One of the unique features of non-Hermitian (NH) systems is the appearance of non-Hermitian degeneracies known as exceptional points (EPs). The extensively studied defective EPs occur when the Hamiltonian becomes non-diagonalizable. Aside from this degeneracy, we show that NH systems may host two further types of degeneracies, namely, non-defective EPs and ordinary (Hermitian) nodal points. The non-defective EPs manifest themselves by i) the diagonalizability of the NH Hamiltonian at these points, ii) the non-diagonalizability of the Hamiltonian along certain intersections of these points and iii) instabilities in the Jordan decomposition when approaching the points from certain directions. We demonstrate that certain discrete symmetries, namely parity-time, parity-particle-hole, and pseudo-Hermitian symmetry, guarantee the occurrence of both defective and non-defective EPs. We extend this list of symmetries by including the NH time-reversal symmetry in two-band systems. Two-band and four-band models exemplify our findings. Through an example, we further reveal that ordinary nodal points may coexist with defective EPs in NH models when the above symmetries are relaxed.

Introduction. Despite violating the axioms of quantum mechanics, non-Hermitian (NH) Hamiltonians offer compelling descriptions for numerous interacting/open systems in various fields of physics [1–5]. The underlying physics of these effective Hamiltonians goes beyond the realm of Hermitian physics and has been immensely studied lately [6–19]. Aside from unraveling rich physics, the properties of NH systems are well-reflected in abstract mathematical frameworks, including homotopy theory [20–24] and K-theory [25–27]. These frameworks provide a reliable toolbox to understand the exotic properties of NH systems and distinguish their behavior from Hermitian physics.

Noticeable distinctions of NH Hamiltonians from their Hermitian counterparts include the appearance of exceptional points (EPs), as NH degeneracies. While one generally should satisfy $n - 1$ complex constraints to realize EPs of order n (EP n s), at which the Hamiltonian casts a Jordan block, recent studies have shown that the presence of certain discrete symmetries, such as parity-time ($\mathcal{PT}$), parity-particle-hole ($\mathcal{CP}$), or pseudo-Hermiticity (psH) symmetry, reduces the total number of constraints [28–38]. Although the main focus of these studies was on characterizing symmetry-induced restrictions on defective EPs, drawing a link between discrete symmetries and non-defective degeneracies associated with the NH Hamiltonian beyond case studies have received little attention. Furthermore, while there is a near consensus on calling defective degeneracies [39, 40] defective EPs [41], non-defective degeneracies in NH systems are referred to as diabolic points [42–45], Fermi points [46], Dirac points and vortex points [47]. These non-defective degeneracies are different in nature, as both Dirac points and vertex points might appear in the vicinity of defective EPs, while diabolic points and Fermi points are similar to (Hermitian) ordinary nodal points (ONPs).

Recalling their mathematical origin, EPs were introduced by Kato as isolated singularities of systems depending on one complex variable [48], and they were recently classified into

type I EPs and type II EPs [2]. EPs of type I are degeneracies with or without algebraic singularities reminiscent of defective EPs and ONPs, while type II EPs are defined as points in the complex plane where the Jordan normal form is unstable, i.e., the eigenprojectors have a pole. While the appearance and existence of degeneracies reminiscent of type I EPs have been studied extensively, type II EPs have hitherto been overlooked in the literature.

In this letter, we introduce a natural extension of type II EPs to higher dimensions, dubbed *non-defective EPs*. We present that the correct criterion for detecting non-defective EPs is the form of the Hamiltonian matrix in the *vicinity* of these degenerate points: Non-defective EPs are surrounded by defective EPs along certain intersections such that the Hamiltonian matrix casts a Jordan block in certain directions away from the non-defective EPs. Furthermore, we show that the Jordan decomposition is singular at these points when approaching the points from certain directions, emphasizing that non-defective EPs indeed are reminiscent of the type II EPs in Ref. 2. To characterize the role of symmetries in witnessing NH degeneracies, we study the coexistence of defective and non-defective EP n s in two-, three- and four-band models in the presence of psH, $\mathcal{PT}$ or $\mathcal{CP}$ symmetry. Additionally, we show that symmetry-protected non-defective EP2s may also appear in models with non-Hermitian time-reversal symmetry. Finally, we find that defective EPs may coexist with ONPs instead of non-defective EPs when lifting symmetry constraints. We illustrate this finding with a fine-tuned example.

