In this paper, we propose a general implementation of the Virasoro generators and Kac–Moody currents in generic tensor network representations of 2-dimensional critical lattice models. Our proposal works even when a quantum Hamiltonian of the lattice model is not available, which is the case in many numerical computations involving numerical blockings. We tested our proposal on the 2d Ising model, and also the dimer model, which works to high accuracy even with a fairly small system size. Our method makes use of eigenstates of a small cylinder to generate descendant states in a larger cylinder, suggesting some intricate algebraic relations between lattice of different sizes.

INTRODUCTION

Critical lattice models provide a profound insight into the emergence of continuous field theory in a discrete world. There are families of classical lattice partition functions that reproduce CFT data, most notably the series of minimal models. These lattice models often are integrable, and their topological/categorical symmetries can be built in in many novel constructions developed recently based on fusion categories [1–4]. These classical lattice partition functions generically admit tensor network representations. The framework of tensor networks is a powerful tool for recovering the CFT. Particularly, it is found that the process of blocking and RG flow can be done in a controlled and efficient way with arbitrary accuracy depending on the bond dimension of the tensors kept. Tensor Renormalization Group (TRG) [5] or Tensor Network Renormalization (TNR) [6] are examples of these blocking algorithms. It is demonstrated that following a recursive blocking algorithm acting on these tensors, one can efficiently read off at least the low lying primaries and descendants from the “fixed-point” tensors. The set of tools thus promises an alternative route to obtaining and perhaps potentially classifying CFTs by constructing their lattice versions with various built-in (categorical symmetries) and solving them numerically to very high accuracy.

One very important property characterising 1+1d CFT is the infinite dimensional Virasoro symmetries and more generally the Kac–Moody symmetries. There have been discussions of how Virasoro [7–10] and Kac–Moody operators [11] can be implemented in lattice models. However, these constructions depend on the knowledge of quantum Hamiltonian retrieved from the transfer matrices of the classical lattice models by taking the highly inhomogenous limit of the parameters. In a generic tensor network representation, particularly one in which we

obtained by extracting the fixed-point of the blocking procedure, the individual tensor is given by some numerical values — there is no analytical parameter that one can expand in to obtain the quantum Hamiltonian. In cases as such, it is unclear how these Virasoro/Kac–Moody generators could be implemented.

In this paper, we develop a novel and efficient technique to construct these operators and insert them into the partition function in an arbitrary tensor network representation. It has been observed that conformal eigenstates, primaries or descendants, are eigenstates of the partition functions made of tensors tiling a cylinder. It is known that to obtain accurate conformal data involving larger conformal dimensions, it is necessary that the total bond dimension of input/output legs of the cylinder is sufficiently large (i.e. by packing a large number of tensors into the cylinder, each with small bond dimensions, or a couple tensors with large bond dimensions). In this paper, we demonstrate that one can obtain the stress tensor T and conserved current J as eigenstates of a very small cylinder, and use them to construct Virasoro/Kac–Moody descendants that are eigenstates of a very large cylinder, to surprising accuracy. The fact that it works suggests that there are interesting algebraic relations between eigenstates of cylinders of different sizes. As a numerical technique, this would open the door to many applications.

The organization of the paper is as follows. We will begin with a brief introduction of tensor network representations of partition functions. Then we will dive into the precise methodology that has been tested on the Ising and dimer model. We will end with some discussions. Some further technical details are relegated to the appendices.

TENSOR NETWORK AND PARTITION FUNCTIONS

Many 1+1 d CFTs are continuous/critical limits of lattice models. These lattice partition functions admit tensor network realizations. It is well known that the transfer matrices of these lattice models can be expressed as a tensor network, the most well-known being the Ising model, which will be the main focus of the current paper.

A generic tensor network representation of a partition function thus takes the following form, as depicted in Fig. 1.

