

# SYMMETRIC INTEGRATORS WITH IMPROVED UNIFORM ERROR BOUNDS AND LONG-TIME CONSERVATIONS FOR THE NONLINEAR KLEIN-GORDON EQUATION IN THE NONRELATIVISTIC LIMIT REGIME

BIN WANG AND YAOLIN JIANG

**ABSTRACT.** In this paper, we are concerned with symmetric integrators for the nonlinear relativistic Klein–Gordon (NRKG) equation with a dimensionless parameter  $0 < \varepsilon \ll 1$ , which is inversely proportional to the speed of light. The highly oscillatory property in time of this model corresponds to the parameter  $\varepsilon$  and the equation has strong nonlinearity when  $\varepsilon$  is small. There two aspects bring significantly numerical burdens in designing numerical methods. We propose and analyze a novel class of symmetric integrators which is based on some formulation approaches to the problem, Fourier pseudo-spectral method and exponential integrators. Two practical integrators up to order four are constructed by using the proposed symmetric property and stiff order conditions of implicit exponential integrators. The convergence of the obtained integrators is rigorously studied, and it is shown that the accuracy in time is improved to be  $\mathcal{O}(\varepsilon^3 \tilde{h}^2)$  and  $\mathcal{O}(\varepsilon^4 \tilde{h}^4)$  for the time stepsize  $\tilde{h}$ . The near energy conservation over long times is established for the multi-stage integrators by using modulated Fourier expansions. These theoretical results are achievable even if large stepsizes are utilized in the schemes. Numerical results on a NRKG equation show that the proposed integrators have improved uniform error bounds, excellent long time energy conservation and competitive efficiency.

## 1. INTRODUCTION

A large amount of dynamics can be described by the following nonlinear relativistic Klein–Gordon (NRKG) equation ([2, 5, 6, 13, 35])

$$\begin{aligned} \varepsilon^2 \partial_{tt} u(x, t) - \Delta u(x, t) + \frac{1}{\varepsilon^2} u(x, t) + \lambda f(u(x, t)) &= 0, \quad x \in \Omega^d, \quad t \in [0, T], \\ u(x, 0) &= \psi_1(x), \quad u_t(x, 0) = \frac{1}{\varepsilon^2} \psi_2(x), \end{aligned} \quad (1.1)$$

where  $t$  is time,  $x \in \Omega^d$  is the spatial coordinate with  $d$ -dimensional ( $d \geq 1$ ) space torus  $\Omega^d$ ,  $\Delta$  is the Laplacian operator,  $u(x, t)$  is a complex-valued scalar field,  $0 < \varepsilon \ll 1$  is a dimensionless parameter inversely proportional to the speed of light,  $\lambda \in \mathbb{R}$  is a given dimensionless parameter (positive and negative for defocusing and focusing self-interaction, respectively), and  $\psi_1$  and  $\psi_2$  are given complex-valued  $\varepsilon$ -independent initial values.

If we further assume that  $f(u) = \nabla H_1(u)$  with a smooth potential  $H_1$ , the model (1.1) is a Hamiltonian system with the following Hamiltonian function :

$$H(u, v) = \int_{\Omega^d} \left( \varepsilon^2 |v|^2 + |\nabla u|^2 + \frac{1}{\varepsilon^2} |u|^2 + \lambda H_1(u) \right) dx \equiv H(\psi_1, \psi_2 / \varepsilon^2), \quad (1.2)$$

where  $v := \partial_t u$ . This energy is conserved along the exact solution of (1.1). It is noted that the scales of  $\psi_1, \psi_2$  will lead to different properties of the system. In this paper, we consider the following scale of  $\psi_1, \psi_2$ :

$$\text{large initial data: } \psi_1 = \mathcal{O}(1), \psi_2 = \mathcal{O}(1) \rightarrow \text{energy unbounded system (1.1)}. \quad (1.3)$$

Although this type of system can be transformed into energy bounded case by using a scaling to the variables, the large initial data case has more essential differences such as the stronger oscillation feature and this makes the construction and analysis of numerical methods be more difficult and challenging [45]. We should note that all the methods and analysis presented in this paper are applicable to energy bounded system (1.1) where a small  $\psi_2$  is chosen as  $\psi_2 = \mathcal{O}(\varepsilon^2)$ .

This model often arises in a variety of fields such as plasma physics for modeling interaction between Langmuir and ion sound waves and cosmology as a phonological model for dark-matter and/or black-hole evaporation. Its computation represents major challenges because of two aspects. a) The solution of (1.1) becomes highly oscillatory in time when large frequencies are involved in the equation, which corresponds to the parameter  $0 < \varepsilon \ll 1$ . b) The nonlinearity is very strong when  $0 < \varepsilon \ll 1$ , which also brings great challenges for effective scientific computing.

The time integration of such equation (1.1) is a basic algorithmic task and it has been received much attention in recent decades. Due to the high oscillations and strong nonlinearity, the traditional methods such as symplectic/symmetric Runge–Kutta–Nyström (RKN) methods ([21, 37]) or energy-preserving Runge–Kutta methods ([8, 39]) often result in convergence problems. In order to get more competitive methods for second-order systems, Gautschi-type trigonometric integrators were developed in [31] and different kinds of trigonometric integrators were formulated and studied in [22, 23, 26, 27, 40, 44]. However, for these integrators, they at most have uniform second order accuracy in the absolute position error w.r.t.  $\varepsilon$  and only have uniform first order accuracy in velocity error [26] for not strong nonlinearity. As a result, it is challenging to get trigonometric integrators with uniform accuracy for the nonlinear Klein-Gordon equation in the nonrelativistic limit regime.

Recently, some new methods with uniform accuracy (w.r.t  $\varepsilon$ ) for highly oscillatory systems have been proposed and analysed such as two-scale formulation methods [13, 14], uniformly accurate exponential-type integrators [6, 7], nested Picard iterative integrators [12], multiscale time integrators [3, 4, 15], multi-revolution composition methods [35], uniformly accurate methods with averaging [16, 17] and low regularity integrators [11]. In [5], various uniformly accurate (UA) methods have been compared systematically for solving the NRKG equation (1.1). Recently, time-splitting methods were proved to have improved uniform error bounds for solving nonlinear Klein-Gordon equation with weak nonlinearity [2]. Most of these uniformly accurate methods can be applied to the system (1.1) and they have uniform accuracy in both position and velocity ([5]). Unfortunately, most of them do not have good long time conservation behaviour when applied to conservative systems. More precisely, if a UA method is considered as the approximation of (1.1), the numerical energy error will increase as time evolves. In a recent work [16], the UA method named as pullback method is shown to hold the long time conservation by the numerical results but without rigorous analysis. In a more recent work [43], the authors succeed in making the two-scale method with near conservation laws for first-order systems. However, only one-stage type methods of order two are presented there and the equation (1.1) does not share the form of the system considered in [43], which means that the analysis of [43] is no longer applicable for the system (1.1) of this paper. Moreover, the second-order differential equation (1.1) has its special structure which will be neglected if we rewrite it as a general highly oscillatory first-order differential equation. Therefore, it is necessary and meaningful to design and analyze UA methods with uniform high order and good long time energy conservation for solving the second-order system (1.1). It is worth pointing out that the integrators derived in this paper will be shown to have long time conservation and better accuracy than uniform accuracy, which is  $\mathcal{O}(\varepsilon^3 \tilde{h}^2)$  and  $\mathcal{O}(\varepsilon^4 \tilde{h}^4)$  for the time stepsize  $\tilde{h}$ . The accuracy is improved as  $\varepsilon$  decreases. This improved uniformly high accuracy is different from the existing UA methods [3, 4, 5, 6, 12, 13, 14, 15, 16, 17, 35, 43] and seems surprising at the first glance of (1.1) due to the  $\mathcal{O}(1/\varepsilon^4)$  commutator and  $\mathcal{O}(1/\varepsilon^2)$  strong nonlinearity.

In this paper we are interested in using numerical integrators with time stepsizes that are much larger than the  $\varepsilon$  of the system to obtain improved uniform accuracy and good long-time energy conservation when solving (1.1). To obtain the integrators with improved uniform accuracy, we take advantage of two-scale formulation approach, spectral semi-discretisation and exponential integrators with more than one stage. However, this brings some challenges and difficulties in the achievement and analysis of long time energy conservation. a) The two-scale formulation approach results in a new system which has a completely different linear part and nonlinear function in comparison with the original problem (1.1). This brings more difficulties in the proof of energy conservation of the original problem (1.1). b) To achieve high order improved uniform accuracy and good long time behaviour, two-stage and three-stage exponential integrators are chosen in this

paper. Unfortunately, however, for a method with more than one stage applied to highly oscillatory systems, long time analysis has not been done for any method so far. As pointed out in [18], there is the technical difficulty coming from the identification of invariants in the corresponding modulation system. Thus, it remains a challenge to study long time behaviour for a method with more than one stage. c) The third challenge comes from the diversity of (1.1) considered in this paper. Large initial data case (1.3) usually leads to large bounds of the coefficient functions in the modulated Fourier expansion, which prevents the derivation of the long time conservation.

To overcome these difficulties and make the analysis go smoothly, a novel approach to the design of integrators is established. The main contributions of this paper are as follows.

a) We consider three transformations of the original system and use symmetric exponential integrators which satisfy the derived stiff order conditions. The transformations of the system and stiff order conditions proposed in this paper can keep the improved uniform accuracy, and the symmetry yields good long time energy conservation. It will be shown that these both important properties can be hold for the integrators used with large time stepsizes, which is very effective and efficient in scientific computing over long times.

b) Compared with the existing UA methods, the accuracy of our integrators is improved to be  $\mathcal{O}(\varepsilon^3 \tilde{h}^2)$  and  $\mathcal{O}(\varepsilon^4 \tilde{h}^4)$  for solving (1.1) and as  $\varepsilon$  decreases, the integrators are more accurate. This improved uniformly high accuracy is very competitive in the numerical computation of NRKG equation where  $0 < \varepsilon \ll 1$ .

c) Moreover, we should note that we managed to derive the long-time energy conservation for the two-stage and three-stage methods applied to the large initial value system (1.3), which is different from the existing long term analysis work [18, 19, 20, 25, 27, 29, 41, 43], where only one-stage type methods and small initial value are both necessary. The long time analysis presented in this paper provides an extension of the powerful technique named as modulated Fourier expansion [18, 20, 25, 27, 29] to multi-stage methods and with such extension it is believed that more numerical methods with complicated scheme can be studied.

