

Averages of exponential twists of the von Mangoldt function

Xiumin Ren¹ and Wei Zhang²

Abstract In this paper, we obtain some improved results for the exponential sum $\sum_{x < n \leq 2x} \Lambda(n) e(\alpha k n^\theta)$ with $\theta \in (0, 5/12)$, where $\Lambda(n)$ is the von Mangoldt function. Such exponential sums have relations with the so-called quasi-Riemann hypothesis and were considered by Vinogradov [8] and Murty-Srinivas [5].

Keywords Exponential sums over primes, zero-density estimates

2000 Mathematics Subject Classification 11L20, 11M26

1. INTRODUCTION

In this paper, we are interested in the exponential sum

$$S(k, x, \theta) := \sum_{x < n \leq 2x} \Lambda(n) e(k \alpha n^\theta),$$

where $x \geq 2$ and $k \in \mathbb{Z}^+$ are the main parameters, $\alpha \neq 0$ and $0 < \theta < 1$ are fixed, $\Lambda(n)$ is the von Mangoldt function, and $e(z) = e^{2\pi i z}$.

We call $S(k, x, \theta)$ Vinogradov's exponential sum, since it was first considered by I. M. Vinogradov [8] in the special case $\theta = 1/2$. Actually, he proved in [8] that, for $k \leq x^{1/10}$,

$$S(k, x, 1/2) \ll k^{1/4} x^{7/8+\varepsilon},$$

where the implied constant may depend on α and ε . Iwaniec and Kowalski (see (13.55) in [4]) remarked that the stronger inequality

$$S(1, x, 1/2) \ll x^{5/6} \log^4 x$$

follows from an application of Vaughan's identity. For general θ and k , Murty and Srinivas [5] proved that

$$S(k, x, \theta) \ll k^{1/8} x^{(7+\theta)/8} \log(x k^3),$$

where the implied constant may depend on α and θ . In 2006, Ren [6] proved that

$$S(k, x, \theta) \ll (k^{1/2} x^{(1+\theta)/2} + x^{4/5} + k^{-1/2} x^{1-\theta/2}) \log^A x, \quad (1.1)$$

for arbitrary $A > 0$, and for $\theta \leq 1/2$ and $k < x^{1/2-\theta}$,

$$S(k, x, \theta) \ll (k^{1/10} x^{3/4+\theta/10} + k^{-1/2} x^{1-\theta/2}) \log^{11} x. \quad (1.2)$$

In this paper, we will prove the following Theorem 1.1, which is new for $\theta \in (0, 5/12)$. In [3], Iwaniec, Luo and Sarnak showed that such type exponential sums are connected to the quasi-Riemann Hypothesis (or the existence of zero-free region) for $L(s, f)$, where f is any holomorphic cusp form of integral weight for $SL(2, \mathbb{Z})$.

Theorem 1.1. *For $0 < \theta < 5/12$ and $1 \leq k < x^{5/12-\theta-\varepsilon}$, there exists an absolute constant $c_0 > 0$ such that*

$$S(k, x, \theta) \ll k^{-1/2} x^{1-\theta/2} \exp(-c_0(\log x)^{1/3-\varepsilon}),$$

where the implied constant may depend on α , θ , and ε , which denotes an arbitrarily small positive constant.

Obviously, when $\theta < 5/12$ and $k < x^{5/12-\theta-\varepsilon}$, Theorem 1.1 improve (1.2). Some much sharper estimates can be obtained if one assumes the zero-density hypothesis, i.e,

$$N(\sigma, T) \ll T^{2(1-\sigma)} \log^B T, \quad \sigma \geq 1/2, \quad (1.3)$$

where $N(\sigma, T)$ is the number of zeros of $\zeta(s)$ in the region $\{\sigma \leq \Re s \leq 1, |t| \leq T\}$ and B is some positive constant. In fact, under (1.3), it is proved in [6] that

$$S(k, x, \theta) \ll (k^{1/2} x^{(1+\theta)/2} + k^{-1/2} x^{1-\theta/2}) \log^{B+2} x, \quad (1.4)$$

where the implied constant may depend on α , θ and B . In fact, our idea can also be used to give a better result than (1.4).

Theorem 1.2. *Under (1.3), for $0 < \theta < 1/2$ and $1 \leq k < x^{1/2-\theta-\varepsilon}$, there exists an absolute constant c_0 such that*

$$S(k, x, \theta) \ll k^{-1/2} x^{1-\theta/2} \exp(-c_0(\log x)^{1/3-\varepsilon}),$$

where the implied constant may depend on α , ε and θ .

It is worth pointing out that, comparing with Theorem 1.1, the ranges of θ and k have been extended in Theorem 1.2.

2. PROOF OF THEOREM 1.1

To prove Theorem 1.1, we will borrow the idea in [6] by using the results related to zeros of Riemann zeta function. The following lemma will be used in the proof of Theorem 1.1 and Theorem 1.2.

