#### Abstract

Motivated by putting empirical work based on (synthetic) election data on a more solid mathematical basis, we analyze six distances among elections, including, e.g., the challenging-to-compute but very precise swap distance and the distance used to form the so-called map of elections. Among the six, the latter seems to strike the best balance between its computational complexity and expressiveness.

## 1 Introduction

We study the properties of several distances (metrics) among elections. ${ }^{1}$ We focus on the ordinal model, where each voter ranks the candidates from the most to the least appealing one, and on metrics that are independent of renaming the candidates and voters. Such metrics were introduced by Faliszewski et al. [12], who argued about their usefulness to compare two elections generated from some statistical models, or to evaluate which statistical model is most likely to generate elections similar to given real-life ones. Indeed, in such applications the names of the candidates and voters do not carry any information and should be disregarded. Unfortunately, while the metrics studied by Faliszewski et al. [12] are naturally motivated-for example, one of them extends the widely accepted swap distance-many of them are not only NP-hard to compute (even approximately), but also difficult to compute in practice.

Yet, many of the motivating ideas of Faliszewski et al. [12] were soon implemented in the maps of elections, introduced by Szufa et al. [25] and extended by Boehmer et al. [6]. Briefly put, such a map is a collection of election instances, typically generated from some statistical models (but Boehmer et al. [6] also used real-life ones from PrefLib [21]), together with their distances. The elections are represented graphically as points in the plane, whose Euclidean distances are as similar to the distances between the respective elections as possible. Since maps of elections typically contain hundreds of elections, instead of using the appealing-but-hard-to-compute extension of the swap distance, Szufa et al. [25] introduced and used a much simpler metric. Yet, the maps proved to be quite useful. For example, Szufa et al. [25] used their map to find hard instances for some multiwinner voting rule, Boehmer et al. [6] and Boehmer and Schaar [4] obtained insights about different types of real-life elections, and Boehmer et al. [5] used the maps to study the robustness of elections.

[^0]In this work, we take a step back and analyze the properties of several metrics, including those of Faliszewski et al. [12] and Szufa et al. [25]. Our goal is to help putting empirical work with election data on a more solid mathematical basis and, in particular, to understand if basing the election maps on the simpler metric was a good decision, what was its price, and if one should have used other metrics. We view the swap distance as a yardstick against which we measure the other ones. In particular, we consider the following issues:

1. As a basic test, we compare the metrics' ability to distinguish nonisomorphic elections. Since some metrics act on aggregate representations of elections, they may sometimes fail at this task. We also study the complexity of computing an election with a given representation.
2. We analyze distances between four "compass" elections, which capture four types of (dis)agreement among the voters [6]. We find that two of them are the most distant elections under each of our metrics.
3. We compute the correlation between the values provided by the swap distance and the other metrics; we also compare the maps that they produce.
4. We note that the swap distance can be understood in terms of the shortest paths on a certain graph and we analyze to what extent this applies to the other metrics.

Some proofs and arguments are in the appendix.

## 2 Preliminaries

For an integer $n$, let $[n]:=\{1, \ldots, n\}$.

Preference Orders. Let $C$ be set of candidates. By $\mathcal{L}(C)$ we denote the set of all total orders over $C$, referred to either as preference orders or votes, depending on the context.

Elections. An election $E=(C, V)$ consists of a candidate set $C=\left\{c_{1}, \ldots, c_{m}\right\}$ and a preference profile $V=\left(v_{1}, \ldots, v_{n}\right)$, where each $v_{i}$ is a preference order from $\mathcal{L}(C)$. For example, a preference order $v_{i}: a \succ b \succ c$ indicates that the $i$-th voter ranks candidate $a$ highest, followed by candidates $b$ and $c$. Given a vote $v$ and a candidate $c$, we write $\operatorname{pos}_{v}(c)$ to denote the position of $c$ in $v$ (the top-ranked candidate has position 1 , the next one has position 2 , and so on).

Example 1. Consider elections $E=(C, V)$ and $E^{\prime}=\left(C^{\prime}, V^{\prime}\right)$, where $C=\{a, b, c\}, C^{\prime}=\{x, y, z\}$, $V=\left(v_{1}, v_{2}, v_{3}\right), V^{\prime}=\left(v_{1}^{\prime}, v_{2}^{\prime}, v_{3}^{\prime}\right)$, and the votes are:

$$
\begin{array}{rlrl}
v_{1}: a \succ b \succ c, & v_{2}: b \succ c \succ a, & v_{3}: b \succ a \succ c, \\
v_{1}^{\prime}: x \succ y \succ z, & v_{2}^{\prime}: x & \succ y \succ z, & v_{3}^{\prime}: y \succ x \succ z .
\end{array}
$$

Aggregate Representations. Let $E=(C, V)$ be an election. We use the following aggregate representations of $E$ :

1. For each two candidates $c, d \in C, \mathcal{M}_{E}(c, d)$ is the number of voters that prefer $c$ to $d$ in election $E$. We call it the weighted majority relation and represent it as an $m \times m$ matrix where rows and columns correspond to the candidates (the diagonal is undefined). A relative weighted majority relation is a weighted majority relation from whose entries we subtract $n / 2$ (let $n$ be even here).
2. For a candidate $c \in C$ and a position $i \in[m], \mathcal{P}_{E}(c, i)$ is the number of voters from $E$ that rank $c$ on position $i ; \mathcal{P}_{E}(c)=\left(\mathcal{P}_{E}(c, 1), \ldots, \mathcal{P}_{E}(c, m)\right)$ is a (column) position vector of $c$. We view $\mathcal{P}_{E}$ as a matrix with columns $\mathcal{P}_{E}\left(c_{1}\right), \ldots, \mathcal{P}_{E}\left(c_{m}\right)$ and call it a position matrix.
3. For a candidate $c \in C, \mathcal{B}_{E}(c):=\sum_{i=1}^{n}\left(m-\operatorname{pos}_{v_{i}}(c)\right)$ is the Borda score of $c$ in $E$. Then, $\mathcal{B}_{E}$ is the Borda score vector, whose entries correspond to the candidates.

Example 2. Below we provide $\mathcal{M}_{E}, \mathcal{P}_{E}$, and $\mathcal{B}_{E}$, respectively, for election $E$ from Example 1:

$$
\begin{gathered}
a \\
b \\
c
\end{gathered}\left[\begin{array}{ccc}
a & b & c \\
- & 1 & 2 \\
2 & - & 3 \\
1 & 0 & -
\end{array}\right],
$$

$$
\begin{aligned}
& 1 \\
& 2 \\
& 2
\end{aligned}\left[\begin{array}{lll}
a & b & c \\
1 & 2 & 0 \\
1 & 1 & 1 \\
1 & 0 & 2
\end{array}\right],
$$

$$
\left[\begin{array}{lll}
a & b & c \\
3 & 5 & 1
\end{array}\right] .
$$

(Pseudo)Metrics. Given a set $X$, a function $d: X \times X \rightarrow \mathbb{R}$ is a pseudometric over $X$ if for each three elements $a, b, c \in X$ it holds that (i) $d(a, b)=d(b, a) \geq 0$, (ii) $d(a, a)=0$, and (iii) $d(a, c) \leq$ $d(a, b)+d(b, c)$. For brevity, we will refer to our pseudometrics as metrics (formally, a metric should assume value 0 only if both its arguments are identical).

Metrics Among Vectors. Let $x=\left(x_{1}, \ldots, x_{n}\right)$ and $y=\left(y_{1}, \ldots, y_{n}\right)$ be two real-valued vectors. Then, $\ell_{1}(x, y):=\left|x_{1}-y_{1}\right|+\cdots+\left|x_{n}-y_{n}\right|$ is the $\ell_{1}$-metric between $x$ and $y$. Given a real-valued vector $z=\left(z_{1}, \ldots, z_{n}\right)$, we write $\hat{z}$ to denote its prefix-sum variant, i.e., an $n$-dimensional vector such that for each $i \in[n]$, its $i$-th entry is $\hat{z}_{i}=z_{1}+z_{2}+\cdots+z_{i}$. If the entries of $x$ and $y$ sum up to the same value and contain only nonnegative entries, then their earth mover's distance is defined as [24]:

$$
\operatorname{emd}(x, y):=\ell_{1}(\hat{x}, \hat{y})
$$

Alternatively, $\operatorname{emd}(x, y)$ is defined as the minimum total cost of a sequence of operations that transform vector $x$ into vector $y$, where each operation is of the form "subtract value $\alpha$ from some $x_{i}$ (where, at the time of performing the operation, we have $x_{i} \geq \alpha$ ) and add $\alpha$ to $x_{j}$ " and has cost $\alpha \cdot|j-i|$. Both definitions are equivalent [24].

Bijections. Given two equal-sized sets $X$ and $Y$, let $\Pi(X, Y)$ denote the set of all one-to-one mappings from $X$ to $Y$. For a positive integer $n$, let $S_{n}$ be the set of all permutations of $[n]$ (i.e., $S_{n}=\Pi([n],[n])$ ). Given two equal-sized candidate sets $C$ and $D$, a preference order $v \in \mathcal{L}(C)$, and a function $\sigma \in$ $\Pi(C, D)$, we write $\sigma(v)$ to denote the preference order obtained from $v$ by replacing each candidate $c \in C$ with the candidate $\sigma(c) \in D$. Given a preference profile $V=\left(v_{1}, \ldots, v_{n}\right) \in(\mathcal{L}(C))^{n}$, by $\sigma(V)$ we mean $\left(\sigma\left(v_{1}\right), \ldots, \sigma\left(v_{n}\right)\right)$. We use analogous notation for other objects defined over candidate sets. For example, for an election $E=(C, V)$, we write $\sigma\left(\mathcal{M}_{E}\right)$ to denote the weighted majority relation of the election $(\sigma(C), \sigma(V))=(D, \sigma(V))$.

## 3 Metrics Among Elections

In this section, we define the six metrics among elections that we study. All but the last one already appeared in the literature. We only consider distances between elections with the same numbers of candidates and the same numbers of voters.

### 3.1 Swap and Discrete Isomorphic Metrics

Let $C$ be a candidate set and let $u, v \in \mathcal{L}(C)$ be two votes. Their discrete distance, $d_{\text {disc }}(u, v)$, is 0 if they are identical and it is 1 otherwise. Their swap distance, $d_{\text {swap }}(u, v)$, is the number of inversions between $u$ and $v$, i.e., the number of pairs of candidates $c, d \in C$ such that $u$ and $v$ rank these candidates in opposite order.

Let $d$ be either $d_{\text {disc }}$ or $d_{\text {swap }}$. For two elections, $E=(C, V)$ and $E^{\prime}=\left(C^{\prime}, V^{\prime}\right)$, where $|C|=\left|C^{\prime}\right|$, $V=\left(v_{1}, \ldots, v_{n}\right)$, and $V^{\prime}=\left(v_{1}^{\prime}, \ldots, v_{n}^{\prime}\right)$, Faliszewski et al. [12] extended $d$ to elections as follows:

$$
d\left(E, E^{\prime}\right):=\min _{\sigma \in \Pi\left(C, C^{\prime}\right)} \min _{\rho \in S_{n}} \sum_{i=1}^{n} d\left(\sigma\left(v_{i}\right), v_{\rho(i)}^{\prime}\right) .
$$

In other words, under the extended distance we match the candidates and the votes of the two input elections so that the sum of the distances between the matched votes is minimal.

Example 3. The discrete distance between elections $E$ and $E^{\prime}$ from Example 1 is one, as witnessed by the candidate matching $\sigma(a)=x, \sigma(b)=y$, and $\sigma(c)=z$. For the same matching, the swap distance between $E$ and $E^{\prime}$ is two.

We refer to the extensions of $d_{\text {disc }}$ and $d_{\text {swap }}$ as the discrete and swap isomorphic metrics. This stems from the fact that two elections are isomorphic (i.e., can be made identical by renaming candidates and reordering the votes) if and only if their discrete distance (equivalently, swap distance) is zero.

Faliszewski et al. [12] have shown that while computing the discrete isomorphic distance can be done in polynomial time, the same task for the swap distance is NP-hard (in essence, this follows from the hardness proofs for the Kemeny voting rule [2, 9]).

### 3.2 Positionwise and Pairwise Metrics

To circumvent the hardness of computing the isomorphic swap distance, Szufa et al. [25] introduced two other metrics, based on analyzing aggregate representations of elections.

Let $E=(C, V)$ and $E^{\prime}=\left(C^{\prime}, V^{\prime}\right)$ be two elections such that $|C|=\left|C^{\prime}\right|$ and $|V|=\left|V^{\prime}\right|$. The EMD-positionwise distance between $E$ and $E^{\prime}$ is:

$$
d_{\mathrm{pos}}^{\mathrm{emd}}\left(E, E^{\prime}\right):=\min _{\sigma \in \Pi\left(C, C^{\prime}\right)} \sum_{c \in C} \operatorname{emd}\left(\mathcal{P}_{E}(c), \mathcal{P}_{E^{\prime}}(\sigma(c)) .\right.
$$

Note that we view each candidate as her or his position vector and we seek a candidate matching that minimizes the earth mover's distances between the vectors of matched candidates.

Example 4. Consider the same elections and the same matching $\sigma$ as in Example 3. We have that $\mathcal{P}_{E}(a)=(1,1,1)$, whereas $\mathcal{P}_{E^{\prime}}(\sigma(a))=(2,1,0)$ and their earth mover's distance is 2 . Altogether, $d_{\text {pos }}^{\text {emd }}\left(E, E^{\prime}\right)=2+1+1=4$.

Szufa et al. [25] based their metric on EMD because they felt it was intuitively appropriate. We aim to verify this intuition and, thus, we also consider the $\ell_{1}$-positionwise metric, which uses the $\ell_{1}$ distance instead of EMD.

Szufa et al. [25] also introduced the pairwise metric, which works on top of the weighted majority relation:

$$
d_{\text {pair }}\left(E, E^{\prime}\right):=\min _{\sigma \in \Pi\left(C, C^{\prime}\right.} \sum_{\substack{a, b \in C \\ a \neq b}}\left|\mathcal{M}_{E}(a, b)-\mathcal{M}_{E^{\prime}}(\sigma(a), \sigma(b))\right| .
$$

| $\|C\| \times\|V\|$ | ANECs | Positionwise | Pairwise | Bordawise |
| :---: | :---: | :---: | :---: | :---: |
| $3 \times 3$ | 10 | 10 | 8 | 8 |
| $3 \times 4$ | 24 | 23 | 17 | 13 |
| $3 \times 5$ | 42 | 40 | 25 | 18 |
| $4 \times 3$ | 111 | 93 | 50 | 37 |
| $4 \times 4$ | 762 | 465 | 200 | 76 |
| $4 \times 5$ | 4095 | 1746 | 513 | 131 |

Table 1: Number of equivalence classes under our metrics.

Example 5. Take the elections from Example 1 and matching $\sigma^{\prime}(a)=y, \sigma^{\prime}(b)=x$, and $\sigma^{\prime}(c)=z$; $\mathcal{M}_{E}$ and $\sigma^{\prime}\left(\mathcal{M}_{E^{\prime}}\right)$ are:

$$
\left.\begin{array}{c}
a \\
a \\
b \\
c
\end{array} \begin{array}{ccc}
a & b & c \\
- & 1 & 2 \\
2 & - & 3 \\
1 & 0 & -
\end{array}\right],
$$

$$
\begin{gathered}
\sigma^{\prime}(a) \\
\sigma^{\prime}(b) \\
\sigma^{\prime}(c)
\end{gathered}\left[\begin{array}{ccc}
\sigma^{\prime}(a) & \sigma^{\prime}(b) & \sigma^{\prime}(c) \\
- & 1 & 3 \\
2 & - & 3 \\
0 & 0 & -
\end{array}\right]
$$

and we see that the pairwise distance of our elections (for this matching) is $0+1+0+0+1+0=2$.
The positionwise distances can be computed in polynomial time [25], whereas the pairwise distance is NP-hard to compute $[16,25]$ ).

### 3.3 Bordawise Metric

We introduce one new metric, similar in spirit to the positionwise and pairwise ones, but defined on top of the election's Borda score vectors. Given two equal-sized elections $E$ and $E^{\prime}$, their Bordawise distance is defined as:

$$
d_{\text {Borda }}\left(E, E^{\prime}\right):=\operatorname{emd}\left(\operatorname{sort}\left(\mathcal{B}_{E}\right), \operatorname{sort}\left(\mathcal{B}_{E^{\prime}}\right)\right)
$$

where for a vector $x, \operatorname{sort}(x)$ means a vector obtained from $x$ by sorting it in nonincreasing order. The Bordawise metric is defined to be as simple as possible, while trying to still be meaningful. For example, sorting the score vectors ensures that two isomorphic elections are at distance zero and removes the use of an explicit matching between the candidates.

Example 6. The distance between the elections from Example 1 is $\operatorname{emd}((5,3,1),(5,4,0))=1$.

## 4 Aggregate Representations

First, we discuss how the aggregate representations that underlie our metrics affect their ability to distinguish nonisomorphic elections. Then, we study the complexity of deciding if a given representation indeed corresponds to some election.

Given a metric, two elections are in the same equivalence class if their distance is zero. An anonymous, neutral equivalence class (ANEC) consists of all isomorphic elections with a given number of candidates and voters [11]. While ANECs are the equivalence classes of the swap and discrete metrics, the other metrics are less precise and their equivalence classes are unions of some ANECs.

To get a feeling as to how much precision is lost due to various aggregate representations, in Table 1 we compare the number of ANECs and the numbers of equivalence classes of the positionwise, pairwise, and Bordawise metrics, for small elections; we computed the table using exhaustive search ${ }^{2}$

[^1](note that EMD- and $\ell_{1}$-positionwise metrics have the same equivalence classes). Among these metrics, positionwise ones perform best and Bordawise performs worst. Next, we provide a partial theoretical explanation for this observation.

We say that a metric $d$ is at least as fine as a metric $d^{\prime}$ if for each two elections $A$ and $B, d(A, B)=0$ implies that $d^{\prime}(A, B)=0$ (i.e., each equivalence class of $d$ is a subset of some equivalence class of $d^{\prime}$ ). Metric $d$ is finer than $d^{\prime}$ if it is at least as fine as $d^{\prime}$ but $d^{\prime}$ is not at least as fine as $d$.

Proposition 1. Swap and discrete isomorphic metrics are finer than EMD/ $\ell_{1}$-positionwise and pairwise, which both are finer than Bordawise. Neither EMD/ $\ell_{1}$-positionwise is finer than pairwise nor the other way round.

