# Weighted approximation in higher-dimensional missing digit sets 

Demi Allen Benjamin Ward<br>(Exeter)<br>(York)

May 17, 2022

#### Abstract

In this note, we use the mass transference principle for rectangles, recently obtained by Wang and Wu (Math. Ann., 2021), to study the Hausdorff dimension of sets of "weighted $\Psi$-well-approximable" points in certain self-similar sets in $\mathbb{R}^{d}$. Specifically, we investigate weighted $\Psi$-well-approximable points in "missing digit" sets in $\mathbb{R}^{d}$. The sets we consider are natural generalisations of Cantor-type sets in $\mathbb{R}$ to higher dimensions and include, for example, four corner Cantor sets (or Cantor dust) in the plane with contraction ratio $\frac{1}{n}$ with $n \in \mathbb{N}$.

## 1 Introduction and motivation

The work of this current paper is motivated by a question posed in a seminal paper by Mahler [36]; namely, how well can we approximate points in the middle-third Cantor set by:
(i) rational numbers contained in the Cantor set, or
(ii) rational numbers not in the Cantor set?

The first contribution to this question was arguably made by Weiss [47], who showed that almost no point in the middle-third Cantor set is very well approximable with respect to the natural probability measure on the middle-third Cantor set. Since this initial contribution, numerous authors have contributed to answering these questions, approaching them from many different perspectives. For example, Levesley, Salp, and Velani [35] considered triadic approximation in the middle-third Cantor set, different subsets of the first named author, Baker, Chow, and Yu $[3,6,13]$ studied dyadic approximation in the middle-third Cantor set, Kristensen [34] considered approximation of points in the middle-third Cantor set by algebraic numbers, and Tan, Wang and Wu [42] have recently studied part (i) by introducing a new notion of the "height" of a rational number. There has also been considerable effort invested in trying to generalise some of the above results to more general self-similar sets in $\mathbb{R}$ and also to various fractal sets in higher dimensions. See, for example, $[4,10-12,14,18,22$,
$23,27,31,38,46,48]$ and references therein. The results in this paper can be thought of as a contribution to answering a natural $d$-dimensional weighted variation of part (i) of Mahler's question. In particular, we will be interested in weighted approximation in $d$-dimensional "missing digit" sets.

Before we introduce the general framework we will consider here, we provide a very brief overview of some of the classical results on weighted Diophantine approximation in the "usual" Euclidean setting which provide further motivation for the current work. Fix $d \in \mathbb{N}$ and let $\Psi=\left(\psi_{1}, \ldots, \psi_{d}\right)$ be a $d$-tuple of approximating functions $\psi_{i}: \mathbb{N} \rightarrow[0, \infty)$ with $\psi_{i}(r) \rightarrow 0$ as $r \rightarrow \infty$ for each $1 \leq i \leq d$. The set of weighted simultaneously $\Psi$-wellapproximable points in $\mathbb{R}^{d}$ is defined as
$W_{d}(\Psi):=\left\{\mathbf{x}=\left(x_{1}, \ldots, x_{d}\right) \in[0,1]^{d}:\left|x_{i}-\frac{p_{i}}{q}\right|<\psi_{i}(q), 1 \leq i \leq d\right.$, for i.m. $\left.\left(p_{1}, \ldots p_{d}, q\right) \in \mathbb{Z}^{d} \times \mathbb{N}\right\}$,
where i.m. denotes infinitely many. Note that the special case where each approximating function is the same, that is $\Psi=(\psi, \ldots, \psi)$, is generally the more intensively studied set. The case where each approximating function is potentially different, usually referred to as weighted simultaneous approximation, is a natural generalisation of this. Simultaneous approximation (i.e. when the approximating function is the same in each coordinate axis) can generally be seen as a metric generalisation of Dirichlet's Theorem, whereas weighted simultaneous approximation is a metric generalisation of Minkowski's Theorem. Weighted simultaneous approximation has earned interest in the past few decades due to Schmidt and natural connections to Littlewood's Conjecture, see for example [7-9, 15, 41].

Motivated by classical works due to the likes of Khintchine [28, 29] and Jarník [26] which tell us, respectively, about the Lebesgue measure and Hausdorff measures of the sets of classical simultaneously $\Psi$-well-approximable points (i.e. when $\Psi=(\psi, \ldots, \psi)$ ), one may naturally also wonder about the "size" of sets of weighted simultaneously $\Psi$-wellapproximable points in terms of Lebesgue measure, Hausdorff dimension, and Hausdorff measures. Khintchine [30] showed that if $\psi: \mathbb{N} \rightarrow[0, \infty)$ and $\Psi(q)=\left(\psi(q)^{\tau_{1}}, \ldots, \psi(q)^{\tau_{d}}\right)$ for some $\boldsymbol{\tau}=\left(\tau_{1}, \ldots, \tau_{d}\right) \in(0,1)^{d}$ with $\tau_{1}+\tau_{2}+\cdots+\tau_{d}=1$, then

$$
\lambda_{d}\left(W_{d}(\Psi)\right)=\left\{\begin{array}{lll}
0 & \text { if } \quad \sum_{q=1}^{\infty} q^{d} \psi(q)<\infty \\
1 & \text { if } \quad \sum_{q=1}^{\infty} q^{d} \psi(q)=\infty, \text { and } q^{d} \psi(q) \text { is monotonic. }
\end{array}\right.
$$

Throughout we use $\lambda_{d}(X)$ to denote the $d$-dimensional Lebesgue measure of a set $X \subset \mathbb{R}^{d}$. For more general approximating functions $\Psi(q)=\left(\psi_{1}(q), \ldots, \psi_{d}(q)\right)$, with $\prod_{i=1}^{d} \psi_{i}(q)$ monotonically decreasing and $\psi_{i}(q)<q^{-1}$ for each $1 \leq i \leq d$, it has been proved, see [19,24,30,40], that

$$
\lambda_{d}\left(W_{d}(\Psi)\right)=\left\{\begin{array}{lll}
0 & \text { if } & \sum_{q=1}^{\infty} q^{d} \psi_{1}(q) \ldots \psi_{d}(q)<\infty \\
1 & \text { if } & \sum_{q=1}^{\infty} q^{d} \psi_{1}(q) \ldots \psi_{d}(q)=\infty
\end{array}\right.
$$

For approximating functions of the form $\Psi(q)=\left(\psi_{1}(q), \ldots, \psi_{d}(q)\right)$ where

$$
\psi_{i}(q)=q^{-t_{i}-1}, \quad \text { for some vector } \mathbf{t}=\left(t_{1}, \ldots, t_{d}\right) \in \mathbb{R}_{>0}^{d}
$$

Rynne [39] proved that if $\sum_{i=1}^{d} t_{i} \geq 1$, then

$$
\operatorname{dim}_{\mathrm{H}} W_{d}(\Psi)=\min _{1 \leq k \leq d}\left\{\frac{1}{t_{k}+1}\left(d+1+\sum_{i: t_{k} \geq t_{i}}\left(t_{k}-t_{i}\right)\right)\right\}
$$

Throughout, we write $\operatorname{dim}_{H} X$ to denote the Hausdorff dimension of a set $X \subset \mathbb{R}^{d}$, we refer the reader to [20] for definitions and properties of Hausdorff dimension and Hausdorff measures. Rynne's result has recently been extended to a more general class of approximating functions by Wang and Wu [44, Theorem 10.2].

In recent years, there has been rapidly growing interest in whether similar statements can be proved when we intersect $W_{d}(\Psi)$ with natural subsets of $[0,1]^{d}$, such as submanifolds or fractals. The study of such questions has been further incentivised by many remarkable works of the recent decades, such as $[31,32,43]$, and applications to other areas, such as wireless communication theory [1].

## 2 d-dimensional missing digit sets and main results

In this paper we study weighted approximation in $d$-dimensional missing digit sets, which are natural extensions of classical missing digit sets (i.e. generalised Cantor sets) in $\mathbb{R}$ to higher dimensions. A very natural class of higher dimensional missing digit sets included within our framework are the four corner Cantor sets (or Cantor dust) in $\mathbb{R}^{2}$ with contraction ratio $\frac{1}{n}$ for $n \in \mathbb{N}$.