Finding possibilities to detect ONPs and (non-)defective EPs may pave the way to advance applications of Hermitian and non-Hermitian topological properties in various fields of research. For instance, topological lasers are one of the platforms which owe their success to either Hermitian [49, 50] or non-Hermitian [51–54] topological properties. Moreover, our systems, especially $\mathcal{PT}$ -symmetric models, are experimentally feasible as they can be implemented in experimental optical setups with balanced gain and loss effectively [55]. Exploring the role of EPs in $\mathcal{PT}$ -symmetric optical systems has already unraveled many interesting phenomena, such as unidirectional invisibility [56], induced mode-transition by encircling EPs [57], loss induced optical transparency [58], and sta-

* sharareh.sayyad@mpl.mpg.de

ble single-mode lasing in multi-mode optical setups [59, 60].

Symmetry-stabilized (non-)defective EPs. A generic n -band Hamiltonian can be decomposed as $\mathcal{H} = d_\mu \Upsilon^\mu$, where $\mu \in \{0, \dots, n^2 - 1\}$, d_μ are continuously differentiable complex-valued functions of the lattice momentum $\mathbf{k}$, Υ^0 denotes the identity matrix of order n and Υ is the basis of the $SU(n)$ group, which consists of three Pauli matrices when $n = 2$, eight Gell-Mann matrices when $n = 3$, and fifteen generalized Gell-Mann matrices when $n = 4$ (see supplemental materials (SM) for the explicit presentation of these matrices [61]). The Hamiltonian $\mathcal{H}$ displays $\mathcal{PT}$ symmetry with generator $\mathcal{PT}$, $\mathcal{CP}$ symmetry with generator $\mathcal{CP}$, or psH with generator ς , if it satisfies one of the following relations, namely,

$$\mathcal{PT} : \mathcal{H}(\mathbf{k}) = (\mathcal{PT}) \mathcal{H}^*(\mathbf{k}) (\mathcal{PT})^{-1}, \quad (1)$$

$$\mathcal{CP} : \mathcal{H}(\mathbf{k}) = -(\mathcal{CP}) \mathcal{H}^*(\mathbf{k}) (\mathcal{CP})^{-1}, \quad (2)$$

$$\text{psH} : \mathcal{H}(\mathbf{k}) = \varsigma \mathcal{H}^\dagger(\mathbf{k}) \varsigma^{-1}. \quad (3)$$

These symmetry considerations reduce the number of nonzero d_μ values. More precisely, for each basis matrix Υ^μ merely a real or imaginary part of d_μ remains nonzero, i.e., only one real-valued function d_μ per each dimension of Υ^μ survives [38]. Trivial band touching points occur when the traceless part of $\mathcal{H}$ becomes a Null matrix ($[0]_{n \times n}$), i.e., all of the nonzero d_μ values for $\mu > 0$ must vanish, which means that one needs to satisfy $n^2 - 1$ real constraints. For $n = 2, 3, 4$, we have collected these d_μ 's for each symmetry operation along side a choice for its generator in Tables I, II, and III, respectively.

The $n - 1$ complex constraints to find defective EPns can be expressed in terms of the traces and the determinant of $\mathcal{H}$, which for two-, three-, and four-band models, respectively, read [38]

$$n = 2 : \eta^{2b} = \text{tr}[\mathcal{H}]^2 - 4 \det[\mathcal{H}], \quad (4)$$

$$n = 3 : \begin{cases} \eta^{3b} &= \frac{1}{2} (\text{tr}[\mathcal{H}]^2 - 3 \text{tr}[\mathcal{H}^2]) , \\ \nu^{3b} &= \frac{1}{2} (54 \det[\mathcal{H}] - 5 \text{tr}[\mathcal{H}]^3 + 9 \text{tr}[\mathcal{H}] \text{tr}[\mathcal{H}^2]) , \end{cases} \quad (5)$$

$$n = 4 : \begin{cases} \eta^{4b} &= -3ac + b^2 + 12d, \\ \nu^{4b} &= 27a^2d - 9abc + 2b^3 - 72bd + 27c^2, \\ \kappa^{4b} &= a^3 - 4ab + 8c, \end{cases} \quad (6)$$

where $a = \text{tr}[\mathcal{H}]$, $b = ((\text{tr}[\mathcal{H}])^2 - \text{tr}[\mathcal{H}^2])/2$, $d = \det[\mathcal{H}]$ and $c = (\text{tr}[\mathcal{H}]^3 - 3 \text{tr}[\mathcal{H}] \text{tr}[\mathcal{H}^2] + 2 \text{tr}[\mathcal{H}^3])/6$. We refer to the SM for details on how to derive these expressions [61].