The rest of this paper is organized as follows. In Section 2, we firstly present the formulation process of the integrators, and then we construct two practical integrators by using the proposed symmetry and stiff order conditions. The main results concerning the improved uniformly accuracy and near energy conservation are given in Section 3, and some numerical results are made to show these two properties. The improved uniform error bounds are proved in Section 4, and the long-time analysis of energy conservation is drawn in Section 5. The last section includes the conclusions of this paper.

## 2. FORMULATION OF THE NUMERICAL INTEGRATORS

**2.1. The construction process of integrators.** In the formulation of the numerical scheme, we first make some transformations of the system and then consider the numerical integration. There are in all three steps in the process and we present them one by one.

**Step 1. Some transformations of the system.** Firstly, we rewrite the original system (1.1) as

$$\partial_{tt}u(x, t) + \frac{1-\varepsilon^2\Delta}{\varepsilon^4}u(x, t) + \frac{1}{\varepsilon^2}\lambda f(u(x, t)) = 0. \quad (2.1)$$

By using a scaling to the variables

$$\tilde{u}(x, t) := u(x, t) \quad \text{and} \quad \tilde{v}(x, t) := \varepsilon^2 \partial_t u(x, t),$$

a new system is obtained immediately

$$\begin{aligned} \partial_t \tilde{u}(x, t) &= \frac{1}{\varepsilon^2} \tilde{v}(x, t), & \tilde{u}(x, 0) &= \psi_1(x), \\ \partial_t \tilde{v}(x, t) &= -\frac{1-\varepsilon^2\Delta}{\varepsilon^2} \tilde{u}(x, t) - \lambda f(\tilde{u}(x, t)), & \tilde{v}(x, 0) &= \psi_2(x), \quad t \in [0, T]. \end{aligned} \quad (2.2)$$

Introducing a re-scale in time

$$\tilde{t} = \frac{t}{\varepsilon}, \quad \tilde{u}(x, \tilde{t}) = \tilde{u}(x, t), \quad \tilde{v}(x, \tilde{t}) = \tilde{v}(x, t),$$

the NLSE (2.2) is equivalent to

$$\begin{aligned} \partial_{\tilde{t}} \tilde{u}(x, \tilde{t}) &= \frac{1}{\varepsilon} \tilde{v}(x, \tilde{t}), & \tilde{u}(x, 0) &= \psi_1(x), \\ \partial_{\tilde{t}} \tilde{v}(x, \tilde{t}) &= -\frac{1-\varepsilon^2\Delta}{\varepsilon} \tilde{u}(x, \tilde{t}) - \varepsilon \lambda f(\tilde{u}(x, \tilde{t})), & \tilde{v}(x, 0) &= \psi_2(x), \quad \tilde{t} \in [0, \frac{T}{\varepsilon}]. \end{aligned} \quad (2.3)$$

Then letting

$$\begin{aligned} \tilde{u}(x, \tilde{t}) &:= (\sqrt{1-\varepsilon^2\Delta})^{-1} \left[ \cos\left(\frac{\tilde{t}\sqrt{1-\varepsilon^2\Delta}}{\varepsilon}\right) q(x, \tilde{t}) + \sin\left(\frac{\tilde{t}\sqrt{1-\varepsilon^2\Delta}}{\varepsilon}\right) p(x, \tilde{t}) \right], \\ \tilde{v}(x, \tilde{t}) &:= -\sin\left(\frac{\tilde{t}\sqrt{1-\varepsilon^2\Delta}}{\varepsilon}\right) q(x, \tilde{t}) + \cos\left(\frac{\tilde{t}\sqrt{1-\varepsilon^2\Delta}}{\varepsilon}\right) p(x, \tilde{t}), \end{aligned}$$

we obtain

$$\begin{aligned} \partial_{\tilde{t}} q(x, \tilde{t}) &= -\varepsilon \sin\left(\frac{\tilde{t}\sqrt{1-\varepsilon^2\Delta}}{\varepsilon}\right) F(q(x, \tilde{t}), p(x, \tilde{t})), & q(x, 0) &= \sqrt{1-\varepsilon^2\Delta} \psi_1(x), \\ \partial_{\tilde{t}} p(x, \tilde{t}) &= \varepsilon \cos\left(\frac{\tilde{t}\sqrt{1-\varepsilon^2\Delta}}{\varepsilon}\right) F(q(x, \tilde{t}), p(x, \tilde{t})), & p(x, 0) &= \psi_2(x), \end{aligned} \quad (2.4)$$

where

$$F(q, p) = -\lambda f\left((\sqrt{1-\varepsilon^2\Delta})^{-1} \left[ \cos\left(\frac{\tilde{t}\sqrt{1-\varepsilon^2\Delta}}{\varepsilon}\right) q + \sin\left(\frac{\tilde{t}\sqrt{1-\varepsilon^2\Delta}}{\varepsilon}\right) p \right]\right).$$

*Remark 2.1.* Without loss of generality, it is assumed in this paper that the propagators  $\sin\left(\frac{\tilde{t}\sqrt{1-\varepsilon^2\Delta}}{\varepsilon}\right)$  and  $\cos\left(\frac{\tilde{t}\sqrt{1-\varepsilon^2\Delta}}{\varepsilon}\right)$  are  $2\pi$ -periodic in  $\tilde{t}/\varepsilon$ . If this is not true, the equation (2.1) can be transformed into this case by decomposing a leading part from  $\sqrt{1-\varepsilon^2\Delta}$  with the help of the asymptotical expansion [13] or the Diophantine approximation [15]. For simplicity, this paper only focuses on the simple case that the propagators  $\sin\left(\frac{\tilde{t}\sqrt{1-\varepsilon^2\Delta}}{\varepsilon}\right)$  and  $\cos\left(\frac{\tilde{t}\sqrt{1-\varepsilon^2\Delta}}{\varepsilon}\right)$  are  $2\pi$ -periodic in  $\tilde{t}/\varepsilon$  and further discussions are referred to [15].

**Step 2. Two-scale formulation.** By isolating the fast time variable  $\tilde{t}/\varepsilon$  as another variable  $\tau$  and denoting

$$U(x, \tilde{t}, \tilde{t}/\varepsilon) := q(x, \tilde{t}), \quad V(x, \tilde{t}, \tilde{t}/\varepsilon) := p(x, \tilde{t}),$$

the two-scale pattern of (2.4) can be formulated as follows:

$$\begin{aligned} \partial_{\tilde{t}} U(x, \tilde{t}, \tau) + \frac{1}{\varepsilon} \partial_{\tau} U(x, \tilde{t}, \tau) &= -\varepsilon \sin\left(\tau\sqrt{1-\varepsilon^2\Delta}\right) F_{\tau}(U(x, \tilde{t}, \tau), V(x, \tilde{t}, \tau)), \\ \partial_{\tilde{t}} V(x, \tilde{t}, \tau) + \frac{1}{\varepsilon} \partial_{\tau} V(x, \tilde{t}, \tau) &= \varepsilon \cos\left(\tau\sqrt{1-\varepsilon^2\Delta}\right) F_{\tau}(U(x, \tilde{t}, \tau), V(x, \tilde{t}, \tau)), \end{aligned} \quad (2.5)$$

$\tilde{t} \in [0, T/\varepsilon], \quad \tau \in \mathbb{T},$

where  $U(x, \tilde{t}, \tau)$  and  $V(x, \tilde{t}, \tau)$  are the unknowns which are periodic in  $\tau$  on the torus  $\mathbb{T} = \mathbb{R}/2\pi\mathbb{Z}$  and

$$F_{\tau}(U, V) = -\lambda f\left((\sqrt{1-\varepsilon^2\Delta})^{-1} \left[ \cos\left(\tau\sqrt{1-\varepsilon^2\Delta}\right) U + \sin\left(\tau\sqrt{1-\varepsilon^2\Delta}\right) V \right]\right).$$

Letting

$$G_{\tau}(X(x, \tilde{t}, \tau)) := \begin{pmatrix} -\varepsilon \sin\left(\tau\sqrt{1-\varepsilon^2\Delta}\right) F_{\tau}(U(x, \tilde{t}, \tau), V(x, \tilde{t}, \tau)) \\ \varepsilon \cos\left(\tau\sqrt{1-\varepsilon^2\Delta}\right) F_{\tau}(U(x, \tilde{t}, \tau), V(x, \tilde{t}, \tau)) \end{pmatrix}$$

with  $X := [U; V]$ , the above system can be rewritten in a compact form

$$\partial_{\tilde{t}} X(x, \tilde{t}, \tau) + \frac{1}{\varepsilon} \partial_{\tau} X(x, \tilde{t}, \tau) = G_{\tau}(X(x, \tilde{t}, \tau)), \quad \tilde{t} \in [0, T/\varepsilon], \quad \tau \in \mathbb{T}. \quad (2.6)$$

For this new system, the following assumption is required in this paper.

**Assumption 2.2.** Consider that the unknowns of (1.1)  $t \rightarrow u$  and  $t \rightarrow \partial_t u$  are smooth maps onto the Sobolev spaces  $H^{\nu+1}(\Omega^d)$  and  $H^\nu(\Omega^d)$  with integrals  $\nu \geq 0$  and the  $d$ -dimensional space torus  $\Omega^d$  ( $d \geq 1$ ), respectively. In addition, it is required that  $\nu \geq 4 + d$  which is necessary for the analysis in Banach algebras. For all  $\alpha \in \{0, 1, \dots, 4\}$ ,  $\beta \in \{0, 1, \dots, 4\}$  and for the function  $G_\tau(X)$ , it is assumed that the functional  $\partial_\tau^\alpha \partial_X^\beta G_\tau(X)$  is continuous and locally bounded w.r.t.  $\varepsilon$  from  $\mathbb{T} \times H^\nu$  to  $\mathcal{L}(\underbrace{H^\sigma \times \dots \times H^\sigma}_{\beta \text{ times}}, H^{\sigma-\alpha})$ , where  $\nu \geq \sigma \geq \alpha + d$ .

*Remark 2.3.* It is noted that this new variable  $\tau$  of (2.6) offers a free degree for designing the initial data  $X(x, 0, \tau)$ . This two-scale equation (2.5) with a modified initial data is analysed in [13, 17] to construct uniformly accurate methods. We here use the strategy from [13, 17] to obtain the fourth-order initial data for (2.5), which is presented briefly as follows.