Throughout we consider $\mathbb{R}^{d}$ equipped with the supremum norm, which we denote by $\|\cdot\|$. For subsets $X, Y \subset \mathbb{R}^{d}$ we define $\operatorname{diam}(X)=\sup \{\|u-v\|: u, v \in X\}$ and $\operatorname{dist}(X, Y)=$ $\inf \{\|x-y\|: x \in X, y \in Y\}$. We define higher-dimensional missing digit sets via iterated function systems as follows. Let $b \in \mathbb{N}$ be such that $b \geq 3$ and let $J_{1}, \ldots, J_{d}$ be proper subsets of $\{0,1, \ldots, b-1\}$ such that for each $1 \leq i \leq d$, we have

$$
N_{i}:=\# J_{i} \geq 2
$$

Suppose $J_{i}=\left\{a_{1}^{(i)}, \ldots, a_{N_{i}}^{(i)}\right\}$. For each $1 \leq i \leq d$, we define the iterated function system

$$
\Phi^{i}=\left\{f_{j}:[0,1] \rightarrow[0,1]\right\}_{j=1}^{N_{i}} \quad \text { where } \quad f_{j}(x)=\frac{x+a_{j}^{(i)}}{b}
$$

Let $K_{i}$ be the attractor of $\Phi^{i}$; that is, $K_{i} \subset \mathbb{R}$ is the unique non-empty compact set which satisfies

$$
K_{i}=\bigcup_{j=1}^{N_{i}} f_{j}\left(K_{i}\right)
$$

We know that such a set exists due to work of Hutchinson [25]. Equivalently $K_{i}$ is the set of $x \in[0,1]$ for which there exists a base $b$ expansion of $x$ consisting only of digits from $J_{i}$. In view of this, we will also use the notation $K_{b}\left(J_{i}\right)$ to denote this set. For example, in this notation, the classical middle-third Cantor set is precisely the set $K_{3}(\{0,2\})$. We call the
sets $K_{b}\left(J_{i}\right)$ missing digit sets since they consist of numbers with base- $b$ expansions missing specified digits. Note that, for each $1 \leq i \leq d$, the Hausdorff dimension of $K_{i}$, which we will denote by $\gamma_{i}$, is given by

$$
\gamma_{i}=\operatorname{dim}_{\mathrm{H}} K_{i}=\frac{\log N_{i}}{\log b}
$$

We will be interested in the higher-dimensional missing digit set

$$
K:=\prod_{i=1}^{d} K_{i}
$$

formed by taking the Cartesian product of the sets $K_{i}, 1 \leq i \leq d$. As a natural concrete example, we note that the four corner Cantor set in $\mathbb{R}^{2}$ with contraction ratio $\frac{1}{b}$ (with $b \geq 3$ an integer) can be written in our notation as $K_{b}(\{0, b-1\}) \times K_{b}(\{0, b-1\})$.

We note that $K$ is the attractor of the iterated function system

$$
\Phi=\left\{f_{\left(j_{1}, \ldots, j_{d}\right)}:[0,1]^{d} \rightarrow[0,1]^{d},\left(j_{1}, \ldots, j_{d}\right) \in \prod_{i=1}^{d} J_{i}\right\}
$$

where

$$
f_{\left(j_{1}, \ldots, j_{d}\right)}\left(\begin{array}{c}
x_{1} \\
\vdots \\
x_{d}
\end{array}\right)=\left(\begin{array}{c}
\frac{x_{1}+j_{1}}{b} \\
\vdots \\
\frac{x_{d}+j_{d}}{b}
\end{array}\right) .
$$

Notice that $\Phi$ consists of

$$
N:=\prod_{i=1}^{d} N_{i}
$$

maps and so, for convenience, we will write

$$
\Phi=\left\{g_{j}:[0,1]^{d} \rightarrow[0,1]^{d}\right\}_{j=1}^{N}
$$

where the $g_{j}$ 's are just the maps $f_{\left(j_{1}, \ldots, j_{d}\right)}$ from above written in some order. The Hausdorff dimension of $K$, which we denote by $\gamma$, is

$$
\gamma=\operatorname{dim}_{\mathrm{H}} K=\frac{\log N}{\log b} .
$$

We will write

$$
\Lambda=\{1,2, \ldots, N\} \quad \text { and } \quad \Lambda^{*}=\bigcup_{n=0}^{\infty} \Lambda^{n}
$$

We write $\mathbf{i}$ to denote a word in $\Lambda$ or $\Lambda^{*}$ and we write $|\mathbf{i}|$ to denote the length of $\mathbf{i}$. For $\mathbf{i} \in \Lambda^{*}$ we will also use the shorthand notation

$$
g_{\mathbf{i}}=g_{i_{1}} \circ g_{i_{2}} \circ \cdots \circ g_{i_{\mathbf{i} \mid}} .
$$

We adopt the convention that $g_{\emptyset}(x)=x$.

Let $\Psi: \Lambda^{*} \rightarrow[0, \infty)$ be an approximating function. For each $x \in K$, we define the set

$$
W(x, \Psi)=\left\{y \in K:\left\|y-g_{\mathbf{i}}(x)\right\|<\Psi(\mathbf{i}) \text { for infinitely many } \mathbf{i} \in \Lambda^{*}\right\}
$$

The following theorem is a special case of [4, Theorem 1.1].
Theorem 1. Let $\Phi$ and $K$ be as defined above. Let $x \in K$ and let $\varphi: \mathbb{N} \rightarrow[0, \infty)$ be a monotonically decreasing function. Let $\Psi(\mathbf{i})=\operatorname{diam}\left(g_{\mathbf{i}}(K)\right) \varphi(|\mathbf{i}|)$. Then, for $s>0$,

$$
\mathcal{H}^{s}(W(x, \Psi))=\left\{\begin{array}{lll}
0 & \text { if } & \sum_{\mathbf{i} \in \Lambda^{*}} \Psi(\mathbf{i})^{s}<\infty \\
\mathcal{H}^{s}(K) & \text { if } & \sum_{\mathbf{i} \in \Lambda^{*}} \Psi(\mathbf{i})^{s}=\infty
\end{array}\right.
$$

Of particular interest to us here is the following easy corollary.
Corollary 1. Let $\Phi$ and $K$ be as above and suppose that $\operatorname{diam}(K)=1$. Let $\psi: \mathbb{N} \rightarrow[0, \infty)$ be such that $b^{n} \psi\left(b^{n}\right)$ is monotonically decreasing and define $\varphi: \mathbb{N} \rightarrow[0, \infty)$ by $\varphi(n)=b^{n} \psi\left(b^{n}\right)$. Let $\Psi(\mathbf{i})=\operatorname{diam}\left(g_{\mathbf{i}}(K)\right) \varphi(|\mathbf{i}|)$. Recall that $\gamma=\operatorname{dim}_{\mathrm{H}} K$. Then, for $x \in K$, we have

$$
\mathcal{H}^{\gamma}(W(x, \Psi))=\left\{\begin{array}{ll}
0 & \text { if } \\
\sum_{n=1}^{\infty}\left(b^{n} \psi\left(b^{n}\right)\right)^{\gamma}<\infty \\
\mathcal{H}^{\gamma}(K) & \text { if }
\end{array} \quad \sum_{n=1}^{\infty}\left(b^{n} \psi\left(b^{n}\right)\right)^{\gamma}=\infty .\right.
$$

Proof. It follows from Theorem 1 that

$$
\mathcal{H}^{\gamma}(W(x, \Psi))=\left\{\begin{array}{lll}
0 & \text { if } & \sum_{\mathbf{i} \in \Lambda^{*}} \Psi(\mathbf{i})^{\gamma}<\infty \\
\mathcal{H}^{\gamma}(K) & \text { if } & \sum_{\mathbf{i} \in \Lambda^{*}} \Psi(\mathbf{i})^{\gamma}=\infty
\end{array}\right.
$$

However, in this case, by the definition of $\varphi$ and our assumption that $\operatorname{diam}(K)=1$, we have

$$
\sum_{\mathbf{i} \in \Lambda^{*}} \Psi(\mathbf{i})^{\gamma}=\sum_{n=1}^{\infty} \sum_{\substack{\mathbf{i} \in \Lambda^{*} \\|\mathbf{i}|=n}}\left(\operatorname{diam}\left(g_{\mathbf{i}}(K)\right) \varphi(|\mathbf{i}|)\right)^{\gamma}=\sum_{n=1}^{\infty} \sum_{\substack{\mathbf{i} \in \Lambda^{*} \\|\mathbf{i}|=n}} \psi\left(b^{n}\right)^{\gamma}=\sum_{n=1}^{\infty} N^{n} \psi\left(b^{n}\right)^{\gamma}=\sum_{n=1}^{\infty}\left(b^{n} \psi\left(b^{n}\right)\right)^{\gamma}
$$

For an approximating function $\psi: \mathbb{N} \rightarrow[0, \infty)$, define

$$
\begin{equation*}
W(x, \psi)=\left\{y \in K:\left\|y-g_{\mathbf{i}}(x)\right\|<\psi\left(b^{\mathbf{|} \mid}\right) \text { for infinitely many } \mathbf{i} \in \Lambda^{*}\right\} \tag{1}
\end{equation*}
$$

In essence, $W(x, \psi)$ is a set of "simultaneously $\psi$-well-approximable" points in $K$. The following statement regarding these sets can be deduced immediately from Corollary 1.