In the presence of $\mathcal{PT}$, $\mathcal{CP}$ and psH symmetry, some of these constraints are automatically satisfied leaving us with exactly $n - 1$ real constraints, cf. Tables I, II and III [38]. It is notable that at trivial solutions ($\mathbf{d} = 0$), all traces and the determinant of $\mathcal{H}$ acquire zero values and subsequently, the constraints in Eqs. (4)-(6) are also satisfied. As a result, the trivial solutions mark non-defective EPns with the binding signature that $\mathcal{H}$ is diagonalizable at these points. Perturbing the system away from these non-defective points along intersections at which the constraints vanish brings the Hamiltonian into a

Table I. Summarized symmetries, their generators and their associated constraints to find defective and non-defective EP2s in two-band systems.

Symm.	Generator	Constr. def. EP2s	Constr. non-def. EP2s
$\mathcal{PT}$	$\mathbb{1}$	$\eta_R^{2b} = 0$	$d_{xR} = d_{yI} = d_{zR} = 0$
$\mathcal{CP}$	$\mathbb{1}$	$\eta_R^{2b} = 0$	$d_{xI} = d_{yR} = d_{zI} = 0$
psH	$\text{adiag}[1, 1]$	$\eta_R^{2b} = 0$	$d_{xR} = d_{yI} = d_{zI} = 0$
$\text{TRS}^\dagger$	$\text{adiag}[1, -1]$	$\eta_R^{2b} = \eta_I^{2b} = 0$	$d_{xa} = d_{ya} = d_{za} = 0$

Here we use either $d_j = d_{jR} + id_{jI}$ or $d_j = d_{js} + d_{ja}$, where $d_{js}(d_{ja})$ is (anti-)symmetric with respect to $\mathbf{k} \rightarrow -\mathbf{k}$. η^{2b} is given in Eq. (4) with $\eta^{2b} = \eta_R^{2b} + i\eta_I^{2b}$.

Figure 1. Real part (a) and imaginary part (b) of spectra for Eq. (7) along $k_x = k_y$ with $k_z = \pi/2$. Red points indicate non-defective EPs. Here we set $t = V = \lambda_0 = 1.0$.

non-diagonalizable structure. We set this behavior as a criterion to detect non-defective EPs. We note that this is opposed to the situation in which trivial solutions are isolated, and thus band touching points behave similarly to Hermitian degeneracies, i.e., ONPs.

The diagonalizability of the Hamiltonian at non-defective EPs enables us to map our NH Hamiltonians into their Hermitian counterparts with nodal points. In addition, having $n^2 - 1$ nonzero d_μ 's as in Hermitian systems enforces non-defective EPs to always appear in pairs. This statement originates from the Poincaré-Hopf theorem [62], as the number of nonzero d_μ functions equals the dimension of the vector space ($n^2 - 1$), cf. last columns in Tables I, II, and III [63].

Aside from $\mathcal{PT}$, $\mathcal{CP}$ and psH symmetries, a particular non-Hermitian time-reversal symmetry, known as $\text{TRS}^\dagger$, in two-band systems may also give rise to realizing non-defective EPs. To evidently see this behavior, we recall that respecting $\text{TRS}^\dagger$ symmetry imposes $\mathcal{H}(-\mathbf{k}) = \mathcal{C}_+ \mathcal{H}^\dagger(\mathbf{k}) \mathcal{C}_+^\dagger$. This non-(momentum)-local transformation does not reduce the number of non-vanishing (real/imaginary) parts of d_μ . However, when $\mathcal{C}_+ = i\sigma_y$, it enforces all symmetric parts of d_μ to become zero. We further know that right at time-reversal invariant momenta (TRIM), e.g., $\mathbf{k}_{\text{TRIM}} = \{(0, 0), (0, \pi), (\pi, 0), (\pi, \pi)\}$ on the square Brillouin zone, anti-symmetric functions vanish. Therefore, at $\mathbf{k}_{\text{TRIM}}$ both real and imaginary parts of anti-symmetric d_μ functions become zero, which gives rise to observing non-defective EPs in the spectra of two-band $\text{TRS}^\dagger$ -symmetric $\mathcal{H}$, cf. Table I.

Before moving on to examples, we note that the differ-

Table II. Summarized symmetries, their generators and their associated constraints to find defective and non-defective EP3s in three-band systems.