For some periodic  $v(\cdot)$  on  $\mathbb{T}$ , we introduce the notations

$$L := \partial_\tau, \quad \Pi v := \frac{1}{2\pi} \int_0^{2\pi} v(\tau) d\tau, \quad A := L^{-1}(I - \Pi).$$

It is obvious that

$$\begin{aligned} L^{-1}v &= (I - \Pi) \int_0^\tau v(\theta) d\theta, \quad L\Pi = 0, \quad \Pi^2 = \Pi, \\ \Pi L v &= \frac{1}{2\pi} \int_0^{2\pi} \partial_\tau v d\tau = \frac{1}{2\pi} (v(2\pi) - v(0)) = 0, \\ \Pi A &= \Pi L^{-1}(I - \Pi) = \Pi(I - \Pi) \int_0^\tau v(\theta) d\theta (I - \Pi) = 0, \\ L A &= I - \Pi, \quad L A^2 = (I - \Pi)A = A - \Pi A = A. \end{aligned} \tag{2.7}$$

Based on the Chapman-Enskog expansion ([16, 17]), the solution  $X(x, \tilde{t}, \tau)$  of this equation can be formulated as

$$X(x, \tilde{t}, \tau) = \underline{X}(x, \tilde{t}) + \kappa(x, \tilde{t}, \tau) \quad \text{with} \quad \underline{X}(x, \tilde{t}) = \Pi X(x, \tilde{t}, \tau), \quad \Pi \kappa(x, \tilde{t}, \tau) = 0.$$

From the fact (2.6), it follows that

$$\partial_{\tilde{t}} \underline{X}(x, \tilde{t}) = \Pi G_\tau(\underline{X}(x, \tilde{t}) + \kappa(x, \tilde{t}, \tau)).$$

Then the correction  $\kappa$  satisfies the differential equation

$$\partial_{\tilde{t}} \kappa(x, \tilde{t}, \tau) + \frac{1}{\varepsilon} \partial_\tau \kappa(x, \tilde{t}, \tau) = (I - \Pi) G_\tau(\underline{X}(x, \tilde{t}) + \kappa(x, \tilde{t}, \tau)),$$

which can be reformulated as

$$\kappa(x, \tilde{t}, \tau) = \varepsilon A G_\tau(\underline{X}(x, \tilde{t}) + \kappa(x, \tilde{t}, \tau)) - \varepsilon L^{-1}(\partial_{\tilde{t}} \kappa(x, \tilde{t}, \tau)). \tag{2.8}$$

We seek an expansion in powers of  $\varepsilon$  for the composer  $\kappa$ :

$$\kappa(x, \tilde{t}, \tau) = \varepsilon \kappa_1(\tau, \underline{X}(x, \tilde{t})) + \varepsilon^2 \kappa_2(\tau, \underline{X}(x, \tilde{t})) + \varepsilon^3 \kappa_3(\tau, \underline{X}(x, \tilde{t})) + \mathcal{O}_{\mathcal{X}^\nu}(\varepsilon^4), \tag{2.9}$$

where  $\mathcal{O}_{\mathcal{X}^\nu}$  denotes the term uniformly bounded with the  $\mathcal{X}^\nu$ -norm and

$$\mathcal{X}^\nu := \bigcap_{0 \leq l \leq \nu-d} C^l(\mathbb{T}; H^{\nu-l}).$$

Inserting (2.9) into (2.8) and using the Taylor series of  $G_\tau$  at  $\underline{X}$  yield (we omit  $(x, \tilde{t})$  and  $(\tau, \underline{X}(x, \tilde{t}))$  for conciseness)

$$\begin{aligned} \varepsilon \kappa_1 + \varepsilon^2 \kappa_2 + \varepsilon^3 \kappa_3 + \mathcal{O}_{\mathcal{X}^\nu}(\varepsilon^4) &= \varepsilon A G_\tau(\underline{X}) + \varepsilon A \partial_X G_\tau(\underline{X})(\varepsilon \kappa_1 + \varepsilon^2 \kappa_2) \\ &\quad + \frac{1}{2} \varepsilon A \partial_U^2 G_\tau(\underline{X})(\varepsilon \kappa_1, \varepsilon \kappa_1) - \varepsilon L^{-1}(\varepsilon \partial_{\tilde{t}} \kappa_1 + \varepsilon^2 \partial_{\tilde{t}} \kappa_2) + \mathcal{O}_{\mathcal{X}^\nu}(\varepsilon^4). \end{aligned}$$

By comparing the coefficients of  $\varepsilon^j$  with  $j = 1, 2, 3$ , one gets

$$\begin{aligned} \kappa_1 &= A G_\tau(\underline{X}), \quad \kappa_2 = A \partial_X G_\tau(\underline{X}) A G_\tau(\underline{X}) - L^{-1} \partial_{\tilde{t}} \kappa_1, \\ \kappa_3 &= A \partial_X G_\tau(\underline{X}) \kappa_2 + \frac{1}{2} A \partial_U^2 G_\tau(\underline{X})(\kappa_1, \kappa_1) - L^{-1} \partial_{\tilde{t}} \kappa_2. \end{aligned} \tag{2.10}$$

We further compute

$$\begin{aligned}\partial_{\tilde{t}}\kappa_1 &= A\partial_{\tilde{t}}G_\tau(\underline{X}) = A\partial_X G_\tau(\underline{X})\dot{\underline{X}} = A\partial_X G_\tau(\underline{X})\Pi G_\tau(X), \\ \partial_{\tilde{t}}\kappa_2 &= A\partial_X^2 G_\tau(\underline{X})(\Pi G_\tau(X), AG_\tau(\underline{X})) + A\partial_X G_\tau(\underline{X})A\partial_X G_\tau(\underline{X})\Pi G_\tau(X) \\ &\quad - A^2\partial_X^2 G_\tau(\underline{X})(\Pi G_\tau(X), \Pi G_\tau(X)) - A^2\partial_X G_\tau(\underline{X})\Pi\partial_X G_\tau(X)\partial_{\tilde{t}}X,\end{aligned}$$

and then (2.10) becomes

$$\begin{aligned}\kappa_1(\tau, \underline{X}) &= AG_\tau(\underline{X}), \quad \kappa_2(\tau, \underline{X}) = A\partial_X G_\tau(\underline{X})AG_\tau(\underline{X}) - A^2\partial_X G_\tau(\underline{X})\Pi G_\tau(\underline{X}), \\ \kappa_3(\tau, \underline{X}) &= A\partial_X G_\tau(\underline{X})A\partial_X G_\tau(\underline{X})AG_\tau(\underline{X}) - A\partial_X G_\tau(\underline{X})A^2\partial_X G_\tau(\underline{X})\Pi G_\tau(\underline{X}) \\ &\quad + \frac{1}{2}A\partial_X^2 G_\tau(\underline{X})(AG_\tau(\underline{X}), AG_\tau(\underline{X})) - A^2\partial_X^2 G_\tau(\underline{X})(\Pi G_\tau(\underline{X}), AG_\tau(\underline{X})) \\ &\quad - A^2\partial_X G_\tau(\underline{X})A\partial_X G_\tau(\underline{X})\Pi G_\tau(\underline{X}) + A^3\partial_X^2 G_\tau(\underline{X})(\Pi G_\tau(\underline{X}), \Pi G_\tau(\underline{X})) \\ &\quad + A^3\partial_X G_\tau(\underline{X})\Pi\partial_X G_\tau(\underline{X})\Pi G_\tau(\underline{X}) - A^2\partial_X G_\tau(\underline{X})\Pi\partial_X G_\tau(\underline{X})AG_\tau(\underline{X}).\end{aligned}\tag{2.11}$$

Here we have used the results  $X = \underline{X} + \mathcal{O}_{\mathcal{X}^\nu}(\varepsilon)$  and  $G_\tau(X) = G_\tau(\underline{X}) + \varepsilon\partial_X G_\tau(\underline{X})\kappa_1 + \mathcal{O}_{\mathcal{X}^\nu}(\varepsilon^2)$ , and removed the term

$$-\varepsilon A^2\partial_X G_\tau(\underline{X})\Pi\partial_X G_\tau(\underline{X})AG_\tau(\underline{X})$$

from  $\kappa_2$  to  $\kappa_3$ . With these preparations, consider the following initial condition

$$X_0(\tau) := \underline{X}^{[0]} + \varepsilon\kappa_1(\tau, \underline{X}^{[0]}) + \varepsilon^2\kappa_2(\tau, \underline{X}^{[0]}) + \varepsilon^3\kappa_3(\tau, \underline{X}^{[0]}),\tag{2.12}$$

where  $\underline{X}^{[0]}$  is given

$$\underline{X}^{[0]} := \Pi[q(x, 0); p(x, 0)]$$

and  $\kappa_1, \kappa_2, \kappa_3$  are defined by (2.11). Observing that  $\Pi, A$  are bounded on  $C^0(\mathbb{T}; H^\sigma)$  for any  $\sigma$ , it is deduced that  $\kappa_1, \kappa_2, \kappa_3$  all belong to  $\mathcal{X}^\nu$ . For the two-scale system (2.5) with this initial data, the following estimate of the solution is obtained.

**Proposition 2.4.** *Under the conditions given in Assumption 2.2, it is clear that  $\underline{X}^{[0]}$  is uniformly bounded in  $\varepsilon$  w.r.t. the  $H^\nu$  norm. Then, the two-scale system (2.6) with the initial condition (2.12) has a unique solution  $X(\cdot, \tilde{t}, \tau) \in C^0([0, T/\varepsilon] \times \mathbb{T}; H^\nu)$  with the bound*

$$\|X(\cdot, \tilde{t}, \tau)\|_{H^\nu} \leq C_1 \|X_0(\tau)\|_{H^\nu} \leq C_2 \forall \tilde{t} \in (0, T/\varepsilon],$$

where the constants  $C_1, C_2 > 0$  are independent of  $\varepsilon$  but depend on  $T$ . Moreover, the derivatives of  $X(\cdot, \tilde{t}, \tau)$  are bounded by

$$\|\partial_{\tilde{t}}^\mu X(\cdot, \tilde{t}, \tau)\|_{L^\infty(H^{\nu-\mu})} \leq C_3 \varepsilon^\mu \forall \tilde{t} \in (0, T/\varepsilon],$$

where  $\mu = 1, 2, 3, 4$  and  $C_3$  is independent of  $\varepsilon$  but depends on  $T$ .