Proof. Since two isomorphic elections are at distance zero according to each of our metrics, we see that swap and discrete isomorphic metrics are at least as fine as all the other ones. Next, let $d$ be one of the EMD $/ \ell_{1}$-positionwise metrics or the pairwise metric. For each two elections $A$ and $B$ (with the same number of candidates and the same number of voters), if $d(A, B)=0$ then either the position matrices of $A$ and $B$ are isomorphic (if $d$ is a positionwise metric) or their weighted majority relations are (if $d$ is the pairwise metric). Since the Borda score vectors can be computed both from the position matrices and from the weighted majority relations, it must be that $d_{\text {Borda }}(A, B)=0$.

Let us now show that EMD $/ \ell_{1}$-positionwise are not as fine as the swap and discrete ones. We form election $X$ with preference profile:

$$
\begin{array}{lll}
x_{1}: a \succ b \succ c, & x_{2}: b \succ a \succ c, & x_{3}: c \succ a \succ b, \\
x_{4}: a \succ c \succ b, & x_{5}: b \succ c \succ a, & x_{6}: c \succ b \succ a .
\end{array}
$$

That is, $X$ contains each possible vote from $\mathcal{L}(\{a, b, c\})$. We also from election $Y$ with the following preference profile:

$$
\begin{array}{lll}
y_{1}: a \succ b \succ c, & y_{2}: b \succ c \succ a, & y_{3}: c \succ a \succ b, \\
y_{4}: a \succ b \succ c, & y_{5}: b \succ c \succ a, & y_{6}: c \succ a \succ b .
\end{array}
$$

The two elections are not isomorphic (e.g., because all the votes in $X$ are distinct, but this is not the case for $Y$ ), but under positionwise metrics their distance is zero. This is so because their position matrices are identical:

$$
\mathcal{P}_{X}=\mathcal{P}_{Y}=\begin{aligned}
& 1 \\
& 2 \\
& 3
\end{aligned}\left[\begin{array}{lll}
a & b & c \\
2 & 2 & 2 \\
2 & 2 & 2 \\
2 & 2 & 2
\end{array}\right] .
$$

Since we also have that the pairwise distance between $X$ and $Y$ is nonzero, it holds that the positionwise metrics are not at least as fine as the pairwise one. To see that the pairwise distance between $X$ and $Y$ is nonzero, note that:

$$
\left.\mathcal{M}_{X}=\begin{array}{c}
a \\
a \\
b
\end{array} \begin{array}{ccc}
a & b & c \\
- & 3 & 3 \\
3 & - & 3 \\
3 & 3 & -
\end{array}\right],
$$

$$
\left.\mathcal{M}_{Y}=\begin{array}{c}
a \\
b \\
\\
\\
\end{array} \begin{array}{ccc}
a & b & c \\
- & 4 & 2 \\
2 & - & 4 \\
4 & 2 & -
\end{array}\right] .
$$

Since all entries of $\mathcal{M}_{X}$ are equal but this is not the case for $\mathcal{M}_{Y}$, the two elections must be at nonzero pairwise distance.

To see that the pairwise metric is not as fine as the swap and discrete isomorphic ones, let us consider election $Z$ with preference profile:

$$
z_{1}: a \succ b \succ c, \quad z_{2}: a \succ b \succ c, \quad z_{3}: a \succ b \succ c,
$$

$$
z_{4}: c \succ b \succ a, \quad z_{5}: c \succ b \succ a, \quad z_{6}: c \succ b \succ a
$$

Clearly, $X$ and $Z$ are not isomorphic. Further, their EMD $/ \ell_{1}$-positionwise distances are nonzero, but their pairwise distance is zero. To see why this is the case, note that:

$$
\left.\mathcal{M}_{X}=\mathcal{M}_{Z}=\begin{array}{c}
a \\
a \\
b \\
c
\end{array}\left[\begin{array}{cc}
a & c \\
- & 3
\end{array}\right]+\begin{array}{ccc}
a & b & c \\
3 & - & 3 \\
3 & 3 & -
\end{array}\right], \quad \quad \mathcal{P}_{Z}=\begin{gathered}
1 \\
2 \\
3
\end{gathered}\left[\begin{array}{ccc}
3 \\
0 & 6 & 0 \\
3 & 0 & 3
\end{array}\right]
$$

Since $\mathcal{P}_{X}$ and $\mathcal{P}_{Z}$ contain different values (e.g., the latter contains value 6 and the former does not) it must be that the positionwise distances between $X$ and $Z$ are nonzero. Pairwise distance between $X$ and $Z$ is zero because their weighted majority relations are identical.

Nonetheless, having many equivalence classes does not automatically make a metric desirable. For example, the discrete isomorphic metric is as fine as the swap one, but has many unappealing properties.

Let us now move to the problem of deciding if a given matrix/vector indeed represents some election. For position matrices, Boehmer et al. [6] have shown this to be easy: If a matrix $M$ has nonnegative entries and its rows and columns sum up to the same value, then there is a polynomial-time computable election $E$ with $M=\mathcal{P}_{E}$. Hence, one can work directly on the matrices and recover elections when needed. Unfortunately, for Borda score vectors and weighted majority relations analogous problems are NP-complete. Thus, by operating on them directly, we may leave the space of elections.

Theorem 1. Given a vector $x$ of nonnegative integers, it is NP-complete to decide if there is an election $E$ with $\mathcal{B}_{E}=x$.

Proof. Yu et al. [27] showed that given a sequence of positive integers $a_{1}, \ldots, a_{m}$ such that $a_{1} \geq$ $a_{2} \geq \cdots \geq a_{m}, \sum_{i=1}^{m} a_{i}=m(m+1)$, and for each $i \in[m]$ we have $2 \leq a_{i} \leq 2 m$, it is NPcomplete to decide if there are two permutations $\phi, \phi^{\prime} \in S_{m}$ such that for all $i \in[m]$ it holds that $\phi(i)+\phi^{\prime}(i)=a_{i}$. We reduce this problem to the one from the statement of the theorem by forming a vector $x=\left(a_{1}-2, \ldots, a_{m}-2\right)$.

If there are two permutations $\phi$ and $\phi^{\prime}$ that satisfy the conditions of Yu et al.'s problem, then we form a two-voter election $E=(C, V)$ as follows: We let $C=[m]$ and we form two votes, $v$ and $v^{\prime}$. For each candidate $i \in C$, the first (the second) voter ranks $i$ on position $m-\phi(i)+1\left(m-\phi^{\prime}(i)+1\right)$; note that the produced votes rank exactly one candidate in each position because $\phi$ and $\phi^{\prime}$ are permutations. Then, the Borda score of each $i \in C$ is $\phi(i)-1+\phi^{\prime}(i)-1=a_{i}-2$.

For the other direction, assume that there is an election $E=(C, V)$ with Borda score vector $x$. Then, $E$ must contain exactly two voters because otherwise the sum of the candidates' scores would either be too large or too small. W.l.o.g., we assume that $C=[m]$ and that each candidate $i \in C$ has Borda score $a_{i}-2$. Let $v$ and $v^{\prime}$ be the two votes in $E$. We form a permutation $\phi$ so that for each $i \in C$ we have $\phi(i)=m-\operatorname{pos}_{v}(i)+1$, We form $\phi^{\prime}$ analogously, but using $v^{\prime}$ instead of $v$. It follows that for each $i \in[m]$ we have $\phi(i)+\phi^{\prime}(i)=\left(a_{i}-2\right)+2=a_{i}$. This completes the proof.

On the positive side, there is an FPT-algorithm for the above problem, parameterized by the number of candidates (note that we take the number $n$ as part of the input for simplicity; it can always be concluded from the sum of the required Borda scores).

Proposition 2. There is an algorithm that given a vector $y=\left(y_{1}, \ldots, y_{m}\right)$ of nonnegative integers and a number $n$, decides if there is an election $E$ with $m$ candidates and $n$ voters in time $\mathcal{O}\left(m^{2 m+1} \cdot n\right)$.

Proof. We construct an Integer Linear Program (ILP) to solve the problem. Let $C=[m]$ be a set of $m$ candidates. For each $v \in \mathcal{L}(C)$, we introduce a variable $x_{v}$ that denotes the number of copies of $v$ in the
election to be constructed. For each candidate $i \in C, y_{i}$ is the Borda score that $i$ should end up with. Our ILP consists of the following constraints, one for each candidate $i \in C$ :

$$
\sum_{v \in \mathcal{L}(C)} x_{v} \cdot\left(m-\operatorname{pos}_{v}(i)\right)=y_{i}
$$

It is immediate that each solution to the ILP corresponds to an election realizing the given score vector and the other way around. Concerning the running time, Eisenbrand and Weismantel [10] proved that an ILP with $t$ constraints, where each entry in the constraint matrix is upper bounded by $\Delta$ and each entry of the vector on the right hand side is upper bounded by $\Gamma$ can be solved in time $\mathcal{O}\left((t \cdot \Delta)^{t} \cdot \Gamma^{2}\right)$. Thus, our problem is solvable in $\mathcal{O}\left(m^{2 m+1} \cdot n\right)$.

The hardness of deciding whether there is an election with a given Borda score vector is not too surprising because it is closely related to strategic voting under the Borda rule, which is also NPcomplete $[3,8]$. The case of weighted majority relation is more intriguing because the classic McGarvey's theorem [22] gives a polynomial-time algorithm for recovering an election with a given relative weighted majority relation (but see also the work of Bachmeier et al. [1]).

Theorem 2. Given an $m \times m$ matrix $M$, it is NP-complete to decide if there is an election $E$ with $\mathcal{M}_{E}=M$.

Proof. We reduce from the NP-complete Restricted X3C problem (RX3C) [15]. Its instances consist of a universe $X=\left\{x_{1}, \ldots, x_{3 t}\right\}$ and a family $\mathcal{S}=\left\{S_{1}, \ldots, S_{3 t}\right\}$ of size- 3 subsets of $X$, where each $x_{i}$ appears in exactly three sets from $\mathcal{S}$. We ask if there is a family $\mathcal{S}^{\prime} \subseteq \mathcal{S}$ of $t$ sets such that $\bigcup_{S_{i} \in \mathcal{S}^{\prime}} S_{i}=X$ (i.e., we ask if there is an exact cover of $X$ ). Let $(X, \mathcal{S})$ be an instance of RX3C. We form a candidate set:

$$
C=\{d\} \cup X \cup\left\{s_{1} \ldots, s_{3 t}\right\} \cup\left\{b_{1}, b_{2}, b_{3}\right\} \cup A \cup F
$$

where $A=\left\{a_{1}, \ldots, a_{3 t}\right\}$ and $F=\left\{f_{1}, \ldots, f_{3 t}\right\}$ are sets of "location" candidates. The candidates $s_{1}, \ldots, s_{3 t}$ correspond to the sets from $\mathcal{S}, b_{1}, b_{2}, b_{3}$ will delineate blocks in the votes, and $d$ will be used to encode the exact cover (if one exists). For each $i \in[3 t]$, by $A(i)$ and $F(i)$ we mean the orderings:

$$
\begin{aligned}
A(i): a_{1} \succ \cdots & \succ a_{i} \succ s_{i} \succ a_{i+1} \succ \cdots \succ a_{3 t} \\
F(i): f_{1} \succ s_{1} & \succ f_{2} \succ s_{2} \succ \cdots \succ f_{i-1} \succ s_{i-1} \\
& \succ f_{i} \succ f_{i+1} \succ s_{i+1} \succ \ldots f_{3 t} \succ s_{3 t} .
\end{aligned}
$$

For a subset $C^{\prime} \subseteq C$ of candidates, $\left[C^{\prime}\right]$ denotes an arbitrary, fixed ordering of the candidates from $C^{\prime}$. For every $S_{i}=\left\{x_{j}, x_{k}, x_{\ell}\right\} \in \mathcal{S}$, let $v_{i}$ denote the following vote:

$$
b_{1} \succ x_{j} \succ x_{k} \succ x_{\ell} \succ b_{2} \succ A(i) \succ\left[X \backslash S_{i}\right] \succ b_{3} \succ F(i)
$$

Let $E^{\prime}=\left(C \backslash\{d\},\left(v_{1}, \ldots, v_{3 t}\right)\right)$ be an election. We form a weighted majority relation $M$ by taking $\mathcal{M}_{E^{\prime}}$ and extending it to include $d$ as follows: We require that $d$ is placed behind $b_{1}$ in exactly $t$ votes, $d$ is placed behind each candidate from $X$ in exactly one vote, and $d$ is never placed behind any other candidate. We claim that there is an election $E$ such that $M=\mathcal{M}_{E}$ if and only if $\mathcal{S}$ contains an exact cover of $X$.
$(\Rightarrow)$ First, let $\mathcal{S}^{\prime} \subseteq \mathcal{S}$ be an exact cover of $X$. To construct $E$, for each $S_{i} \in \mathcal{S}^{\prime}$, we include vote $v_{i}$ with $d$ inserted right in front of $b_{2}$, and for each $S_{i} \in \mathcal{S} \backslash \mathcal{S}^{\prime}$, we include $v_{i}$ with $d$ inserted before $b_{1}$. As $\mathcal{S}^{\prime}$ is an exact cover, $M=\mathcal{M}_{E}$.
$(\Leftarrow)$ It remains to prove that if there is an election realizing $M$, then there is a solution to the given X3C instance. Let $E=(C, V)$ be an election such that $M=\mathcal{M}_{E}$. From now on, speaking of votes, we mean the votes appearing in $E$. We claim the following.

Claim 1. In each vote from $E$, exactly one $s_{i}$ ranks before $b_{3}$.
Proof. We make the following observations, which follow directly from the definition of $M$ :

1. We have $b_{2} \succ a_{1} \succ a_{2} \succ \cdots \succ a_{3 t} \succ b_{3} \succ f_{1} \succ f_{2} \succ \ldots f_{3 t}$ in each vote.
2. Each $s_{i}$ is placed before $b_{3}$ in exactly one vote, behind $f_{i}$ in all but one vote, and before $f_{i+1}$ in each vote. Further, $s_{i}$ is placed behind $a_{i}$ in all votes and before $a_{i+1}$ in one.

From these observations we conclude that in one vote $s_{i}$ is placed before $b_{3}$ and between $a_{i}$ and $a_{i+1}$, and in all other votes $s_{i}$ is placed behind $b_{3}$, between $f_{i}$ and $f_{i+1}$.

Now, for the sake of contradiction, assume that there is a vote where both $s_{i}$ and $s_{j}$, with $i<j$, are placed before $b_{3}$. By the above discussion and by Item 1 from the above list, in this vote it holds that $a_{i} \succ s_{i} \succ \cdots \succ a_{j} \succ s_{j}$ and in all other votes it holds that $f_{i} \succ s_{i} \succ \cdots \succ f_{j} \succ s_{j}$. Thus, $s_{i}$ is ranked ahead of $s_{j}$ in all the votes. But $M$ requires that there is one vote where $s_{j}$ is ranked ahead of $s_{i}$ (due to vote $v_{j}$ in the construction of $M$ ). This proves the claim.

Next, we make the following observations based on $M$ :

1. Each $s_{i}$ is placed behind $b_{2}$ in all votes and before $b_{3}$ in exactly one vote.
2. Each $x_{\ell} \in X$ is placed before $b_{3}$ in all votes.
3. For each $x_{\ell} \in X$ and each $S_{i} \in \mathcal{S}$ not containing $x_{\ell}, x_{\ell}$ is ranked behind $s_{i}$ in exactly one vote.
4. Candidate $d$ is placed in the first position in $2 t$ votes ( $b_{1}$ is always placed before all candidates from $C \backslash\left\{d, b_{1}\right\}$ and $d$ is placed before $b_{1}$ in $2 t$ votes), and before $b_{2}$ in all votes.
5. For each $x_{\ell} \in X$, there is exactly one vote where $x_{\ell}$ is placed before $d$.

By Items 1 to 3 from the above list and by Claim 1, we conclude that for each $S_{i} \in \mathcal{S}$, in the one vote where $s_{i}$ is placed before $b_{3}$ (but still behind $b_{2}$ ), $s_{i}$ is also placed before all candidates from $X \backslash S_{i}$, implying that candidates from $X \backslash S_{i}$ are placed behind $b_{2}$ in this vote.

Let $V^{\prime} \subseteq V$ be the subset of those votes where $d$ is not in the first position. Let $\mathcal{S}^{\prime}$ be the family containing those sets $S_{i}$ for which candidate $s_{i}$ is placed before $b_{3}$ in a vote from $V^{\prime}$. We claim that $\mathcal{S}^{\prime}$ is an exact cover. First, by Claim 1 and by Item 4 from the above list, it follows that $\mathcal{S}^{\prime}$ contains exactly $t$ sets. By Claim 1, it follows that in each vote from $V^{\prime}$ there is a candidate $s_{i}$ corresponding to a member of $\mathcal{S}^{\prime}$ ranked before $b_{3}$. For the sake of contradiction, assume that there is an $x_{\ell} \in X$ such that $x_{\ell}$ is not part of any set from $\mathcal{S}^{\prime}$. Then, by the preceding paragraph, it holds that $x_{\ell}$ is placed behind $b_{2}$ in all votes from $V^{\prime}$. As by Item 4 from the above list $d$ is always placed before $b_{2}, d$ is placed before $x_{\ell}$ in all the votes from $V^{\prime}$. As $d$ is placed in the first position in all other votes, $d$ is always ahead of $x_{\ell}$, contradicting the definition of $M$.