Symm.	Generator	Constr. def. EP3s	Constr. non-def. EP3s
$\mathcal{PT}$	$\text{diag}[1, -1, 1]$	$\eta_R^{3b} = 0 \ \& \ \nu_R^{3b} = 0$	$d_{1R} = d_{4I} = d_{2I} = d_{5R} = d_{3R} = d_{6I} = d_{7R} = d_{8R} = 0$
$\mathcal{CP}$	$\text{diag}[1, -1, 1]$	$\eta_R^{3b} = 0 \ \& \ \nu_I^{3b} = 0$	$d_{1I} = d_{4R} = d_{2R} = d_{5I} = d_{3I} = d_{6R} = d_{7I} = d_{8I} = 0$
psH	$\text{diag}[1, -1, 1]$	$\eta_R^{3b} = 0 \ \& \ \nu_R^{3b} = 0$	$d_{1I} = d_{4I} = d_{2R} = d_{5R} = d_{3I} = d_{6I} = d_{7R} = d_{8R} = 0$

Here we use $d_j = d_{jR} + id_{jI}$. Complex valued η^{3b} and ν^{3b} constraints are given in Eq. (5) with $\alpha^{3b} = \alpha_R^{3b} + i\alpha_I^{3b}$ for $\alpha \in \{\eta, \nu\}$.

Table III. Summarized symmetries, their generators and their associated constraints to get defective and non-defective EP4s in four-band systems.

Symm.	Generator	Constr. def. EP4s	Constr. non-def. EP4s
$\mathcal{PT}$	$\text{diag}[1, -1, 1, -1]$	$\eta_R^{4b} = 0 \ \& \ \nu_R^{4b} = 0 \ \& \ \kappa_R^{4b} = 0$	$d_{1R} = d_{2I} = d_{3R} = d_{4R} = d_{5I} = d_{6R} = d_{7I} = d_{8R} = 0$ $d_{9I} = d_{10I} = d_{11R} = d_{12I} = d_{13R} = d_{14R} = d_{15R} = 0$
$\mathcal{CP}$	$\text{diag}[1, -1, 1, -1]$	$\eta_R^{4b} = 0 \ \& \ \nu_R^{4b} = 0 \ \& \ \kappa_I^{4b} = 0$	$d_{1I} = d_{2R} = d_{3I} = d_{4I} = d_{5R} = d_{6I} = d_{7R} = d_{8I} = 0$ $d_{9R} = d_{10R} = d_{11I} = d_{12R} = d_{13I} = d_{14I} = d_{15I} = 0$
psH	$\text{diag}[1, -1, 1, -1]$	$\eta_R^{4b} = 0 \ \& \ \nu_R^{4b} = 0 \ \& \ \kappa_R^{4b} = 0$	$d_{1I} = d_{2R} = d_{3I} = d_{4I} = d_{5R} = d_{6I} = d_{7I} = d_{8R} = 0$ $d_{9I} = d_{10I} = d_{11R} = d_{12I} = d_{13R} = d_{14R} = d_{15R} = 0$

Here we use $d_j = d_{jR} + id_{jI}$. Complex valued η^{4b} , ν^{4b} and κ^{4b} constraints are given in Eq. (6) with $\alpha^{4b} = \alpha_R^{4b} + i\alpha_I^{4b}$ for $\alpha \in \{\eta, \nu, \kappa\}$.

ent number of constraints that need to be satisfied to find symmetry-protected defective and non-defective EPns also result in a different codimension of these EPs. Here, the codimension is given by the difference between the total dimension of the system and the dimension of the exceptional feature. Equivalently, the codimension corresponds precisely to the number of nonvanishing constraints. In particular, while the presence of $\mathcal{PT}$, $\mathcal{CP}$ and psH symmetries reduces the number of real constraints for finding defective EPns to $n-1$, the number of real constraints to detect non-defective EPns is n^2-1 . As a consequence, in the case of $n=2$, defective EP2s have codimension *one*, whereas non-defective EP2s have codimension *three*. Therefore, the latter appear as points in three-dimensional systems, whereas defective EP2s appear as two-dimensional surfaces. For the TRS[†] invariant two-band model, the codimension is *two*, and hence the defective EP2s are curves connected at the TRIMs.

Examples for the coexistence of defective and non-defective EPs. We start with introducing a two-band $\mathcal{PT}$ -symmetric Weyl-like tight-binding model described by

$$\begin{aligned} \mathcal{H}_{\mathcal{PT}}^{2b} &= d_0 \Upsilon^0 + d_{xR} \Upsilon^1 + id_{yI} \Upsilon^2 + d_{zR} \Upsilon^3 \\ &= 2\lambda_0 \sin(k_x) \Upsilon^0 + 2t \sin(k_x) \Upsilon^1 + 2t \sin(k_y) \Upsilon^3 \\ &\quad + i \{2t \cos(k_z) + 2V[2 - \cos(k_x) - \cos(k_y)]\} \Upsilon^2. \end{aligned} \quad (7)$$

Here λ_0 , t and V are real-valued parameters. The real and imaginary parts of the band structure are shown in Figs. 1(a) and (b), respectively.