Corollary 2. Let $\Phi$ and $K$ be defined as above and let $\psi: \mathbb{N} \rightarrow[0, \infty)$ be such that $b^{n} \psi\left(b^{n}\right)$ is monotonically decreasing. Suppose further that $\operatorname{diam}(K)=1$. Then,

$$
\mathcal{H}^{\gamma}(W(x, \psi))=\left\{\begin{array}{lll}
0 & \text { if } & \sum_{n=1}^{\infty}\left(b^{n} \psi\left(b^{n}\right)\right)^{\gamma}<\infty \\
\mathcal{H}^{\gamma}(K) & \text { if } & \sum_{n=1}^{\infty}\left(b^{n} \psi\left(b^{n}\right)\right)^{\gamma}=\infty
\end{array}\right.
$$

Here we will be interested in weighted versions of the sets $W(x, \psi)$. More specifically, for $\mathbf{t}=\left(t_{1}, \ldots, t_{d}\right) \in \mathbb{R}_{\geq 0}^{d}$ and for $x \in K$, we define the weighted approximation set

$$
W(x, \psi, \mathbf{t})=\left\{\mathbf{y}=\left(y_{1}, \ldots, y_{d}\right) \in K:\left|y_{j}-g_{\mathbf{i}}(x)_{j}\right|<\psi\left(b^{|\mathbf{i}|}\right)^{1+t_{i}}, 1 \leq j \leq d, \text { for i.m. } \mathbf{i} \in \Lambda^{*}\right\} .
$$

Here we are using the notation $g_{\mathbf{i}}(x)=\left(g_{\mathbf{i}}(x)_{1}, \ldots, g_{\mathbf{i}}(x)_{d}\right)$. Our main results relating to the Hausdorff dimension of sets of the form $W(x, \psi, \mathbf{t})$ are as follows.

Theorem 2. Let $\Phi$ and $K$ be defined as above. Recall that $\gamma=\operatorname{dim}_{H} K$ and $\gamma_{i}=\operatorname{dim}_{H} K_{i}$ for each $1 \leq i \leq d$. Let $\psi: \mathbb{N} \rightarrow[0, \infty)$ be such that $b^{n} \psi\left(b^{n}\right)$ is monotonically decreasing. Further suppose that $\operatorname{diam}(K)=1$ and

$$
\sum_{n=1}^{\infty}\left(b^{n} \psi\left(b^{n}\right)\right)^{\gamma}=\infty
$$

Then, for $\mathbf{t}=\left(t_{1}, \ldots, t_{d}\right) \in \mathbb{R}_{\geq 0}^{d}$, we have

$$
\operatorname{dim}_{\mathrm{H}} W(x, \psi, \mathbf{t}) \geq \min _{1 \leq k \leq d}\left\{\frac{1}{1+t_{k}}\left(\gamma+\sum_{j: t_{j} \leq t_{k}}\left(t_{k}-t_{j}\right) \gamma_{j}\right)\right\} .
$$

If $\psi$ satisfies more stringent divergence conditions, then we an show that the lower bound given in Theorem 2 in fact gives an exact formula for the Hausdorff dimension of $W(x, \psi, \mathbf{t})$. More precisely, we are able to show the following.

Theorem 3. Let $\Phi$ and $K$ be as defined above. Let $x \in K$ and let $\psi: \mathbb{N} \rightarrow[0, \infty)$ be such that:
(i) $b^{n} \psi\left(b^{n}\right)$ is monotonically decreasing,
(ii) $\sum_{n=1}^{\infty}\left(b^{n} \psi\left(b^{n}\right)\right)^{\gamma}=\infty, \quad$ and
(iii) $\sum_{n=1}^{\infty}\left(b^{n} \psi\left(b^{n}\right)^{1+\varepsilon}\right)^{\gamma}<\infty \quad$ for every $\varepsilon>0$.

Then, for $\mathbf{t}=\left(t_{1}, \ldots, t_{d}\right) \in \mathbb{R}_{\geq 0}^{d}$, we have

$$
\operatorname{dim}_{\mathrm{H}} W(x, \psi, \mathbf{t})=\min _{1 \leq k \leq d}\left\{\frac{1}{1+t_{k}}\left(\gamma+\sum_{j: t_{j} \leq t_{k}}\left(t_{k}-t_{j}\right) \gamma_{j}\right)\right\} .
$$

As an example of an approximating function which satisifies conditions $(i)-(i i i)$, one can think of $\psi(q)=\left(q\left(\log _{b} q\right)^{1 / \gamma}\right)^{-1}$. This function naturally appears when one considers analogues of Dirichlet's theorem in missing digit sets (see [18, 22]). As a corollary to Theorem 3 we deduce the following statement which can be interpreted as a higher-dimensional
weighted generalisation of [35, Theorem 4]. In [35, Theorem 4], Levesley, Salp, and Velani establish the Hausdorff measure of the set of points in a one-dimensional base-b missing digit set (i.e. of the form $K_{b}(J)$ in our present notation) which can be well-approximated by rationals with denominators which are powers of $b$. Before we state our corollary, we fix one more piece of notation. Given an approximating function $\psi: \mathbb{N} \rightarrow[0, \infty)$, an infinite subset $\mathcal{B} \subset \mathbb{N}$, and $\mathbf{t}=\left(t_{1}, \ldots, t_{d}\right) \in \mathbb{R}_{\geq 0}^{d}$, we define

$$
W_{\mathcal{B}}(\psi, \mathbf{t})=\left\{x \in K:\left|x_{i}-\frac{p_{i}}{q}\right|<\psi(q)^{1+t_{i}}, 1 \leq i \leq d, \text { for i.m. }\left(p_{1}, \ldots, p_{d}, q\right) \in \mathbb{Z}^{d} \times \mathcal{B}\right\} .
$$

Corollary 3. Fix $b \in \mathbb{N}$ with $b \geq 3$ and let $\mathcal{B}=\left\{b^{n}: n=0,1,2, \ldots\right\}$. Let $K$ be $a$ higher dimensional missing digit set as defined above (with base b) and write $\gamma=\operatorname{dim}_{\mathrm{H}} K$. Furthermore, suppose that $\{0, b-1\} \subset J_{i}$ for every $1 \leq i \leq d$. In particular, this also means that $\operatorname{diam} K=1$. Let $\psi: \mathbb{N} \rightarrow[0, \infty)$ be an approximating function such that
(i) $b^{n} \psi\left(b^{n}\right)$ is monotonically decreasing with $b^{n} \psi\left(b^{n}\right) \rightarrow 0$ as $n \rightarrow \infty$,
(ii) $\sum_{n=1}^{\infty}\left(b^{n} \psi\left(b^{n}\right)\right)^{\gamma}=\infty$, and
(iii) $\sum_{n=1}^{\infty}\left(b^{n} \psi\left(b^{n}\right)^{1+\varepsilon}\right)^{\gamma}<\infty \quad$ for every $\varepsilon>0$.

