\right\|_{\infty} \sqrt{n} t_{n}^{-1} \mathbb{E}\left[\left|\left(\boldsymbol{\beta}_{0, \mathrm{~A}}-\boldsymbol{\beta}_{\mathrm{A}}^{*}\right)^{\mathrm{T}} \mathbf{x}_{\mathrm{A}}\right|^{3}\right]^{1 / 3} \mathbb{E}\left[\left|\mathbf{v}^{\mathrm{T}} \mathbf{x}_{\mathrm{A}}\right|^{3}\right]^{1 / 3} \mathbb{E}\left[\left|\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right)^{\mathrm{T}} \mathbf{x}_{\mathrm{A}}\right|^{3}\right]^{1 / 3} \\
& \leq\left\|\chi_{1}\right\|_{\infty} \sqrt{n} t_{n}^{-1} \mathbb{E}\left[\left\|\mathbf{x}_{\mathrm{A}}\right\|_{2}^{3}\right]\left\|\boldsymbol{\beta}_{0, \mathrm{~A}}-\boldsymbol{\beta}_{\mathrm{A}}^{*}\right\|_{2}\left\|\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right\|_{2},
\end{aligned}
$$

where, in the last inequality, we used Cauchy-Schwartz's inequality and the fact that $\|\mathbf{v}\|_{2}=1$. Therefore, for any $\omega \in \mathcal{D}_{n}$, we have that

$$
\left|S_{1, n}\right| \leq t_{n}^{-1}\left\|\chi_{1}\right\|_{\infty} C_{1}^{2} \mathbb{E}\left[\left\|\mathbf{x}_{\mathrm{A}}\right\|_{2}^{3}\right] \frac{k}{\sqrt{n}} \leq\left\|\chi_{1}\right\|_{\infty} C_{1}^{2} K_{3}^{1 / 2} t_{n}^{-1} \frac{k}{\sqrt{n}}
$$

where $K_{3}$ is the constant given in assumption Z6. Noticing that Z7 entails that $t_{n}=\mathbf{v}^{\mathrm{T}} \mathbf{B}_{\mathrm{A}}^{(k)} \mathbf{v} \geq$ $\iota_{1}\left(\mathbf{B}_{\mathrm{A}}^{(k)}\right) \geq \tau_{2}$, we conclude that $\left|S_{1, n}\right| \leq\left\|\chi_{1}\right\|_{\infty} C_{1}^{2} K_{3}^{1 / 2} \tau_{2}^{-1} k / \sqrt{n}$. Finally, using that $k^{2} / n \rightarrow 0$, we get that there exists $n_{0} \in \mathbb{N}$ such that for any $n \geq n_{0}, \mathcal{D}_{n} \subset\left\{\left\|S_{1, n}\right\| \leq \varepsilon\right\}$, which concludes the proof of (A.23).
We will now show that $S_{2, n} \xrightarrow{p} 0$. Define $\mathbf{u}_{n}=\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right) /\left\|\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right\|_{2}$ and note that

$$
\begin{aligned}
S_{2, n} & =\sqrt{n} t_{n}^{-1}\left\|\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right\|_{2}\left\{\mathbb{E}\left[\chi\left(y, \mathbf{x}_{\mathrm{A}}^{\mathrm{T}} \boldsymbol{\beta}_{\mathrm{A}}^{*}\right) \mathbf{v}^{\mathrm{T}} \mathbf{x}_{\mathrm{A}} \mathbf{x}_{\mathrm{A}}^{\mathrm{T}} \mathbf{u}_{n}\right]-\frac{1}{n} \sum_{i=1}^{n} \chi\left(y_{i}, \mathbf{x}_{i, \mathrm{~A}}^{\mathrm{T}} \boldsymbol{\beta}_{\mathrm{A}}^{*}\right) \mathbf{v}^{\mathrm{T}} \mathbf{x}_{i, \mathrm{~A}} \mathbf{x}_{i, \mathrm{~A}}^{\mathrm{T}} \mathbf{u}_{n}\right\} \\
& =\sqrt{n} t_{n}^{-1}\left\|\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right\|_{2}\left(P-P_{n}\right)\left(h_{\mathbf{v}, \boldsymbol{\beta}_{\mathrm{A}}^{*}, \mathbf{u}_{n}}\right)
\end{aligned}
$$