Non-defective EPs appear when all components of the Hamiltonian, except d_0 , vanish. More specifically, these degeneracies emerge when the solutions of $d_{xR} = 0$ (at $k_x = n\pi$ with $n \in \mathbb{Z}$), $d_{yI} = 0$ (orange curves in Fig. 2), and $d_{zR} = 0$ (grey line) intersect. Red points at $\mathbf{k} = (0, 0, \pm\pi/2)$ in Fig. 2 exemplify such solutions. Note that the criterion for detecting non-defective EPs is satisfied for the red points in

Figure 2. Solutions of d_{yI} (orange), d_{zR} (gray), and η_R^{2b} (dashed blue) at $k_x = 0$, which is a solution to $d_{xR} = 0$. Red points at $\mathbf{k} = (0, 0, \pm\pi/2)$ indicate the intersection between solutions to $\eta_R^{2b} = d_{yI} = d_{zR} = 0$, and are non-defective EPs. Here we set $t = V = \lambda_0 = 1.0$.

Fig. 2 as they are surrounded by defective EPs (dashed blue curves), residing on $\eta_R^{2b} = 0$, where η_R^{2b} is the real part of η^{2b} in Eq. (4).

Along the defective EPs, defined by $d_{xR}^2 + d_{zR}^2 = d_{yI}^2$, the Jordan decomposition reads $\mathcal{H}_{\mathcal{PT}}^{2b} = SJS^{-1}$ with $S = (s_1, s_2)$, where

$$s_1 = \begin{pmatrix} \frac{\sqrt{t^4[2 - \cos(2k_x) - \cos(2k_y)] - \sqrt{2}t^2 \sin(k_x)}}{\sqrt{2}t^2 \sin(k_y)} \\ 1 \end{pmatrix}, \quad (8)$$

$$s_2 = \begin{pmatrix} \frac{\sqrt{2}\sqrt{t^4[2 - \cos(2k_x) - \cos(2k_y)] - 2t^2 \sin(k_x)}}{4t^3 \sin(k_y)^2} \\ 0 \end{pmatrix}, \quad (9)$$

$$J = \begin{pmatrix} 2\lambda_0 \sin(k_x) & 1 \\ 0 & 2\lambda_0 \sin(k_x) \end{pmatrix}. \quad (10)$$

The second column in the transformation matrix, s_2 , has a singularity when k_x and k_y goes to $n\pi$ simultaneously, corre-

Figure 3. Real (a) and imaginary (b) parts of band structure for $\mathcal{H}_{\text{psH}}^{4b}$ in Eq. (11) along $k_x = k_y$ and k_z . Note that both bands are doubly degenerate. Red points indicate non-defective EPs at $\mathbf{k} = (0, 0, \pm k_0)$. Here we set $t = t_z = 1.0$, $\lambda_{Ixx} = \lambda_{Ixy} = 0.15$, $m'_I = -0.27$ and $k_0 = \pi/2$.

sponding exactly to the non-defective EP. Hence, the Jordan decomposition is unstable at the non-defective EPs.

We further note that the defective EPs separate two regions in the real part of spectrum, where $\text{Re}[\Delta\epsilon] = 0$ and $\text{Re}[\Delta\epsilon] \neq 0$ with $\Delta\epsilon$ the difference between the two energy bands as shown in Fig. 1(a). Regions where $\text{Re}[\Delta\epsilon] = 0$ are sometimes referred to as NH bulk real-Fermi states, which merely appear in NH systems [6]. In the SM, we show that besides these bulk Fermi states, this model also hosts states on the boundary [61]. Therefore, there is a coexistence between defective and non-defective EPs as well as between bulk Fermi states and boundary states.

Let us now turn to a four-band model. We consider a Dirac-like psH-symmetric model described by

$$\begin{aligned} \mathcal{H}_{\text{psH}}^{4b} = & t [\cos(k_x) + \cos(k_y) - 2] \left(\frac{2}{\sqrt{3}} \Upsilon^{14} + \sqrt{\frac{2}{3}} \Upsilon^{15} \right) \\ & + t_z [\cos(k_z) - \cos(k_0)] \left[\frac{2}{\sqrt{3}} \Upsilon^{14} + \sqrt{\frac{2}{3}} \Upsilon^{15} \right] \\ & + i\lambda_{Ixy} \sin(k_y) (\Upsilon^3 + \Upsilon^4) \\ & + i\lambda_{Ixx} \sin(k_x) (\Upsilon^9 + \Upsilon^{10}) \\ & + im'_I \sin(k_z) [\cos(k_x) - \cos(k_y)] (\Upsilon^7 - \Upsilon^{12}), \end{aligned} \quad (11)$$