Then

$$
\operatorname{dim}_{\mathrm{H}} W_{\mathcal{B}}(\psi, \mathbf{t})=\min _{1 \leq k \leq d}\left\{\frac{1}{1+t_{k}}\left(\gamma+\sum_{j: t_{j} \leq t_{k}}\left(t_{k}-t_{j}\right) \gamma_{j}\right)\right\}
$$

Proof. Observe that the conditions imposed in the statement of Corollary 3 guarantee that Theorem 3 is applicable. Furthermore, by our assumption that $b^{n} \psi\left(b^{n}\right) \rightarrow 0$ as $n \rightarrow \infty$, we may assume without loss of generality that $\psi\left(b^{n}\right)<b^{-n}$ for all $n \in \mathbb{N}$.

Next, we note that if $\mathbf{p}=\left(p_{1}, \ldots, p_{d}\right) \in \mathbb{Z}^{d}$ and $\frac{\mathbf{p}}{b^{n}}=\left(\frac{p_{1}}{b^{n}}, \ldots, \frac{p_{d}}{b^{n}}\right) \notin K$, then we must have

$$
\operatorname{dist}\left(\frac{\mathbf{p}}{b^{n}}, K\right) \geq b^{-n}, \quad \text { where } \quad \operatorname{dist}(x, K)=\inf \{\|x-y\|: y \in K\}
$$

(Recall that we use $\|\cdot\|$ to denote the supremum norm in $\mathbb{R}^{d}$.) Thus we need only concern ourselves with pairs $(\mathbf{p}, q) \in \mathbb{Z}^{d} \times \mathcal{B}$ for which $\frac{\mathbf{p}}{q} \in K$.

Let $G=\left\{x=\left(x_{1}, \ldots, x_{d}\right) \in\{0,1\}^{d}\right\}$ and note that $G \subset K$ by the assumption that $\{0, b-1\} \subset J_{i}$ for each $1 \leq i \leq d$. For any $x \in G$ and any $\mathbf{j} \in \Lambda^{n}$ it is possible to write $g_{\mathbf{j}}(x)=\frac{\mathbf{p}}{b^{n}}$ for some $\mathbf{p} \in(\mathbb{N} \cup\{0\})^{d}$. Hence

$$
W(x, \psi, \mathbf{t}) \subset W_{\mathcal{B}}(\psi, \mathbf{t})
$$

Furthermore, the set of all rational points of the form $\frac{\mathbf{p}}{b^{n}}$ contained in $K$ is

$$
\bigcup_{x \in G} \bigcup_{\mathbf{j} \in \Lambda^{n}} g_{\mathbf{j}}(x)
$$

Hence

$$
W_{\mathcal{B}}(\psi, \mathbf{t}) \subset \bigcup_{x \in G} W(x, \psi, \mathbf{t}) .
$$

By the finite stability of Hausdorff dimension (see [20]), Corollary 3 now follows from Theorem 3.

Notice that in Theorem 2, Theorem 3, and Corollary 3, we insist on the same underlying base $b$ in each coordinate direction. This is somewhat unsatisfactory and one might hope to be able to obtain results where we can have different bases $b_{i}$ in each coordinate direction. The first steps towards proving results relating to weighted approximation in this setting can be seen in [44, Section 12]. Proving more general results with different bases in different coordinate directions is likely to be a very challenging problem since such sets are selfaffine and, generally speaking, self-affine sets are more difficult to deal with than self-similar or self-conformal sets. Indeed, very little is currently known even regarding non-weighted approximation in self-affine sets.

Structure of the paper: The remainder of the paper will be arranged as follows. In Section 3 we will present some measure theoretic preliminaries which will be required for the proofs of our main results. The key tool required for proving Theorem 2 is a mass transference principle for rectangles proved recently by Wang and Wu [44]. We introduce this in Section 4. In Section 5 we present our proof of Theorem 2 and we conclude in Section 6 with the proof of Theorem 3.

## 3 Some Measure Theoretic Preliminaries

Recall that $\gamma=\operatorname{dim}_{\mathrm{H}} K$ and that $\gamma_{i}=\operatorname{dim}_{\mathrm{H}} K_{i}$ for $1 \leq i \leq d$, where $K$ and $K_{i}$ are as defined above. Furthermore, note that $0<\mathcal{H}^{\gamma}(K)<\infty$ and $0<\mathcal{H}^{\gamma_{i}}\left(K_{i}\right)<\infty$ for each $1 \leq i \leq d$, see for example [20, Theorem 9.3]. Let us define the measures

$$
\mu:=\frac{\left.\mathcal{H}^{\gamma}\right|_{K}}{\mathcal{H}^{\gamma}(K)} \quad \text { and } \quad \mu_{i}:=\frac{\left.\mathcal{H}^{\gamma_{i}}\right|_{K_{i}}}{\mathcal{H}^{\gamma_{i}}\left(K_{i}\right)} \quad \text { for each } 1 \leq i \leq d
$$

So, for $X \subset \mathbb{R}^{d}$, we have

$$
\mu(X)=\frac{\mathcal{H}^{\gamma}(X \cap K)}{\mathcal{H}^{\gamma}(K)}
$$

Similarly, for $X \subset \mathbb{R}$, for each $1 \leq i \leq d$ we have

$$
\mu_{i}(X)=\frac{\mathcal{H}^{\gamma_{i}}\left(X \cap K_{i}\right)}{\mathcal{H}^{\gamma_{i}}\left(K_{i}\right)}
$$

Note that $\mu$ defines a probability measure supported on $K$ and, for each $1 \leq i \leq d, \mu_{i}$ defines a probability measure supported on $K_{i}$. Note also that the measure $\mu$ is $\delta$-Ahlfors regular with $\delta=\gamma$ and, for each $1 \leq i \leq d$, the measure $\mu_{i}$ is $\delta$-Ahlfors regular with $\delta=\gamma_{i}$ (see, for example, [37, Theorem 4.14]).

We will also be interested in the product measure

$$
\mathrm{M}:=\prod_{i=1}^{d} \mu_{i} .
$$

We note that M is $\delta$-Ahlfors regular with $\delta=\gamma$. This fact follows straightforwardly from the Ahlfors regularity of each of the $\mu_{i}$ 's.
Lemma 1. The product measure $\mathrm{M}=\prod_{i=1}^{d} \mu_{i}$ on $\mathbb{R}^{d}$ is $\delta$-Ahlfors regular with $\delta=\gamma$.
Proof. Let $B=\prod_{i=1}^{d} B\left(x_{i}, r\right), r>0$, be an arbitrary ball in $\mathbb{R}^{d}$. The aim is to show that $\mathrm{M}(B) \asymp r^{\gamma}$. Recall that for each $1 \leq i \leq d$, the measure $\mu_{i}$ is $\delta$-Ahlfors regular with $\delta=\gamma_{i}=\operatorname{dim}_{\mathrm{H}} K_{i}=\frac{\log N_{i}}{\log b}$. Also recall that $N=\prod_{i=1}^{d} N_{i}$ and $\gamma=\operatorname{dim}_{\mathrm{H}} K=\frac{\log N}{\log b}$. Thus, we have

$$
\mathrm{M}(B)=\prod_{i=1}^{d} \mu_{i}\left(B\left(x_{i}, r\right)\right) \asymp \prod_{i=1}^{d} r^{\gamma_{i}}=r^{\sum_{i=1}^{d} \gamma_{i}} .
$$

Note that

$$
\sum_{i=1}^{d} \gamma_{i}=\sum_{i=1}^{d} \frac{\log N_{i}}{\log b}=\frac{\log \left(\prod_{i=1}^{d} N_{i}\right)}{\log b}=\frac{\log N}{\log b}=\gamma
$$

Hence, $\mathrm{M}(B) \asymp r^{\gamma}$ as claimed.
We also note that, up to a constant factor, the product measure M is equivalent to the measure $\mu=\frac{\left.\mathcal{H}^{\gamma}\right|_{K}}{\mathcal{H}^{\gamma}(K)}$.
Lemma 2. Let $\mathrm{M}=\prod_{i=1}^{d} \mu_{i}$. Then, up to a constant factor, M is equivalent to $\mu$; i.e. for any Borel set $F \subset \mathbb{R}^{d}$, we have $\mathrm{M}(F) \asymp \mu(F)$.