VIRASORO AND KAC-MOODY FROM EIGENSTATES OF A SMALL CYLINDER

In a CFT, it is well known that there is a one-to-one correspondence between states and operators, i.e. consider performing a path-integral over a disk with an operator inserted at the origin. This is expected to produce the wavefunction of a state on the boundary of the disk which corresponds to the inserted operator. If the inserted operator has a well-defined conformal dimension (i.e. either a primary or a descendant), then the state produced would be an eigenstate of the dilation operator. The dilation operator is nothing but the path-integral on an annulus. An annulus with complex coordinates z can be conformally mapped to a path-integral covering a cylinder with coordinates $\omega = \sigma + i\tau$ via the conformal map $z = \exp(\omega)$. Therefore operator insertions in a planar path-integral can be achieved by cutting out a disk from the plane and replacing the disk by eigenstates of the cylinder corresponding to the particular conformal operator. In the case of a lattice partition function, the same local tensors A_{ijkl} defining the lattice partition Z on a plane can be used to cover a cylinder instead. The cylinder contains one layer of tensors in the vertical direction, and with N sites in the horizontal direction, see also Fig. 1. It is a matrix with in-coming and out-going indices corresponding to dangling legs of the local tensors at the two boundaries of the cylinder. Up to normalizations, the eigenstates of this cylinder can be used to approximate operator insertion on a plane. To distinguish the spin of the operators, one can diagonalize simultaneously with the translation operator P to obtain the finite-size spectrum $\{\phi_\alpha\}$ along with the conformal data [1, 5, 6, 12–14], i.e. scaling dimensions Δ_α and the conformal spins s_α .

In analogy to the Virasoro generators in the continuum, the lattice version on an N -site cylinder can be written as

$$L_n \sim \sum_{j=1}^N e^{ijn \frac{2\pi}{N}} T(j), \quad \bar{L}_n \sim \sum_{j=1}^N e^{-ijn \frac{2\pi}{N}} \bar{T}(j) \quad (1)$$

FIG. 1. (Left) Partition function constructed from four-leg tensors A with an operator ϕ inserted. (Right) The tensors ϕ corresponding to a conformal operator are obtained by solving for eigenstates of a cylinder built from either A tensors.

where $T(j)/\bar{T}(j)$ are lattice representations of energy-momentum tensor acting on lattice site j .

However, for a general tensor network representation of the partition function, the energy-momentum tensor T is often unknown analytically. To overcome this obstacle, we propose the following ansatz for constructing approximate Virasoro operators.

Consider a generic tensor network made up of local tensor A_{ijkl} of bond dimension $\chi_A = d$. We apply exact diagonalization on a small cylinder of four copies of tensor A and identify the eigenstate $|\phi_T\rangle$ that corresponds to the energy-momentum tensor. To reach satisfactory accuracy of the spectrum with a cylinder of just 4 sites, coarse-graining schemes such as direct blocking, TRG or TNR may be required to obtain this local tensor A . This state $|\phi_T\rangle$ of size d^4 is then reshaped into a four-leg tensor of bond dimension $\chi = d$ so it could fit back into the lattice as the approximate T operator, see Fig. 2.

FIG. 2. Tensor network implementation of Eq. (1). Eigenstate $|\phi_T\rangle$ or $|\phi_J\rangle$ that corresponds to energy-momentum tensor or Kac-Moody current is solved using a cylinder of 4 sites and reshaped into the four-leg blue tensor T or J . The blue tensor T/J is inserted at site j and we sum over the contributions of different site j 's weighted by appropriate Fourier modes on the ring.

Now using this approximate energy-momentum tensor T obtained from cylinder of 4 sites, we can build the Virasoro generators for a larger cylinder of N sites, as illustrated in Fig. 2. To represent $T(j)$, the energy-

momentum tensor inserted at site j , we replace a local tensor A at site j in the transfer matrix with the approximate energy-momentum tensor T . The lattice Virasoro generator L_n is then constructed as in Eq. (1).

When the model possesses additional symmetries, the Virasoro symmetry in the underlying CFT theory can get extended to Kac–Moody symmetry. In those cases, the associated Kac–Moody generators on the lattice can be constructed as

$$J_n \sim \sum_{j=1}^N e^{ijn\frac{2\pi}{N}} J(j), \quad \bar{J}_n \sim \sum_{j=1}^N e^{-ijn\frac{2\pi}{N}} \bar{J}(j). \quad (2)$$

where J and $\bar{J}$ are current operators with conformal dimensions $(1, 0)$ and $(0, 1)$.

Again we solve the eigenstate $|\phi_J\rangle$ that corresponds to the conserved current from a cylinder of 4 copies of A by exact diagonalization. This vector $|\phi_J\rangle$ is subsequently reshaped into a four-leg operator and used to build the Kac–Moody generators J_n on a larger cylinder, as described in Fig. 2.

FIG. 3. Lattice Virasoro and Kac–Moody generators acting on eigenstates from the cylinder.