**Step 3. Fully discrete scheme.** This step is devoted to the fully discrete scheme.

Firstly, for the problem (1.1), from the point of practical computations, the operator  $\Delta$  is in general approximated by a symmetric and positive semi-definite differential matrix. In this paper, we consider the Fourier spectral collocation (FSC) (see, [38]). Then a discrete two-scale system for (2.6) is obtained

$$\partial_{\tilde{t}}Z(\tilde{t}, \tau) + \frac{1}{\varepsilon}\partial_\tau Z(\tilde{t}, \tau) = \widehat{G}_\tau(Z(\tilde{t}, \tau)), \quad \tilde{t} \in [0, T/\varepsilon], \quad \tau \in \mathbb{T},\tag{2.13}$$

where

$$\widehat{G}_\tau(Z(\tilde{t}, \tau)) := \begin{pmatrix} -\varepsilon \sin(\tau\sqrt{A})F_\tau(Z^U(\tilde{t}, \tau), Z^V(\tilde{t}, \tau)) \\ \varepsilon \cos(\tau\sqrt{A})F_\tau(Z^U(\tilde{t}, \tau), Z^V(\tilde{t}, \tau)) \end{pmatrix}$$

with  $Z := [Z^U; Z^V]$ . Here,  $A$  is a  $\hat{d}$ -dimensional matrix,  $Z^U$  and  $Z^V$  are  $\hat{d}$ -dimensional vectors which are respectively referred to the discrete  $U$  and  $V$  in  $x$ , and the initial value of (2.13) is

$$Z_0(\tau) := \underline{Z}^{[0]} + \varepsilon\kappa_1(\tau, \underline{Z}^{[0]}) + \varepsilon^2\kappa_2(\tau, \underline{Z}^{[0]}) + \varepsilon^3\kappa_3(\tau, \underline{Z}^{[0]}),\tag{2.14}$$

where  $\underline{Z}^{[0]} := \Pi[\hat{q}(0); \hat{p}(0)]$  and  $\hat{q}(0)$  or  $\hat{p}(0)$  denotes the discrete  $q(x, 0)$  or  $p(x, 0)$  in  $x$ . By the analysis presented in [38], it is obtained immediately that

$$\|X(x, \tilde{t}, \tau) - Z(\tilde{t}, \tau)\|_{H^\nu} \leq \delta_{\mathcal{F}}^x,$$

where  $\delta_{\mathcal{F}}^x$  denotes the projection error in  $x$  brought by the Fourier pseudo-spectral method.

We now present the fully discrete scheme for (2.5) which is constructed by making use of the spectral semi-discretisation (see [38]) in  $\tau$  and exponential integrators (see [33]) in time.

For the spectral semi-discretisation used in  $\tau$ , let  $\mathcal{M} := \{-N_\tau/2, -N_\tau/2 + 1, \dots, N_\tau/2\}$  with a positive integer  $N_\tau > 1$  and  $Y_{\mathcal{M}} = \text{span}\{e^{ik\tau}, k \in \mathcal{M}, \tau \in [-\pi, \pi]\}$ . For any periodic function  $v(\tau)$  on  $[-\pi, \pi]$ , define the standard projection operator  $P_{\mathcal{M}} : L^2([-\pi, \pi]) \rightarrow Y_{\mathcal{M}}$  and the trigonometric interpolation operator  $I_{\mathcal{M}} : C([-\pi, \pi]) \rightarrow Y_{\mathcal{M}}$  respectively as

$$(P_{\mathcal{M}}v)(\tau) = \sum_{k \in \mathcal{M}} \tilde{v}_k e^{ik\tau}, \quad (I_{\mathcal{M}}v)(\tau) = \sum_{k \in \mathcal{M}} \hat{v}_k e^{ik\tau}, \quad (2.15)$$

where  $i = \sqrt{-1}$ ,  $\tilde{v}_k$  for  $k \in \mathcal{M}$  are the Fourier transform coefficients of the periodic function  $v(\tau)$  and  $\hat{v}_k$  are the discrete Fourier transform coefficients of the vector  $\{v(\tau_k)\}_{\tau_k := \frac{2\pi}{N_\tau}k}$ . For consistency reasons, we assume that the first term and the last one in the summation are taken with a factor  $1/2$  here and after. Then the Fourier spectral method is given by finding the trigonometric polynomial  $Z^{\mathcal{M}}(\tilde{t}, \tau) = (Z_l^{\mathcal{M}}(\tilde{t}, \tau))_{l=1,2,\dots,2\hat{d}}$ ,  $(\tilde{t}, \tau) \in [0, T/\varepsilon] \times [-\pi, \pi]$  with  $Z_l^{\mathcal{M}}(\tilde{t}, \tau) = \sum_{k \in \mathcal{M}} \widetilde{Z_{k,l}}(\tilde{t}) e^{ik\tau}$  such that

$$\partial_{\tilde{t}} Z^{\mathcal{M}}(\tilde{t}, \tau) + \frac{1}{\varepsilon} \partial_{\tau} Z^{\mathcal{M}}(\tilde{t}, \tau) = \hat{G}_{\tau}(Z^{\mathcal{M}}(\tilde{t}, \tau)).$$

It follows from the orthogonality of the Fourier functions and collecting all the  $\widetilde{Z_{k,l}}$  in  $(N_\tau + 1)$ -periodic coefficient vectors  $\widetilde{\mathbf{Z}}(\tilde{t}) = (\widetilde{Z_{k,l}}(\tilde{t}))$  that

$$\frac{d}{d\tilde{t}} \widetilde{\mathbf{Z}}(\tilde{t}) = i\Omega \widetilde{\mathbf{Z}}(\tilde{t}) + \varepsilon \Gamma(\widetilde{\mathbf{Z}}(\tilde{t})), \quad (2.16)$$

where  $\Gamma(\widetilde{\mathbf{Z}}) := -\lambda \begin{pmatrix} -\mathcal{F}\mathbf{S}f(\mathcal{C}\widetilde{\mathbf{Z}}^1 + \mathcal{S}\widetilde{\mathbf{Z}}^2) \\ \mathcal{F}\mathbf{C}f(\mathcal{C}\widetilde{\mathbf{Z}}^1 + \mathcal{S}\widetilde{\mathbf{Z}}^2) \end{pmatrix}$ , the vector  $\widetilde{\mathbf{Z}} := [\widetilde{\mathbf{Z}}^1; \widetilde{\mathbf{Z}}^2]$  is in dimension  $D := 2\hat{d} \times (N_\tau + 1)$  with its block vectors  $\widetilde{\mathbf{Z}}^1, \widetilde{\mathbf{Z}}^2$  in dimension  $D/2$ ,  $\mathcal{F}$  denotes the discrete Fourier transform,  $\Omega := \text{diag}(\Omega_1, \Omega_2, \dots, \Omega_{2\hat{d}})$  with  $\Omega_1 = \Omega_2 = \dots = \Omega_{2\hat{d}} := \frac{1}{\varepsilon} \text{diag}(\frac{N_\tau}{2}, \frac{N_\tau}{2} - 1, \dots, -\frac{N_\tau}{2})$ ,  $\mathbf{S} := \sin(\sqrt{A}) \otimes \Omega_1$ ,  $\mathbf{C} := \cos(\sqrt{A}) \otimes \Omega_1$ ,  $\mathcal{S} := (\sqrt{A}^{-1} \sin(\sqrt{A})) \otimes \Omega_1$ ,  $\mathcal{C} := (\sqrt{A}^{-1} \cos(\sqrt{A})) \otimes \Omega_1$ . Our analysis presented below will use the entries of  $\widetilde{\mathbf{Z}}$ , which are denoted by

$$\begin{aligned} \widetilde{\mathbf{Z}} = & (\widetilde{Z_{-\frac{N_\tau}{2},1}}, \widetilde{Z_{-\frac{N_\tau}{2}+1,1}}, \dots, \widetilde{Z_{\frac{N_\tau}{2},1}}, \widetilde{Z_{-\frac{N_\tau}{2},2}}, \widetilde{Z_{-\frac{N_\tau}{2}+1,2}}, \dots, \widetilde{Z_{\frac{N_\tau}{2},2}}, \\ & \dots, \widetilde{Z_{-\frac{N_\tau}{2},2\hat{d}}}, \widetilde{Z_{-\frac{N_\tau}{2}+1,2\hat{d}}}, \dots, \widetilde{Z_{\frac{N_\tau}{2},2\hat{d}}}). \end{aligned}$$

The same notation is used for all the vectors and diagonal matrices with the same dimension as  $\widetilde{\mathbf{Z}}$ . We also use the notations

$$\widetilde{\mathbf{Z}}_{:,l} = (\widetilde{Z_{-\frac{N_\tau}{2},l}}, \widetilde{Z_{-\frac{N_\tau}{2}+1,l}}, \dots, \widetilde{Z_{\frac{N_\tau}{2},l}})$$

for  $l = 1, 2, \dots, 2\hat{d}$  and the  $\mathcal{F}\widetilde{\mathbf{Z}}$  denotes the discrete Fourier transform acting on each  $\widetilde{\mathbf{Z}}_{:,l}$  of  $\widetilde{\mathbf{Z}}$ . Then the fully discrete scheme (FS-F) can read

$$Z_{\mathcal{M},l}^{ni}(\tau) = \sum_{k \in \mathcal{M}} \widetilde{Z_{k,l}^{ni}} e^{ik\tau}, \quad Z_{\mathcal{M},l}^{n+1}(\tau) = \sum_{k \in \mathcal{M}} \widetilde{Z_{k,l}^{n+1}} e^{ik\tau},$$

for  $i = 1, 2, \dots, s$ , where we consider the following  $s$ -stage exponential integrators ([33]) applied to (2.16):

$$\begin{aligned} \widetilde{Z^{ni}} &= e^{c_i \tilde{h} M} \widetilde{Z^n} + \varepsilon \tilde{h} \sum_{\rho=1}^s \bar{a}_{i\rho}(\tilde{h} M) \Gamma(\widetilde{Z^{n\rho}}), \\ \widetilde{Z^{n+1}} &= e^{\tilde{h} M} \widetilde{Z^n} + \varepsilon \tilde{h} \sum_{\rho=1}^s \bar{b}_{\rho}(\tilde{h} M) \Gamma(\widetilde{Z^{n\rho}}). \end{aligned} \quad (2.17)$$

Here  $i = 1, 2, \dots, s$  with  $s \geq 1$ ,  $\tilde{h}$  is the time stepsize,  $n = 0, 1, \dots, \frac{T}{\varepsilon\tilde{h}} - 1$ ,  $M := i\Omega$ ,  $c_i$  are constants belonging to  $[0, 1]$ , and  $\bar{a}_{i\rho}(\tilde{h}M)$ ,  $\bar{b}_i(\tilde{h}M)$  are matrix-valued functions of  $\tilde{h}M$ .