## 5 Diameter and Compass Elections

In this section, we analyze the distances between four "compass" elections of Boehmer et al. [6]. These elections capture four different types of (dis)agreement among the voters and, thus, we expect good metrics to put them far apart. Since the smallest nonzero distances under all our metrics are either 1,2 , or 4 , the larger are the distances between the compass elections, the more space there is between them for other elections. For technical reasons, we fix the number $m$ of candidates to be even, and the number of voters to be $n=t \cdot m!$, where $t$ is some positive integer (we will see ways to relax this assumption). The compass elections are defined as follows:

|  | Discrete | Swap | $\ell_{1}$-Pair. | $\ell_{1}$-Pos. | EMD-Pos. | EMD-Borda. |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| $d($ ID, UN $), m!\mid n$ | $n \frac{m!-1}{m!}$ | $\frac{1}{4} n\left(m^{2}-m\right)$ | $\frac{1}{2} n\left(m^{2}-m\right)$ | $2 n(m-1)$ | $\frac{1}{3} n\left(m^{2}-1\right)$ | $\frac{1}{12} n\left(m^{3}-m\right)$ |
| $d(\mathrm{ID}, \mathrm{AN}), 2 \mid n$ | $\frac{1}{2} n$ | $\frac{1}{4} n\left(m^{2}-m\right)$ | $\frac{1}{2} n\left(m^{2}-m\right)$ | $\frac{1}{2} n m$ | $\frac{1}{4} n m^{2}$ | $\frac{1}{12} n\left(m^{3}-m\right)$ |
| $d(\mathrm{ID}, \mathrm{ST}), \left.\left(\left(\frac{m}{2}\right)!\right)^{2} \right\rvert\, n$ | $n \frac{((m / 2)!)^{2}-1}{((m / 2)!)^{2}}$ | $\frac{1}{8} n\left(m^{2}-2 m\right)$ | $\frac{1}{4} n\left(m^{2}-2 m\right)$ | $2 n(m-2)$ | $\frac{1}{6} n\left(m^{2}-4\right)$ | $\frac{1}{48} n\left(m^{3}+3 m^{2}-4 m\right)$ |
| $d(\mathrm{UN}, \mathrm{AN}), m!\mid n$ | $n \frac{m!-2}{m!}$ | $\Theta\left(n m^{2}\right)^{\dagger}$ | 0 | $2 n(m-2)$ | $\frac{1}{6} n\left(m^{2}-4\right)$ | 0 |
| $d(\mathrm{UN}, \mathrm{ST}), m!\mid n$ | $n \frac{m!-(m / 2)!^{2}}{m!}$ | $\frac{1}{8} n m^{2}$ | $\frac{1}{4} n m^{2}$ | $\frac{1}{2} m$ | $\frac{1}{4} n m^{2}$ | $\frac{1}{16} n\left(m^{3}-m\right)$ |
| $d(\mathrm{AN}, \mathrm{ST}), \left.\left(\left(\frac{m}{2}\right)!\right)^{2} \right\rvert\, n$ | $n \frac{((m / 2)!)^{2}-1}{((m / 2)!)^{2}}$ | $\Theta\left(n m^{2}\right)^{\dagger}$ | $\frac{1}{4} n m^{2}$ | $2 n(m-2)$ | $\frac{13}{48} n\left(m^{2}-\frac{16}{13}\right)$ | $\frac{1}{48} n\left(m^{3}+3 m^{2}-4 m\right)$ |

Table 2: Overview of the distances of the compass matrices for our metrics. In the leftmost column, we denote conditions on $m$ and $n$ that need to hold in order for the two respective compass elections to be well-defined and our formula to hold. $\dagger$ For $d_{\text {swap }}(\mathrm{UN}, \mathrm{AN})$ and $d_{\text {swap }}(\mathrm{AN}, \mathrm{ST})$, we do not have a closed form formula (and we are not sure if it exists), however it holds that $1 / 8 n\left(m^{2}-3 m+2\right) \leq d_{\text {swap }}(\mathrm{UN}, \mathrm{AN}) \leq 1 / 4 n\left(m^{2}-m\right)$ and also $1 / 8 n\left(m^{2}-2 m\right) \leq d_{\text {swap }}(\mathrm{AN}, \mathrm{ST}) \leq 1 / 4 n\left(m^{2}-m\right)$. Results for EMD-positionwise come from Boehmer et al. [6].

1. In the identity elections, denoted ID, all voters have the same, fixed preference order.
2. In the antagonism elections, denoted AN, half of the voters rank the candidates in one way and half of the voters rank them in the opposite way.
3. In the uniformity elections, denoted UN, each possible vote appears the same number of times.
4. In the stratification elections, denoted ST, the candidates are partitioned into two equal-sized sets $A$ and $B$. Each possible preference order where all members of $A$ are ranked ahead of $B$ appears the same number of times.

The next proposition gives asymptotic distances between the compass elections (we provide exact values in Table 2).

Proposition 3. Let $X$ and $Y$ be two distinct compass elections. Then, $d_{\text {Borda }}(X, Y)=\Theta\left(n m^{3}\right)$, $d_{\text {swap }}(X, Y)=d_{\text {pos }}^{\text {emd }}(X, Y)=d_{\text {pair }}(X, Y)=\Theta\left(n m^{2}\right), d_{\text {pos }}^{\ell_{1}}(X, Y)=\Theta(n m)$, and $d_{\text {disc }}(X, Y)=$ $\Theta(n)$, except that $d_{\text {pair }}(\mathrm{AN}, \mathrm{UN})=d_{\text {Borda }}(\mathrm{AN}, \mathrm{UN})=0$.

The distances between the compass elections are the largest under the swap and EMD-positionwise metrics, followed by those under $\ell_{1}$-positionwise and discrete isomorphic metrics. Pairwise and Bordawise metrics perform particularly badly because they cannot distinguish between UN and AN. Yet, except for this, the compass elections are asymptotically as distant under each of our metrics as possible. Indeed, ID and UN even form diameters of our election spaces (this also confirms a conjecture of Boehmer et al. [6]). We present only the proof for EMD-positionwise here and defer the proofs for all other metrics to Appendix A.

Theorem 3. Let $d$ be one of our six metrics. For each two elections $X$ and $Y$ (with sizes as specified at the beginning of this section) it holds that $d(X, Y) \leq d($ ID, UN $)$.

Proof (EMD-positionwise). The EMD-positionwise metric can be seen as working over matrices whose entries are nonnegative and whose rows and columns sum up to the same value. Let $A$ and $B$ be two such matrices, whose rows and columns sum up to some value $n^{\prime}$. Let $A / n^{\prime}$ and $B / n^{\prime}$ be the same matrices, but with their entries divided by $n^{\prime}$. Note that $d_{\mathrm{pos}}^{\mathrm{emd}}(A, B)=n^{\prime} \cdot d_{\mathrm{pos}}^{\mathrm{emd}}\left(A / n^{\prime}, B / n^{\prime}\right)$. From now on, we focus on matrices whose entries are nonnegative and whose rows and columns sum up to 1 (they are called bistochastic).

Boehmer et al. [6] have shown that $d_{\mathrm{pos}}^{\mathrm{emd}}(\mathrm{ID}, \mathrm{UN})=n\left(m^{2}-1\right) / 3$. We claim that for each two $m \times m$ bistochastic matrices $X$ and $Y$ it holds that $d_{\text {pos }}^{\text {emd }}(X, Y) \leq\left(m^{2}-1\right) / 3$. For the sake of contradiction, assume that the opposite holds. Let $x_{1}, \ldots, x_{m}$ be the columns of $X$ and $y_{1}, \ldots, y_{m}$ be the columns
of $Y$. Without loss of generality, we assume that $d_{\mathrm{pos}}^{\mathrm{emd}}(X, Y)=\sum_{i \in[m]} \mathrm{emd}\left(x_{i}, y_{i}\right)$; otherwise we could reorder the columns of one of the matrices. By definition of the EMD metric, we have that $\sum_{i \in[m]} \operatorname{emd}\left(x_{i}, y_{i}\right)=\sum_{i \in[m]} \ell_{1}\left(\hat{x}_{i}, \hat{y}_{i}\right)$. For each $i \in[m]$, we write $\hat{x}_{i, 1}, \ldots, \hat{x}_{i, m}$ to denote the entries of the cumulative vector $\hat{x}_{i}$; we use analogous notation for $\hat{y}_{i}$. Note that in the matrices with columns $\hat{x}_{1}, \ldots, \hat{x}_{m}$ and $\hat{y}_{1}, \ldots, \hat{y}_{m}$, for each $j \in[m]$, the $j$-th row sums up to $j$ (we refer to this as cumulative rows property). Using these observations, we note that:

$$
\begin{aligned}
\sum_{i \in[m]} & \mathrm{emd}\left(x_{i}, y_{i}\right)=\sum_{i \in[m]} \ell_{1}\left(\hat{x}_{i}, \hat{y}_{i}\right) \\
& =\sum_{i, j \in[m]}\left|\hat{x}_{i, j}-\hat{y}_{i, j}\right| \\
& =\sum_{i, j \in[m]}\left(\max \left(\hat{x}_{i, j}, \hat{y}_{i, j}\right)-\min \left(\hat{x}_{i, j}, \hat{y}_{i, j}\right)\right) \\
& =\sum_{i, j \in[m]}\left(\hat{x}_{i, j}+\hat{y}_{i, j}\right)-2 \sum_{i, j \in[m]} \min \left(\hat{x}_{i, j}, \hat{y}_{i, j}\right) \\
& =2\left(\sum_{j \in[m]} j\right)-2 \sum_{i, j \in[m]} \min \left(\hat{x}_{i, j}, \hat{y}_{i, j}\right) \\
& =m(m+1)-2 \sum_{i, j \in[m]} \min \left(\hat{x}_{i, j}, \hat{y}_{i, j}\right) .
\end{aligned}
$$

Thus, if $d_{\text {pos }}^{\mathrm{emd}}(X, Y)>\left(m^{2}-1\right) / 3$, then it must hold that:

$$
\begin{aligned}
\sum_{i, j \in[m]} & \min \left(\hat{x}_{i, j}, \hat{y}_{i, j}\right)<\frac{1}{2}\left(m(m+1)-\frac{m^{2}-1}{3}\right) \\
& =\left(2 m^{2}+3 m+1\right) / 6=(2 m+1)(m+1) / 6
\end{aligned}
$$

In the following, for each $i, k \in[m]$ with $i+k>m$, if $i+k$ is used as a column index, then we take it to be $i+k-m$ (i.e., column indices "cycle"). For each $k \in[m]$, we have $d_{\mathrm{pos}}^{\mathrm{emd}}(X, Y) \leq \sum_{i \in[m]} \mathrm{emd}\left(x_{i}, y_{i+k}\right)$; if this were not the case, then our assumption that $d_{\mathrm{pos}}^{\mathrm{emd}}(X, Y)=$ $\sum_{i \in[m]} \operatorname{emd}\left(x_{i}, y_{i}\right)$ would have been false. Consequently, for every $k \in[m]$, repeating the above reasoning, we get:

$$
\sum_{i, j \in[m]} \min \left(\hat{x}_{i, j}, \hat{y}_{i+k, j}\right)<(2 m+1)(m+1) / 6,
$$

If $a, b \in[0,1]$ then $a \cdot b \leq \min (a, b)$. As for each $i, j \in[m]$ we have $\hat{x}_{i, j}, \hat{y}_{i, j} \in[0,1]$, for each $k \in[m]$ we have:

$$
\sum_{i, j \in[m]} \hat{x}_{i, j} \cdot \hat{y}_{i+k, j}<(2 m+1)(m+1) / 6 .
$$

By summing this inequality sidewise for all $k \in[m]$, we get:

$$
\sum_{i, j \in[m]} \hat{x}_{i, j} \cdot \sum_{k \in[m]} \hat{y}_{k, j}<m(2 m+1)(m+1) / 6 .
$$

By applying the cumulative rows property, we obtain:

$$
\sum_{j=1}^{m} j^{2}<m(2 m+1)(m+1) / 6 .
$$

Since we know that $\sum_{j=1}^{m} j^{2}=m(2 m+1)(m+1) / 6$, this is a contradiction. Hence, for all $m \times m$ bistochastic matrices $X, Y$ we have $d_{\mathrm{pos}}^{\mathrm{emd}}(X, Y) \leq\left(m^{2}-1\right) / 3$. Thus, for all elections with $m$ candidates and $n$ voters, their EMD-positionwise distance is at most $n\left(m^{2}-1\right) / 3$.

In the above proof we do not work directly with elections, but, rather, with normalized position matrices. Viewed this way, ID is a unit diagonal matrix and UN is a matrix whose entries are all equal. Indeed, this is how Boehmer et al. [6] defined them. In this way, the proof works for any number of voters (this also applies to $\ell_{1}$-positionwise and, using normalized weighted majority relations, to pairwise).

For Bordawise, the proof of Theorem 3 shows that for each election the sum of its distances from ID and UN is the same. That is, under this metric every election lays on the diameter.

| $\|C\| \times\|V\|$ | EMD-Pos. | $\ell_{1}$-Pos. | $\ell_{1}$-Pair. | Bordawise | Discrete |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $3 \times 3$ | 0.942 | 0.748 | 0.860 | 0.587 | 0.614 |
| $3 \times 4$ | 0.900 | 0.697 | 0.860 | 0.659 | 0.636 |
| $3 \times 5$ | 0.920 | 0.759 | 0.843 | 0.606 | 0.680 |
| $4 \times 3$ | 0.850 | 0.577 | 0.735 | 0.442 | 0.402 |
| $4 \times 4$ | 0.782 | 0.561 | 0.689 | 0.415 | 0.434 |
| $4 \times 5$ | 0.772 | 0.567 | 0.672 | 0.439 | 0.432 |
| $10 \times 50$ <br> $(340$ elections) | 0.745 | 0.563 | 0.708 | 0.430 | 0.342 |

Table 3: Pearson correlation coefficients between swap distances and the other ones computed for our datasets.

## 6 Maps and Correlations

While in the previous section we studied distances between hand-crafted elections, now we analyze automatically-generated ones. We test how our metrics correlate with the swap one, and we compare their maps of elections.

We use two datasets. The first one consists of all small elections, as in Section 4. The second one resembles those used in the maps of Szufa et al. [25] and Boehmer et al. [6], but consists of elections with 10 candidates and 50 voters, ${ }^{3}$ generated according to the following statistical models (see the just-cited papers for more details):

IC, Urn, and Mallows We generated 20 elections using the impartial culture model (IC), where each vote is selected uniformly at random, and 60 elections for each of the classic urn and Mallows models (we used the same sampling protocol as Boehmer et al. [6]).

SP, SC, and SPOC We generated 20 single-peaked elections (SP elections) uniformly at random (this is known as the SP Walsh model [26]), 20 such elections using the Conitzer model [7], and 20 singlepeaked on a circle elections (SPOC elections), uniformly at random [23]. We also generated 20 single-crossing elections (SC elections) using the sampling protocol of Szufa et al. [25].

Euclidean In these elections, each candidate and voter is a point from some Euclidean space and the voters rank the candidates with respect to their increasing distances from them. We have generated the points uniformly at random from (i) a 1D interval, (ii) a 2D sphere, (iii) a 2D disc, and (iv) a 3D cube; in each case we generated 20 elections.

Group-Separable Group-separable elections were introduced by Inada [17, 18]. We use a definition based on trees (see, e.g., the works of Karpov [19] and Faliszewski et al. [13] for a discussion and motivation). Consider an ordered, rooted tree where each leaf is a unique candidate. To obtain a vote, for each of the nodes we can choose to reverse the order of its children and, then, rank the candidates by reading them off from left to right. Given such a tree, we sample a vote by reversing the order of each node's children with probability $1 / 2$. We generated 20 elections using complete binary trees, and 20 elections using binary caterpillar trees (a binary caterpillar tree is defined recursively to either be a leaf, or a root whose one child is a leaf and whose other child is a root of a binary caterpillar tree.)

For each dataset we have computed the Pearson Correlation Coefficient (PCC) between the swap distances and those provided by the other metrics. PCC is a classic measure of correlation that takes

[^2]| name | EMD-Pos. | $\ell_{1}$-Pos. | $\ell_{1}$-Pair. | EMD-Borda. | Discrete |

Table 4: Pearson correlation coefficients between swap distances and the other ones computed for each used statistical culture.
values between -1 and 1 ; its absolute value gives the strength of the correlation and the sign indicates its positive or negative nature. Szufa et al. [25] presented a similar experiment, but on a much smaller scale, and on a limited set of metrics. We present our results in Table 3. We see that EMD-positionwise is most strongly correlated with the swap metric, with a large advantage over all the metrics, except for pairwise (where the advantage is smaller). While in Table 3, we have provided the Person correlation coefficient between swap distances and the other ones for our $34010 \times 50$ elections, in Table 4 we take a more fine grained view: Recall that the synthetic dataset that we use consists of elections sampled from 13 synthetic models: for 11 of them we generated 20 elections and for the Urn and Mallows model we sampled 60 elections. In Table 3, for each statistical culture, we give the correlation coefficients between the swap distances of all pairs of elections from this culture and their distances according to our other metrics. In Figure 1, we depict the correlation between swap distances and the other ones on the level of election pairs for the full 340 elections dataset.

Next, we used the techniques of Szufa et al. [25] to draw the maps of elections from the $10 \times 50$ dataset. We show these maps in Figure 2 (we omit the discrete metric as its visualization is nearly meaningless); each dot is an election, its color corresponds to the statistical model it comes from, and the points are placed so that their Euclidean distances resemble those according to a given metric as much as possible (following Szufa et al. [25], we used the algorithm of Fruchterman and Reingold [14] to place the points). We also included the compass elections on the maps (for the swap metric, their location is approximate).

The maps provided by the isomorphic swap distance and both positionwise metrics are remarkably similar, but, nonetheless, there are some differences. For example, under the swap metric groupseparable caterpillar elections are closer to the IC ones than the group-separable balanced elections (both on the map and in terms of actual distances), whereas according to the positionwise metrics this relation is reversed. Also, $\ell_{1}$-positionwise clearly distinguishes between 2D-Sphere and group-separable balanced elections (like the swap metric), but EMD-positionwise does not. Generally, the area between UN and AN is quite challenging for our metrics (fortunately, according to Boehmer et al. [6], only few real-life elections land there). The maps for the pairwise and Bordawise metrics illustrate their flaws identified in the previous sections (e.g., Bordawise and pairwise conflate UN and AN, and the former also puts all the elections on the diameter, which explains its elongated shape; the curvature is an artifact of the drawing algorithm).

All in all, the positionwise metrics seem to perform best in this section, with the PCC values pointing to the EMD one.

Figure 1: For each of our five non-swap metrics $d$, we show the correlation between the swap distances and $d$ distances in our synthetic dataset of $34010 \times 50$ elections. Each point represents a pair of elections and its $x$-coordinate displays the swap distance of this pair and the $y$-coordinate its $d$ distance. Moreover, the Pearson correlation coefficient and the Spearman correlation coefficient between the swap distances and $d$ distances of all pairs are included.

## 7 Metrics as Graphs

We conclude by discussing the intrinsicness of our metrics (see, e.g., the textbook of Khamsi and Kirk [20] for more details on this notion). Consider a graph whose vertices are equivalence classes of a given metric and where the edges connect those classes that are at minimum nonzero distance from each other. Under the swap distance, each edge corresponds to a swap of adjacent candidates and each shortest path corresponds to the distance between its endpoints. This means that the swap distance is intrinsic.