where the function $h_{\mathbf{v}_{n}, \boldsymbol{\beta}_{A}^{*}, \mathbf{u}_{n}}$ is defined in (A.19). Let $\varepsilon$ and $\delta$ be positive real numbers. Using that $\mathbb{P}\left(\mathcal{B}_{n}\right)=\mathbb{P}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{NA}}=\mathbf{0}_{p-k}\right) \rightarrow 1$, we get that there exists $n_{0} \in \mathbb{N}$ such that, for any $n \geq n_{0}$, we have $\mathbb{P}\left(\mathcal{B}_{n}\right)>1-\delta / 4$. On the other hand, recall that $\mathbb{P}\left(\mathcal{D}_{n}\right)>1-\delta / 4$, where $\mathcal{D}_{n}$ is defined in (A.26). Hence, if $\widetilde{\mathcal{D}_{n}}=\left\{\left\|\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}-\boldsymbol{\beta}_{0, \mathrm{~A}}\right\|_{2} \leq C_{1} \sqrt{k / n}\right\}$, we have that $\mathcal{B}_{n} \cap \mathcal{D}_{n} \subset \widetilde{\mathcal{D}_{n}}$ leading to $\mathbb{P}\left(\widetilde{\mathcal{D}_{n}}\right)>1-\delta / 2$. Moreover, define the event

$$
\mathcal{C}_{n}=\left\{\sup _{h \in \mathcal{H}}\left|\left(P_{n}-P\right)(h)\right|<\frac{2 C}{\delta} \sqrt{\frac{k}{n}}\right\},
$$

where $\mathcal{H}$ is defined in (A.19) and $C$ is the constant from Lemma A.5. Applying Markov's inequality, we get that $\mathbb{P}\left(\mathcal{C}_{n}\right)>1-\delta / 2$, which implies that $\mathbb{P}\left(\widetilde{\mathcal{D}_{n}} \cap \mathcal{C}_{n}\right)>1-\delta$.
Let $n_{1} \geq n_{0}$ be such that, for any $n \geq n_{1}, C_{1} \sqrt{k / n}<1$. Then, restricting to the event $\widetilde{\mathcal{D}_{n}} \cap \mathcal{C}_{n}$, we obtain

$$
\left|S_{2, n}\right| \leq \sqrt{n} t_{n}^{-1} C_{1} \sqrt{\frac{k}{n}} \frac{2 C}{\delta} \sqrt{\frac{k}{n}} \leq \frac{C_{3}}{\delta} \frac{k}{\sqrt{n}}
$$

where $C_{3}=2 C C_{1} / \tau_{2}$ and we again used that $t_{n} \geq \tau_{2}$. Finally, the fact that $k^{2} / n \rightarrow 0$ entails that there exists $n_{2} \geq n_{1}$ such that $\widetilde{\mathcal{D}_{n}} \cap \mathcal{C}_{n} \subset\left\{\left|S_{2, n}\right| \leq \varepsilon\right\}$ for all $n \geq n_{2}$, thus (A.24) holds.
To conclude the proof, we need to show that (A.25) holds, i.e., that $S_{3, n} \xrightarrow{D} N(0,1)$. Using (A.22), we have that

$$
\begin{aligned}
S_{3, n} & =-\sqrt{n} t_{n}^{-1} \frac{1}{n} \sum_{i=1}^{n} \mathbf{v}^{\mathrm{T}} \Psi\left(y_{i}, \mathbf{x}_{i, \mathrm{~A}}^{\mathrm{T}} \boldsymbol{\beta}_{0, \mathrm{~A}}\right) \mathbf{x}_{i, \mathrm{~A}}-\sqrt{n} t_{n}^{-1} \mathbf{v}^{\mathrm{T}} \nabla I_{\lambda_{n}}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}\right)-\sqrt{n} t_{n}^{-1} \mathbf{v}_{n}^{\mathrm{T}} \mathbf{r}_{n} \\
& =S_{31, n}+S_{32, n}+S_{33, n}
\end{aligned}
$$