The above procedure, however, is unsuitable in practice because of the computation of Fourier transform coefficients. In order to find an efficient implementation, we now consider the discrete Fourier transform coefficients instead of Fourier transform coefficients. This gives the following scheme. For a positive integer  $N_\tau > 1$ , let  $\tau_k = \frac{2\pi}{N_\tau}k$  with  $k \in \mathcal{M} := \{-N_\tau/2, -N_\tau/2 + 1, \dots, N_\tau/2\}$  and  $Z_{k,l}^{ni} \approx Z_l(\tilde{t}_n + c_i\tilde{h}, \tau_k)$ ,  $Z_{k,l}^n \approx Z_l(\tilde{t}_n, \tau_k)$  for  $l = 1, 2, \dots, 2\tilde{d}$ . An exponential Fourier spectral discretization (FS-D) is defined as

$$Z_{j,l}^{ni} = \sum_{k \in \mathcal{M}} \widehat{Z}_{k,l}^{ni} e^{ik\tau_j}, \quad Z_{j,l}^{n+1} = \sum_{k \in \mathcal{M}} \widehat{Z}_{k,l}^{n+1} e^{ik\tau_j}, \quad (2.18)$$

where  $j \in \mathcal{M}$  and

$$\begin{aligned} \widehat{Z}^{ni} &= e^{c_i\tilde{h}M} \widehat{Z}^n + \varepsilon\tilde{h} \sum_{\rho=1}^s \bar{a}_{i\rho}(\tilde{h}M) \Gamma(\widehat{Z}^{n\rho}), \\ \widehat{Z}^{n+1} &= e^{\tilde{h}M} \widehat{Z}^n + \varepsilon\tilde{h} \sum_{\rho=1}^s \bar{b}_\rho(\tilde{h}M) \Gamma(\widehat{Z}^{n\rho}). \end{aligned} \quad (2.19)$$

Here  $0 < \tilde{h} < 1$  is the time stepsize, and  $s \geq 1$  is the stage of the implicit exponential integrator with the coefficients  $c_i$ ,  $\bar{a}_{i\rho}(\tilde{h}M)$  and  $\bar{b}_\rho(\tilde{h}M)$ .

Based on the above three steps, we obtain the fully discrete scheme, which is described as follows.

**Definition 2.5. (Fully discrete scheme)** The fully discrete scheme for the nonlinear relativistic Klein–Gordon equation (1.1) is defined as follows.

- With the time re-scaling and two-scale technologies stated in Steps 1-2, we get a highly oscillatory two-scale system (2.6) with the initial condition (2.12) over a long time interval  $[0, T/\varepsilon]$ .
- Consider the Fourier spectral collocation ([38]) for the approximation of the operator  $\Delta$  and then a discrete two-scale system (2.13) over  $[0, T/\varepsilon]$  with the initial value (2.14) is obtained.
- Then choose a positive time stepsize  $\tilde{h}$ , and use the exponential Fourier spectral discretization (FS-D) (2.18) to solve (2.13). This produces the numerical approximation

$$Z_l^n := \sum_{j \in \mathcal{M}} \widehat{Z}_{j,l}^n e^{ijn\tilde{h}/\varepsilon} \approx Z(n\tilde{h}, n\tilde{h}/\varepsilon)$$

of (2.13) for  $l = 1, 2, \dots, 2\tilde{d}$  and  $n = 1, 2, \dots, \frac{T}{\varepsilon\tilde{h}}$ .

- Finally, the numerical approximation  $u^n \approx u(\cdot, n\tilde{h}\varepsilon)$ ,  $v^n \approx v(\cdot, n\tilde{h}\varepsilon)$  of the original system (1.1) is given by

$$\begin{aligned} u^n &= \sqrt{A}^{-1} \left[ \cos(n\tilde{h}\sqrt{A}/\varepsilon) (Z_l^n)_{l=1,2,\dots,\tilde{d}} + \sin(n\tilde{h}\sqrt{A}/\varepsilon) (Z_{\tilde{d}+l}^n)_{l=1,2,\dots,\tilde{d}} \right], \\ v^n &= \varepsilon^{-2} \left[ -\sin(n\tilde{h}\sqrt{A}/\varepsilon) (Z_l^n)_{l=1,2,\dots,\tilde{d}} + \cos(n\tilde{h}\sqrt{A}/\varepsilon) (Z_{\tilde{d}+l}^n)_{l=1,2,\dots,\tilde{d}} \right]. \end{aligned}$$

**2.2. Some practical integrators.** The above procedure fails to be practical unless the coefficients  $c_i$ ,  $\bar{a}_{i\rho}(\tilde{h}M)$  and  $\bar{b}_i(\tilde{h}M)$  appearing in (2.19) are determined. To this end, the symmetry and stiff order conditions of (2.19) are needed.

**Proposition 2.6. (Symmetry)** The  $s$ -stage implicit exponential integrator (2.19) is symmetric if and only if for  $i, \rho = 1, 2, \dots, s$ , its coefficients satisfy

$$\begin{aligned} c_i &= 1 - c_{s+1-i}, \quad \bar{b}_\rho(\tilde{h}M) = e^{\tilde{h}M} \bar{b}_{s+1-\rho}(-\tilde{h}M), \\ \bar{a}_{i\rho}(\tilde{h}M) &= e^{c_i\tilde{h}M} \bar{b}_{s+1-\rho}(-\tilde{h}M) - \bar{a}_{s+1-i, s+1-\rho}(-\tilde{h}M). \end{aligned} \quad (2.20)$$

*Proof.* Under the conditions (2.20), it is trivial to verify that the method (2.19) remains the same after exchanging  $n+1 \leftrightarrow n$  and  $\tilde{h} \leftrightarrow -\tilde{h}$ . This completes the proof immediately.  $\square$

<i>Stiff order conditions</i>	<i>Order <math>r</math></i>
$\psi_1(\tilde{h}M) = 0$	1
$\psi_2(\tilde{h}M) = 0, \psi_{1,i}(\tilde{h}M) = 0$	2
$\psi_3(\tilde{h}M) = 0, \psi_{2,i}(\tilde{h}M) = 0$	3
$\psi_4(\tilde{h}M) = 0, \psi_{3,i}(\tilde{h}M) = 0$	4

TABLE 1. Stiff order conditions.

**Proposition 2.7.** (*Stiff order conditions*) Define

$$\begin{aligned}\psi_\rho(z) &= \varphi_\rho(z) - \sum_{i=1}^s \bar{b}_i(z) \frac{c_i^{\rho-1}}{(\rho-1)!}, \\ \psi_{\rho,i}(z) &= \varphi_\rho(c_i z) c_i^\rho - \sum_{\tilde{i}=1}^s \bar{a}_{\tilde{i}}(z) \frac{c_{\tilde{i}}^{\rho-1}}{(\rho-1)!}, \quad i = 1, 2, \dots, s,\end{aligned}$$

where the notations  $\varphi_\rho$  ([33]) are defined by  $\varphi_\rho(z) = \int_0^1 \theta^{\rho-1} e^{(1-\theta)z} / (\rho-1)! d\theta$  for  $\rho = 1, 2, \dots$ . For a fixed number  $1 \leq r \leq 4$ , the order conditions of Table 1 are assumed to be true up to order  $r$  and the condition  $\psi_r(\tilde{h}M) = 0$  is weakened to the form  $\psi_r(0) = 0$ . Under these assumptions, the conditions of Assumption 2.2, and the local assumptions of  $\widetilde{Z}^n = \widetilde{X(\tilde{t}_n)}$ , there exists a constant  $\tilde{h}_0$  independent of  $\varepsilon$  such that for  $0 < \tilde{h} \leq \tilde{h}_0$ , the local error bounds satisfy the following inequalities

$$\begin{aligned}\|\widetilde{Z^{ni}} - \widetilde{Z(\tilde{t}_n + c_i \tilde{h})}\|_{H^{\nu-r}} &\leq C \varepsilon^r \tilde{h}^r, \quad i = 1, 2, \dots, s, \\ \|\widetilde{Z^{n+1}} - \widetilde{Z(\tilde{t}_{n+1})}\|_{H^{\nu-r}} &\leq C(\varepsilon^r \tilde{h}^r \|\psi_r(\tilde{h}M)\|_{H^{\nu-r+1}} + \varepsilon^{r+1} \tilde{h}^{r+1}),\end{aligned}$$

where  $0 \leq n \leq \frac{T}{\varepsilon \tilde{h}}$ , and  $C > 0$  is a constant depending on  $T$  but is independent of  $\varepsilon$  and  $\tilde{h}$ .

*Proof.* The proof will be given in Section 4 combined with the analysis of convergence.  $\square$

The practical integrators presented below will be based on these symmetric conditions and stiff order conditions.

**Second-order integrator.** We first consider two-stage integrators, i.e.,  $s = 2$ . Solving the order conditions  $\psi_1(\tilde{h}M) = \psi_2(\tilde{h}M) = 0$  leads to

$$\bar{b}_1(\tilde{h}M) = \frac{-c_2 \varphi_1(\tilde{h}M) + \varphi_2(\tilde{h}M)}{c_1 - c_2}, \quad \bar{b}_2(\tilde{h}M) = \frac{c_1 \varphi_1(\tilde{h}M) - \varphi_2(\tilde{h}M)}{c_1 - c_2}.$$

Then using some other order conditions  $\psi_{1,1}(\tilde{h}M) = \psi_{1,2}(\tilde{h}M) = \psi_{2,2}(\tilde{h}M) = 0$  and a symmetric condition  $\bar{a}_{12}(\tilde{h}M) + \bar{a}_{21}(-\tilde{h}M) = \varphi_0(c_1 \tilde{h}M) \bar{b}_1(-\tilde{h}M)$ , we get the results of  $\bar{a}_{i\rho}$  as

$$\begin{aligned}\bar{a}_{21} &= \frac{c_2^2(-\varphi_{12} + \varphi_{22})}{c_1 - c_2}, \quad \bar{a}_{11} = -\bar{a}_{12} + c_1 \varphi_{11}, \quad \bar{a}_{22} = -\bar{a}_{21} + c_2 \varphi_{12}, \\ \bar{a}_{12} &= -\bar{a}_{21}(-\tilde{h}M) + \varphi_{01} \bar{b}_1(-\tilde{h}M),\end{aligned}$$

where  $\varphi_{ij} := \varphi_i(c_j \tilde{h}M)$ . On noticing  $c_1 = 1 - c_2$ , it can be verified that this class of integrators is symmetric and is of order two. As an example, we choose  $c_1 = 0$  and denote the corresponding method as **S2O2**.