Lemma 2.1 (see page 71 of [7]). *Let $F(u)$ and $G(u)$ be real functions in $[a, b]$, satisfying $|G(u)| \leq M$ and that $G(u)$ and $1/F'(u)$ are monotone.*

(1) *If $F'(u) \geq m > 0$ or $F'(u) \leq -m < 0$, then*

$$\int_a^b G(u) e(F(u)) du \ll \frac{M}{m};$$

(2) *If $F''(u) \geq r > 0$ or $F''(u) \leq -r < 0$, then*

$$\int_a^b G(u) e(F(u)) du \ll \frac{M}{\sqrt{r}}.$$

Proof of Theorem 1.1 Using partial summation and the explicit formula (see (5.53) in [4]): for $1 \leq T \leq x$,

$$\sum_{n \leq x} \Lambda(n) = x - \sum_{|\gamma| \leq T} \frac{x^\rho}{\rho} + O\left(\frac{x}{T} (\log xT)^2\right),$$

2

we have

$$\begin{aligned}
\sum_{x < n \leq 2x} \Lambda(n) e(k\alpha n^\theta) &= \int_x^{2x} e(k\alpha u^\theta) d \sum_{n \leq u} \Lambda(n) \\
&= \int_x^{2x} e(k\alpha u^\theta) du - \sum_{|\gamma| \leq T} \int_x^{2x} u^{\rho-1} e(k\alpha u^\theta) du \\
&\quad + O\left((1 + k|\alpha|x^\theta) \frac{x \log^2 x}{T}\right).
\end{aligned} \tag{2.1}$$

Here $\rho = \beta + i\gamma$ denotes a zero of $\zeta(s)$ with $0 < \beta < 1$, $|\gamma| \leq T$. Set

$$T = T_0 = x,$$

then the error-term is $O((1 + k|\alpha|x^\theta) \log^2 x) = O_\alpha(kx^\theta \log^2 x)$. Moreover, we have

$$\int_x^{2x} e(k\alpha u^\theta) du = \frac{1}{\theta} \int_{x^\theta}^{(2x)^\theta} u^{1/\theta-1} e(k\alpha u) du \ll_{\alpha, \theta} k^{-1} x^{1-\theta}. \tag{2.2}$$

Making the change of variable $u^\theta = v$, we get

$$\int_x^{2x} u^{\rho-1} e(k\alpha u^\theta) du = \frac{1}{\theta} \int_{x^\theta}^{(2x)^\theta} v^{\frac{\beta}{\theta}-1} e(f(v)) dv,$$

where

$$f(v) = k\alpha v + \frac{\gamma}{2\pi\theta} \log v.$$

Trivially one has

$$\int_x^{2x} u^{\rho-1} e(k\alpha u^\theta) du \ll x^\beta. \tag{2.3}$$

On the other hand we have

$$\begin{aligned}
|f'(v)| &= |k\alpha + \frac{\gamma}{2\pi\theta v}| \geq \frac{\min_{v \in [x^\theta, (2x)^\theta]} |\gamma + 2\theta\pi k\alpha v|}{2\pi\theta|v|}, \\
|f''(v)| &= \frac{|\gamma|}{2\pi\theta v^2}.
\end{aligned}$$

By Lemma 2.1 and (2.3) we get

$$\int_{x^\theta}^{(2x)^\theta} v^{\frac{\beta}{\theta}-1} e(f(v)) dv \ll \begin{cases} \frac{x^\beta}{\sqrt{1+\theta k|\alpha|x^\theta}} & \text{for } |\gamma| \leq 4(1 + \theta\pi k|\alpha|(2x)^\theta), \\ \frac{x^\beta}{1+|\gamma|} & \text{for } 4(1 + \theta\pi k|\alpha|(2x)^\theta) \leq |\gamma| \leq T_0. \end{cases}$$

Therefore

$$\begin{aligned}
&\sum_{|\gamma| \leq T} \int_x^{2x} u^{\rho-1} e(k\alpha u^\theta) du \\
&\ll \frac{1}{\sqrt{1 + \theta k|\alpha|x^\theta}} \sum_{|\gamma| \leq 4(1+\theta\pi k|\alpha|(2x)^\theta)} x^\beta + \sum_{4(1+\theta\pi k|\alpha|(2x)^\theta) \leq |\gamma| \leq T_0} \frac{x^\beta}{1+|\gamma|}.
\end{aligned}$$