Lemma 2 follows immediately upon combining Lemma 1 with [21, Proposition 2.2 (a) + (b)].

In our present setting, where $K$ is a self-similar set with well-separated components, we can actually show the stronger statement that $\mu=\mathrm{M}$.

Proposition 1. The measures $\mu$ and M are equal, i.e. for every Borel set $F \subset \mathbb{R}^{d}$, we have $\mu(F)=\mathrm{M}(F)$.

Proof. For each $1 \leq i \leq d$, there exists a unique Borel probability measure (see, for example, [21, Theorem 2.8]) $m_{i}$ satisfying

$$
\begin{equation*}
m_{i}=\sum_{j=1}^{N_{i}} \frac{1}{N_{i}} m_{i} \circ f_{j}^{-1} . \tag{2}
\end{equation*}
$$

Likewise, there exists a unique Borel probability measure $m$ satisfying

$$
\begin{equation*}
m=\sum_{j=1}^{N} \frac{1}{N} m \circ g_{j}^{-1} \tag{3}
\end{equation*}
$$

We begin by showing that $\mu_{i}$ satisfies (2) for each $1 \leq i \leq d$. Note that $\mathcal{H}^{\gamma_{i}}\left(f_{j_{1}}\left(K_{i}\right) \cap\right.$ $\left.f_{j_{2}}\left(K_{i}\right)\right)=0$ for any $1 \leq j_{1}, j_{2} \leq N_{i}$ with $j_{1} \neq j_{2}$. Thus, for any Borel set $X \subset \mathbb{R}^{d}$, we have

$$
\begin{aligned}
\mu_{i}(X) & =\frac{1}{\mathcal{H}^{\gamma_{i}}\left(K_{i}\right)} \mathcal{H}^{\gamma_{i}}\left(X \cap K_{i}\right) \\
& =\frac{1}{\mathcal{H}^{\gamma_{i}}\left(K_{i}\right)} \sum_{j=1}^{N_{i}} \mathcal{H}^{\gamma_{i}}\left(X \cap f_{j}\left(K_{i}\right)\right) \\
& =\frac{1}{\mathcal{H}^{\gamma_{i}}\left(K_{i}\right)} \sum_{j=1}^{N_{i}} \mathcal{H}^{\gamma_{i}}\left(f_{j}\left(f_{j}^{-1}(X) \cap K_{i}\right)\right) \\
& =\frac{1}{\mathcal{H}^{\gamma_{i}}\left(K_{i}\right)} \sum_{j=1}^{N_{i}}\left(\frac{1}{b}\right)^{\gamma_{i}} \mathcal{H}^{\gamma_{i}}\left(f_{j}^{-1}(X) \cap K_{i}\right) \\
& =\frac{1}{\mathcal{H}^{\gamma_{i}}\left(K_{i}\right)} \sum_{j=1}^{N_{i}} \frac{1}{N_{i}} \mathcal{H}^{\gamma_{i}}\left(f_{j}^{-1}(X) \cap K_{i}\right) \\
& =\sum_{j=1}^{N_{i}} \frac{1}{N_{i}} \mu_{i} \circ f_{j}^{-1}(X) .
\end{aligned}
$$

By an almost identical argument, it can be shown that $\mu$ satisfies (3).
Finally, we show that M also satisfies (3) and, hence, by the uniqueness of solutions to (3), we conclude that M must be equal to $\mu$. Since $\mu_{i}$ satisfies (2) for each $1 \leq i \leq d$, we have

$$
\begin{aligned}
\mathrm{M} & =\prod_{i=1}^{d} \mu_{i} \\
& =\prod_{i=1}^{d}\left(\sum_{j=1}^{N_{i}} \frac{1}{N_{i}} \mu_{i} \circ f_{j}^{-1}\right) \\
& =\sum_{\mathbf{j}=\left(j_{1}, \ldots, j_{d}\right) \in \prod_{i=1}^{d}\left\{1, \ldots, N_{i}\right\}} \frac{1}{N} \prod_{i=1}^{d} \mu_{i} \circ f_{j_{i}}^{-1} \\
& =\sum_{j=1}^{N} \frac{1}{N} M \circ g_{j}^{-1} .
\end{aligned}
$$

## 4 Mass transference principle for rectangles

To prove Theorem 2, we will use the mass transference principle for rectangles established recently by Wang and Wu in [44]. The work of Wang and Wu generalises the famous Mass Transference Principle originally proved by Beresnevich and Velani [16]. Since its initial discovery in [16], the Mass Transference Principle has found many applications, especially in Diophantine Approximation, and has by now been extended in numerous directions. See
$[2,5,16,17,33,44,45,49]$ and references therein for further information. Here we shall state the general "full measure" mass transference principle from rectangles to rectangles established by Wang and Wu in [44, Theorem 3.4].

Fix an integer $d \geq 1$. For each $1 \leq i \leq d$, let $\left(X,|\cdot|_{i}, m_{i}\right)$ be a bounded locally compact metric space equipped with a $\delta_{i}$-Ahlfors regular probability measure $m_{i}$. We consider the product space $(X,|\cdot|, m)$ where

$$
X=\prod_{i=1}^{d} X_{i}, \quad|\cdot|=\max _{1 \leq i \leq d}|\cdot|_{i}, \quad \text { and } \quad m=\prod_{i=1}^{d} m_{i}
$$

Note that a ball $B(x, r)$ in $X$ is the product of balls in $\left\{X_{i}\right\}_{1 \leq i \leq d}$;

$$
B(x, r)=\prod_{i=1}^{d} B\left(x_{i}, r\right) \quad \text { for } \quad x=\left(x_{1}, \ldots, x_{d}\right)
$$

Let $J$ be an infinite countable index set and let $\beta: J \rightarrow \mathbb{R}_{\geq 0}: \alpha \mapsto \beta_{\alpha}$ be a positive function such that for any $M>1$, the set

$$
\left\{\alpha \in J: \beta_{\alpha}<M\right\}
$$

is finite. Let $\rho: \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}_{\geq 0}$ be a non-increasing function such that $\rho(u) \rightarrow 0$ as $u \rightarrow \infty$.
For each $1 \leq i \leq d$, let $\left\{R_{\alpha, i}: \alpha \in J\right\}$ be a sequence of subsets of $X_{i}$. Then, the resonant sets in $X$ that we will be concerned with are

$$
\left\{R_{\alpha}=\prod_{i=1}^{d} R_{\alpha, i}: \alpha \in J\right\}
$$

For a vector $\mathbf{a}=\left(a_{1}, \ldots, a_{d}\right) \in \mathbb{R}_{>0}^{d}$, write

$$
\Delta\left(R_{\alpha}, \rho\left(\beta_{\alpha}\right)^{\mathbf{a}}\right)=\prod_{i=1}^{d} \Delta\left(R_{\alpha, i}, \rho\left(\beta_{\alpha}\right)^{a_{i}}\right)
$$

where $\Delta\left(R_{\alpha, i}, \rho\left(\beta_{\alpha}\right)^{a_{i}}\right)$ appearing on the right-hand side denotes the $\rho\left(\beta_{\alpha}\right)^{a_{i}}$-neighbourhood of $R_{\alpha, i}$ in $X_{i}$. We call $\Delta\left(R_{\alpha, i}, \rho\left(\beta_{\alpha}\right)^{a_{i}}\right)$ the part of $\Delta\left(R_{\alpha}, \rho\left(\beta_{\alpha}\right)^{\mathbf{a}}\right)$ in the ith direction.

Fix $\mathbf{a}=\left(a_{1}, \ldots, a_{d}\right) \in \mathbb{R}_{>0}^{d}$ and suppose $\mathbf{t}=\left(t_{1}, \ldots, t_{d}\right) \in \mathbb{R}_{\geq 0}^{d}$. We are interested in the set

$$
W_{\mathbf{a}}(\mathbf{t})=\left\{x \in X: x \in \Delta\left(R_{\alpha}, \rho\left(\beta_{\alpha}\right)^{\mathbf{a}+\mathbf{t}}\right) \quad \text { for i.m. } \alpha \in J\right\} .
$$

We can think of $\Delta\left(R_{\alpha}, \rho\left(\beta_{\alpha}\right)^{\mathbf{a}+\mathbf{t}}\right)$ as a smaller "rectangle" obtained by shrinking the "rectangle" $\Delta\left(R_{\alpha}, \rho\left(\beta_{\alpha}\right)^{\mathbf{a}}\right)$.