**Fourth-order integrator.** We now continue with three-stage ( $s = 3$ ) integrators and obtain their coefficients by solving  $\psi_i(\tilde{h}M) = 0$  and  $\psi_{\rho,i}(\tilde{h}M) = 0$  for  $i, \rho = 1, 2, 3$ . The choice of  $c_1 =$

1,  $c_2 = 1/2$ ,  $c_3 = 0$  and the corresponding results

$$\begin{aligned}\bar{a}_{31} &= \bar{a}_{32} = \bar{a}_{33} = 0, \quad \bar{a}_{21} = -\frac{1}{4}\varphi_{22} + \frac{1}{2}\varphi_{32}, \quad \bar{a}_{22} = \varphi_{22} - \varphi_{32}, \\ \bar{a}_{23} &= \frac{1}{2}\varphi_{12} - \frac{3}{4}\varphi_{22} + \frac{1}{2}\varphi_{32}, \quad \bar{a}_{11} = \bar{b}_1 = 4\varphi_3 - \varphi_2, \quad \bar{a}_{12} = \bar{b}_2 = 4\varphi_2 - 8\varphi_3, \\ \bar{a}_{13} &= \bar{b}_3 = \varphi_1 - 3\varphi_2 + 4\varphi_3,\end{aligned}$$

determine this integrator. It is noted that this method satisfies all the stiff order conditions of order four and symmetric conditions. This integrator is referred as **S3O4**.

### 3. MAIN RESULTS AND NUMERICAL TESTS

In this section, we shall present the main results of this paper. The first one is about improved uniformly accuracy and the second is devoted to long time energy conservation. To support these two results, a numerical experiment with numerical results is carried out in the second part of this section.

#### 3.1. Main results.

**Theorem 3.1. (Improved uniformly high accuracy)** *Under the conditions of Assumption 2.2, Propositions 2.4 and 2.7, for the final numerical solutions  $u^n$ ,  $v^n$  produced by Definition 2.5 with S2O2 or S3O4, the global errors are*

$$\begin{aligned}\text{S2O2: } & \|u^n - u(\cdot, n\tilde{h}\varepsilon)\|_{H^{\nu-1}} \leq C(\varepsilon^3\tilde{h}^2 + \delta_{\mathcal{F}}), \\ & \|v^n - v(\cdot, n\tilde{h}\varepsilon)\|_{H^{\nu-2}} \leq C(\varepsilon\tilde{h}^2 + \delta_{\mathcal{F}}), \\ \text{S3O4: } & \|u^n - u(\cdot, n\tilde{h}\varepsilon)\|_{H^{\nu-3}} \leq C(\varepsilon^4\tilde{h}^4 + \delta_{\mathcal{F}}), \\ & \|v^n - v(\cdot, n\tilde{h}\varepsilon)\|_{H^{\nu-4}} \leq C(\varepsilon^2\tilde{h}^4 + \delta_{\mathcal{F}}),\end{aligned}$$

where  $0 \leq n \leq \frac{T}{h\varepsilon}$ ,  $C$  depends on  $T$  but is independent of  $n, \tilde{h}, \varepsilon$ , and  $\delta_{\mathcal{F}}$  denotes the projection error in  $x$  and  $\tau$  brought by the Fourier pseudo-spectral method.

*Remark 3.2.* We point out that the requirement  $\nu \geq 4 + d$  is proposed for the analysis. In fact it can be weakened to  $\nu \geq 2 + d$  for S2O2. It is noted that these two methods have a very nice improved accuracy which is  $\mathcal{O}_{H^{\nu-1}}(\varepsilon^3\tilde{h}^2)$  for S2O2 and  $\mathcal{O}_{H^{\nu-3}}(\varepsilon^4\tilde{h}^4)$  for S3O4 in  $u$ , and  $\mathcal{O}_{H^{\nu-2}}(\varepsilon\tilde{h}^2)$  for S2O2 and  $\mathcal{O}_{H^{\nu-4}}(\varepsilon^2\tilde{h}^4)$  for S3O4 in  $v$ . This is very significant for the numerical methods applied to highly oscillatory systems where  $\varepsilon$  is a very small value.

The next theorem requires a non-resonance condition and to describe it, we introduce the notations ([43])

$$\begin{aligned}\mathbf{k} &:= (k_{-\frac{N_{\tau}}{2},1}, k_{-\frac{N_{\tau}}{2}+1,1}, \dots, k_{\frac{N_{\tau}}{2},1}, k_{-\frac{N_{\tau}}{2},2}, k_{-\frac{N_{\tau}}{2}+1,2}, \dots, k_{\frac{N_{\tau}}{2},2}, \\ &\quad \dots, k_{-\frac{N_{\tau}}{2},2\hat{d}}, \dots, k_{\frac{N_{\tau}}{2},2\hat{d}}), \\ \boldsymbol{\omega} &:= (\omega_{-\frac{N_{\tau}}{2},1}, \omega_{-\frac{N_{\tau}}{2}+1,1}, \dots, \omega_{\frac{N_{\tau}}{2},1}, \omega_{-\frac{N_{\tau}}{2},2}, \omega_{-\frac{N_{\tau}}{2}+1,2}, \dots, \omega_{\frac{N_{\tau}}{2},2}, \\ &\quad \dots, \omega_{-\frac{N_{\tau}}{2},2\hat{d}}, \dots, \omega_{\frac{N_{\tau}}{2},2\hat{d}}), \\ |\mathbf{k}| &:= \sum_{l=1}^{2\hat{d}} \sum_{j=-\frac{N_{\tau}}{2}}^{\frac{N_{\tau}}{2}} |k_{j,l}|, \quad \mathbf{k} \cdot \boldsymbol{\omega} := \sum_{l=1}^{2\hat{d}} \sum_{j=-\frac{N_{\tau}}{2}}^{\frac{N_{\tau}}{2}} k_{j,l} \omega_{j,l},\end{aligned}$$

where  $(\omega_{-\frac{N_{\tau}}{2},l}, \omega_{-\frac{N_{\tau}}{2}+1,l}, \dots, \omega_{\frac{N_{\tau}}{2},l}) := \frac{1}{\varepsilon}(\frac{N_{\tau}}{2}, \frac{N_{\tau}}{2} - 1, \dots, -\frac{N_{\tau}}{2})$  for any  $1 \leq l \leq 2\hat{d}$ . Denote the resonance module by  $\mathcal{M} := \{\mathbf{k} \in \mathcal{Q} : \mathbf{k} \cdot \boldsymbol{\omega} = 0\}$ , where  $\mathcal{Q} := \{\mathbf{k} \in \mathbb{Z}^D : \text{there exists an } l \in \{1, \dots, 2\hat{d}\} \text{ such that } |\mathbf{k}_{\cdot,l}| = |\mathbf{k}|\}$ . Let  $\langle j \rangle_l$  be the unit coordinate vector  $(0, \dots, 0, 1, 0, \dots, 0)^{\top} \in \mathbb{R}^D$  with the only entry 1 at the  $(j, l)$ -th position. Further let  $\mathcal{K}$  be a set of representatives of the equivalence classes in  $\mathcal{Q}/\mathcal{M}$ . The set  $\mathcal{K}$  is determined by two requirements. The first is that if  $\mathbf{k} \in \mathcal{K}$ , we have  $-\mathbf{k} \in \mathcal{K}$ . The other is to minimize the sum  $|\mathbf{k}|$  in the equivalence class  $[\mathbf{k}] = \mathbf{k} + \mathcal{M}$  for each  $\mathbf{k} \in \mathcal{K}$ . Meanwhile, for those elements having the same minimal sum  $|\mathbf{k}|$ , all of them are

kept in  $\mathcal{K}$ . Denote  $\mathcal{N}_N = \{\mathbf{k} \in \mathcal{K} : |\mathbf{k}| \leq N\}$  and  $\mathcal{N}_N^* = \mathcal{N}_N \cup \{\langle 0 \rangle_l\}_{l=1,2,\dots,2\hat{d}}$  for a positive integer  $N$ .

**Theorem 3.3. (Long time energy conservation)** Denote the initial value appeared in Definition 2.5 by  $\delta_0 := \left\| \widehat{Z^0} \right\|_{H^\nu}$  which is a value between 0 and 1<sup>1</sup>. The non-linearity  $f(u)$  is assumed to be smooth and satisfy  $f(0) = f'(0) = 0$ . For the time stepsize  $h$ , we assume a lower bound  $\tilde{h}/\sqrt{\varepsilon} \geq c_0 > 0$  and  $\tilde{h} \leq \delta_0^2$ . It is further required that the numerical non-resonance condition  $|\sin(\frac{1}{2}\tilde{h}\omega_{j,1})| \geq c_1\sqrt{\varepsilon}$  holds for a constant  $c_1 > 0$  and  $j = -\frac{N_\tau}{2}, -\frac{N_\tau}{2} + 1, \dots, \frac{N_\tau}{2}$ . Then the long time energy conservation of  $u^n, v^n$  produced by Definition 2.5 with S2O2 or S3O4 is estimated by

$$\frac{\varepsilon^2}{\delta_0^2} (H(u^n, v^n) - H(u^0, v^0)) = \mathcal{O}_{abs}(\varepsilon^4 \delta_0^2) + \mathcal{O}_{abs}(\delta_{\mathcal{F}}), \quad 0 \leq n\tilde{h} \leq \frac{\varepsilon^2 \delta_0^{-N+3}}{\tilde{h}}, \quad (3.1)$$

where  $\mathcal{O}_{abs}$  denotes the term bounded with the absolute value which depends on  $N, N_\tau, c_0, c_1$  but is independent of  $n, h, \varepsilon$ , and  $\delta_{\mathcal{F}}$  denotes the error brought by the Fourier pseudospectral method. Since  $N$  can be arbitrarily large, the conservation law holds for a long time.

*Remark 3.4.* The above statement (3.1) seems a little surprised since these two methods (with different order) have the same result of energy conservation. It is noted here that this fact comes from the same boundedness of the coefficient functions appeared in the modulated Fourier expansion. Moreover, the numerical results of the test given in Section 3.2 demonstrate and support this behaviour (see Figures 7-8).

*Remark 3.5.* Although the smallness of the parameter  $\delta_0$  is technically required, we should note here that  $\delta_0$  is totally independent of  $\varepsilon$ . This means that the initial value of (1.1) is large, which has not been considered yet in the long term analysis of any methods. In all the previous work on this topic, small initial data is required (see, e.g. [18, 19, 20, 25, 27, 29, 41, 43]). Moreover, we only need the lower bound on the time stepsize  $\tilde{h} \geq c_0\sqrt{\varepsilon}$ , which means that large stepsize can be used to keep the long time energy conservation. Compared with the analysis of [43], a looser numerical non-resonance requirement is posed in this theorem and this is because the methods derived in this paper avoid  $\sin(\frac{1}{2}\tilde{h}(\omega_{j,1} - (\mathbf{k} \cdot \boldsymbol{\omega})))$  with  $\mathbf{k} \in \mathcal{N}_N$  but  $\neq \langle j \rangle_l$  in the denominator of the ansatz (5.8) of the modulated Fourier functions.