Definition 1. Let $\alpha \geq 1$ be a number. A metric $d$ is $\alpha$-intrinsic if for each pair of elections $X$ and $Y$ (with the same number of candidates and the same number of voters), there are elections $X=$ $E_{0}, E_{1}, E_{2}, \ldots, E_{k-1}, E_{k}=Y$ such that $\sum_{i=1}^{k} d\left(E_{i-1}, E_{i}\right) \leq \alpha \cdot d(X, Y)$, and for each $i \in[k]$, $d\left(E_{i-1}, E_{i}\right)$ is the smallest nonzero distance between elections under $d$. If $\alpha=1$, then $d$ is intrinsic.

An intrinsic metric can be viewed as performing a series of simple, unit operations. Among our metrics only swap and discrete are intrinsic, but the positionwise ones are 2 -intrinsic (this is, perhaps, the most technically involved of our results). We defer the rather technically involved proof in Appendix B.

Theorem 4. The swap and discrete metrics are intrinsic, but neither of the EMD $/ \ell_{1}$-positionwise, pairwise, and Bordawise metric is intrinsic, but the EMD- and $\ell_{1}$-positionwise metrics are 2 -intrinsic yet not $\alpha$-intrinsic for any $\alpha<2$.

We conjecture that pairwise is not $\alpha$-intrinsic for any $\alpha \geq 1$.

Figure 2: Maps of elections prepared using each of our metrics.

## 8 Summary

We found that the EMD- and $\ell_{1}$-positionwise metrics are quite similar to the swap one (which, computational issues aside, we view as ideal), but the EMD variant seems better. This justifies the choice of the EMD-positionwise metric for the maps of Szufa et al. [25] and Boehmer et al. [6]. Yet, we ask for a metric that would perform even better, especially on elections between the uniform and antagonism ones. With our study of intrinsicness, we have initiated an axiomatic analysis of our metrics; it would be interesting to extend this analysis to better understand their properties.

## A Proof of Theorem 3

In this section, we prove the following theorem:
Theorem 3. For each two elections $X$ and $Y$ (with an even number $m$ of candidates and $n=t \cdot m$ ! voters where $t$ is some positive integer) it holds that $d(X, Y) \leq d(\mathrm{ID}, \mathrm{UN})$.

We do this by separately proving the statement for each of our metrics. We first prove it in Lemma 1 for the swap and discrete metric. Then, in Lemma 2 for the $\ell_{1}$-positionwise metric. Subsequently, in Lemma 3 for the EMD-positionwise metric, in Lemma 4 for the $\ell_{1}$-pairwise metric, and finally in Lemma 5 for the Bordawise metric.

## A. 1 Swap and Discrete Isomorphic Metrics

Lemma 1. For each two elections $X$ and $Y$ with $m$ candidates and $t \cdot m$ ! voters it holds that

$$
\begin{aligned}
d_{\text {swap }}(X, Y) & \leq d_{\text {swap }}(\mathrm{ID}, \mathrm{UN}), \quad \text { and } \\
d_{\text {disc }}(X, Y) & \leq d_{\text {disc }}(\text { ID, UN }) .
\end{aligned}
$$

Proof. Let $d$ be either $d_{\text {swap }}$ or $d_{\text {disc }}$. Consider arbitrary elections $X=(C, V)$ and $Y=(D, U)$ with $|C|=|D|=m$ and $|V|=|U|=n=t \cdot m!$ for some $t \in \mathbb{N}$. Let us denote $V=\left\{v_{1}, v_{2}, \ldots, v_{n}\right\}$ and $U=\left\{u_{1}, u_{2}, \ldots, u_{n}\right\}$. From the definition of isomorphic metrics, we get for each bijection $\sigma \in$ $\Pi(C, D)$ the following bound for the distance between $X$ and $Y$ :

$$
d(X, Y) \leq \sum_{i=1}^{n} d\left(\sigma\left(v_{i}\right), u_{i}\right)
$$

Now, if we take the right hand side of this inequality and sum it for all possible bijections $\sigma$, then by rearranging the order of summation we get:

$$
\sum_{\sigma \in \Pi(C, D)} \sum_{i=1}^{n} d\left(\sigma\left(v_{i}\right), u_{i}\right)=\sum_{i=1}^{n} \sum_{\sigma \in \Pi(C, D)} d\left(\sigma\left(v_{i}\right), u_{i}\right) .
$$

Observe that for each $i \in[n], \sum_{\sigma \in \Pi(C, D)} d\left(\sigma\left(v_{i}\right), u_{i}\right)$ is the sum of distances between one vote and all possible votes. Hence, it is exactly the distance between identity and uniformity elections with $m$ candidates and $m$ ! votes, which is $t$ times smaller than the distance between the considered elections ID and UN with $m$ candidates and $t \cdot m!$ votes. Thus,

$$
\begin{aligned}
\sum_{\sigma \in \Pi(C, D)} \sum_{i=1}^{n} d\left(\sigma\left(v_{i}\right), u_{i}\right) & =\sum_{i=1}^{n} \frac{1}{t} \cdot d(\mathrm{ID}, \mathrm{UN}) \\
& =\frac{n}{t} \cdot d(\mathrm{ID}, \mathrm{UN})
\end{aligned}
$$

Hence, from pigeonhole principle, there exists a bijection $\sigma^{*} \in \Pi(C, D)$ such that:

$$
\sum_{i=1}^{n} d\left(\sigma^{*}\left(v_{i}\right), u_{i}\right) \leq \frac{n}{t \cdot|\Pi(C, D)|} \cdot d(\mathrm{ID}, \mathrm{UN})=d(\mathrm{ID}, \mathrm{UN})
$$

Inserting this into the original bound for the distance between $X$ and $Y$, we get:

$$
d(X, Y) \leq d(\mathrm{ID}, \mathrm{UN})
$$

## A. $2 \quad \ell_{1}$-Positionwise Metric

Lemma 2. For each two elections $X$ and $Y$ with $m$ candidates and $t \cdot m$ ! voters it holds that

$$
d_{\mathrm{pos}}^{\ell_{1}}(X, Y) \leq d_{\mathrm{pos}}^{\ell_{1}}(\mathrm{ID}, \mathrm{UN}) .
$$

Proof. The $\ell_{1}$-positionwise metric can be seen as working over matrices whose entries are nonnegative and whose rows and columns sum up to the same value. Let $A$ and $B$ be two such matrices, whose rows and columns sum up to some value $n^{\prime}$. Then, by $A / n^{\prime}$ and $B / n^{\prime}$ let us denote the same matrices, but with their entries divided by $n^{\prime}$. Note that $d_{\text {pos }}^{\ell_{1}}(A, B)=n^{\prime} \cdot d_{\text {pos }}^{\ell_{1}}\left(A / n^{\prime}, B / n^{\prime}\right)$. From now on, we focus on matrices whose entries are nonnegative and whose rows and columns sum up to 1 (they are called bistochastic).

It is easy to check that $d_{\mathrm{pos}}^{\ell_{1}}(\mathrm{ID}, \mathrm{UN})=n(2 m-2)$. We prove that for each two $m \times m$ bistochastic matrices $X$ and $Y$ it holds that $d_{\text {pos }}^{\ell_{1}}(X, Y) \leq 2 m-2$. For the sake of contradiction, assume otherwise, i.e., there exist matrices $X$ and $Y$ such that $d_{\text {pos }}^{\ell_{1}}(X, Y)>2 m-2$. Let $x_{1}, \ldots, x_{m}$ be the columns of matrix $X$ and $y_{1}, \ldots, y_{m}$ the columns of $Y$. Without loss of generality, we assume that $d_{\text {pos }}^{\ell_{1}}(X, Y)=$ $\sum_{i \in m} \ell_{1}\left(x_{i}, y_{i}\right)$; otherwise we could rearrange the columns of one of the matrices. For each $i \in[m]$, we write $x_{i, 1}, \ldots, x_{i, m}$ to denote the entries of column $x_{i}$; we use analogous notation for $y_{i}$. Then, observe that

$$
\begin{align*}
d_{\text {pos }}^{\ell_{1}}(X, Y) & =\sum_{i, j \in[m]}\left|x_{i, j}-y_{i, j}\right| \\
& =\sum_{i, j \in[m]}\left(\max \left(x_{i, j}, y_{i, j}\right)-\min \left(x_{i, j}, y_{i, j}\right)\right) \\
& =\sum_{i, j \in[m]}\left(x_{i, j}+y_{i, j}\right)-2 \sum_{i, j \in[m]} \min \left(x_{i, j}, y_{i, j}\right) \\
& =\sum_{j \in[m]} 2-2 \sum_{i, j \in[m]} \min \left(x_{i, j}, y_{i, j}\right) \\
& =2 m-2 \sum_{i, j \in[m]} \min \left(x_{i, j}, y_{i, j}\right) . \tag{1}
\end{align*}
$$

Thus, if $d_{\text {pos }}^{\ell_{1}}(X, Y)>2 m-2$, then it must hold that:

$$
\begin{equation*}
\sum_{i, j \in[m]} \min \left(x_{i, j}, y_{i, j}\right)<1 . \tag{2}
\end{equation*}
$$

In the following, for each $i, k \in[m]$, if $i+k>m$ and $i+k$ is used as a column index, then we take it to be $i+k-m$ (i.e., column indices "cycle"). For each $k \in[m]$, we have $d_{\text {pos }}^{\ell_{1}}(X, Y) \leq$ $\sum_{i \in[m]} \ell_{1}\left(x_{i}, y_{i+k}\right)$; if this was not the case, then our assumption that $d_{\text {pos }}^{\ell_{1}}(X, Y)=\sum_{i \in[m]} \ell_{1}\left(x_{i}, y_{i}\right)$ would have been false. Consequently, for every $k \in[m]$, repeating the reasoning from Eq. (1) and Eq. (2), we get:

$$
\sum_{i, j \in[m]} \min \left(x_{i, j}, y_{i+k, j}\right)<1 .
$$

Observe that if $a, b \in[0,1]$, then it holds that $a \cdot b \leq \min (a, b)$. Since for each $i, j \in[m]$, we have $x_{i, j}, y_{i, j} \in[0,1]$, for each $k \in[m]$, it holds that:

$$
\sum_{i, j \in[m]} x_{i, j} \cdot y_{i+k, j}<1 .
$$

By summing this inequality sidewise for all $k \in\{1, \ldots, m\}$, we obtain:

$$
\sum_{i, j \in[m]} x_{i, j} \cdot \sum_{k=1}^{m} y_{k, j}<m
$$

Since $Y$ is bistochastic, we get that $\sum_{k=1}^{m} y_{k, j}=1$. Thus,

$$
\sum_{i, j \in[m]} x_{i, j}<m
$$

which contradicts the fact that $X$ is a bistochastic matrix, as the entries of a bistochastic matrix sum up to $m$. Hence, for all $m \times m$ bistochastic matrices $X, Y$ we have $d_{\text {pos }}^{\ell_{1}}(X, Y) \leq 2 m-2$. Thus, for all elections with $m$ candidates and $n=t \cdot m$ ! voters, their $\ell_{1}$-positionwise distance is at most $2 n(m-1)$.

## A. 3 EMD-Positionwise Metric

Lemma 3. For each two elections $X$ and $Y$ with $m$ candidates and $t \cdot m$ ! voters it holds that

$$
d_{\mathrm{pos}}^{\mathrm{emd}}(X, Y) \leq d_{\mathrm{pos}}^{\mathrm{emd}}(\mathrm{ID}, \mathrm{UN})
$$

Proof. The EMD-positionwise metric can be seen as working over matrices whose entries are nonnegative and whose rows and columns sum up to the same value. Let $A$ and $B$ be two such matrices, whose rows and columns sum up to some value $n^{\prime}$. Let $A / n^{\prime}$ and $B / n^{\prime}$ be the same matrices, but with their entries divided by $n^{\prime}$. Note that $d_{\mathrm{pos}}^{\mathrm{emd}}(A, B)=n^{\prime} \cdot d_{\mathrm{pos}}^{\mathrm{emd}}\left(A / n^{\prime}, B / n^{\prime}\right)$. From now on, we focus on matrices whose entries are nonnegative and whose rows and columns sum up to 1 (they are called bistochastic).

Boehmer et al. [6] have shown that $d_{\mathrm{pos}}^{\mathrm{emd}}(\mathrm{ID}, \mathrm{UN})=n\left(m^{2}-1\right) / 3$. We claim that for each two $m \times m$ bistochastic matrices $X$ and $Y$ it holds that $d_{\text {pos }}^{\mathrm{emd}}(X, Y) \leq\left(m^{2}-1\right) / 3$. For the sake of contradiction, assume that the opposite holds. Let $x_{1}, \ldots, x_{m}$ be the columns of $X$ and $y_{1}, \ldots, y_{m}$ be the columns of $Y$. Without loss of generality, we assume that $d_{\text {pos }}^{\mathrm{emd}}(X, Y)=\sum_{i \in[m]} \operatorname{emd}\left(x_{i}, y_{i}\right)$; otherwise we could reorder the columns of one of the matrices. By definition of the EMD metric, we have that $\sum_{i \in[m]} \operatorname{emd}\left(x_{i}, y_{i}\right)=\sum_{i \in[m]} \ell_{1}\left(\hat{x}_{i}, \hat{y}_{i}\right)$. For each $i \in[m]$, we write $\hat{x}_{i, 1}, \ldots, \hat{x}_{i, m}$ to denote the entries of the cumulative vector $\hat{x}_{i}$; we use analogous notation for $\hat{y}_{i}$. Note that in the matrices with columns $\hat{x}_{1}, \ldots, \hat{x}_{m}$ and $\hat{y}_{1}, \ldots, \hat{y}_{m}$, for each $j \in[m]$, the $j$-th row sums up to $j$ (we refer to this as the cumulative rows property). Using these observations, we note that:

$$
\begin{align*}
\sum_{i \in[m]} & \operatorname{emd}\left(x_{i}, y_{i}\right)=\sum_{i \in[m]} \ell_{1}\left(\hat{x}_{i}, \hat{y}_{i}\right) \\
& =\sum_{i, j \in[m]}\left|\hat{x}_{i, j}-\hat{y}_{i, j}\right| \\
& =\sum_{i, j \in[m]}\left(\max \left(\hat{x}_{i, j}, \hat{y}_{i, j}\right)-\min \left(\hat{x}_{i, j}, \hat{y}_{i, j}\right)\right) \\
& =\sum_{i, j \in[m]}\left(\hat{x}_{i, j}+\hat{y}_{i, j}\right)-2 \sum_{i, j \in[m]} \min \left(\hat{x}_{i, j}, \hat{y}_{i, j}\right) \\
& =2\left(\sum_{j \in[m]} j\right)-2 \sum_{i, j \in[m]} \min \left(\hat{x}_{i, j}, \hat{y}_{i, j}\right) \\
& =m(m+1)-2 \sum_{i, j \in[m]} \min \left(\hat{x}_{i, j}, \hat{y}_{i, j}\right) . \tag{3}
\end{align*}
$$

Thus, if $d_{\mathrm{pos}}^{\mathrm{emd}}(X, Y)>\left(m^{2}-1\right) / 3$, then it must hold that:

$$
\begin{align*}
& \sum_{i, j \in[m]} \min \left(\hat{x}_{i, j}, \hat{y}_{i, j}\right)<\frac{1}{2}\left(m(m+1)-\frac{m^{2}-1}{3}\right) \\
& \quad=\left(2 m^{2}+3 m+1\right) / 6=(2 m+1)(m+1) / 6 \tag{4}
\end{align*}
$$

In the following, for each $i, k \in[m]$ with $i+k>m$, if $i+k$ is used as a column index, then we take it to be $i+k-m$ (i.e., column indices "cycle"). For each $k \in[m]$, we have $d_{\mathrm{pos}}^{\mathrm{emd}}(X, Y) \leq \sum_{i \in[m]} \mathrm{emd}\left(x_{i}, y_{i+k}\right)$; if this were not the case, then our assumption that $d_{\mathrm{pos}}^{\mathrm{emd}}(X, Y)=$ $\sum_{i \in[m]} \mathrm{emd}\left(x_{i}, y_{i}\right)$ would have been false. Consequently, repeating the reasoning from Eq. (3) and Eq. (4) for every $k \in[m]$, we get:

$$
\sum_{i, j \in[m]} \min \left(\hat{x}_{i, j}, \hat{y}_{i+k, j}\right)<(2 m+1)(m+1) / 6
$$

If $a, b \in[0,1]$ then $a \cdot b \leq \min (a, b)$. As for each $i, j \in[m]$ we have $\hat{x}_{i, j}, \hat{y}_{i, j} \in[0,1]$, for each $k \in[m]$ we have:

$$
\sum_{i, j \in[m]} \hat{x}_{i, j} \cdot \hat{y}_{i+k, j}<(2 m+1)(m+1) / 6
$$

By summing this inequality sidewise for all $k \in[m]$, we get:

$$
\sum_{i, j \in[m]} \hat{x}_{i, j} \cdot \sum_{k \in[m]} \hat{y}_{k, j}<m(2 m+1)(m+1) / 6 .
$$

By applying the cumulative rows property, we obtain:

$$
\sum_{j=1}^{m} j^{2}<m(2 m+1)(m+1) / 6
$$

Since we know that $\sum_{j=1}^{m} j^{2}=m(2 m+1)(m+1) / 6$, this is a contradiction. Hence, for all $m \times m$ bistochastic matrices $X, Y$ we have $d_{\mathrm{pos}}^{\mathrm{emd}}(X, Y) \leq\left(m^{2}-1\right) / 3$. Thus, for all elections with $m$ candidates and $n$ voters, their EMD-positionwise distance is at most $n\left(m^{2}-1\right) / 3$.

## A. 4 Pairwise Metric

Lemma 4. For each two elections $X$ and $Y$ with $m$ candidates and $t \cdot m$ ! voters it holds that

$$
d_{\text {pair }}(X, Y) \leq d_{\text {pair }}(\mathrm{ID}, \mathrm{UN})
$$

Proof. The pairwise metric can be seen as working over matrices whose entries are nonnegative, the entries on the diagonal are zero, and the sum of entries symmetrical with respect to the diagonal is constant, i.e., there is some $n^{\prime}$ such that $x_{i, j}+x_{j, i}=n^{\prime}$, for each $i, j \in[m], i \neq j$. Let $A$ and $B$ be two such matrices and by $A / n^{\prime}$ and $B / n^{\prime}$ we denote the same matrices but with entries divided by $n^{\prime}$. Note that $d_{\text {pair }}(A, B)=n^{\prime} \cdot d_{\text {pair }}\left(A / n^{\prime}, B / n^{\prime}\right)$. From now on, we focus on matrices with nonnegative entries, zeros on the diagonal, and s.t. entries symmetrical with respect to the diagonal sum up to 1 (let us call them normalized pairwise matrices).