We check the validity of our proposal by applying the so constructed Virasoro/Kac–Moody generators to the low energy eigenstates of the transfer matrix of the Ising and the Dimer models, as to be explained in further details in the next section.

EXAMPLES

Ising model & Ising CFT

As our first test, we study the Ising model on the square lattice $Z = \sum_{\langle ij \rangle} \exp(-\beta \sigma_i \sigma_j)$, where $\sigma \in \{-1, +1\}$ is an Ising spin. This partition function can be encoded into a square tensor network consisting of copies of local tensor $A_{ijkl}^{(0)}$ with components

$$A_{ijkl}^{(0)} = \exp[\beta(\sigma_i \sigma_j + \sigma_j \sigma_k + \sigma_k \sigma_l + \sigma_l \sigma_i)] \quad (3)$$

where $\beta = \beta_c = \log(1 + \sqrt{2})/2$ at criticality.

We start by blocking the tensor $A^{(0)}$ into 2×2 square block to form a new tensor A of bond dimension $\chi = 4$, which is used as the unit tensor in the following calculation. The idea is that we can use the eigenstates of small cylinder with $N = 4$ copies of A to construct the

Virasoro generators L_n and $\bar{L}_n$ for eigenstates of a larger cylinder (in this example, $N = 8$). For both cylinders, low energy eigenstates together with conformal spins and scaling dimensions are obtained by exact diagonalization, see Fig. 4.

In the spectrum of the small cylinder, we identify the state with conformal spin $s = 2$ and scaling dimension $\Delta \approx 2$ as $|\phi_T\rangle$ that corresponds to the energy-momentum tensor T and reshape it into a four-leg operator with bond dimension $\chi = 4$. The approximate operator for the anti-holomorphic partner $\bar{T}$ is obtained similarly. (Technical subtlety involved in separating $|\phi_T\rangle$ and $|\phi_{\bar{T}}\rangle$ as degenerate states on a cylinder of 4 sites will be explained in the appendices.)

Using the approximate T and $\bar{T}$ from cylinder of 4 sites, L_n and $\bar{L}_n$ for the larger $N = 8$ cylinder can be built via the construction as described in Fig. 2 and Fig. 3. The behaviors of L_n and L_{-n} are explored by examining the matrix elements $\langle \phi_\beta | L_n | \phi_\alpha \rangle$ in the low energy subspace of the $N = 8$ transfer matrix.

FIG. 4. Low energy spectra of Ising model in terms of scaling dimensions Δ and conformal spins s . Primary states are labeled with their corresponding primary operators in the CFT. We use the approximate lattice operators T and $\bar{T}$ solved from a cylinder of 4 copies of A (left) to construct lattice Virasoro generators L_n and $\bar{L}_n$ for a cylinder of $N = 8$ sites (right). As an example, actions of lattice L_{-1} are illustrated on the right. Actions of other L_n and $\bar{L}_n$ and the supporting matrix elements can be found in the appendices.

In the CFT, Virasoro generators L_n act as ladder operators on eigenstates, $L_n |\Delta_\alpha, s_\alpha\rangle \propto |\Delta_\alpha - n, s_\alpha - n\rangle$, raising Δ for $n < 0$ and lowering Δ for $n > 0$. Our numerical results show that, overall L_n and $\bar{L}_n$ successfully map the states to their descendants as predicted by CFT with high fidelity $\frac{\|\langle \phi_\beta | L_n | \phi_\alpha \rangle\|}{\|\langle \phi_\beta \rangle\| \cdot \|\langle \phi_\alpha \rangle\|} \gtrsim 0.9$ (tested with $n = \pm 1, \pm 2$ on cylinder of $N = 8$ sites and bond dimension $\chi = 4$). We do observe few erroneous matrix elements (one or two orders of magnitude less than the correct matrix elements) within the same Virasoro tow-

ers due to the finite size effect of lattice model and that T and $\bar{T}$ are approximated from a very small cylinder.

Dimer model & free boson CFT

The second example is the dimer model [15–17] which can be mapped to a bosonic theory via the height mapping [18–20]. The partition function of dimer model can be represented using a square lattice consisting of a local tensor $B_{ijkl}^{(0)}$ which has non-zero components $B_{1111}^{(0)} = B_{2211}^{(0)} = B_{2121}^{(0)} = B_{1212}^{(0)} = B_{2222}^{(0)} = 1$ and $B_{1122}^{(0)} = 2$ [21]. In the continuum limit, this model corresponds to $c = 1$ free boson CFT with vertex operators of scaling dimensions $\Delta_{e,m} = e^2 + \frac{1}{4}m^2$ and conformal spin $s_{e,m} = em$, where e and m are the electromagnetic charges in the Coulomb gas description of the dimer model. In addition to Virasoro symmetry, the continuum limit of dimer model exhibits an extended symmetry, Kac–Moody symmetry.