Assume that, for some positive constant C ,

$$N(\sigma, T) \ll T^{A(\sigma)(1-\sigma)} \log^C T.$$

Then by the Riemann-Von Mangoldt formula, for $2 \leq U \leq T_0$ we have

$$\begin{aligned} \sum_{|\gamma| \leq U} x^\beta &= - \int_0^1 x^\sigma dN(\sigma, U) \\ &\ll x^{1/2} U \log U + (\log U)^C \log x \max_{1/2 \leq \sigma \leq \sigma_0} U^{A(\sigma)(1-\sigma)} x^\sigma, \end{aligned}$$

where

$$\sigma_0 = 1 - c_0 (\log T)^{-2/3} (\log \log T)^{-1/3}$$

with c_0 an absolute positive constant. Here we have used the well known zero-free region results (for example, see [4, 7]) which states that $\zeta(s) \neq 0$ for $\sigma > \sigma_0$,

Let x be sufficiently large such that $\theta \pi k |\alpha| (2x)^\theta \gg 1$, then we have

$$\begin{aligned} &\frac{1}{\sqrt{1 + \theta k |\alpha| x^\theta}} \sum_{|\gamma| \leq 4(1 + \theta \pi k |\alpha| (2x)^\theta)} x^\beta \\ &\ll (\log x)^{C+1} \left(k^{1/2} x^{(1+\theta)/2} + \max_{1/2 \leq \sigma \leq \sigma_0} k^{A(\sigma)(1-\sigma)-1/2} x^{\sigma + \theta A(\sigma)(1-\sigma) - \theta/2} \right), \end{aligned}$$

and

$$\begin{aligned} &\sum_{4(1 + \theta \pi k |\alpha| (2x)^\theta) \leq |\gamma| \leq T_0} \frac{x^\beta}{1 + |\gamma|} \\ &\ll (\log x) \max_{4(1 + \theta \pi k |\alpha| (2x)^\theta) < T_1 \leq T} T_1^{-1} \sum_{T_1 \leq |\gamma| \leq 2T_1} x^\beta \\ &\ll (\log x)^{C+2} \left(x^{1/2} + \max_{1/2 \leq \sigma \leq \sigma_0} k^{A(\sigma)(1-\sigma)-1} x^{\sigma + \theta A(\sigma)(1-\sigma) - \theta} \right). \end{aligned}$$

Writing

$$g(\sigma) = \sigma + \theta A(\sigma)(1 - \sigma) - \frac{\theta}{2},$$

and collecting the above estimates we get

$$\begin{aligned} &\sum_{|\gamma| \leq T} \int_x^{2x} u^{\rho-1} e(k\alpha u^\theta) du \\ &\ll (\log x)^{C+2} \left(k^{1/2} x^{(1+\theta)/2} + \max_{1/2 \leq \sigma \leq \sigma_0} k^{A(\sigma)(1-\sigma)-1/2} x^{g(\sigma)} \right). \end{aligned}$$

By the well know result of Ingham [2] and Huxley [1], we can choose $A(\sigma) = 12/5$. Thus we have

$$\begin{aligned} &\max_{1/2 \leq \sigma \leq \sigma_0} k^{A(\sigma)(1-\sigma)-1/2} x^{g(\sigma)} \\ &\ll (\log x)^{C_1} \sup_{1/2 \leq \sigma \leq \sigma_0} k^{A(\sigma)(1-\sigma)-1/2} x^{\sigma + 12\theta(1-\sigma)/5 - \theta/2} \\ &\ll k^{-1/2} x^{1-\theta/2} (\log x)^{C_1} \sup_{1/2 \leq \sigma \leq \sigma_0} \left(k^{12/5} x^{12\theta/5-1} \right)^{1-\sigma}. \end{aligned}$$

Thus for $\theta < 5/12$ and $k < x^{5/12-\theta-\varepsilon}$, we get

$$\begin{aligned}
& \max_{1/2 \leq \sigma \leq \sigma_0} k^{A(\sigma)(1-\sigma)-1/2} x^{g(\sigma)} \\
& \ll k^{-1/2} x^{1-\theta/2} (\log x)^{C_1} \sup_{1/2 \leq \sigma \leq \sigma_0} x^{-c_0(\log x)^{-2/3}(\log \log x)^{-1/3}} \\
& \ll k^{-1/2} x^{1-\theta/2} \exp(-c_0(\log x)^{1/3}(\log x \log x)^{-1/3}) \\
& \ll k^{-1/2} x^{1-\theta/2} \exp(-c_0(\log x)^{1/3-\varepsilon}).
\end{aligned}$$

This together with (2.1) and (2.2) shows that, for $\theta \in (0, 5/12)$ and $1 \leq k < x^{5/12-\theta-\varepsilon}$,

$$\begin{aligned}
& \sum_{x < n \leq 2x} \Lambda(n) e(\alpha n^\theta) \\
& \ll k^{1/2} x^{(1+\theta)/2} (\log x)^C + k^{-1/2} x^{1-\theta/2} \exp(-c_0(\log x)^{1/3-\varepsilon}) + k^{-1} x^{1-\theta} + k x^\theta \\
& \ll k^{-1/2} x^{1-\theta/2} \exp(-c_0(\log x)^{1/3-\varepsilon}).
\end{aligned}$$

This finishes the proof of Theorem 1.1. \square