Observe that $d_{\text {pair }}(\mathrm{ID}, \mathrm{UN})=n\left(m^{2}-m\right) / 2$. We show that for each two $m \times m$ normalized pairwise matrices $X$ and $Y$ it holds that $d_{\text {pair }}(X, Y) \leq\left(m^{2}-m\right) / 2$. For the sake of contradiction, assume that there exist two normalized pairwise matrices $X$ and $Y$ such that $d_{\text {pair }}(X, Y)>\left(m^{2}-m\right) / 2$. Let $x_{1}, \ldots, x_{m}$ be the columns of matrix $X$ and $y_{1}, \ldots, y_{m}$ the columns of $Y$. Also, for each $i \in[m]$, let $x_{i, 1}, \ldots, x_{i, m}$ be the entries of column $x_{i}$; we use analogous notation for $y_{i}$ and the columns of matrices introduced later on. Without loss of generality, we assume that $d_{\text {pair }}(X, Y)=\sum_{i, j \in[m], i \neq j}\left|x_{i, j}-y_{i, j}\right|$; otherwise we can change the order of columns and their corresponding rows. Thus, we have:

$$
d_{\text {pair }}(X, Y)=\sum_{\substack{i, j \in[m] \\ i \neq j}}\left|x_{i, j}-y_{i, j}\right|
$$

$$
\begin{align*}
& =\sum_{\substack{i, j \in[m] \\
i \neq j}}\left(\max \left(x_{i, j}, y_{i, j}\right)-\min \left(x_{i, j}, y_{i, j}\right)\right) \\
& =\sum_{\substack{i, j \in[m] \\
i \neq j}}\left(x_{i, j}+y_{i, j}\right)-2 \sum_{\substack{i, j \in[m] \\
i \neq j}} \min \left(x_{i, j}, y_{i, j}\right) \\
& =m(m-1)-2 \sum_{\substack{i, j \in[m] \\
i \neq j}} \min \left(x_{i, j}, y_{i, j}\right) . \tag{5}
\end{align*}
$$

Hence, if $d_{\text {pair }}(X, Y)>\left(m^{2}-m\right) / 2$, we get that:

$$
\begin{align*}
\sum_{\substack{i, j \in[m] \\
i \neq j}} \min \left(x_{i, j}, y_{i, j}\right) & <\frac{1}{2}\left(m(m-1)-\left(m^{2}-m\right) / 2\right) \\
& =m(m-1) / 4 \tag{6}
\end{align*}
$$

Now, consider matrix $Y^{\prime}$ with columns $y_{1}^{\prime}, \ldots, y_{m}^{\prime}$ given by $y_{i, j}^{\prime}=y_{j, i}$ (i.e., matrix $Y^{\prime}$ is a transposition of matrix $Y$ ). Observe that $Y^{\prime}$ is still a normalized pairwise matrix and it corresponds to the same elections as $Y$, but with the ordering of candidates reversed. Hence, it must hold that $d_{\text {pair }}(X, Y) \leq$ $\sum_{i, j \in[m], i \neq j}\left|x_{i, j}-y_{i, j}^{\prime}\right|$; otherwise our assumption that $d_{\text {pair }}(X, Y)=\sum_{i, j \in[m], i \neq j}\left|x_{i, j}-y_{i, j}\right|$ would have been false. Thus, repeating the reasoning from Eq. (5) and Eq. (6) we get:

$$
\sum_{\substack{i, j \in[m] \\ i \neq j}} \min \left(x_{i, j}, y_{i, j}^{\prime}\right)<m(m-1) / 4
$$

Recall that $y_{i, j}^{\prime}=y_{j, i}$. Thus, adding this inequality sidewise to Eq. (6) we get that:

$$
\sum_{\substack{i, j \in[m] \\ i \neq j}}\left(\min \left(x_{i, j}, y_{j, i}\right)+\min \left(x_{i, j}, y_{i, j}\right)\right)<m(m-1) / 2
$$

If $a, b \in[0,1]$ then $a \cdot b \leq \min (a, b)$. As for each $i, j \in[m]$ we have $x_{i, j}, y_{i, j} \in[0,1]$, we obtain:

$$
\sum_{\substack{i, j \in[m] \\ i \neq j}} x_{i, j} \cdot\left(y_{j, i}+y_{i, j}\right)<m(m-1) / 2
$$

$Y$ is a normalized pairwise matrix, hence $y_{j, i}+y_{i, j}=1$ for every $i \neq j$ and we get that:

$$
\sum_{\substack{i, j \in[m] \\ i \neq j}} x_{i, j}<m(m-1) / 2
$$

Since $X$ is also a normalized pairwise matrix, we know that $\sum_{i, j \in[m], i \neq j} x_{i, j}=m(m-1) / 2$. Thus, we arrive at a contradiction. Hence, for all $m \times m$ normalized pairwise matrices $X, Y$ we have $d_{\text {pair }}(X, Y) \leq\left(m^{2}-m\right) / 2$. Therefore, for all elections with $m$ candidates and $n$ voters, their pairwise distance is at most $n\left(m^{2}-m\right) / 2$.

## A. 5 Bordawise Distance

Lemma 5. For each two elections $X$ and $Y$ with $m$ candidates and $n=t \cdot m!$ voters it holds that:

$$
d_{\text {Borda }}(X, Y) \leq d_{\text {Borda }}(\mathrm{ID}, \mathrm{UN})
$$

Proof. We first show that for every two elections $E$ and $E^{\prime}$, such that $E^{\prime}$ can be obtained from $E$ by a single swap of adjacent candidates in a single vote, it holds that:

$$
\begin{align*}
& d_{\text {Borda }}(E, \mathrm{ID})+d_{\text {Borda }}(E, \mathrm{UN})= \\
& \quad d_{\text {Borda }}\left(E^{\prime}, \mathrm{ID}\right)+d_{\text {Borda }}\left(E^{\prime}, \mathrm{UN}\right) . \tag{7}
\end{align*}
$$

In other words, we will show that the sum of the distances of an election from ID and UN is constant under the Bordawise metric (and equal to $d_{\text {Borda }}(I D, U N)$ as every election can be obtained from ID by sufficiently many swaps). Let the sorted Borda score vector of election $E$ be $z=\left(z_{1}, \ldots, z_{m}\right)$. Without loss of generality, we assume that there are numbers $i, j \in[m], i<j$, such that the sorted Borda score vector of $E^{\prime}$ is $z^{\prime}=\left(z_{1}^{\prime}, \ldots, z_{m}^{\prime}\right)$, where (a) $z_{i}^{\prime}=z_{i}+1$, (b) $z_{j}^{\prime}=z_{j}-1$, (c) for each $k \in[m] \backslash\{i, j\}$, $z_{k}^{\prime}=z_{k}$. Indeed, a single swap of adjacent candidates can only increase the score of one candidate by one point and decrease the score of another one by the same value (note that we can swap the roles of $E$ and $E^{\prime}$, to ensure that the assumption that $i<j$ is correct $)$. Let $\hat{z}=\left(\hat{z}_{1}, \ldots, \hat{z}_{m}\right), \hat{z}^{\prime}=\left(\hat{z}_{1}^{\prime}, \ldots, \hat{z}_{m}^{\prime}\right)$ be the prefix-sum variants of vectors $z$ and $z^{\prime}$. For each $t \in[m] \backslash\{i, \ldots, j-1\}$, we have that $\hat{z}_{t}^{\prime}=\hat{z}_{t}$, and for each $t \in\{i, \ldots, j-1\}$, we have that $\hat{z}_{t}^{\prime}=\hat{z}_{t}+1$.

Let us now consider the value $d_{\text {Borda }}(E, \mathrm{UN})-d_{\text {Borda }}\left(E^{\prime}, \mathrm{UN}\right)$. The sorted Borda score vector of UN is $u=\left(u_{1}, \ldots, u_{m}\right)$, where for each $t \in[m], u_{t}=\frac{1}{2} n(m-1)$. Let $\hat{u}=\left(\hat{u}_{1}, \ldots, \hat{u}_{m}\right)$ be its prefix-sum variant. For each $t \in[m]$, we have that $\hat{u}_{t}=\frac{1}{2} \operatorname{tn}(m-1)$. Since vectors $z, z^{\prime}$, and $u$ are sorted non-increasingly and sum up to the same value, by a simple counting argument we see that for each $t \in[m]$, we have $\hat{z}_{t} \geq \hat{u}_{t}$ and $\hat{z}_{t}^{\prime} \geq \hat{u}_{t}$. Using this fact, the relation between $\hat{z}$ and $\hat{z}^{\prime}$, and the definition of the EMD distance, we make the following calculations:

$$
\begin{aligned}
d_{\text {Borda }}(E, \mathrm{UN}) & -d_{\text {Borda }}\left(E^{\prime}, \mathrm{UN}\right)=\operatorname{emd}(z, u)-\operatorname{emd}\left(z^{\prime}, u\right) \\
& =\ell_{1}(\hat{z}, \hat{u})-\ell_{1}\left(\hat{z}^{\prime}, \hat{u}\right) \\
& =\sum_{t=1}^{m}\left|\hat{z}_{t}-\hat{u}_{t}\right|-\sum_{t=1}^{m}\left|\hat{z}_{t}^{\prime}-\hat{u}_{t}\right| \\
& =\sum_{t=i}^{j-1}\left|\hat{z}_{t}-\hat{u}_{t}\right|-\sum_{t=i}^{j-1}\left|\hat{z}_{t}^{\prime}-\hat{u}_{t}\right| \\
& =\sum_{t=i}^{j-1}\left(\left|\hat{z}_{t}-\hat{u}_{t}\right|-\left|\hat{z}_{t}^{\prime}-\hat{u}_{t}\right|\right) \\
& =\sum_{t=i}^{j-1}\left(\left|\hat{z}_{t}-\hat{u}_{t}\right|-\left|\hat{z}_{t}+1-\hat{u}_{t}\right|\right) \\
& =i-j .
\end{aligned}
$$

Next, we calculate $d_{\text {Borda }}(E$, ID $)-d_{\text {Borda }}\left(E^{\prime}, \mathrm{ID}\right)$. Let the sorted Borda score vector of ID be $v=\left(v_{1}, \ldots, v_{m}\right)$ and let its prefix sum variant be $\hat{v}=\left(\hat{v}_{1}, \ldots, \hat{v}_{m}\right)$. For each $t \in[m]$, we have that $v_{t}=n(m-t)$. Further, for each $t \in[m]$ we have that $\hat{v}_{t} \geq \hat{z}_{t}$ and $\hat{v}_{t} \geq \hat{z}_{t}^{\prime}$ (too see this, observe that $\hat{v}_{t}$ is a sum of the $t$ highest possible Borda scores, multiplied by $n$ ). Thus we have the following calculations (very similar to the previous ones):

$$
\begin{aligned}
d_{\text {Borda }}(E, \text { ID }) & -d_{\text {Borda }}\left(E^{\prime}, \mathrm{ID}\right)=\operatorname{emd}(z, v)-\operatorname{emd}\left(z^{\prime}, v\right) \\
& =\ell_{1}(\hat{z}, \hat{v})-\ell_{1}\left(\hat{z}^{\prime}, \hat{v}\right) \\
& =\sum_{t=1}^{m}\left|\hat{z}_{t}-\hat{v}_{t}\right|-\sum_{t=1}^{m}\left|\hat{z}_{t}^{\prime}-\hat{v}_{t}\right| \\
& =\sum_{t=i}^{j-1}\left(\left|\hat{z}_{t}-\hat{v}_{t}\right|-\left|\hat{z}_{t}+1-\hat{v}_{t}\right|\right) \\
& =j-i .
\end{aligned}
$$

(The final equality is subtle. It follows by noting that for $t \in\{i, \ldots, j-1\}$, it must be that $\hat{z}_{t}<\hat{v}_{t}$, which, itself, follows from the fact that $\hat{z}_{t}+1=\hat{z}_{t}^{\prime} \leq \hat{v}_{t}$.) Taken together, the above calculations show that:

$$
d_{\text {Borda }}(E, \mathrm{ID})-d_{\text {Borda }}\left(E^{\prime}, \mathrm{ID}\right)=
$$

$$
d_{\text {Borda }}\left(E^{\prime}, \mathrm{UN}\right)-d_{\text {Borda }}(E, \mathrm{UN}),
$$

which is equivalent to Eq. (7), and which shows that the sum of the distances from a given election to ID and UN is equal to $d_{\text {Borda }}(\mathrm{ID}, \mathrm{UN})$.

Finally, we show that this means that for every two elections $X$ and $Y$ we have $d_{\text {Borda }}(X, Y) \leq$ $d_{\text {Borda }}(\mathrm{ID}, \mathrm{UN})$. By the previous reasoning, we have that:

$$
\begin{align*}
d_{\text {Borda }}(\mathrm{ID}, X)+d_{\text {Borda }}(X, \mathrm{UN}) & =d_{\text {Borda }}(\mathrm{ID}, \mathrm{UN}), \text { and } \\
d_{\text {Borda }}(\mathrm{ID}, Y)+d_{\text {Borda }}(Y, \mathrm{UN}) & =d_{\text {Borda }}(\mathrm{ID}, \mathrm{UN}) . \tag{8}
\end{align*}
$$

We claim that one of the following two inequalities holds:

$$
\begin{align*}
d_{\text {Borda }}(\mathrm{ID}, X)+d_{\text {Borda }}(\mathrm{ID}, Y) & \leq d_{\text {Borda }}(\mathrm{ID}, \mathrm{UN}), \text { or } \\
d_{\text {Borda }}(\mathrm{UN}, X)+d_{\text {Borda }}(\mathrm{UN}, Y) & \leq d_{\text {Borda }}(\mathrm{ID}, \mathrm{UN}) . \tag{9}
\end{align*}
$$

If both inequalities do not hold, then we can sum them up arriving at:

$$
\begin{array}{r}
d_{\text {Borda }}(\mathrm{ID}, X)+d_{\text {Borda }}(\mathrm{ID}, Y)+d_{\text {Borda }}(\mathrm{UN}, X)+ \\
d_{\text {Borda }}(\mathrm{UN}, Y)>2 \cdot d_{\text {Borda }}(\mathrm{ID}, \mathrm{UN}),
\end{array}
$$

which contradicts Eq. 8. Thus, one of the inequalities from Eq. 9 holds and by triangle inequality, we have $d_{\text {Borda }}(X, Y) \leq d_{\text {Borda }}($ ID, UN$)$.

From Lemmas 1 to 5, Theorem 3 follows.

## B Proof of Section 7

In this section, we prove the following theorem:
Theorem 4. The swap and discrete metrics are intrinsic, but neither of the EMD/ $\ell_{1}$-positionwise, pairwise, and Bordawise metric is intrinsic, but the EMD- and $\ell_{1}$-positionwise metrics are 2 -intrinsic yet not $\alpha$-intrinsic for any $\alpha<2$.

We split the proof in three sections. In Appendix B.1, we prove that swap and discrete metrics are intrinsic. In Appendix B.2, we show that pairwise and Bordawise metrics are not intrinsic. Finally in Appendix B.3, we prove that $\ell_{1}$ - and EMD-positionwise are both 2 -intrinsic but not $\alpha$-intrinsic for any $\alpha<2$ (which, in particular proves that both violate intrinsicness).

## B. 1 Discrete and Swap

Lemma 6. Swap and discrete metrics are intrinsic.
Proof. For the swap metric, by definition of the metric, there is a sequence of $k$ swaps of adjacent candidates in some votes that transforms $E_{s}$ into an election that is isomorphic to $E_{t}$. With $E_{i}$ being the election that arises after performing the first $i$ swaps, intrinsicness follows.

For the discrete metric, given $E_{s}=\left(C_{s}, V_{s}=\left(v_{1}, \ldots v_{n}\right)\right)$ and $E_{t}=\left(C_{t}, V_{t}=\left(v_{1}^{\prime}, \ldots v_{n}^{\prime}\right)\right)$, let $\sigma \in$ $\Pi\left(C_{s}, C_{t}\right)$ be the candidate and $\rho \in S_{n}$ be the voter mapping witnessing the discrete distance between $E_{s}$ and $E_{t}$ and let $v_{i_{1}}, \ldots, v_{i_{k}} \in V_{s}$ be the votes that contribute one to the discrete distance between $E_{s}$ and $E_{t}$ under $\sigma$ and $\rho$. Further, let $V_{s}^{\prime}:=V_{s} \backslash\left\{v_{i_{1}}, \ldots, v_{i_{k}}\right\}$. For some vote $v_{i} \in V_{s}$ let $\tau\left(v_{i}\right)$ be the vote $v_{\rho(i)}^{\prime}$ where each candidate $c \in C_{t}$ is replaced by $\sigma^{-1}(c) \in C_{s}$. For each $j \in[k-1]$, to construct $E_{j}$, we add all votes from $V_{s}^{\prime}$ and $v_{i_{j}+1}, \ldots, v_{i_{k}}$ and the votes $\tau\left(v_{i_{1}}\right), \ldots, \tau\left(v_{i_{j}}\right)$. Note that using $\sigma$ and $\rho$ as the candidate and voter mapping each two subsequent elections from $E_{s}, E_{1}, E_{2}, \ldots, E_{k-1}, E_{t}$ are clearly at distance at most one from each other, and, in fact by triangle inequality at distance exactly 1 . Form this, intrinsicness follows.

## B. 2 Pairwise and Bordawise

Lemma 7. Pairwise and Bordawise metrics are not intrinsic.
Proof. For Bordawise, consider elections $E_{s}=(\{a, b, c\},(a \succ b \succ c, a \succ b \succ c))$ and $E_{t}=$ $(\{a, b, c\},(a \succ b \succ c, c \succ b \succ a))$. We have here that $d_{\text {Borda }}\left(E_{s}, E_{t}\right)=2$ which is two times the smallest nonzero distance between two elections under Bordawise; however no $3 \times 2$ election is at distance 1 from both $E_{s}$ and $E_{t}$ :

- $E_{1}=(\{a, b, c\},(a \succ b \succ c, a \succ b \succ c)): d_{\text {Borda }}\left(E_{1}, E_{t}\right)=2$.
- $E_{1}=(\{a, b, c\},(a \succ b \succ c, a \succ c \succ b)): d_{\text {Borda }}\left(E_{1}, E_{t}\right)=3$.
- $E_{1}=(\{a, b, c\},(a \succ b \succ c, b \succ a \succ c)): d_{\text {Borda }}\left(E_{1}, E_{t}\right)=3$.
- $E_{1}=(\{a, b, c\},(a \succ b \succ c, b \succ c \succ a)): d_{\text {Borda }}\left(E_{1}, E_{s}\right)=2$
- $E_{1}=(\{a, b, c\},(a \succ b \succ c, c \succ b \succ a)): d_{\text {Borda }}\left(E_{1}, E_{s}\right)=2$.