Since the construction of Virasoro generators has already been tested in the previous case, here we will just focus on the applications of our ansatz in constructing the Kac–Moody generators. Again, we take a 2×2 block of tensors $B^{(0)}$ to form a new tensor B with bond dimension $\chi = 4$. From the spectrum of a cylinder of 4 copies of B , we identify the lowest state with conformal spin $s = 1$ as $|\phi_J\rangle$ and the lowest state with $s = -1$ as $|\phi_{\bar{J}}\rangle$. They are then reshaped into four-leg tensors as approximate lattice current operators J and $\bar{J}$. We construct lattice Kac–Moody generators using approximate J and $\bar{J}$ as in Fig. 2 and check their behaviors as in Fig. 3 on low energy eigenstates from cylinder of $N = 8$ copies of B .

In the CFT the Virasoro generators L_n and Kac–Moody generators J_n satisfy the commutation relation that $[L_m, J_n] = -nJ_{m+n}$. Therefore J_n act on eigenstates as ladder operators as well i.e. $J_n|\Delta_\alpha, s_\alpha\rangle \propto |\Delta_\alpha - n, s_\alpha - n\rangle$, raising Δ for $n < 0$ and lowering Δ for $n > 0$. We check the property of our lattice Kac–Moody generator by computing the matrix elements $\langle\phi_\beta|J_n|\phi_\alpha\rangle$. We confirm numerically that the correct Kac–Moody descendants $|\phi_\beta\rangle = |\Delta_\beta, s_\beta\rangle$ can be reached by acting J_n and $\bar{J}_n$ on an initial state $|\phi_\alpha\rangle = |\Delta_\alpha, s_\alpha\rangle$. However, apart from those correct connections, errors in the matrix elements are also observed. In the case of dimer model, the errors are noticeably larger than those in the Ising case, as the dimer model suffers greater finite size effect. The errors fall in two classes: (i) the mixing of different Kac–Moody towers (mainly the tower of identity $|s = 0, \Delta = 0\rangle$ and that of $|s = 0, \Delta = 1\rangle$), which likely results from the fact that the lowest eigenstate of the cylinder is not the true vacuum but instead polluted by other primary states; (ii) the mixing of lowering and raising actions within the same Kac–Moody towers, sug-

FIG. 5. Low energy spectra of dimer model in terms of scaling dimensions Δ and conformal spins s . Using approximate current operators J and $\bar{J}$ obtained from a 4-site cylinder (left) we construct lattice Kac–Moody generators J_n and $\bar{J}_n$ for a cylinder of $N = 8$ sites (right) and examine their behaviors in the low energy subspace. Actions of lattice J_{-1} that match with CFT predictions are illustrated using solid black arrows and the erroneous actions are marked with dashed gray arrows. See the appendices more examples.

gesting that the holomorphic part of the lattice current and the anti-holomorphic part are not fully separated. Having said that, one can refer to the appendix for the numerical results of the matrix element to see that the mixing is a consistent pattern of mixing – meaning that the ground state is a definite mixing of the vacuum and several low lying degenerate excited states, and the mixing between J and $\bar{J}$ is also consistent. Apart from this mixing, there is a 5-6 orders of magnitude separation in the matrix elements with states not supposed to be generated by the algebra from a given primary, suggesting that the method is working and that one can in principle isolate the eigenstates.

To enhance the precision of this method, one could increase both the bond dimension χ of the local tensor in the small cylinder that is used for obtaining the lattice energy-momentum tensor or current, and lattice size N of the cylinder on which the Virasoro/Kac–Moody generators are constructed. Tensor network techniques such as TNR can also be employed for approaching the fixed-point tensor of the model and therefore achieving a more accurate representation of the local energy-momentum tensor/current. It would also be interesting to combine the idea here with the scaling map approach as introduced in [13].