Finally, we require that the resonant sets satisfy a certain $\kappa$-scaling property, which in essence ensures that locally our sets behave like affine subspaces.

Definition 1. Let $0 \leq \kappa<1$. For each $1 \leq i \leq d$, we say that $\left\{R_{\alpha, i}\right\}_{\alpha \in J}$ has the $\kappa$-scaling property if for any $\alpha \in J$ and any ball $B(x, r)$ in $X_{i}$ with centre $x_{i} \in R_{\alpha, i}$ and radius $r>0$, for any $0<\varepsilon<r$, we have

$$
c_{1} r^{\delta_{i} \kappa} \varepsilon^{\delta_{i}(1-\kappa)} \leq m_{i}\left(B\left(x_{i}, r\right) \cap \Delta\left(R_{\alpha, i}, \varepsilon\right)\right) \leq c_{2} r^{\delta_{i} \kappa} \varepsilon^{\delta_{i}(1-\kappa)}
$$

for some absolute constants $c_{1}, c_{2}>0$.
In our case $\kappa=0$ since our resonant sets are points. For justification of this, and calculations of $\kappa$ for other resonant sets, see [2]. Wang and Wu established the following mass transference principle for rectangles in [44].

Theorem 4 (Wang - Wu, [44]). Assume that for each $1 \leq i \leq d$, the measure $m_{i}$ is $\delta_{i}$-Ahlfors regular and that the resonant set $R_{\alpha, i}$ has the $\kappa$-scaling property for $\alpha \in J$. Suppose

$$
m\left(\limsup _{\substack{\alpha \in J \\ \beta_{\alpha} \rightarrow \infty}} \Delta\left(R_{\alpha}, \rho\left(\beta_{\alpha}\right)^{\mathbf{a}}\right)\right)=m(X)
$$

Then we have
$\operatorname{dim}_{\mathrm{H}} W_{\mathbf{a}}(\mathbf{t}) \geq s(\mathbf{t}):=\min _{A \in \mathcal{A}}\left\{\sum_{k \in \mathcal{K}_{1}} \delta_{k}+\sum_{k \in \mathcal{K}_{2}} \delta_{k}+\kappa \sum_{k \in \mathcal{K}_{3}} \delta_{k}+(1-\kappa) \frac{\sum_{k \in \mathcal{K}_{3}} a_{k} \delta_{k}-\sum_{k \in \mathcal{K}_{2}} t_{k} \delta_{k}}{A}\right\}$,
where

$$
\mathcal{A}=\left\{a_{i}, a_{i}+t_{i}: 1 \leq i \leq d\right\}
$$

and for each $A \in \mathcal{A}$, the sets $\mathcal{K}_{1}, \mathcal{K}_{2}, \mathcal{K}_{3}$ are defined as

$$
\mathcal{K}_{1}=\left\{k: a_{k} \geq A\right\}, \quad \mathcal{K}_{2}=\left\{k: a_{k}+t_{k} \leq A\right\} \backslash \mathcal{K}_{1}, \quad \mathcal{K}_{3}=\{1, \ldots, d\} \backslash\left(\mathcal{K}_{1} \cup \mathcal{K}_{2}\right)
$$

and thus give a partition of $\{1, \ldots, d\}$.

## 5 Proof of Theorem 2

To prove Theorem 2, we will apply Theorem 4 with $X_{i}=K_{i}, m_{i}=\mu_{i}$ and $|\cdot|_{i}=|\cdot|$ (absolute value in $\mathbb{R}$ ) for each $1 \leq i \leq d$. Then, in our setting, we will be interested in the product space $(X,\|\cdot\|, \mathrm{M})$ where

$$
X=\prod_{i=1}^{d} K_{i}=K, \quad \mathrm{M}=\prod_{i=1}^{d} \mu_{i},
$$

and $\|\cdot\|$ denotes the supremum norm in $\mathbb{R}^{d}$. Recall that for each $1 \leq i \leq d$, the measure $\mu_{i}$ is $\delta_{i}$-Ahlfors regular with

$$
\delta_{i}=\gamma_{i}=\operatorname{dim}_{\mathrm{H}} K_{i}
$$

and the measure M is $\delta$-Ahlfors regular with

$$
\delta=\gamma=\operatorname{dim}_{\mathrm{H}} K
$$

For us, the appropriate indexing set is

$$
\mathcal{J}=\left\{\mathbf{i} \in \Lambda^{*}\right\} .
$$

We define our weight function $\beta: \Lambda^{*} \rightarrow \mathbb{R}_{\geq 0}$ by

$$
\beta_{|\mathbf{i}|}=\beta(\mathbf{i})=|\mathbf{i}| .
$$

Note that $\beta$ satisfies the requirement that for any real number $M>1$ the set $\left\{\mathbf{i} \in \Lambda^{*}: \beta_{\mathbf{i}}<\right.$ $M\}$ is finite. Next we define $\rho: \mathbb{R}_{\geq 0} \rightarrow \mathbb{R}_{\geq 0}$ by

$$
\rho(u)=\psi\left(b^{u}\right) .
$$

Since $b^{n} \psi\left(b^{n}\right)$ is monotonically decreasing by assumption, it follows that $\psi\left(b^{n}\right)$ is monotonically decreasing and $\psi\left(b^{n}\right) \rightarrow 0$ as $n \rightarrow \infty$.

For a fixed $x=\left(x_{1}, \ldots, x_{d}\right) \in K$, we define the resonant sets of interest as follows. For each $\mathbf{i} \in \Lambda^{*}$, take

$$
R_{\mathbf{i}}^{x}=g_{\mathbf{i}}(x)
$$

Correspondingly, for each $1 \leq j \leq d$,

$$
R_{\mathbf{i}, j}^{x}=g_{\mathbf{i}}(x)_{j}
$$

where $g_{\mathbf{i}}(x)=\left(g_{\mathbf{i}}(x)_{1}, \ldots, g_{\mathbf{i}}(x)_{d}\right)$. So, $R_{\mathbf{i}, j}^{x}$ is the coordinate of $g_{\mathbf{i}}(x)$ in the $j$ th direction. In each coordinate direction, the $\kappa$-scaling property is satisfied with $\kappa=0$, since our resonant sets are points.

Let us fix $\mathbf{a}=(1,1, \ldots, 1) \in \mathbb{R}_{>0}^{d}$. Then, in this case, we note that

$$
\underset{\substack{\alpha \in \mathcal{J} \\ \beta_{\alpha} \rightarrow \infty}}{\lim \sup } \Delta\left(R_{\alpha}^{x}, \rho\left(\beta_{\alpha}\right)^{\mathbf{a}}\right)=\underset{\substack{\mathbf{i} \in \Lambda^{*} \\|\mathbf{i}| \rightarrow \infty}}{\lim \sup } \Delta\left(g_{\mathbf{i}}(x), \psi\left(b^{\mathbf{i} \mid}\right)^{\mathbf{a}}\right)=W(x, \psi),
$$

where $W(x, \psi)$ is as defined in (1). Moreover, it follows from Corollary 2 and Proposition 1 that $\mathrm{M}(W(x, \psi))=\mathrm{M}(K)$, since we assumed that $\sum_{n=1}^{\infty}\left(b^{n} \psi\left(b^{n}\right)\right)^{\gamma}=\infty$.