However, by intrinsicness, such an election needs to exist, a contradiction to Bordawise being intrinsic.
For pairwise, consider elections $E_{s}=(\{a, b, c, d, e, f, g\},(a \succ b \succ c \succ d \succ e \succ f \succ g, e \succ b \succ$ $g \succ d \succ a \succ f \succ c)$ ) and $E_{t}=(\{a, b, c, d, e, f, g\},(a \succ b \succ c \succ g \succ d \succ e \succ f, e \succ b \succ d \succ a \succ$ $f \succ g \succ c))$. It holds that $d_{\text {pair }}\left(E_{s}, E_{t}\right)=4$, which is two times the smallest nonzero distance between two elections under pairwise; however we have verified using exhaustive search that no election is at distance 2 from both $E_{s}$ and $E_{t}$ under pairwise (see our code appendix).

## B. $3 \ell_{1}$-Positionwise and EMD-Positionwise

We start by considering $\ell_{1}$-positionwise and afterwards examine EMD-positionwise. However, first let us prove a useful lemma that allows us to consider only paths on elections with the same matching of candidates.

Lemma 8. Let $d$ be one of our six metrics. For any sequence of elections $E_{0}, E_{1}, \ldots, E_{k}$, there exists a sequence of elections $E_{0}^{\prime}, E_{1}^{\prime}, \ldots, E_{k}^{\prime}$ such that $E_{0}=E_{0}^{\prime}$, and for every $i \in[k]$ we have that $d\left(E_{i}^{\prime}, E_{i}\right)=$ $0, d\left(E_{i-1}^{\prime}, E_{i}^{\prime}\right)=d\left(E_{i-1}, E_{i}\right)$, and an optimal matching between candidates in $E_{i}^{\prime}$ and $E_{i-1}^{\prime}$ is the identity.

Proof. Let us show the statement by the induction on $k$. For $k=0$ the statement is trivial. Thus, assume that $k>0$ and that the statement holds for $k-1$.

Fix an arbitrary sequence of elections $E_{0}, E_{1}, \ldots, E_{k}$. By the induction assumption, there exists a sequence of elections $E_{0}^{\prime}, E_{1}^{\prime}, \ldots, E_{k-1}^{\prime}$ such that $E_{0}=E_{0}^{\prime}$ and for every $i \in[k-1]$ we have that $d\left(E_{i}^{\prime}, E_{i}\right)=0, d\left(E_{i-1}^{\prime}, E_{i}^{\prime}\right)=d\left(E_{i-1}, E_{i}\right)$, and an optimal matching between candidates in $E_{i}^{\prime}$ and $E_{i-1}^{\prime}$ is the identity. Since $d\left(E_{k-1}^{\prime}, E_{k-1}\right)=0$, we have that $d\left(E_{k-1}, E_{k}\right)=d\left(E_{k-1}^{\prime}, E_{k}\right)$. Let $\sigma$ be an optimal matching of candidates between $E_{k-1}^{\prime}$ and $E_{k}$. Then, let us construct election $E_{k}^{\prime}$ from $E_{k}=\left(C_{k}, V_{k}\right)$ by exchanging each vote $v \in V_{k}$ by vote $\sigma(v)$, i.e., $E_{k}^{\prime}=\left(C_{k}, \sigma\left(V_{k}\right)\right)$. In this way, $d\left(E_{k}^{\prime}, E_{k}\right)=0$,

$$
d\left(E_{k-1}^{\prime}, E_{k}^{\prime}\right)=d\left(E_{k-1}^{\prime}, E_{k}\right)=d\left(E_{k-1}, E_{k}\right)
$$

and the optimal matching between $E_{k}^{\prime}$ and $E_{k-1}^{\prime}$ is identity. This concludes the proof.

## B.3.1 $\ell_{1}$-Positionwise

Lemma 9. The $\ell_{1}$-positionwise metric is 2 -intrinsic.
Proof. We need to show that for every two elections $E_{s}$ and $E_{t}$ there exist elections $E_{s}=$ $E_{0}, E_{1}, \ldots, E_{k-1}, E_{k}=E_{t}$ such that $\sum_{i=1}^{k} d_{\mathrm{pos}}^{\ell_{1}}\left(E_{i-1}, E_{i}\right) \leq 2 \cdot d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{t}\right)$, and for each $i \in$ $[k], d_{\text {pos }}^{\ell_{1}}\left(E_{i-1}, E_{i}\right)=4$, which is the smallest nonzero distance under the $\ell_{1}$-positionwise metric. We prove this by induction on $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{t}\right)$. Fix arbitrary elections $E_{s}$ and $E_{t}$ with $n$ voters and $m$ candidates. If $d_{\text {pos }}^{\ell_{1}}\left(E_{s}, E_{t}\right)=0$ or $d_{\text {pos }}^{\ell_{1}}\left(E_{s}, E_{t}\right)=4$, the statement trivially follows. Thus, assume that $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{t}\right)>4$ and that the statement holds for all elections $\hat{E}_{s}$ and $\hat{E}_{t}$ with $d_{\text {pos }}^{\ell_{1}}\left(\hat{E}_{s}, \hat{E}_{t}\right)<d_{\text {pos }}^{\ell_{1}}\left(E_{s}, E_{t}\right)$. Let $X$ with columns $x_{1}, \ldots, x_{m}$ be the position matrix of $E_{s}$ and $Y$ with columns $y_{1}, \ldots, y_{m}$ be the position matrix of $E_{t}$. Without loss of generality, let us assume that $d_{\text {pos }}^{\ell_{1}}\left(E_{s}, E_{t}\right)=\sum_{i \in[m]} \ell_{1}\left(x_{i}, y_{i}\right)$; otherwise we could reorder the columns of one of the matrices.

Intuitively, in what follows, we examine matrix $X$ and consider two columns $c, c^{\prime}$ from $X$, two rows $r, r^{\prime}$ from $X$, and matrix $X^{\prime}$ that results from $X$ by, in column $c$, subtracting 1 from row $r$ and adding 1 to row $r^{\prime}$ and, in column $c^{\prime}$, adding 1 to row $r$ and subtracting 1 from row $r^{\prime}$. As we will show later there always exist such $c, c^{\prime}, r, r^{\prime}$ that $X^{\prime}$ is a position matrix of some election $E_{s}^{\prime}$, and it holds that $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}^{\prime}, E_{t}\right) \leq d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{t}\right)-2$ and $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{s}^{\prime}\right)=4$. Using this, our statement will then follow by induction. As an illustration of our approach, see the following example:

Example 7. Let the first two of the following matrices be example position matrices $X$ and $Y$ of some elections $E_{s}$ and $E_{t}$, respectively (we have $n=5$ voters and $m=4$ candidates). Then, the third matrix is a constructed position matrix $X^{\prime}$ created following our above described approach of some election $E_{s}^{\prime}$.

X

Y

Observe that $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{t}\right)=8$. Hence, indeed, we get that $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}^{\prime}, E_{t}\right)=6 \leq d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{t}\right)-2$. Moreover, we have $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{s}^{\prime}\right)=4$. This concludes the example.

For each $i \in[m]$ we write $x_{i, 1}, \ldots, x_{i, m}$ to the denote the entries of $x_{i}$; we use analogous notation for $y_{i}$ and the columns of matrices introduced later on. Since $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{t}\right)>4$, there must exist a column, $c \in[m]$, such that $\ell_{1}\left(x_{c}, y_{c}\right)>0$. Moreover, the sums of entries in both $x_{c}$ and $y_{c}$ are equal (to $n$ ), hence there is an $r \in[m]$ such that $x_{c, r}>y_{c, r}$ and also $r^{\prime} \in[m]$ such that $x_{c, r^{\prime}}<y_{c, r^{\prime}}$. Furthermore, the sums of entries in row $r^{\prime}$ in both matrices are equal (to $n$ ), thus the fact that $x_{c, r^{\prime}}<y_{c, r^{\prime}}$ implies that there exists column $c^{\prime} \in[m]$ such that $x_{c^{\prime}, r^{\prime}}>y_{c^{\prime}, r^{\prime}}$. Building upon this, let us construct matrix $X^{\prime}$ with columns $x_{1}^{\prime}, \ldots, x_{m}^{\prime}$ defined as follows:

$$
x_{i, j}^{\prime}= \begin{cases}x_{i, j}-1, & \text { if }(i, j) \in\left\{(c, r),\left(c^{\prime}, r^{\prime}\right)\right\} \\ x_{i, j}+1, & \text { if }(i, j) \in\left\{\left(c, r^{\prime}\right),\left(c^{\prime}, r\right)\right\} \\ x_{i, j}, & \text { otherwise }\end{cases}
$$

Observe that for $(i, j) \in\left\{(c, r),\left(c^{\prime}, r^{\prime}\right)\right\}$ we have that $x_{i, j}^{\prime}=x_{i, j}-1 \geq y_{i, j} \geq 0$. Thus, $x_{i, j}^{\prime} \geq 0$ for every $i, j \in[m]$. Moreover, the sums of entries of each row and column of matrix $X^{\prime}$ are still equal to $n$. Thus, as proven by Boehmer et al. [6], $X^{\prime}$ is a position matrix of some election- which we denote by $E_{s}^{\prime}$.

Observe that $X$ and $X^{\prime}$ differ only on columns $c$ and $c^{\prime}$. Also, for column $c$ we have $\ell_{1}\left(x_{c}^{\prime}, y_{c}\right)=$ $\ell_{1}\left(x_{c}, y_{c}\right)-2$. Moreover, for column $c^{\prime}$ we get $\ell_{1}\left(x_{c^{\prime}}^{\prime}, y_{c^{\prime}}\right)=\ell_{1}\left(x_{c^{\prime}}, y_{c^{\prime}}\right)-2$, if $x_{c^{\prime}, r}<y_{c^{\prime}, r}$, and $\ell_{1}\left(x_{c^{\prime}}^{\prime}, y_{c^{\prime}}\right)=\ell_{1}\left(x_{c^{\prime}}, y_{c^{\prime}}\right)$, otherwise. Since other columns of $X$ and $X^{\prime}$ are identical, we get that

$$
\sum_{i \in[m]} \ell_{1}\left(x_{i}^{\prime}, y_{i}\right)= \begin{cases}\sum_{i \in[m]} \ell_{1}\left(x_{i}, y_{i}\right)-4, & \text { if } x_{c^{\prime}, r}<y_{c^{\prime}, r}, \\ \sum_{i \in[m]} \ell_{1}\left(x_{i}, y_{i}\right)-2, & \text { otherwise } .\end{cases}
$$

Hence, $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}^{\prime}, E_{t}\right) \leq d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{t}\right)-2$. By the induction assumption, this means that there exist elections $E_{s}^{\prime}=E_{0}, E_{1}, \ldots, E_{k-1}, E_{k}=E_{t}$ such that

$$
\begin{equation*}
\sum_{i=1}^{k} d_{\mathrm{pos}}^{\ell_{1}}\left(E_{i-1}, E_{i}\right) \leq 2 \cdot d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}^{\prime}, E_{t}\right) \leq 2 \cdot d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}^{\prime}, E_{t}\right)-4 \tag{10}
\end{equation*}
$$

and for each $i \in[k]$, we have that $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{i-1}, E_{i}\right)=4$.
On the other hand, observe that

$$
\sum_{i \in[m]} \ell_{1}\left(x_{i}, x_{i}^{\prime}\right)=\ell_{1}\left(x_{c}, x_{c}^{\prime}\right)+\ell_{1}\left(x_{c^{\prime}}, x_{c^{\prime}}^{\prime}\right)=4
$$

Since $E_{s}^{\prime}$ is closer to $E_{t}$ than $E_{s}$, it is not possible that $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{s}^{\prime}\right)=0$. Thus, $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{s}^{\prime}\right)=4$.
Building upon this, let us denote $E_{-1}=E_{s}$. Then, by Eq. (10) elections $E_{s}=$ $E_{-1}, E_{0}, E_{1}, \ldots, E_{k-1}, E_{k}=E_{t}$ are such that

$$
\begin{aligned}
\sum_{i=0}^{k} d_{\mathrm{pos}}^{\ell_{1}}\left(E_{i-1}, E_{i}\right) & \leq 2 \cdot d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}^{\prime}, E_{t}\right)-4+d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}^{\prime}, E_{s}\right) \\
& =2 \cdot d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{t}\right)
\end{aligned}
$$

Moreover, for each $i \in\{0,1, \ldots, k\}$, we have that $d_{\text {pos }}^{\ell_{1}}\left(E_{i-1}, E_{i}\right)=4$, which concludes the proof.
Lemma 10. The $\ell_{1}$-positionwise metric is not $\alpha$-intrinsic for any $\alpha<2$.
Proof. Let us consider an identity election, ID over candidates $c_{1}, \ldots, c_{m}$, with $n>m>2$ votes: $c_{1} \succ c_{2} \succ \cdots \succ c_{m}$. Also, let us consider election $E$ that is obtained from ID by exchanging one of the votes by vote $c_{2} \succ c_{3} \succ \cdots \succ c_{m} \succ c_{1}$. Observe that position matrix of $E$ is:

$$
\left[\begin{array}{cccccc}
n-1 & 1 & 0 & \cdots & 0 & 0 \\
0 & n-1 & 1 & \cdots & 0 & 0 \\
0 & 0 & n-1 & \cdots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & \cdots & n-1 & 1 \\
1 & 0 & 0 & \cdots & 0 & n-1
\end{array}\right] .
$$

Thus, it is optimal to match $c_{i}$ in ID to $c_{i}$ in $E$ for every $i \in[m]$ and we get that $d_{\mathrm{pos}}^{\ell_{1}}(E$, ID $)=2 m$.
Let $A$ be an $m \times m$ matrix. Let $a_{1}, \ldots, a_{m}$ be the columns of matrix $A$ and for each $i \in[m]$, let $a_{i, 1}, \ldots, a_{i, m}$ be the entries of $a_{i}$. We will say that matrix $A$ is atomic, if there exist $c, c^{\prime}, r, r^{\prime} \in[m]$ such that

$$
a_{i, j}= \begin{cases}1, & \text { if }(i, j) \in\left\{(c, r),\left(c^{\prime}, r^{\prime}\right)\right\} \\ -1, & \text { if }(i, j) \in\left\{\left(c, r^{\prime}\right),\left(c^{\prime}, r\right)\right\} \\ 0, & \text { otherwise }\end{cases}
$$

Observe that for every two elections $F, F^{\prime}$ with position matrices $X, X^{\prime}$ having columns $x_{1}, \ldots, x_{m}$ and $x_{1}^{\prime}, \ldots, x_{m}^{\prime}$ such that $d_{\text {pos }}^{\ell_{1}}\left(F, F^{\prime}\right)=\sum_{i \in[m]} \ell_{1}\left(x_{i}, x_{i}^{\prime}\right)=4$, it holds that there exists an atomic matrix $A$ such that $X=X^{\prime}+A$. Hence, by Lemma 8, finding an intrinsic path of length $k$ between elections ID and $E$ is equivalent to finding atomic matrices $A_{1}, \ldots, A_{k}$ such that their sum is equal to

$$
\left[\begin{array}{cccccc}
-1 & 1 & 0 & \cdots & 0 & 0 \\
0 & -1 & 1 & \cdots & 0 & 0 \\
0 & 0 & -1 & \cdots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & \cdots & -1 & 1 \\
1 & 0 & 0 & \cdots & 0 & -1
\end{array}\right] .
$$

Observe that the rank of this matrix is equal to $m-1$. Also, the rank of each atomic matrix is equal to 1 . Since the rank of a matrix is subadditive, we get that $k \geq m-1$. From the definition of the intrinsicness degree we obtain that $\alpha \geq k \cdot d_{\min } / d_{\text {pos }}^{\ell_{1}}(E$, ID $)$. Thus,

$$
\alpha \geq \frac{4(m-1)}{2 m}=2-\frac{2}{m}
$$

Since $m$ can be arbitrarily large, we get that $\alpha \geq 2$.

## B.3.2 EMD-Positionwise

Lemma 11. EMD-positionwise metric is 2-intrinsic.
Proof. We need to show that for every two elections $E_{s}$ and $E_{t}$ there exist elections $E_{s}=$ $E_{0}, E_{1}, \ldots, E_{k-1}, E_{k}=E_{t}$ such that $\sum_{i=1}^{k} d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{i-1}, E_{i}\right) \leq 2 \cdot d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{t}\right)$, and for each $i \in[k], d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{i-1}, E_{i}\right)=2$, which is the smallest nonzero distance of two elections under the EMDpositionwise metric. We prove this by induction on $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{t}\right)$. For this fix two arbitrary elections $E_{s}$ and $E_{t}$ with $n$ voters and $m$ candidates. If $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{t}\right)=0$ or $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{t}\right)=2$, the statement trivially follows. Thus, assume that $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{t}\right)>2$ and that the statement holds for all elections $\hat{E}_{s}$ and $\hat{E}_{t}$ with $d_{\mathrm{pos}}^{\mathrm{emd}}\left(\hat{E}_{s}, \hat{E}_{t}\right)<d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{t}\right)$. Let $X$ with columns $x_{1}, \ldots, x_{m}$ be the position matrix of $E_{s}$ and $Y$ with columns $y_{1}, \ldots, y_{m}$ the position matrix of $E_{t}$. Without loss of generality, let us assume that $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{t}\right)=\sum_{i \in[m]} \mathrm{emd}\left(x_{i}, y_{i}\right)$; otherwise we could reorder columns of one of the matrices. For each column $i \in[m]$ we write $x_{i, 1}, \ldots, x_{i, m}$ to the denote the entries of $x_{i}$; we use analogous notation for $y_{i}$ and the columns of matrices introduced later on. Recall also that for any vector $v$, by $\hat{v}$ we denote the vector of its prefix sums.