CONCLUSION

In this paper, we proposed a method to insert descendant operators in a tensor network representation of the partition function of a critical lattice model. The method was inspired by “discrete holomorphicity” — observations made in 1980s that many CFT symmetries are actually preserved all the way up to the lattice scale (see [22] for a review). In this paper, we demonstrate that the stress tensor and the Kac–Moody current constructed from eigenstates of a tiny cylinder can be used to generate descendents of states defined on a big cylinder. In fact, in the examples considered, namely the Ising model and also the dimer model corresponding to a $c = 1$ free boson CFT, we only need to use eigenstates of a cylinder with 4 sites to construct descendent states in a bigger cylinder. These conserved quantities seem to be defined at the smallest scale, mirroring the situation when these quantum operators were constructed to act on lattice states on a ring [7, 9–11]. In the case of discrete holomorphic operators, their conservation follows from co-product structures of quantum algebra which are symmetries of the integrable lattice models involved. It would be very interesting to explore if a new algebraic structure is involved in the realization of the Virasoro and Kac–Moody symmetries.

Aside of its theoretical appeal, the method proposed here is, to our knowledge, the first method available to date to deal with the Virasoro and Kac–Moody symmetries when the quantum Hamiltonian is not readily accessible, an issue particularly pronounced in numerical computations. This should open the door to many applications.

Here, operators H_{CFT} and P denote the Hamiltonian and the total momentum operators that generate translations along the time and space directions, while c is the central charge. τ is a complex modular parameter that parametrizes the geometry of the torus.

For a local field ϕ_α with conformal dimension $(h_\alpha, \bar{h}_\alpha)$, from Virasoro algebra we know that

$$\begin{aligned} Z_{\text{CFT}} &= \sum_{\alpha} \exp \left[-2\pi \text{Im} \tau \left(h_0 + \bar{h}_0 - \frac{c}{12} \right) + 2\pi i \text{Re} \tau (h_0 - \bar{h}_0) \right] \\ &= \sum_{\alpha} \exp \left[-2\pi \text{Im} \tau \left(\Delta_\alpha - \frac{c}{12} \right) + 2\pi i \text{Re} \tau \cdot s_\alpha \right], \end{aligned} \quad (5)$$

where $\Delta_\alpha = h_0 + \bar{h}_0$ and $s_\alpha = h_0 - \bar{h}_0$ are the scaling dimension and conformal spin of ϕ_α respectively.

In the continuum limit, a critical classical lattice model with periodic boundary conditions can be described by the torus CFT, with modular parameter $\tau = im/N$. The partition function is then

$$Z = \sum_{\alpha} \exp \left[-2\pi \frac{m}{N} \left(\Delta_\alpha - \frac{c}{12} \right) + mNf + \mathcal{O}\left(\frac{m}{N^\gamma}\right) \right], \quad (6)$$

where f is the free energy per each site at the thermodynamic limit, and $\mathcal{O}(m/N^\gamma)$ is the finite-size corrections. If the partition function can be written as $Z = \text{Tr} M^m$ where M is the transfer matrix, the eigenvalues of M are then

$$\lambda_\alpha = \exp \left[-\frac{2\pi}{N} \left(\Delta_\alpha - \frac{c}{12} \right) + Nf + \mathcal{O}\left(\frac{1}{N^\gamma}\right) \right]. \quad (7)$$

The conformal spin can be calculated by introducing the translation operator $\exp(2\pi i P/N)$, whose eigenvalues are $\exp(2\pi i s_\alpha/N)$. For a translationally invariant model, $\exp(2\pi i P/N)$ commutes with the transfer matrix M , so they can be diagonalized simultaneously to produce a set of eigenvectors with eigenvalues $\{\lambda, P_\alpha\}$. One way of estimate the scaling dimension Δ_α is to fix the identity state $|\phi_I\rangle$ and state $|\phi_T\rangle$ corresponding to energy momentum tensor to have $\Delta_I = 0$ and $\Delta_T = 2$ so that

$$\Delta_\alpha = \frac{2}{\log \lambda_T - \log \lambda_I} (\log \lambda_\alpha - \log \lambda_I). \quad (8)$$

Conformal spin is obtained from the eigenvalues of the lattice translation operator P as

$$s_\alpha = \frac{N}{2\pi} P_\alpha. \quad (9)$$

Numerical details for the Ising model

Here we provide the numerical details of the Ising model example discussed in the main text. In this example, we first apply one step of direct blocking as illustrated in Fig. 6 to obtain coarse-grained tensor $A = A^{(1)}$ of bond dimension $\chi = 4$ from standard square lattice Ising tensor $A^{(0)}$. More blocking steps or tensor network techniques such as TRG and TNR could be applied to obtain a unit tensor that is closer to the fixed-point, but here we find $A^{(1)}$ is sufficient for the purpose of illustrating our method. Low energy spectrum in terms of conformal spins and scaling dimensions can be obtained by exact diagonalization of transfer matrix on a cylinder, as discussed in last section.