where t , t_z , λ_{Ixy} , λ_{Ixx} , and m'_I are real-valued parameters. This model is a psH generalization of the tight-binding model studied in Ref. 64. The trivial band touching points for obtaining the null form of the traceless part of $\mathcal{H}_{\text{psH}}^{4b}$ in Eq. (11) are located at $\mathbf{k} = \mathbf{k}_{\text{psH}} = (0, 0, \pm k_0)$. Right at these points and on lines connecting these points, constraints for realizing EP4s, summarized in Table III and given in Eq. (6), are also satisfied. Hence, points at $\mathbf{k} = \mathbf{k}_{\text{psH}}$ in our psH-symmetric model are non-defective EP4s. We present these nodal points (red spheres) in the band structure of $\mathcal{H}_{\text{psH}}^{4b}$ in Fig. 3. The real part of the spectra (a) shows that two arc-shaped surfaces with (non)zero real (imaginary) parts are terminated by the non-defective EPs as well as the defective exceptional lines. These surfaces are the aforementioned NH

bulk real-Fermi surfaces. While our model hosts bulk Fermi surfaces, boundary states are not stable, similar to its Hermitian counterpart [64].

Searching for the coexistence of ONPs and defective EPs. So far, we have explored how the presence of one of the $\mathcal{PT}$, $\mathcal{CP}$ or psH symmetries leads to the general coexistence of defective and non-defective EPs. In the remaining, we address whether ONPs may also exist in NH spectra. For this purpose, we lift (discrete) symmetry restrictions such that some (or all) d_μ 's have real and imaginary parts. We emphasize that in this situation, in contrast to the EPs in the previous sections, band degeneracies are generally unstable to small perturbations [65]. This is because finding solutions to $\mathbf{d} = 0$ generally requires satisfying $n^2 - 1$ complex constraints. Consequently, the appearance of ONPs in NH models is vulnerable to the fine-tuning of parameters. Nevertheless, we show in the following that this setting provides a platform to observe ONPs.

To illustrate our idea, we introduce a two-band model given by

$$\begin{aligned} \mathcal{H}_{\text{ONP}}^{2b} = & \sin(k_x) [1/2 + i \cos(k_y)] \Upsilon^1 \\ & + \sin(k_y) [1/2 + i \cos(k_z)] \Upsilon^2 \\ & + \sin(k_z) [1/2 + i \cos(k_x)] \Upsilon^3. \end{aligned} \quad (12)$$

Fig. 4 exhibits real (a) and imaginary (b) parts of the energy dispersion of this system along $k_z = \pi$. The black points in these panels mark real and imaginary band touching points, located at $k_{x,y,z}^{\text{ONP}} = \pm n\pi$. Even though at these momenta the traceless part of $\mathcal{H}_{\text{ONP}}^{2b}$ becomes a null matrix, we emphasize that $\mathbf{k} = \mathbf{k}^{\text{ONP}}$ indicates the location of ONPs and not non-defective EPs. The reason for this statement lies in the fact that the criterion for the emergence of non-defective EPs is not satisfied, i.e., no defective EPs reside close to $\mathbf{k}^{\text{ONP}}$. This can be seen from Fig. 4 (c) in which we present defective EPs, red curves, as the intersection between $\text{Re}[\eta^{2b}] = 0$, blue spheres,

Figure 4. Real (a) and imaginary (b) parts of band structure for $\mathcal{H}_{\text{ONP}}^{2b}$ in Eq. (12) along $k_z = \pi$. (c) Solutions of the real (blue spheres) and imaginary (green manifold) parts of η^{2b} in Eq. (4). Red closed lines in (c) present the intersection of these manifolds and correspond to defective EPs. Black points in panels (a), (b) indicate ONPs. For visibility purposes, merely a corner of Brillouin zone is shown in panels (a), (b).

and $\text{Im}[\eta^{2b}] = 0$, green manifold. Fig. 4 (c) reveals that defective EPs do not cross $\mathbf{k} = \mathbf{k}^{\text{ONP}}$ and thus the black points at $\mathbf{k}^{\text{ONP}}$ indeed correspond to ONPs. Consequently, H_{ONP}^{2b} is diagonalizable at $\mathbf{k} = \mathbf{k}^{\text{ONP}}$ and in any small neighborhood surrounding the point.

Aside from these ONPs in the momentum-space, introducing models that host boundary states connecting ONPs in NH systems is theoretically feasible. We present an example of such a model in the SM [61].