Intuitively, in what follows, as in proof of Lemma 9, we examine matrix $X$ and consider two columns $c, c^{\prime}$ from $X$, two rows $r, r^{\prime}$ from $X$, and matrix $X^{\prime}$ that results from $X$ by, in column $c$, subtracting 1 from row $r$ and adding 1 to row $r^{\prime}$ and, in column $c^{\prime}$, adding 1 to row $r$ and subtracting 1 from row $r^{\prime}$. As we will show, it is always possible to choose such rows and columns that $X^{\prime}$ is still a position matrix of some elections, $E_{s}^{\prime}$, and $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}^{\prime}, E_{t}\right) \leq d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{t}\right)-2 \cdot\left|r-r^{\prime}\right|$. Furthermore, we will prove that between $E_{s}$ and $E_{s}^{\prime}$ we can find a path of at most $2 \cdot\left|r-r^{\prime}\right|$ elections such that each consecutive two are at EMD-positionwise distance 2. Using this, by induction, we will obtain the statement. See the following example:

Example 8. Let the first two of the following matrices be example position matrices $X$ and $Y$ of some elections $E_{s}$ and $E_{t}$, respectively (we have $n=6$ voters and $m=4$ candidates). Then, the third matrix is a constructed position matrix $X^{\prime}$ created following our above described approach of some election
$E_{s}^{\prime}$.

Observe that we have $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{t}\right)=1+2+0+3=6, d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}^{\prime}, E_{t}\right)=1+0+0+1=2$, and $r-r^{\prime}=2$. So, indeed, $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}^{\prime}, E_{t}\right)=d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{t}\right)-2\left(r-r^{\prime}\right)$. This concludes the example.

We begin by finding the correct columns $c, c^{\prime}$ and rows $r, r^{\prime}$. Our goal is to find them such that $r>r^{\prime}, x_{c, r}>y_{c, r}$ and $x_{c^{\prime}, r^{\prime}}>y_{c^{\prime}, r^{\prime}}$, but at the same time $x_{c, i}=y_{c, i}$ and $x_{c^{\prime}, i}=y_{c^{\prime}, i}$ for every $i \in\left\{r^{\prime}+1, r^{\prime}+2, \ldots, r-1\right\}$. In this way, when we subtract 1 from $x_{c, r}$ and $x_{c^{\prime}, r^{\prime}}$ and add 1 to $x_{c, r^{\prime}}$ and $x_{c^{\prime}, r}$, then both $\operatorname{emd}\left(x_{c}, y_{c}\right)$ and $\operatorname{emd}\left(x_{c^{\prime}}, y_{c^{\prime}}\right)$ decrease by exactly $r-r^{\prime}$ (we will prove it in more detail later on). Thus, the EMD-positionwise distance to election $E_{t}$ decreases by at least $2\left(r-r^{\prime}\right)$.

We want to take $c, r \in[m]$ such that $x_{c, r}>y_{c, r}, \hat{x}_{c, r-1}<\hat{y}_{c, r-1}$, and $r$ is minimal. But first, let us prove that there always exists at least one pair $c, r \in[m]$ such that $x_{c, r}>y_{c, r}$ and $\hat{x}_{c, j}<\hat{y}_{c, j}$. To this end, observe that since $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{t}\right)>2$, there exists a column, $c \in[m]$, such that $\operatorname{emd}\left(x_{c}, y_{c}\right)>0$. Since the sums of entries of column $c$ in both matrices $X$ and $Y$ are equal (to $n$ ), there exists a row, $p \in[m]$, such that $x_{c, p}<y_{c, p}$. Let us fix $c, p \in[m]$ such that $x_{c, p}<y_{c, p}$ and $p$ is minimal, i.e., for every $i, j \in[m]$ such that $x_{i, j}<y_{i, j}$ we have $j \geq p$. Then, in particular, we have $x_{c, j} \geq y_{c, j}$, for each $j \in[p-1]$. Assume that there exists $j \in[p-1]$ such that $x_{c, j}>y_{c, j}$. Since the sums of entries in row $j$ in matrices $X$ and $Y$ are equal (to $n$ ), there exists column $i \in[m]$ such that $x_{i, j}<y_{i, j}$. However, since $j<p$, this contradicts the assumption that $p$ is minimal. Therefore, we get that $x_{c, j}=y_{c, j}$, for each $j \in[p-1]$. Thus, $\hat{x}_{c, p}<\hat{y}_{c, p}$, as $x_{c, p}<y_{c, p}$. Since the sums of entries in column $c$ in both matrices are equal (to $n$ ), there exists such $r$ that $x_{c, r}>y_{c, r}$. Let us take the minimal such $r$. Then, for every $j \in\{p+1, p+2, \ldots, r-1\}$ we have that $x_{c, j} \leq y_{c, j}$. Thus, $\hat{x}_{c, r-1}<\hat{y}_{c, r-1}$. This means that we have found $c, r$ such that $x_{c, r}>y_{c, r}$ and $\hat{x}_{c, r-1}<\hat{y}_{c,{ }^{\prime}-1}$.

Therefore, let us take $c, r \in[m]$ such that $x_{c, r}>y_{c, r}, \hat{x}_{c, r-1}<\hat{y}_{c, r-1}$, and there is no $i, j \in[m]$ such that $j<r, x_{i, j}>y_{i, j}, \hat{x}_{i, j-1}<\hat{y}_{i, j-1}$, i.e., $r$ is minimal with respect to this property. Observe from the fact that $\hat{x}_{c, r-1}<\hat{y}_{c, r-1}$ implies that there exists row $q \in[r-1]$ such that $x_{c, q}<y_{c, q}$. Let us take such $q \in[r-1]$ that is minimal with such property. Then, for every $j \in\{q+1, q+2, \ldots, r-1\}$ we have $x_{c, q}=y_{c, q}$.

Now, let us take $c^{\prime}, r^{\prime} \in[m]$ such that $x_{c^{\prime}, r^{\prime}}>y_{c^{\prime}, r^{\prime}}, q \leq r^{\prime}<r, c^{\prime} \neq c$, and $r^{\prime}$ is maximal with respect to this property. To see that there exists at least one pair $i, j \in[m]$ such that $x_{i, j}>y_{i, j}$, $q \leq j<r$, and $i \neq c$, observe that the sums of entries in row $q$ in matrices $X$ and $Y$ are equal. Hence, since $x_{c, r}<y_{c, q}$, there exists column $i \in[m]$ such that $x_{i, q}>y_{i, q}$. Taking $j=q$, we get that indeed $q \leq j<r$ and $i \neq c$. Hence, there exists $c^{\prime}, r^{\prime} \in[m]$ such that $x_{c^{\prime}, r^{\prime}}>y_{c^{\prime}, r^{\prime}}, q \leq r^{\prime}<r, c^{\prime} \neq c$, and $r^{\prime}$ is maximal. Observe that this means that in every row $j \in\left\{r^{\prime}+1, r^{\prime}+2, \ldots, r-1\right\}$ we have $x_{c^{\prime}, j}=y_{c^{\prime}, j}$; otherwise if $x_{c^{\prime}, j}>y_{c^{\prime}, j}$, then $r^{\prime}$ is not maximal as we assumed ( $r^{\prime}<j<r$ and $c^{\prime} \neq c$ ), and if $x_{c^{\prime}, j}<x_{c^{\prime}, j}$, then there exists column $i \in[m]$ such that $x_{i, j}>x_{i, j}$, thus $r^{\prime}$ is also not maximal ( $r^{\prime}<j<r$ and $i \neq c$ since $q \leq r^{\prime}<j$ ). Furthermore, since we took minimal $r$, the fact that $r^{\prime}<r$ and $x_{c^{\prime}, r^{\prime}}>y_{c^{\prime}, r^{\prime}}$ implies that either $\hat{x}_{c^{\prime}, r^{\prime}-1} \geq \hat{y}_{c^{\prime}, r^{\prime}-1}$ or $r^{\prime}=1$. In both cases, we get that $\hat{x}_{c^{\prime}, r^{\prime}}>\hat{y}_{c^{\prime}, r^{\prime}}$. Thus, the fact that $x_{c^{\prime}, j}=y_{c^{\prime}, j}$, for each $j \in\left\{r^{\prime}+1, r^{\prime}+2, \ldots, r-1\right\}$, implies that

$$
\begin{equation*}
\hat{x}_{c^{\prime}, j}>\hat{y}_{c^{\prime}, j}, \quad \text { for every } j \in\left\{r^{\prime}, r^{\prime}+1, \ldots, r-1\right\} . \tag{11}
\end{equation*}
$$

Similarly, since $q \leq r^{\prime}$ we get that $x_{c, j}=y_{c, j}$, for each $j \in\left\{r^{\prime}+1, r^{\prime}+2, \ldots, r-1\right\}$. Combining it with the fact that $\hat{x}_{c, r-1}<\hat{y}_{c, r-1}$ we get

$$
\begin{equation*}
\hat{x}_{c, j}<\hat{y}_{c, j}, \quad \text { for every } j \in\left\{r^{\prime}, r^{\prime}+1, \ldots, r-1\right\} . \tag{12}
\end{equation*}
$$

Building upon this, let us now construct matrix $X^{\prime}$ with columns $x_{1}^{\prime}, \ldots, x_{m}^{\prime}$ defined as follows:

$$
x_{i, j}^{\prime}= \begin{cases}x_{i, j}-1, & \text { if }(i, j) \in\left\{(c, r),\left(c^{\prime}, r^{\prime}\right)\right\} \\ x_{i, j}+1, & \text { if }(i, j) \in\left\{\left(c, r^{\prime}\right),\left(c^{\prime}, r\right)\right\} \\ x_{i, j}, & \text { otherwise }\end{cases}
$$

Since $x_{c, r}>y_{c, r} \geq 0$ and $x_{c^{\prime}, r^{\prime}}>y_{c, r} \geq 0$ we get that $x_{i, j}^{\prime} \geq 0$ for every $i, j \in[m]$. Moreover, the sums of entries in each row and column of $X^{\prime}$ are still equal to $n$. Thus, $X^{\prime}$ is a position matrix of some election $E_{s}^{\prime}$.

Let us now estimate $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}^{\prime}, E_{t}\right)$. Observe that we have

$$
\hat{x}_{i, j}^{\prime}=\left\{\begin{array}{l}
\hat{x}_{i, j}-1, \text { if }(i, j) \in\left\{\left(c^{\prime}, r^{\prime}\right),\left(c^{\prime}, r^{\prime}+1\right), \ldots,(c, r-1)\right\}, \\
\hat{x}_{i, j}+1, \text { if }(i, j) \in\left\{\left(c, r^{\prime}\right),\left(c, r^{\prime}+1\right), \ldots,(c, r-1)\right\} \\
\hat{x}_{i, j}, \quad \text { otherwise }
\end{array}\right.
$$

Thus, we get that emd $\left(x_{c^{\prime}}^{\prime}, y_{c^{\prime}}^{\prime}\right)=\operatorname{emd}\left(x_{c^{\prime}}, y_{c^{\prime}}\right)-\left(r-r^{\prime}\right)$ from Eq. (11) and emd $\left(x_{c}^{\prime}, y_{c}^{\prime}\right)=$ $\operatorname{emd}\left(x_{c}, y_{c}\right)-\left(r-r^{\prime}\right)$ from Eq. (12). Since EMD of other columns do not change, we get

$$
d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}^{\prime}, E_{t}\right) \leq d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{t}\right)-2\left(r-r^{\prime}\right)
$$

Therefore, by the induction assumption, we get that there exists a sequence of elections $E_{s}^{\prime}=$ $E_{0}, E_{1}, \ldots, E_{k-1}, E_{k}=E_{t}$ such that

$$
\begin{align*}
\sum_{i=1}^{k} d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{i-1}, E_{i}\right) \leq 2 \cdot d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}^{\prime}, E_{t}\right) \leq
\end{aligned} \begin{aligned}
& \\
&  \tag{13}\\
& \leq 2 \cdot d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{t}\right)-4\left(r-r^{\prime}\right)
\end{align*}
$$

and for each $i \in[k]$, we have $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{i-1}, E_{i}\right)=2$.
Hence, it remains to show that there exist elections $E_{s}=E_{-k^{\prime}}, E_{-k^{\prime}+1}, \ldots, E_{-1}, E_{0}=E_{s}^{\prime}$ such that $k^{\prime} \leq 2\left(r-r^{\prime}\right)$ and for every $i \in\left\{-k^{\prime}, \ldots,-2,-1\right\}$, we have $d_{\text {pos }}^{\text {emd }}\left(E_{i}, E_{i+1}\right)=2$. With this and Eq. (13), the induction hypothesis will follow. To this end, we prove the following claim:
Claim 2. For every pair of elections $E_{s}$ and $E_{s}^{\prime}$ such that $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{s}^{\prime}\right)=4$ it holds that there exist elections $E_{s}=E_{-k}, E_{-k+1}, \ldots, E_{1}, E_{0}=E_{s}^{\prime}$ such that $k \leq d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{s}^{\prime}\right)$ and for each $i \in\left\{-k^{\prime}, \ldots,-2,-1\right\}$, we have $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{i}, E_{i+1}\right)=2$.
Proof. We will prove this claim by induction on $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{s}^{\prime}\right)$. If $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{s}^{\prime}\right)=2$, the statement follows trivially. Hence, let us assume that $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{s}^{\prime}\right)>2$.

Take two arbitrary elections $E_{s}$ and $E_{s}^{\prime}$ and let $X$ and $X^{\prime}$ be their position matrices respectively. Let $x_{1}, \ldots, x_{m}$ be columns of $X$ and $x_{1}^{\prime}, \ldots, x_{m}^{\prime}$ columns of $X^{\prime}$. Without loss of generality, let us assume that $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{s}^{\prime}\right)=\sum_{i \in[m]} \mathrm{emd}\left(x_{i}, x_{i}^{\prime}\right)$; otherwise we could rearrange the column order. First, observe that $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{s}^{\prime}\right)=4$ if and only if there exist columns $c, c^{\prime} \in[m]$ and rows $r, r^{\prime} \in[m]$ such that

$$
x_{i, j}^{\prime}= \begin{cases}x_{i, j}-1, & \text { if }(i, j) \in\left\{(c, r),\left(c^{\prime}, r^{\prime}\right)\right\} \\ x_{i, j}+1, & \text { if }(i, j) \in\left\{\left(c^{\prime}, r\right),\left(c, r^{\prime}\right)\right\} \\ x_{i, j}, & \text { otherwise }\end{cases}
$$

Without loss of generality assume that $r>r^{\prime}$. Then, observe that $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{s}^{\prime}\right)=2\left(r-r^{\prime}\right)$. Thus, since we assumed $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{s}^{\prime}\right)>2$, we get that $r^{\prime}<r-1$. In what follows we construct elections $F$ and
$F^{\prime}$ such that $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, F\right) \leq 2, d_{\mathrm{pos}}^{\mathrm{emd}}\left(F^{\prime}, E_{s}^{\prime}\right) \leq 2, d_{\mathrm{pos}}^{\mathrm{emd}}\left(F, F^{\prime}\right)=2\left(r-r^{\prime}-1\right)$, and $d_{\mathrm{pos}}^{\ell_{1}}\left(F, F^{\prime}\right)=4$. Then, the statement will follow from the inductive assumption.

Observe that there exists a column $c^{\prime \prime}$ such that $x_{c^{\prime \prime}, r-1} \geq 1$. If $c^{\prime \prime} \neq c$, let $Z$ be a matrix with columns $z_{1}, \ldots, z_{m}$ defined as follows:

$$
z_{i, j}= \begin{cases}x_{i, j}-1, & \text { if }(i, j) \in\left\{(c, r),\left(c^{\prime \prime}, r-1\right)\right\} \\ x_{i, j}+1, & \text { if }(i, j) \in\left\{(c, r-1),\left(c^{\prime \prime}, r\right)\right\} \\ x_{i, j}, & \text { otherwise }\end{cases}
$$

If $c^{\prime \prime}=c$, let us simply denote $Z=X$. If $c^{\prime \prime} \neq c$, then $z_{c, r}=x_{c, r}-1=x_{c, r}^{\prime} \geq 0$. Also, $z_{c^{\prime \prime}, r-1}=$ $x_{c^{\prime \prime}, r-1}-1 \geq 0$. Hence, $z_{i, j} \geq 0$, for every $i, j \in[m]$. Moreover, sums of entries in every row and column of $Z$ are still equal $n$. Thus, $Z$ is a position matrix of some elections, let us denote them by $F$. If $c^{\prime \prime}=c$, then let us simply denote $F=E_{s}$.

If $c^{\prime \prime} \neq c$, then $\operatorname{emd}\left(z_{c}, x_{c}\right)=\operatorname{emd}\left(z_{c^{\prime \prime}}, x_{c^{\prime \prime}}\right)=1$. Other columns are the same in both $Z$ and $X$, hence

$$
d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, F\right) \leq 2
$$

Now, let us follow a similar construction for election $F^{\prime}$. If $c^{\prime \prime} \neq c^{\prime}$, let $Z^{\prime}$ be a matrix with columns $z_{1}^{\prime}, \ldots, z_{m}^{\prime}$ defined as follows:

$$
z_{i, j}^{\prime}= \begin{cases}x_{i, j}^{\prime}-1, & \text { if }(i, j) \in\left\{\left(c^{\prime}, r\right),\left(c^{\prime \prime}, r-1\right)\right\} \\ x_{i, j}^{\prime}+1, & \text { if }(i, j) \in\left\{\left(c^{\prime}, r-1\right),\left(c^{\prime \prime}, r\right)\right\} \\ x_{i, j}^{\prime}, & \text { otherwise }\end{cases}
$$

If $c^{\prime \prime}=c^{\prime}$, let us simply denote $Z^{\prime}=X^{\prime}$. If $c^{\prime \prime} \neq c^{\prime}$, then $z_{c^{\prime}, r}^{\prime}=x_{c^{\prime}, r}-1=x_{c, r} \geq 0$. Also, $z_{c^{\prime \prime}, r-1}^{\prime}=x_{c^{\prime \prime}, r-1}^{\prime}-1=x_{c^{\prime \prime}, r-1}-1 \geq 0$. Hence, $z_{i, j}^{\prime} \geq 0$, for every $i, j \in[m]$. Moreover, sums of entries in every row and column of $Z^{\prime}$ are still equal $n$. Thus, $Z^{\prime}$ is a position matrix of some elections, let us denote them by $F^{\prime}$. If $c^{\prime \prime}=c^{\prime}$, then let us simply denote $F^{\prime}=E_{s}^{\prime}$.