Now suppose that $\mathbf{t}=\left(t_{1}, \ldots, t_{d}\right) \in \mathbb{R}_{\geq 0}^{d}$. Then, in our case,

$$
W_{\mathbf{a}}(\mathbf{t})=W(x, \psi, \mathbf{t})
$$

which is the set we are interested in. So, recalling that $\kappa=0$ in our setting, we may now apply Theorem 4 directly to conclude that

$$
\operatorname{dim}_{\mathrm{H}} W(x, \psi, \mathbf{t}) \geq \min _{A \in \mathcal{A}}\left\{\sum_{k \in \mathcal{K}_{1}} \delta_{k}+\sum_{k \in \mathcal{K}_{2}} \delta_{k}+\frac{\sum_{k \in \mathcal{K}_{3}} \delta_{k}-\sum_{k \in \mathcal{K}_{2}} t_{k} \delta_{k}}{A}\right\}=: s(\mathbf{t})
$$

where

$$
\mathcal{A}=\{1\} \cup\left\{1+t_{i}: 1 \leq i \leq d\right\}
$$

and for each $A \in \mathcal{A}$ the sets $\mathcal{K}_{1}, \mathcal{K}_{2}, \mathcal{K}_{3}$ are defined as follows:

$$
\mathcal{K}_{1}=\{k: 1 \geq A\}, \quad \mathcal{K}_{2}=\left\{k: 1+t_{k} \leq A\right\} \backslash \mathcal{K}_{1}, \quad \text { and } \quad \mathcal{K}_{3}=\{1, \ldots, d\} \backslash\left(\mathcal{K}_{1} \cup \mathcal{K}_{2}\right) .
$$

Note that $\mathcal{K}_{1}, \mathcal{K}_{2}, \mathcal{K}_{3}$ give a partition of $\{1, \ldots, d\}$.
To obtain a neater expression for $s(\mathbf{t})$, as given in the statement of Theorem 2, we consider the possible cases which may arise. To this end, let us suppose, without loss of generality, that

$$
0<t_{i_{1}} \leq t_{i_{2}} \leq \cdots \leq t_{i_{d}} .
$$

Case 1: $A=1$
If $A=1$, then $\mathcal{K}_{1}=\{1, \ldots, d\}, \mathcal{K}_{2}=\emptyset$, and $\mathcal{K}_{3}=\emptyset$. In this case, the "dimension number" simplifies to

$$
\sum_{j=1}^{d} \delta_{j}=\sum_{j=1}^{d} \operatorname{dim}_{\mathrm{H}} K_{j}=\sum_{j=1}^{d} \frac{\log N_{j}}{\log b}=\frac{\log \left(\prod_{j=1}^{d} N_{j}\right)}{\log b}=\frac{\log N}{\log b}=\operatorname{dim}_{\mathrm{H}} K
$$

Case 2: $A=1+t_{i_{k}}$ with $t_{i_{k}}>0$
Suppose $A=1+t_{i_{k}}$ for some $1 \leq k \leq d$ and that $t_{i_{k}}>0$ (otherwise we are in Case 1). Suppose $k \leq k^{\prime} \leq d$ is the maximal index such that $t_{i_{k}}=t_{i_{k^{\prime}}}$. In this case,

$$
\mathcal{K}_{1}=\emptyset, \quad \mathcal{K}_{2}=\left\{i_{1}, \ldots, i_{k^{\prime}}\right\}, \quad \text { and } \quad \mathcal{K}_{3}=\left\{i_{k^{\prime}+1}, \ldots, i_{d}\right\}
$$

and the "dimension number" is

$$
\begin{aligned}
\sum_{j=1}^{k^{\prime}} \delta_{i_{j}}+\frac{\sum_{j=k^{\prime}+1}^{d} \delta_{i_{j}}-\sum_{j=1}^{k^{\prime}} t_{i_{j}} \delta_{i_{j}}}{1+t_{i_{k}}} & =\frac{1}{1+t_{i_{k}}}\left(\left(1+t_{i_{k}}\right) \sum_{j=1}^{k^{\prime}} \delta_{i_{j}}+\sum_{j=k^{\prime}+1}^{d} \delta_{i_{j}}-\sum_{j=1}^{k^{\prime}} t_{i_{j}} \delta_{i_{j}}\right) \\
& =\frac{1}{1+t_{i_{k}}}\left(\sum_{j=1}^{d} \delta_{i_{j}}+\sum_{j=1}^{k^{\prime}} \delta_{i_{j}}\left(t_{i_{k}}-t_{i_{j}}\right)\right) \\
& =\frac{1}{1+t_{i_{k}}}\left(\operatorname{dim}_{\mathrm{H}} K+\sum_{j=1}^{k^{\prime}}\left(t_{i_{k}}-t_{i_{j}}\right) \operatorname{dim}_{\mathrm{H}} K_{j}\right) .
\end{aligned}
$$

Putting the two cases together, we conclude that

$$
\operatorname{dim}_{\mathrm{H}} W(x, \psi, \mathbf{t}) \geq \min _{1 \leq k \leq d}\left\{\frac{1}{1+t_{k}}\left(\gamma+\sum_{j: t_{j} \leq t_{k}}\left(t_{k}-t_{j}\right) \gamma_{j}\right)\right\}
$$

as claimed. This completes the proof of Theorem 2.

## 6 Proof of Theorem 3

Let

$$
\mathcal{A}_{n}(x, \psi, \mathbf{t}):=\bigcup_{\mathbf{i} \in \Lambda^{n}} \Delta\left(R_{\mathbf{i}}^{x}, \psi\left(b^{n}\right)^{1+\mathbf{t}}\right)=\bigcup_{\mathbf{i} \in \Lambda^{n}} \prod_{j=1}^{d} B\left(R_{\mathbf{i}, j}^{x}, \psi\left(b^{n}\right)^{1+t_{j}}\right)
$$

Then

$$
W(x, \psi, \mathbf{t})=\limsup _{n \rightarrow \infty} \mathcal{A}_{n}(x, \psi, \mathbf{t}) .
$$

For any $m \in \mathbb{N}$ we have that

$$
\begin{equation*}
W(x, \psi, \mathbf{t}) \subset \bigcup_{n \geq m} \mathcal{A}_{n}(x, \psi, \mathbf{t}) \tag{4}
\end{equation*}
$$

Observe that $\mathcal{A}_{n}(x, \psi, \mathbf{t})$ is a collection of $N^{n}=\left(b^{n}\right)^{\gamma}$ rectangles with sidelengths $2 \psi\left(b^{n}\right)^{1+t_{j}}$ in each $j$ th coordinate axis.

Fix some $1 \leq k \leq d$. Throughout suppose that $n$ is sufficiently large such that $\psi\left(b^{n}\right)<1$. Condition (i) of Theorem 3 implies that $\psi\left(b^{n}\right)^{1+t_{k}} \leq \psi\left(b^{n}\right) \rightarrow 0$ as $n \rightarrow \infty$, and so for any $\rho>0$ there exists a sufficiently large positive integer $n_{0}(\rho)$ such that

$$
\psi\left(b^{n}\right)^{1+t_{k}} \leq \rho \quad \text { for all } n \geq n_{0}(\rho)
$$

Suppose $n \geq n_{0}(\rho)$ and that for each $1 \leq j \leq d$ we can construct an efficient finite $\psi\left(b^{n}\right)^{1+t_{k_{-}}}$ cover $\mathcal{B}_{j}(\mathbf{i}, k, \rho)$ for $B\left(R_{\mathbf{i}, j}^{x}, \psi\left(b^{n}\right)^{1+t_{j}}\right)$ with cardinality $\# \mathcal{B}_{j}(\mathbf{i}, k, \rho)$ for each $\mathbf{i} \in \Lambda^{n}$. Then we can construct a $\psi\left(b^{n}\right)^{1+t_{k}}$-cover of $\Delta\left(R_{\mathbf{i}}^{x}, \psi\left(b^{n}\right)^{1+\mathbf{t}}\right)$ for each $\mathbf{i} \in \Lambda^{n}$ with cardinality $\prod_{j=1}^{d} \# \mathcal{B}_{j}(\mathbf{i}, k, \rho)$ by considering the Cartesian product of the individual covers $\mathcal{B}_{j}(\mathbf{i}, k, \rho)$ for each $1 \leq j \leq d$. By (4)

$$
\begin{equation*}
\bigcup_{n \geq n_{0}(\rho)} \mathcal{A}_{n}(x, \psi, \mathbf{t}) \tag{5}
\end{equation*}
$$

is a cover of $W(x, \psi, \mathbf{t})$. So, supposing that we can find such covers $\mathcal{B}_{j}(\mathbf{i}, k, \rho)$, we have that

$$
\bigcup_{n \geq n_{0}(\rho)} \bigcup_{\mathbf{i} \in \Lambda^{n}} \prod_{j=1}^{d} \mathcal{B}_{j}(\mathbf{i}, k, \rho)
$$

is a $\psi\left(b^{n}\right)^{1+t_{k}}$-cover of $W(x, \psi, \mathbf{t})$.
To calculate the values $\# \mathcal{B}_{j}(\mathbf{i}, k, \rho)$ we consider two possible cases depending on the fixed $1 \leq k \leq d$. Without loss of generality suppose that $0<t_{1} \leq t_{2} \leq \cdots \leq t_{d}$. Then, since we are assuming that $\psi\left(b^{n}\right)<1$, we have that $\psi\left(b^{n}\right)^{1+t_{1}} \geq \cdots \geq \psi\left(b^{n}\right)^{1+t_{d}}$.