Conclusion. Despite the intense focus on NH systems in recent studies, the possibility of realizing different types of EPs has hitherto been overlooked. The present work shows that two different types of EPs, dubbed defective and non-defective EPs, may coexist in various setups of physical importance. Concretely, we show that non-defective EPs are stabilized by certain symmetries, including $\mathcal{PT}$, $\mathcal{CP}$, psH, and time-reversal symmetry. To resolve the confusion in the cur-

rent literature, where non-defective EPs are mixed up with ONPs, we have in this work introduced a clear criterion to distinguish these concepts. We also highlight this difference in example models.

Even though the models we discuss in this work are experimentally tractable, we do not expect a difference in the experimental signatures of non-defective EPs and ONPs when single-particle, non-interacting Hamiltonians are explored. Investigating interacting/coupled systems may allow identifying distinct footprints of non-defective EPs and ONPs in experiments.

- [65] More precisely, twofold degeneracies are protected by composite symmetries consisting of multiple symmetry operations [?]. Respecting all these symmetry operations might be easily violated upon introducing perturbations.

Appendix A: Bases matrices for two-, three-, and four-band systems

1. Basis matrices for two-band systems

The basis matrices for two-band systems are Pauli matrices which read

$$\Upsilon^1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \Upsilon^2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \Upsilon^3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \quad (\text{A1})$$

2. Basis matrices for three-band systems

The basis matrices for three-band systems are the Gell-Mann matrices, that span the Lie algebra of the SU(3) group,

$$\Upsilon^1 = \begin{pmatrix} 0 & -i & 0 \\ i & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \Upsilon^2 = \begin{pmatrix} 0 & 0 & -i \\ 0 & 0 & 0 \\ i & 0 & 0 \end{pmatrix}, \quad (\text{A2})$$

$$\Upsilon^3 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & i & 0 \end{pmatrix}, \quad \Upsilon^4 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad (\text{A3})$$

$$\Upsilon^5 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad \Upsilon^6 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \quad (\text{A4})$$

$$\Upsilon^7 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \Upsilon^8 = \begin{pmatrix} \frac{1}{\sqrt{3}} & 0 & 0 \\ 0 & \frac{1}{\sqrt{3}} & 0 \\ 0 & 0 & -\frac{2}{\sqrt{3}} \end{pmatrix}. \quad (\text{A5})$$

3. Basis matrices for four-band systems

The basis matrices for four-band systems are the generalized Gell-Mann matrices, that span the Lie algebra of the SU(4) group,

$$\Upsilon^1 = \begin{pmatrix} 0 & -i & 0 & 0 \\ i & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \Upsilon^2 = \begin{pmatrix} 0 & 0 & -i & 0 \\ 0 & 0 & 0 & 0 \\ i & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad (\text{A6})$$

$$\Upsilon^3 = \begin{pmatrix} 0 & 0 & 0 & -i \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ i & 0 & 0 & 0 \end{pmatrix}, \quad \Upsilon^4 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & -i & 0 \\ 0 & i & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad (\text{A7})$$

Figure S1. Real parts (a) and imaginary parts (b) of spectra for Eq. (7) with open boundary condition in the y direction and $k_x = 0$. Red lines present boundary states. Here we set $t = V = \lambda_0 = 1.0$.

$$\Upsilon^5 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -i \\ 0 & 0 & 0 & 0 \\ 0 & i & 0 & 0 \end{pmatrix}, \quad \Upsilon^6 = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -i \\ 0 & 0 & i & 0 \end{pmatrix}, \quad (\text{A8})$$

$$\Upsilon^7 = \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \Upsilon^8 = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad (\text{A9})$$

$$\Upsilon^9 = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}, \quad \Upsilon^{10} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad (\text{A10})$$

$$\Upsilon^{11} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}, \quad \Upsilon^{12} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}, \quad (\text{A11})$$

$$\Upsilon^{13} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad \Upsilon^{14} = \begin{pmatrix} \frac{1}{\sqrt{3}} & 0 & 0 & 0 \\ 0 & \frac{1}{\sqrt{3}} & 0 & 0 \\ 0 & 0 & -\frac{2}{\sqrt{3}} & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad (\text{A12})$$

$$\Upsilon^{15} = \begin{pmatrix} \frac{1}{\sqrt{6}} & 0 & 0 & 0 \\ 0 & \frac{1}{\sqrt{6}} & 0 & 0 \\ 0 & 0 & \frac{1}{\sqrt{6}} & 0 \\ 0 & 0 & 0 & -\sqrt{\frac{3}{2}} \end{pmatrix}. \quad (\text{A13})$$