If $c^{\prime \prime} \neq c^{\prime}$, then $\operatorname{emd}\left(z_{c^{\prime}}^{\prime}, x_{c^{\prime}}^{\prime}\right)=\operatorname{emd}\left(z_{c^{\prime \prime}}^{\prime}, x_{c^{\prime \prime}}^{\prime}\right)=1$. Other columns are the same in both $Z^{\prime}$ and $X^{\prime}$, hence

$$
d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}^{\prime}, F^{\prime}\right) \leq 2
$$

Now, observe that matrices $Z$ and $Z^{\prime}$ can possibly differ only on entries in columns $c, c^{\prime}$, and $c^{\prime \prime}$ and rows $r, r-1$, and $r^{\prime}$. Specifically,

$$
\begin{aligned}
z_{c, r}^{\prime} & = \begin{cases}x_{c, r}^{\prime}=x_{c, r}-1=z_{c, r}, \quad \text { if } c \neq c^{\prime \prime}, \\
x_{c, r}^{\prime}+1=x_{c, r}=z_{c, r}, & \text { if } c=c^{\prime \prime} .\end{cases} \\
z_{c, r-1}^{\prime} & = \begin{cases}x_{c, r-1}^{\prime}=x_{c, r-1}=z_{c, r-1}-1, & \text { if } c \neq c^{\prime \prime} \\
x_{c, r-1}-1=x_{c, r-1}-1=z_{c, r-1}-1, & \text { if } c=c^{\prime \prime}\end{cases} \\
z_{c, r^{\prime}}^{\prime} & =x_{c, r^{\prime}}^{\prime}=x_{c, r^{\prime}}+1=z_{c, r^{\prime}}+1 . \\
z_{c^{\prime}, r}^{\prime} & = \begin{cases}x_{c^{\prime}, r}^{\prime}-1=x_{c^{\prime}, r}=z_{c^{\prime}, r}, & \text { if } c^{\prime} \neq c^{\prime \prime}, \\
x_{c^{\prime}, r}^{\prime}=x_{c^{\prime}, r}+1=z_{c^{\prime}, r}, & \text { if } c^{\prime}=c^{\prime \prime} .\end{cases} \\
z_{c^{\prime}, r-1}^{\prime} & = \begin{cases}x_{c^{\prime}, r-1}^{\prime}+1=x_{c^{\prime}, r-1}+1=z_{c^{\prime}, r-1}^{\prime}+1, & \text { if } c^{\prime} \neq c^{\prime \prime} \\
x_{c^{\prime}, r-1}^{\prime}=x_{c^{\prime}, r-1}^{\prime}=z_{c^{\prime}, r-1}+1, & \text { if } c^{\prime}=c^{\prime \prime} . \\
z_{c^{\prime}, r^{\prime}}^{\prime} & =x_{c^{\prime}, r^{\prime}}^{\prime}=x_{c^{\prime}, r^{\prime}}^{\prime}-1=z_{c^{\prime}, r^{\prime}}^{\prime}-1 .\end{cases}
\end{aligned}
$$

For column $c^{\prime \prime}$ it suffices to consider the case where $c^{\prime \prime} \neq c$ and $c^{\prime \prime} \neq c^{\prime}$ since other cases has been considered above. In such case,

$$
z_{c^{\prime \prime}, r}^{\prime}=x_{c^{\prime \prime}, r}^{\prime}+1=x_{c^{\prime \prime}, r}+1=z_{c^{\prime \prime}, r}^{\prime}
$$

$$
\begin{aligned}
z_{c^{\prime \prime}, r-1}^{\prime} & =x_{c^{\prime \prime}, r-1}^{\prime}-1=x_{c^{\prime \prime}, r-1}-1=z_{c^{\prime \prime}, r-1} \\
z_{c^{\prime \prime}, r^{\prime}}^{\prime} & =x_{c^{\prime \prime}, r^{\prime}}^{\prime}=x_{c^{\prime \prime}, r^{\prime}}=z_{c^{\prime \prime}, r^{\prime}}
\end{aligned}
$$

All in all, we get that

$$
z_{i, j}^{\prime}= \begin{cases}z_{i, j}-1, & \text { if }(i, j) \in\left\{(c, r-1),\left(c^{\prime}, r^{\prime}\right)\right\} \\ z_{i, j}+1, & \text { if }(i, j) \in\left\{\left(c^{\prime}, r-1\right),\left(c, r^{\prime}\right)\right\} \\ z_{i, j}, & \text { otherwise }\end{cases}
$$

Hence, we get that $\ell_{1}\left(z_{c}, z_{c}^{\prime}\right)=\ell_{1}\left(z_{c^{\prime}}, z_{c^{\prime}}^{\prime}\right)=2$. Since other columns of $Z$ and $Z^{\prime}$ are identical, we get $d_{\mathrm{pos}}^{\ell_{1}}\left(F, F^{\prime}\right) \leq 4$. If $d_{\mathrm{pos}}^{\ell_{1}}\left(F, F^{\prime}\right)=0$, then also $d_{\mathrm{pos}}^{\mathrm{emd}}\left(F, F^{\prime}\right)=0$. Then, since $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{s}^{\prime}\right)>2$, we get that $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{s}^{\prime}\right)=4$ and $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, F\right)=d_{\mathrm{pos}}^{\mathrm{emd}}\left(F, E_{s}^{\prime}\right)=2$. Hence, we can denote $E_{-2}=E_{s}$, $E_{-1}=F$, and $E_{0}=E_{s}^{\prime}$ and the induction hypothesis follows.

Thus, assume that $d_{\mathrm{pos}}^{\ell_{1}}\left(F, F^{\prime}\right)=4$. Then, observe that $\operatorname{emd}\left(z_{c}, z_{c}^{\prime}\right)=\operatorname{emd}\left(z_{c^{\prime}}, z_{c^{\prime}}^{\prime}\right)=r-r^{\prime}-1$. Since other columns of $Z$ and $Z^{\prime}$ are identical, we get $d_{\mathrm{pos}}^{\mathrm{emd}}\left(F, F^{\prime}\right) \leq 2\left(r-r^{\prime}-1\right)$. Recall that $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{s}^{\prime}\right)=2\left(r-r^{\prime}\right)$. Therefore, from the inductive assumption there exist elections $F=E_{-k}, E_{-k+1}, \ldots, E_{1}, E_{0}=F^{\prime}$ such that $k \leq d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, E_{s}^{\prime}\right)-2$ and for each $i \in\{-k, \ldots, 2,1\}$, we have $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{i}, E_{i+1}\right)=2$. Since $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}, F\right) \leq 2$ and $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{s}^{\prime}, F^{\prime}\right) \leq 2$, the induction hypothesis follows.

Finally, observe that $d_{\mathrm{pos}}^{\ell_{1}}\left(x_{c}, x_{c}^{\prime}\right)=d_{\mathrm{pos}}^{\ell_{1}}\left(x_{c^{\prime}}, x_{c^{\prime}}^{\prime}\right)=2$. Other columns of $X$ and $X^{\prime}$ are identical, thus $d_{\mathrm{pos}}^{\ell_{1}}\left(E_{s}, E_{s}^{\prime}\right) \leq 4$. If $d_{\text {pos }}^{\ell_{1}}\left(E_{s}, E_{s}^{\prime}\right)=0$, then also $d_{\text {pos }}^{\text {emd }}\left(E_{s}, E_{s}^{\prime}\right)=0$, from which the thesis follows by Eq. (13). Hence, let us assume that $d_{\text {pos }}^{\ell_{1}}\left(E_{s}, E_{s}^{\prime}\right)=4$.

Then, observe that $\operatorname{emd}\left(x_{c}, x_{c}^{\prime}\right)=\operatorname{emd}\left(x_{c^{\prime}}, x_{c^{\prime}}^{\prime}\right)=r-r^{\prime}$. Other columns of $X$ and $X^{\prime}$ are identical, thus $d_{\text {pos }}^{\mathrm{emd}}\left(E_{s}, E_{s}^{\prime}\right) \leq 2\left(r-r^{\prime}\right)$. Hence, from Claim 2, we get that there exist elections $E_{s}=E_{-k^{\prime}}, E_{-k^{\prime}+1}, \ldots, E_{-1}, E_{0}=E_{s}^{\prime}$ such that $k^{\prime} \leq 2\left(r-r^{\prime}\right)$ and for every $i \in\left\{-k^{\prime}, \ldots,-2,-1\right\}$, we have $d_{\mathrm{pos}}^{\mathrm{emd}}\left(E_{i}, E_{i+1}\right)=2$. Combined with Eq. (13) this concludes the proof.

Lemma 12. EMD-positionwise metric is not $\alpha$-intrinsic for any $\alpha<2$.
Proof. Let us consider an identity election, ID over candidates $c_{1}, \ldots, c_{m}$, with $n>m>2$ votes: $c_{1} \succ c_{2} \succ \cdots \succ c_{m}$. Also, let us consider election $E$ that is obtained from ID by exchanging one of the votes by vote $c_{m} \succ c_{2} \succ c_{3} \succ \cdots \succ c_{m-1} \succ c_{1}$. Observe that position matrix of $E$ is:

$$
\left[\begin{array}{cccccc}
n-1 & 0 & 0 & \cdots & 0 & 1 \\
0 & n & 0 & \cdots & 0 & 0 \\
0 & 0 & n & \cdots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & 0 & \cdots & n & 0 \\
1 & 0 & 0 & \cdots & 0 & n-1
\end{array}\right]
$$

Thus, it is optimal to match $c_{i}$ in ID to $c_{i}$ in $E$ for every $i \in[m]$ and we get that $d_{\mathrm{pos}}^{\mathrm{emd}}(E, \mathrm{ID})=2 m-2$.
Let $k$ be the minimum number such that there are elections $E=E_{0}, E_{1}, \ldots, E_{k-1}, E_{k}=\mathrm{ID}$ such that for each $i \in[k], d_{\mathrm{pos}}^{\ell_{1}}\left(E_{i-1}, E_{i}\right)=2$. Let us denote the position matrix of $E$ by $X^{0}$ (with columns $x_{1}^{0}, \ldots, x_{m}^{0}$ ) and the position matrix of ID by $X^{k}$ (with columns $x_{1}^{k}, \ldots, x_{m}^{k}$ ). By Lemma 8, the existence of elections $E_{0}, E_{1}, \ldots, E_{k-1}, E_{k}$ is equivalent to the existence of position matrices $X^{0}, X^{1}, \ldots, X^{k-1}, X^{k}$ such that for each $s \in[k]$ the columns of matrix $X^{s}$ are $x_{1}^{s}, \ldots, x_{m}^{s}$ and

$$
\sum_{i \in[m]} \operatorname{emd}\left(x_{i}^{s-1}, x_{i}^{s}\right)=2
$$

In what follows, we will prove that $k \geq 2 m-3$.
To this end, for every matrix $X$, let us denote the position of the last nonzero entry in the first column of $X$ by $F(X)$ and by $G(X)$ the position of the first nonzero entry in the last column. In particular, we have that $F\left(X^{0}\right)=m$ and $F\left(X^{k}\right)=1$ while $G\left(X^{0}\right)=1$ and $G\left(X^{k}\right)=m$. We continue by proving the following claim:

Claim 3. For every $s \in[k]$, it holds that $\left|F\left(X^{s-1}\right)-F\left(X^{s}\right)\right| \leq 1$ and $\left|G\left(X^{s-1}\right)-G\left(X^{s}\right)\right| \leq 1$.
Proof. Assume otherwise, i.e., there exists $s \in[k]$ such that $\left|F\left(X^{s-1}\right)-F\left(X^{s}\right)\right|>1$ (or $\mid G\left(X^{s-1}\right)-$ $G\left(X^{s}\right) \mid>1$ ). Observe that in such a case the EMD distance between the first (or last) columns of $X^{s-1}$ and $X^{s}$ is at least two, i.e., $\operatorname{emd}\left(x_{1}^{s-1}, x_{1}^{s}\right) \geq 2\left(\right.$ or $\operatorname{emd}\left(x_{m}^{s-1}, x_{m}^{s}\right) \geq 2$ ). On the other hand, two position matrices cannot differ on only one column. In other words, there exists column $i \neq 1$ (or $i \neq m$ ) such that $\operatorname{emd}\left(x_{i}^{s-1}, x_{i}^{s}\right)>0$. Thus, $\sum_{i \in[m]} \operatorname{emd}\left(x_{i}^{s-1}, x_{i}^{s}\right)>2$, which is a contradiction.

Note that by Claim 3 for each $j \in\{2,3, \ldots, m\}$ there needs to be a matrix $X^{s}$ for some $s \in$ $\{0,1, \ldots, k-1\}$ with $F\left(X^{s}\right)=j$. Thus, there exists a function, $f$, that for every $j \in\{2,3, \ldots, m\}$ returns the maximal index $s$ of a matrix, $X^{s}$, in which the position of the last nonzero entry in the first column is $j$. Formally, let $f:\{2,3, \ldots, m\} \rightarrow\{0,1, \ldots, k-1\}$ such that $F\left(X^{f(j)}\right)=j$ and for every $s \in\{0,1, \ldots, k-1\}$ s.t. $F\left(X^{s}\right)=j$ it holds that $f(j) \geq s$. Since $F\left(X^{k}\right)=1$, applying Claim 3, we get that:

$$
\begin{equation*}
F\left(X^{s}\right)<j, \quad \text { for every } s>f(j) \tag{*}
\end{equation*}
$$

Similarly, Claim 3 implies that for each $j \in[m-1]$ there is a matrix $X^{s}$ for some $s \in\{0,1, \ldots, k-1\}$ with $G\left(X^{s}\right)=j$. Hence, there exists a function, $g$, that for every $j \in[m-1]$ returns the maximal index $s$ of a matrix, $X^{s}$, in which the position of the first nonzero entry in the last column is $j$. Formally, let $g:[m-1] \rightarrow\{0,1, \ldots, k-1\}$ such that $G\left(X^{g(j)}\right)=j$ and for every $s \in\{0,1, \ldots, k-1\}$ s.t. $G\left(X^{s}\right)=j$ it holds that $g(j) \geq s$. Since $G\left(X^{k}\right)=m$, applying Claim 3, we get that:

$$
\begin{equation*}
G\left(X^{s}\right)>j, \quad \text { for every } s>g(j) \tag{**}
\end{equation*}
$$

Next, by $I_{f}$ and $I_{g}$ let us denote the images of the functions $f$ and $g$, respectively. As $f$ and $g$ are injective, $\left|I_{f}\right|=\left|I_{g}\right|=m-1$. On the other hand, as we show in the next claim the intersection of $I_{f}$ and $I_{g}$ is limited.
Claim 4. If $s \in I_{f} \cap I_{g}$, then $F\left(X^{s}\right)-G\left(X^{s}\right)=1$.
Proof. Let us take an arbitrary $s \in I_{f} \cap I_{g}$ and denote $j=F\left(X^{s}\right)$ and $j^{\prime}=G\left(X^{s}\right)$. Since $s \in I_{f}$, this means that $f(j)=s$. Thus, from $(*)$ we get that $F\left(X^{s+1}\right)<j$, which implies that $x_{1, j}^{s+1}=0$ (the last nonzero entry in the first column must be at position smaller than $j$ ). On the other hand, since $F\left(X^{s}\right)=j$, we have $x_{1, j}^{s}>0$. Hence, $\operatorname{emd}\left(x_{1}^{s}, x_{1}^{s+1}\right) \geq 1$. Similarly, the fact that $s \in I_{g}$ implies $g\left(j^{\prime}\right)=s$. Thus, from $(* *)$ we get $G\left(X^{s+1}\right)>j^{\prime}$, which implies that $x_{m, j^{\prime}}^{s+1}=0$ (the first nonzero entry in the first column must be at position greater than $\left.j^{\prime}\right)$. However, since $G\left(X^{s}\right)=j^{\prime}$, we have $x_{m, j^{\prime}}^{s}>0$. Hence, $\operatorname{emd}\left(x_{m}^{s}, x_{m}^{s+1}\right) \geq 1$.

Now, observe that the fact that $\sum_{i \in[m]} \operatorname{emd}\left(x_{i}^{s}, x_{i}^{s+1}\right)=2$ implies that there exist columns $c, c^{\prime}$ and row $r$ such that

$$
x_{i, j}^{s+1}= \begin{cases}x_{i, j}^{s}-1, & \text { if }(i, j) \in\left\{(c, r),\left(c^{\prime}, r-1\right)\right\} \\ x_{i, j}^{s}+1, & \text { if }(i, j) \in\left\{\left(c^{\prime}, r\right),(c, r-1)\right\} \\ x_{i, j}^{s}, & \text { otherwise }\end{cases}
$$

Hence, it must hold that $c=1, c^{\prime}=m, r=j$, and $r-1=j^{\prime}$. Thus,

$$
F\left(X^{s}\right)-G\left(X^{s}\right)=j-j^{\prime}=r-(r-1)=1
$$

From (*) we get that the sequence $f(2), f(3), \ldots, f(m)$ is strictly decreasing. On the other hand, (**) implies that $g(1), g(2), \ldots, g(m-1)$ is strictly increasing. Therefore, there can exists at most one $j$ and one $j^{\prime}$ such that $f(j)=g\left(j^{\prime}-1\right)$. Combining this with Claim 4, we get that $\left|I_{f} \cap I_{g}\right| \leq 1$. Thus, by the inclusion-exclusion principle, we get

$$
\left|I_{f} \cup I_{g}\right| \geq 2 m-3
$$

Clearly, $k \geq\left|I_{f} \cup I_{g}\right|$, hence

$$
k \geq 2 m-3
$$

Finally, from the definition of the level of intrinsicness, we get that $\alpha \geq k \cdot d_{m i n} / d_{\mathrm{pos}}^{\mathrm{emd}}(E$, ID $)$. Thus,

$$
\alpha \geq 2 \cdot \frac{2 m-3}{2 m-2}=2-\frac{1}{m-1}
$$

Since $m$ can be arbitrarily large, we get that $\alpha \geq 2$.

Theorem 4 directly follows from Lemmas 6, 7 and 9 to 12 .

[^0]:    *An extended abstract of this article has been accepted for publication in the proceedings of IJCAI 2022.
    ${ }^{1}$ Generally, we use the word distance when we refer to a value of a metric, but occasionally, reflecting the literature, we break this rule (e.g., to speak of the earth mover's distance or the swap distance).

[^1]:    ${ }^{2}$ There are exact formulas for some columns in Table 1, but not for all. See, e.g., the work of Eğecioğlu and Giritligil [11].

[^2]:    ${ }^{3}$ This is the largest size for which we could compute swap distances within a few weeks. Szufa et al. [25] used $100 \times 100$ elections, and Boehmer et al. [6] used $10 \times 100$ ones.