**3.2. Numerical test.** As a numerical example, we consider the nonlinear relativistic Klein-Gordon equation (1.1) with  $\lambda = -1, d = 1, p = 2, \Omega = (-\pi, \pi)$  and the initial values  $\psi_1(x) = \frac{3 \sin(x)}{\exp(Z^2/2) + \exp(-Z^2/2)}, \psi_2(x) = \frac{2 \exp(-Z^2)}{\sqrt{\pi}}$ . By the fourier spectral collocation method, we consider the second-order Fourier differentiation matrix  $(a_{kj})_{M \times M}$  whose entries are given by

$$a_{kj} = \begin{cases} \frac{(-1)^{k+j}}{2} \sin^{-2} \left( \frac{(k-j)\pi}{M} \right), & k \neq j, \\ \frac{M^2}{12} + \frac{1}{6}, & k = j, \end{cases}$$

with  $M = \frac{2L}{N_x}$ . With the notation  $Z(t) = (u(x_1, t), u(x_2, t), \dots, u(x_{N_x}, t))^T$ , the NRKG equation (1.1) is transformed into

$$\frac{d^2}{dt^2} Z(t) + \frac{I + \varepsilon A}{\varepsilon^2} Z(t) = -\frac{1}{\varepsilon} |Z(t)|^2 Z(t), \quad t > 0, \quad Z(0) = \Psi_1, \quad Z_t(0) = \frac{1}{\varepsilon} \Psi_2, \quad (3.2)$$

where  $\Psi_l = (\psi_l(x_1), \psi_l(x_2), \dots, \psi_l(x_{N_x}))^T$  with  $l = 1, 2$  and  $x_j = -\pi + (j-1)\frac{2\pi}{N_x}$  for  $j = 1, 2, \dots, N_x$ . In this test, we apply the methods to solve this system with  $N_x = 32$  and  $N_\tau = 64$ . For implicit methods, we use standard fixed point iteration as nonlinear solver in the practical computations. We set  $10^{-12}$  as the error tolerance and 200 as the maximum number of each iteration.

<sup>1</sup>If not, it can be achieved by rescaling the solution of the considered system.

<sup>2</sup>It is noted that this restriction is an artificial condition for rigorous proof and is hoped to be improved or removed in future.

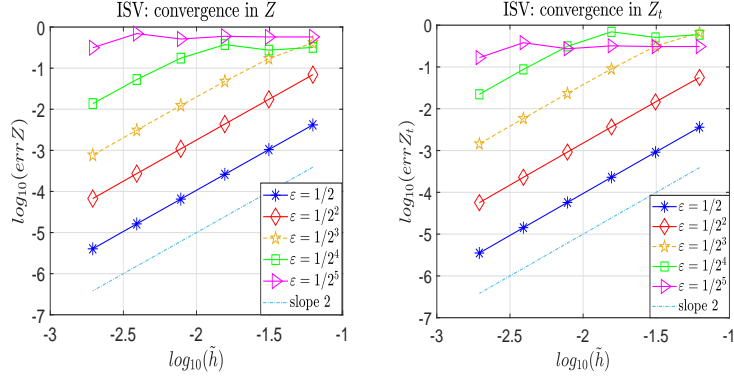

FIGURE 1. ISV: the log-log plot of the temporal errors  $errZ = \frac{\|Z^n - Z(\tilde{t}_n)\|_{H^1}}{\|Z(\tilde{t}_n)\|_{H^1}}$  and  $errZ_t = \frac{\|Z_t^n - Z_t(\tilde{t}_n)\|_{H^0}}{\|Z_t(\tilde{t}_n)\|_{H^0}}$  at  $\tilde{t}_n = 1$  under different  $\tilde{h}$ , where  $\varepsilon = 1/2^k$  with  $k = 1, 2, \dots, 5$ .

FIGURE 2. S2O2: the log-log plot of the temporal errors  $errZ = \frac{\|Z^n - Z(\tilde{t}_n)\|_{H^1}}{\|Z(\tilde{t}_n)\|_{H^1}}$  and  $errZ_t = \frac{\|Z_t^n - Z_t(\tilde{t}_n)\|_{H^0}}{\|Z_t(\tilde{t}_n)\|_{H^0}}$  at  $\tilde{t}_n = 1$  under different  $\tilde{h}$ , where  $\varepsilon = 1/2^k$  with  $k = 1, 2, \dots, 5$ .

**Accuracy.** For comparison, we choose the second-order improved Störmer-Verlet method (ISV) given in [27]. This method is directly used to solve (3.2) without taking the process given in Section 2. Firstly the accuracy of all the methods is shown by displaying the global errors

$$errZ = \frac{\|Z^n - Z(\tilde{t}_n)\|_{H^1}}{\|Z(\tilde{t}_n)\|_{H^1}}, \quad errZ_t = \frac{\|Z_t^n - Z_t(\tilde{t}_n)\|_{H^0}}{\|Z_t(\tilde{t}_n)\|_{H^0}}$$

at  $T = 1$  in Figures 1-6. We use the result given by the S3O4 with a small time stepsize as the reference solution. In the light of these results, we have the following observations.

a) The improved Störmer-Verlet method ISV shows non-uniform accuracy. When  $\varepsilon$  becomes small, the accuracy becomes badly (see Figure 1).

b) The two integrators given in this paper have improved uniformly accuracy, and when  $\varepsilon$  and  $h$  decrease, the accuracy is improved. S2O2 shows second order and S3O4 performs fourth order (see Figures 2-3).

c) Figures 4-6 show the dependence of global errors in  $\varepsilon$ . It can be seen that for a fixed time stepsize, ISV behaves very badly for small  $\varepsilon$  (see Figure 4), S2O2 has  $\mathcal{O}(\varepsilon^3)$  and  $\mathcal{O}(\varepsilon)$  convergence in

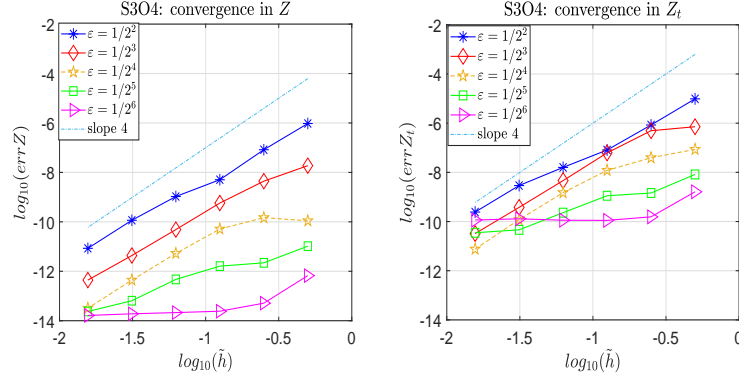

FIGURE 3. S3O4: the log-log plot of the temporal errors  $errZ = \frac{\|Z^n - Z(\tilde{t}_n)\|_{H^1}}{\|Z(\tilde{t}_n)\|_{H^1}}$  and  $errZ_t = \frac{\|Z_t^n - Z_t(\tilde{t}_n)\|_{H^0}}{\|Z_t(\tilde{t}_n)\|_{H^0}}$  at  $\tilde{t}_n = 1$  under different  $\tilde{h}$ , where  $\varepsilon = 1/2^k$  with  $k = 1, 2, \dots, 5$ .

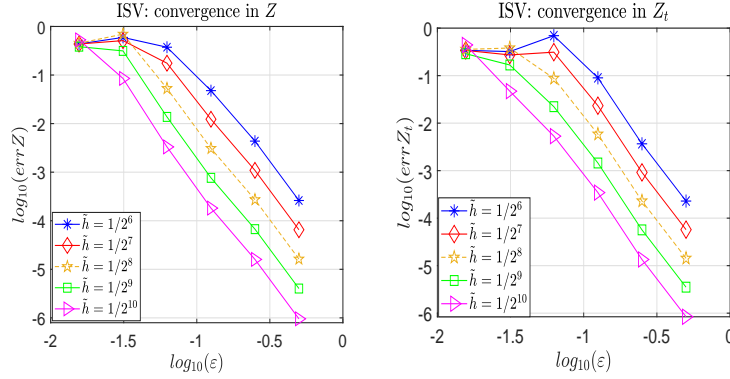

FIGURE 4. ISV: the log-log plot of the temporal errors  $errZ = \frac{\|Z^n - Z(\tilde{t}_n)\|_{H^1}}{\|Z(\tilde{t}_n)\|_{H^1}}$  and  $errZ_t = \frac{\|Z_t^n - Z_t(\tilde{t}_n)\|_{H^0}}{\|Z_t(\tilde{t}_n)\|_{H^0}}$  at  $\tilde{t}_n = 1$  under different  $\varepsilon$ , where  $\tilde{h} = 1/2^k$  with  $k = 6, 7, \dots, 10$ .

$Z$  and  $Z_t$ , respectively (see Figure 5), and the corresponding results for S3O4 are  $\mathcal{O}(\varepsilon^4)$  and  $\mathcal{O}(\varepsilon^2)$  (see Figure 6).

These observations agree with the theoretical results given in Theorem 3.1.

**Energy conservation.** Then we display the long time energy conservation of our methods by presenting the energy error  $err_H = \frac{|H(Z^n, Z_t^n) - H(Z^0, Z_t^0)|}{|H(Z^0, Z_t^0)|}$ . For comparison, we replace S2O2 with the following one-stage exponential integrator:

$$\widehat{Z}^{n+1} = e^{\tilde{h}M/2} \widehat{Z}^n + \varepsilon h/2 \Gamma(\widehat{Z}^{n+1}), \quad \widehat{Z}^{n+1} = e^{\tilde{h}M} \widehat{Z}^n + \varepsilon h \varphi_1(\tilde{h}M) \Gamma(\widehat{Z}^{n+1}).$$

This method is non-symmetric and we shall denote it by **NSM**. The energy errors are shown in Figures 7-9 for different  $\varepsilon$  and large  $\tilde{h}$ . According to these numerical results, the following observations are made.

a) The energy  $H$  is nearly preserved numerically by our integrators over long times. S2O2 and S3O4 have a nice and similar long time conservation, and with large time stepsize  $h$ , the numerical error in the energy can be improved when  $\varepsilon$  decreases (see Figures 7-8). These observations agree with the results given in Theorem 3.3.