Appendix B: Derivation of constraints to find EP_{ns}

Here we briefly summarize how to derive Eqs. (4)-(6) in the main text, where these constraints were originally derived in Ref. 38. There it was shown that the characteristic polynomial of an n -band NH matrix can be expressed in terms of its determinant and traces. Indeed, for two-, three- and four-band matrices, these polynomials read

$$F^{2b}(\lambda) = \lambda^2 - \text{tr}[\mathcal{H}]\lambda + \det[\mathcal{H}] = 0, \quad (\text{B1})$$

$$F^{3b}(\lambda) = \lambda^3 - \text{tr}[\mathcal{H}]\lambda^2 + \frac{\text{tr}[\mathcal{H}]^2 - \text{tr}[\mathcal{H}^2]}{2}\lambda - \det[\mathcal{H}] = 0, \quad (\text{B2})$$

$$F^{4b}(\lambda) = \lambda^4 - a\lambda^3 + b\lambda^2 - c\lambda + d = 0, \quad (\text{B3})$$

Figure S2. Real parts (a) and imaginary parts (b) of spectra for Eq. (D1) with open boundary condition in the y direction and at $k_z = 0$. Red lines present boundary states. Black points mark ONPs. Here we set $t = V = 1.0$, $\lambda_0 = 2.3$.

where

$$a = \text{tr}[\mathcal{H}], \quad b = \frac{\text{tr}[\mathcal{H}]^2 - \text{tr}[\mathcal{H}^2]}{2}, \quad d = \det[\mathcal{H}], \quad (\text{B4})$$

$$c = \frac{\text{tr}[\mathcal{H}]^3 - 3 \text{tr}[\mathcal{H}] \text{tr}[\mathcal{H}^2] + 2 \text{tr}[\mathcal{H}^3]}{6}, \quad (\text{B5})$$

and λ are the eigenvalues.

To find degeneracies, the discriminant $D[\mathcal{H}]$ of these characteristic polynomials need to be set to zero. The discriminants read

$$D[\mathcal{H}^{2b}] = \text{tr}[\mathcal{H}]^2 - 4 \det[\mathcal{H}], \quad (\text{B6})$$

$$D[\mathcal{H}^{3b}] = -\frac{1}{27}[4(\eta^{3b})^3 + (\nu^{3b})^2], \quad (\text{B7})$$

$$D[\mathcal{H}^{4b}] = \frac{1}{27}[4(\eta^{4b})^3 - (\nu^{4b})^2], \quad (\text{B8})$$

where η^{3b} and ν^{3b} , and η^{4b} and ν^{4b} are given in Eqs. (5) and (6) in the main text, respectively. From here, we immediately see that setting the discriminants in Eqs. (B6) and (B7) to zero gives us the constraints in Eqs. (4) and (5) in the main text, respectively. In the case of the four-band model, we note that

for all roots of the discriminant to coincide, not only $\eta^{4b} = 0$ and $\nu^{4b} = 0$ need to be satisfied, but also $\kappa^{4b} = 0$, where κ^{4b} is defined in Eq. (6) in the main text. We refer to Ref. 38 for a more detailed discussion on this point.

Appendix C: Spectra of the two-band model with open boundary condition

In addition to the properties of momentum-dependent spectra for $\mathcal{H}_{\mathcal{PT}}^{2b}$ in Fig. 1, we present real (a) and imaginary (b) parts of the energy dispersion with open boundary condition in the y direction plotted in Fig. S1. The figure exhibits boundary states, red lines, well-separated from the bulk states (blue lines) when $|k_z| > \pi/2$.

Appendix D: Realizing Hermitian boundary states in non-Hermitian systems

Here we present a non-Hermitian tight-binding model hosting Hermitian boundary states, which connects ONPs with zero imaginary parts.

Our model Hamiltonian reads

$$\begin{aligned} \mathcal{H}_{\text{edg}}^{2b} = & \lambda_0 \cos(k_x) \Upsilon^0 - iV [1 - \cos(k_z)] \Upsilon^1 \\ & + [2V \cos(k_y) - 2t \cos(k_x)] \Upsilon^1 \\ & - 2t \sin(k_y) \Upsilon^2 - 2t \sin(k_z) \Upsilon^3, \end{aligned} \quad (\text{D1})$$

where λ_0 , t and V are real-valued coupling constants. Along $k_z = 0$, the above Hamiltonian is fully Hermitian. As a result, nodal points, which live on the (k_x, k_y) plane, are band touching points with zero imaginary parts. For instance, these ordinary nodal points appear at $\mathbf{k}_{\text{ONPs}} = (\pm n\pi, \pm n\pi, 0)$ with $n \in \mathbb{Z}$ when $t = V$. Considering the open boundary condition along the y axis and at $k_z = 0$ results in mid-gap boundary states, red lines in Fig. S2(a), which connects $\mathbf{k}_{\text{ONPs}}$.