Using that $\mathbb{P}\left(\mathbf{r}_{n}=0\right) \rightarrow 1$, the fact that (16) and $\mathbf{Z 7}$ hold, it is easy to see that $S_{32, n} \xrightarrow{p} 0$ and $S_{33, n} \xrightarrow{p} 0$. It remains to show that $S_{31, n} \xrightarrow{D} N(0,1)$. Write $S_{31, n}=\sum_{i=1}^{n} W_{n, i}$, where

$$
W_{n, i}=-t_{n}^{-1} \frac{\Psi\left(y_{i}, \mathbf{x}_{i, \mathrm{~A}}^{\mathrm{T}} \boldsymbol{\beta}_{0, \mathrm{~A}}\right)}{\sqrt{n}} \mathbf{v}^{\mathrm{T}} \mathbf{x}_{i, \mathrm{~A}}
$$

Note that $\mathbb{E} W_{n, i}=0$ for all $n \in \mathbb{N}$ and $1 \leq i \leq n$, whereas

$$
\mathbb{E} W_{n, i}^{2}=\operatorname{VAR}\left(W_{n, i}\right)=\frac{1}{n} t_{n}^{-2} \mathbf{v}^{\mathrm{T}} \mathbb{E}\left[\Psi^{2}\left(y, \mathbf{x}_{\mathrm{A}}^{\mathrm{T}} \boldsymbol{\beta}_{0, \mathrm{~A}}\right) \mathbf{x}_{\mathrm{A}} \mathbf{x}_{\mathrm{A}}^{\mathrm{T}}\right] \mathbf{v}=\frac{1}{n} t_{n}^{-2} \mathbf{v}^{\mathrm{T}} \mathbf{B}_{\mathrm{A}}^{(k)} \mathbf{v}=\frac{1}{n},
$$

which implies $\sum_{i=1}^{n} \mathbb{E} W_{n, i}^{2}=1$.

To apply the central limit theorem for triangular arrays, we will show that the Lyapunov's condition holds, that is, that there exists a value $\delta>0$ such that $\lim _{n \rightarrow \infty} \sum_{i=1}^{n} \mathbb{E}\left[\left|W_{n, i}\right|^{2+\delta}\right]=0$. Note that

$$
\mathbb{E}\left|W_{n, i}\right|^{2+\delta}=\frac{1}{t_{n}^{2+\delta}} \frac{1}{n^{1+\frac{\delta}{2}}} \mathbb{E}\left[\left|\Psi\left(y, \mathbf{x}_{\mathrm{A}}^{\mathrm{T}} \boldsymbol{\beta}_{0, \mathrm{~A}}\right)\right|^{2+\delta}\left|\mathbf{v}^{\mathrm{T}} \mathbf{x}_{\mathrm{A}}\right|^{2+\delta}\right],
$$

and using the fact that $\|\mathbf{v}\|_{2}=1, \Psi$ is bounded and Cauchy-Schwartz's inequality, we obtain

$$
\sum_{i=1}^{n} \mathbb{E}\left[\left|W_{n, i}\right|^{2+\delta}\right] \leq \frac{1}{t_{n}^{2+\delta}} \frac{1}{n^{\frac{\delta}{2}}}\|\Psi\|_{\infty}^{2+\delta} \mathbb{E}\left\|\mathbf{x}_{\mathrm{A}}\right\|^{2+\delta} \leq \frac{1}{n^{\frac{\delta}{2}}} \frac{1}{\tau_{2}^{2+\delta}}\|\Psi\|_{\infty}^{2+\delta} K_{3}^{\frac{2+\delta}{6}}
$$

where the last inequality is a consequence of the fact that $t_{n}^{-1}$ is bounded and assumption Z6 holds. Hence, Lyapunov's condition holds and, using the Lindeberg-Feller's central limit theorem for triangular arrays, we conclude that $S_{31, n} \xrightarrow{D} N(0,1)$ and the desired result follows.