Eigenstates $|\phi_T\rangle$ and $|\phi_{\bar{T}}\rangle$ that correspond to energy-momentum tensor T and $\bar{T}$ have conformal spins $s = 2$ and $s = -2$. Therefore on a cylinder of $N = 4$ sites, these two eigenstates are in fact degenerate. In order to separate these two, one can go back to the original tensor $A^{(0)}$ of bond dimension $\chi = 2$ and solve eigenstates from a cylinder of $N = 8$ sites of $A^{(0)}$. These eigenstates are then reshaped into four-leg tensors T and $\bar{T}$ with bond dimension $\chi = 4$ and subsequently used to construct Virasoro generators L_n and L_{-n} on a cylinder of $N = 8$ sites in the coarse-grained lattice of A .

We check the property of the lattice Virasoro generators by examining their actions on the low energy eigenstates of transfer matrix on the same cylinder of $N = 8$ sites in the coarse-grained lattice. We list the matrix elements $\langle \phi_\alpha | L_n | \phi_\beta \rangle$ and $\langle \phi_\alpha | L_{-n} | \phi_\beta \rangle$ for $n = \pm 1, \pm 2$ in Table I–VIII and illustrate their behaviors on the conformal towers in Fig. 7 and 8. In the tables, the matrix elements between states and their correct Virasoro descendant states are highlighted in bold blue, whereas the erroneous matrix elements are marked in pale blue.

FIG. 6. (Top) The $2 \times 2 \mapsto 1$ coarse-graining procedure. $A^{(s)}$ is made by blocking four copies of $A^{(s-1)}$. (Bottom) The corresponding operator insertion is effected by a square with fewer legs, each with a higher bond dimension.

FIG. 7. Actions of lattice Virasoro generators $L_{\pm 1}$ and $\bar{L}_{\pm 1}$ in the low energy subspace of transfer matrix consisting of a row of $N = 8$ copies of A with bond dimension $\chi = 4$. Corresponding matrix elements are listed in Table I-IV.

TABLE IV. $\langle\phi_\alpha|\bar{L}_{+1}|\phi_\beta\rangle$

FIG. 8. Actions of lattice $L_{\pm 2}$ and $\bar{L}_{\pm 2}$ in the low energy subspace of transfer matrix consisting of a row of $N = 8$ copies of A with bond dimension $\chi = 4$. Corresponding matrix elements are listed in Table V–VIII.

TABLE VIII. $\langle\phi_\alpha|\bar{L}_{+2}|\phi_\beta\rangle$

Numerical details for the dimer model

Similar to the Virasoro algebra case, we start by combining dimer model tensor $B^{(0)}$ into 2×2 square block to get a new tensor $B = B^{(1)}$ of bond dimension $\chi = 4$ and then extract the approximate local current tensor J operator and its holomorphic part $\bar{J}$ from a smaller cylinder of $N = 4$ copies of coarse-grained tensor B . J and $\bar{J}$ are then used to construct Kac–Moody generators J_n and $\bar{J}_n$ on a larger $N = 8$ cylinder.

We verify the actions of the lattice Kac–Moody generators by examining the matrix elements $\langle \phi_\alpha | J_n | \phi_\beta \rangle$ and $\langle \phi_\alpha | \bar{J}_n | \phi_\beta \rangle$ with $n = -1, -2$ using the low energy eigenstates from a cylinder of $N = 8$ sites of B . Numerical results of the matrix elements are provided in Table IX–XI and their behaviors in the low energy subspace are illustrated in Fig. 9. The matrix elements between states and their correct Kac–Moody descendant states are highlighted in bold blue in the tables and illustrated correspondingly by solid black arrows in the figures. The erroneous matrix elements are marked in pale blue in the tables and illustrated by dashed gray arrows in the figures.

FIG. 9. Actions of lattice Kac–Moody generators $J_{-1, -2}$ and $\bar{J}_{-1, -2}$ in the low energy subspace of transfer matrix consisting of a row of $N = 8$ copies of B with bond dimension $\chi = 4$. Corresponding matrix elements are listed in Table IX–XI.