Case 1: $t_{j} \geq t_{k}$
In this case, $\psi\left(b^{n}\right)^{1+t_{k}} \geq \psi\left(b^{n}\right)^{1+t_{j}}$ and so, for any $\mathbf{i} \in \Lambda^{n}$, we have

$$
B\left(R_{\mathbf{i}, j}^{x}, \psi\left(b^{n}\right)^{1+t_{k}}\right) \supset B\left(R_{\mathbf{i}, j}^{x}, \psi\left(b^{\mathbf{i} \mid}\right)^{1+t_{j}}\right)
$$

Hence, we may take our covers to be $\mathcal{B}(\mathbf{i}, k, \rho)=B\left(R_{\mathbf{i}, j}^{x}, \psi\left(b^{n}\right)^{1+t_{k}}\right)$, and so $\# \mathcal{B}_{j}(\mathbf{i}, k, \rho)=1$.
Case 2: $t_{j}<t_{k}$
In this case, $\psi\left(b^{n}\right)^{1+t_{k}}<2 \psi\left(b^{n}\right)^{1+t_{j}}$. Let $u \in \mathbb{N}$ be the unique integer such that

$$
\begin{equation*}
b^{-u} \leq 2 \psi\left(b^{n}\right)^{1+t_{j}}<b^{-u+1} \tag{6}
\end{equation*}
$$

and observe that, for any $\mathbf{i} \in \Lambda^{n}$, we have

$$
B\left(R_{\mathbf{i}, j}^{x}, \psi\left(b^{\mathbf{i} \mid}\right)^{1+t_{j}}\right) \subset \bigcup_{\substack{\mathbf{a}=\left(a_{1}, \ldots, a_{u-1}\right) \in \Lambda_{j}^{u-1} \\ f_{a_{i}} \in \Phi^{j}, 1 \leq i \leq u-1}} f_{\mathbf{a}}([0,1])
$$

where $\Lambda_{j}=\left\{1, \ldots, N_{j}\right\}$. Let $A$ denote the set of $\mathbf{a} \in \Lambda_{j}^{u-1}$ such that

$$
f_{\mathbf{a}}([0,1]) \cap B\left(R_{\mathbf{i}, j}^{x}, \psi\left(b^{n}\right)^{1+t_{j}}\right) \neq \emptyset
$$

Note by the definition of $u$, and the fact that the mappings $f_{\mathbf{a}}$ of the same length are pairwise disjoint up to possibly a single point of intersection, that $\# A \leq 2$ since

$$
\operatorname{diam}\left(f_{\mathbf{a}}([0,1])\right)=b^{-(u-1)}>\operatorname{diam}\left(B\left(R_{\mathbf{i}, j}^{x}, \psi\left(b^{n}\right)^{1+t_{j}}\right)\right)
$$

Observe that $f_{\mathbf{b}}([0,1]) \subset f_{\mathbf{a}}([0,1])$ if and only if $\mathbf{b}=\mathbf{a c}$ for $\mathbf{c} \in \Lambda_{j}^{*}:=\bigcup_{n=0}^{\infty} \Lambda_{j}^{n}$, where we write ac to denote the concatenation of the two words a and $\mathbf{c}$. Let $v \geq 0$ be the unique integer such that

$$
\begin{equation*}
b^{-u-v} \leq \psi\left(b^{n}\right)^{1+t_{k}}<b^{-u-v+1} \tag{7}
\end{equation*}
$$

Note that $v$ is well defined since $\psi\left(b^{n}\right)^{1+t_{k}}<2 \psi\left(b^{n}\right)^{1+t_{j}}<b^{-u+1}$, and so $v \geq 0$. Then

$$
\bigcup_{\substack{\mathbf{a} \in A, \mathbf{c} \in \Lambda_{j}^{v}}} f_{\mathbf{a c}}([0,1]) \supset B\left(R_{\mathbf{i}, j}^{x}, \psi\left(b^{|\mathbf{i}|}\right)^{1+t_{j}}\right) .
$$

Notice that the left-hand side above gives rise to a $\psi\left(b^{n}\right)^{1+t_{k}}$-cover for the right-hand side and let us denote this cover by $\mathcal{B}_{j}(\mathbf{i}, k, \rho)$. By the above arguments an easy upper bound on $\# \mathcal{B}_{j}(\mathbf{i}, k, \rho)$ is seen to be $2 N_{j}^{v}$. Furthermore, by (6) and (7) we have that

$$
\# \mathcal{B}_{j}(\mathbf{i}, k, \rho) \leq 2 N_{j}^{v}=2\left(b^{v}\right)^{\gamma_{j}} \stackrel{(7)}{\leq} 2\left(b^{1-u} \psi\left(b^{n}\right)^{-1-t_{k}}\right)^{\gamma_{j}} \stackrel{(6)}{\leq} 2^{1+\gamma_{j}} b^{\gamma_{j}} \psi\left(b^{n}\right)^{\left(t_{j}-t_{k}\right) \gamma_{j}}
$$

Summing over $1 \leq j \leq d$ and $\mathbf{i} \in \Lambda^{n}$ for each $n \geq n_{0}(\rho)$ we see that

$$
\begin{align*}
\mathcal{H}_{\rho}^{s}(W(x, \psi, \mathbf{t})) & \ll \sum_{n \geq n_{0}(\rho)}\left(\left(\psi\left(b^{n}\right)^{1+t_{k}}\right)^{s} \times \sum_{\mathbf{i} \in \Lambda^{n}} \prod_{j=1}^{d} \# \mathcal{B}_{j}(\mathbf{i}, k, \rho)\right) \\
& \ll \sum_{n \geq n_{0}(\rho)}\left(\psi\left(b^{n}\right)^{1+t_{k}}\right)^{s} N^{n} \prod_{j: t_{j}<t_{k}} b^{\gamma_{j}} \psi\left(b^{n}\right)^{\left(t_{j}-t_{k}\right) \gamma_{j}} \\
& \ll \sum_{n \geq n_{0}(\rho)} \psi\left(b^{n}\right)^{s\left(1+t_{k}\right)+\sum_{j: t_{j}<t_{k}}\left(t_{j}-t_{k}\right) \gamma_{j}-\gamma}\left(\psi\left(b^{n}\right) b^{n}\right)^{\gamma} . \tag{8}
\end{align*}
$$

Thus, it follows from condition (iii) in Theorem 3 that for any

$$
s \geq s_{0}=\frac{\gamma+\sum_{j: t_{j}<t_{k}}\left(t_{k}-t_{j}\right) \gamma_{j}+\delta \gamma}{1+t_{k}} \quad \text { with } \delta>0
$$

we have

$$
\mathcal{H}_{\rho}^{s}(W(x, \psi, \mathbf{t})) \rightarrow 0 \quad \text { as } \rho \rightarrow 0 .
$$

This implies that $\operatorname{dim}_{\mathrm{H}} W(x, \psi, \mathbf{t}) \leq s_{0}$. The above argument holds for any initial choice of $k$, and so we conclude that

$$
\operatorname{dim}_{\mathrm{H}} W(x, \psi, \mathbf{t}) \leq \min _{1 \leq k \leq d}\left\{\frac{1}{1+t_{k}}\left(\gamma+\sum_{j: t_{j}<t_{k}}\left(t_{k}-t_{j}\right) \gamma_{j}\right)\right\}
$$

Combining this upper bound with the lower bound result from Theorem 2 completes the proof of Theorem 3.

Acknowledgements. The authors are grateful to Balázs Bárány, Victor Beresnevich, Jason Levesley, Baowei Wang, and Wenmin Zhong for useful discussions.