Proof of Corollary 4.5, It suffices to show that the MCP and SCAD penalties satisfy (16) under the assumptions N2 and N3, Let $a>0$ be the second tuning parameter for these penalization functions (which we are assuming to be fixed constants) and recall that for any of these penalties we can write $I_{\lambda_{n}}(\boldsymbol{\beta})=\sum_{j=1}^{p} J_{\lambda_{n}}\left(\left|\beta_{j}\right|\right)$ where $J_{\lambda_{n}}(t)$ is constant in $\left[a \lambda_{n}, \infty\right)$ and $J_{\lambda_{n}}(0)=0$. Hence, for any $\mathbf{b} \in \mathbb{R}^{k}$, $I_{\lambda_{n}}\left(\left(\mathbf{b}^{\mathrm{T}}, \mathbf{0}_{p-k}^{\mathrm{T}}\right)^{\mathrm{T}}\right)=\sum_{j=1}^{k} J_{\lambda_{n}}\left(\left|b_{j}\right|\right)$ and $\nabla I_{\lambda_{n}}(\mathbf{b})=\sum_{j=1}^{k} J_{\lambda_{n}}^{\prime}\left(\left|b_{j}\right|\right)$.
Taking into account that $\left\|\widehat{\boldsymbol{\beta}}_{n}-\boldsymbol{\beta}_{0}\right\|_{2}=O_{\mathbb{P}}(\sqrt{k / n})$, we get that given $\delta>0$, there exists $C_{1}>0$ such that $\mathbb{P}\left(\mathcal{D}_{n}\right)>1-\delta$, where $\mathcal{D}_{n}$ is the set defined in (A.26).

Note that, for every $\omega \in \mathcal{D}_{n}$ and $1 \leq j \leq k$,

$$
\left|\widehat{\beta}_{n, j}\right| \geq\left|\beta_{0, j}\right|-\left|\widehat{\beta}_{n, j}-\beta_{0, j}\right| \geq m_{0, n}-C_{1} \sqrt{\frac{k}{n}}=\lambda_{n}\left(\frac{m_{0, n}}{\lambda_{n}}-C_{1} \sqrt{\frac{k}{n}} \frac{1}{\lambda_{n}}\right)
$$

Assumption N3 implies that there exists a constant $C_{2}>0$ such that $k / n \leq C_{2} \lambda_{n}^{2}$, whereas N2 entails that there exists $n_{0} \in \mathbb{N}$ such that $\left(m_{0, n} / \lambda_{n}\right)>a+1+C_{1} \sqrt{C_{2}}$ for all $n \geq n_{0}$. Thus, for any $n \geq n_{0}$, we have that for each $j=1, \ldots, k$,

$$
\left|\widehat{\beta}_{n, j}\right| \geq \lambda_{n}\left(\frac{m_{0, n}}{\lambda_{n}}-C_{1} \sqrt{C_{2}}\right)>a \lambda_{n}
$$

Finally, using that $J_{\lambda_{n}}(t)$ is constant in $\left[a \lambda_{n}, \infty\right)$, we conclude that $\mathcal{D}_{n} \subset\left\{\left\|\nabla I_{\lambda_{n}}\left(\widehat{\boldsymbol{\beta}}_{n, \mathrm{~A}}\right)\right\|_{2}=0\right\}$, which shows that (16) holds for these penalizations.