FIGURE 5. S2O2: the log-log plot of the temporal errors  $errZ = \frac{\|Z^n - Z(\tilde{t}_n)\|_{H^1}}{\|Z(\tilde{t}_n)\|_{H^1}}$  and  $errZ_t = \frac{\|Z_t^n - Z_t(\tilde{t}_n)\|_{H^0}}{\|Z_t(\tilde{t}_n)\|_{H^0}}$  at  $\tilde{t}_n = 1$  under different  $\varepsilon$ , where  $\tilde{h} = 1/2^k$  with  $k = 6, 7, \dots, 10$ .

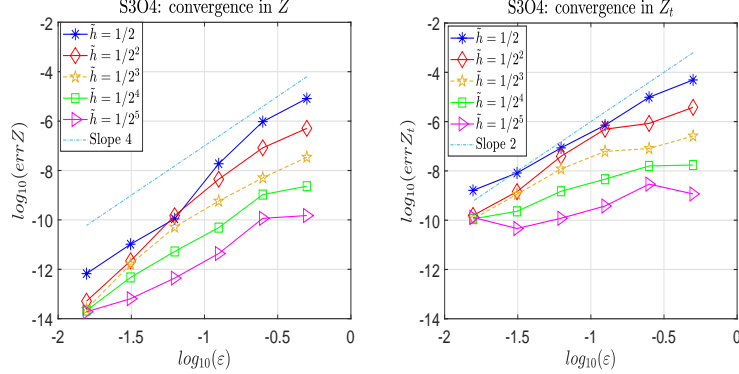

FIGURE 6. S3O4: the log-log plot of the temporal errors  $errZ = \frac{\|Z^n - Z(\tilde{t}_n)\|_{H^1}}{\|Z(\tilde{t}_n)\|_{H^1}}$  and  $errZ_t = \frac{\|Z_t^n - Z_t(\tilde{t}_n)\|_{H^0}}{\|Z_t(\tilde{t}_n)\|_{H^0}}$  at  $\tilde{t}_n = 1$  under different  $\varepsilon$ , where  $\tilde{h} = 1/2^k$  with  $k = 6, 7, \dots, 10$ .

b) In contrast, NSM shows substantial drift in the energy quantity and thus it does not have long-term performance in the energy conservation (see Figure 9). The reason is that it is not a symmetric method. This observation demonstrates that symmetry plays an important role in the numerical behaviour of energy conservation.

**Efficiency.** Compared with ISV applied to (3.2) directly, the scheme of our integrators given in this paper is more complicate. For example, the two-scale method enlarges the dimension of the original system and this usually adds some computation cost. Fortunately, Fast Fourier Transform (FFT) techniques can be used in the integrators and we hope that the efficiency of our integrators is still acceptable even compared with methods applied to (??) directly. To show this point, we solve this problem on the time interval  $[0, 1/\varepsilon]$ . The efficiency<sup>3</sup> of each integrator (measured by the log-log plot of the temporal error at  $t = 10$  against CPU time) is displayed in Figure 10. Clearly, our integrators have very competitive efficiency.

<sup>3</sup>This test is conducted in a sequential program in MATLAB R2020b on a laptop ThinkPad X1 nano (CPU: i7-1160G7 @ 1.20GHz 2.11 GHz, Memory: 16 GB, Os: Microsoft Windows 10 with 64bit).

FIGURE 7. S2O2: the plot of the energy error  $err_H = \frac{|H(Z^n, Z_t^n) - H(Z^0, Z_t^0)|}{|H(Z^0, Z_t^0)|}$  against  $t$  with  $\tilde{h} = 1/5$ .

FIGURE 8. S3O4: the plot of the energy error  $err_H = \frac{|H(Z^n, Z_t^n) - H(Z^0, Z_t^0)|}{|H(Z^0, Z_t^0)|}$  against  $t$  with  $\tilde{h} = 1/5$ .

FIGURE 9. NSM: the plot of the energy error  $err_H = \frac{|H(Z^n, Z_t^n) - H(Z^0, Z_t^0)|}{|H(Z^0, Z_t^0)|}$  against  $t$  with  $\tilde{h} = 1/5$ .

#### 4. PROOF OF IMPROVED UNIFORMLY HIGH ACCURACY (THEOREM 3.1)

The convergence of the three-stage integrator of order four (S3O4 with  $s = 3, r = 4$ ) is studied in this section. The proof is easily presented for the second order S2O2 and we omit it for brevity.

FIGURE 10. Efficiency: the plot of the error  $err = errZ + errZ_t$  against the cpu time (CPU) with  $\tilde{h} = 1/2^k$  for  $k = 1, 2, \dots, 6$ .

*Proof.* The proof is presented in four steps.

**I. A lemma and its proof.** A preliminary result is needed in the analysis and we present it by the following lemma.

**Lemma 4.1.** *Under the conditions of Proposition 2.4, for any  $\kappa > 0$ , there exists  $0 < T_\kappa \leq T$  such that for all  $0 < \varepsilon \leq \varepsilon_0$ , the two-scale system (2.6) with the initial condition  $X_0$  (2.12) has a unique solution  $X(\cdot, \tilde{t}, \tau) \in C^0([0, T_\kappa/\varepsilon] \times \mathbb{T}; H^\nu)$  with the bound*

$$\sup_{0 < \varepsilon \leq \varepsilon_0} \|X(\cdot, \tilde{t}, \cdot)\|_{L^\infty_\tau(H^\nu)} \leq \kappa \sup_{0 < \varepsilon \leq \varepsilon_0} \|X_0(\cdot)\|_{L^\infty_\tau(H^\nu)} \quad \forall \tilde{t} \in [0, T_\kappa/\varepsilon]. \quad (4.1)$$

*In addition, the solution  $X(\cdot, \tilde{t}, \tau)$  has first derivatives w.r.t. both  $\tau$  and  $\tilde{t}$  and they satisfy*

$$\partial_\tau X(\cdot, \tilde{t}, \tau) \in C^0([0, T_\kappa/\varepsilon] \times \mathbb{T}; H^{\nu-1}), \quad \partial_{\tilde{t}} X(\cdot, \tilde{t}, \tau) \in C^0([0, T_\kappa/\varepsilon] \times \mathbb{T}; H^{\nu-1}).$$

*Moreover, if the nonlinear function  $G_\tau(X)$  satisfies  $\|G_\tau(X)\|_{H^\nu} \leq C_1 \|X\|_{H^\nu} + C_2$  for some positive constants  $C_1, C_2$ , then the unique solution  $X(\cdot, \tilde{t}, \tau) \in C^0([0, T/\varepsilon] \times \mathbb{T}; H^\nu)$  of (2.6) further has the following estimate*

$$\sup_{0 < \varepsilon \leq \varepsilon_0} \|X(\cdot, \tilde{t}, \cdot)\|_{L^\infty_\tau(H^\nu)} \leq \left( \sup_{0 < \varepsilon \leq \varepsilon_0} \|X_0(\cdot)\|_{L^\infty_\tau(H^\nu)} + C_2 \tilde{t} \varepsilon \right) e^{C_1 \tilde{t} \varepsilon}$$

*for  $\tilde{t} \in [0, T/\varepsilon]$ .*

*Proof.* This lemma can be shown in a similar way as Proposition 2.1 of [13] with some modifications. Denote the smooth solution  $X(\cdot, \tilde{t}, \tau)$  of (2.6) by a new function  $\chi(\tilde{t}, \tau) = X(\cdot, \tilde{t}, \tau + \tilde{t}/\varepsilon)$ . Based on (2.6), it can be seen that

$$\partial_{\tilde{t}} \chi(\tilde{t}, \tau) = G_{\tau + \tilde{t}/\varepsilon}(\chi(\tilde{t}, \tau))$$

with  $\chi(0, \tau) = X_0(\tau)$ . Hence  $\partial_{\tilde{t}} \chi$  is in  $H^\nu$ . From the Cauchy–Lipschitz theorem in  $H^\nu$ , it follows that this system has a unique solution on  $[0, T]$  which satisfies

$$\|\chi(\tilde{t}, \tau)\|_{H^\nu} \leq C_1 \|X_0(\tau)\|_{H^\nu} + \varepsilon \int_0^{\tilde{t}} \|G_{\tau + \theta/\varepsilon}(\chi(\theta, \tau))\|_{H^\nu} d\theta.$$

Based on this result and with the same arguments of [13], we obtain the estimate (4.1).

Now we derive the differential equation of  $\partial_\tau \chi(\tilde{t}, \tau)$  which reads

$$\partial_{\tilde{t}}(\partial_\tau \chi)(\tilde{t}, \tau) = \partial_\tau(\partial_{\tilde{t}} \chi)(\tilde{t}, \tau) = \partial_\tau G_{\tau + \tilde{t}/\varepsilon}(\chi(\tilde{t}, \tau)) + \partial_X G_{\tau + \tilde{t}/\varepsilon}(\chi(\tilde{t}, \tau)) \partial_\tau \chi(\tilde{t}, \tau). \quad (4.2)$$

Observing that the initial value  $\partial_\tau \chi(0, \tau) = \partial_\tau X_0(\tau) \in H^{\nu-1}$  and  $\partial_\tau G$  (resp.  $\partial_X G$ ) is a continuous and locally bounded function from  $\mathbb{T} \times H^\nu$  to  $H^{\nu-1}$  (resp.  $\mathcal{L}(H^{\nu-1}, H^{\nu-1})$ ), one gets that the solution  $\partial_\tau \chi$  of differential equation (4.2) is unique and in  $H^{\nu-1}$ . Moreover, according to  $\chi(\tilde{t}, \tau) = X(\cdot, \tilde{t}, \tau + \tilde{t}/\varepsilon)$ , it is deduced that

$$\partial_\tau X(\cdot, \tilde{t}, \tau) = \partial_\tau \chi(\tilde{t}, \tau - \tilde{t}/\varepsilon) \in H^{\nu-1}$$

and

$$\partial_{\tilde{t}}X(\cdot, \tilde{t}, \tau) = \partial_{\tilde{t}}\chi(\tilde{t}, \tau - \tilde{t}/\varepsilon) - \frac{1}{\varepsilon}\partial_{\tau}\chi(\tilde{t}, \tau - \tilde{t}/\varepsilon) \in H^{\nu-1}.$$

The last result can be done using the bootstrap type argument and the Gronwall lemma.  $\square$

**II. Proof of Proposition 2.4 (bounds of the solution of the two-scale system).** Noticing that the operators  $\Pi$  and  $A$  are both bounded on  $C^0(\mathbb{T}; H^\sigma)$ , the initial value (2.12) can be estimated that  $X_0$  (2.12) is uniformly bounded w.r.t.  $\varepsilon$  in  $L^\infty_\tau(H^\nu)$ . Combining this with Lemma 4.1, it is known that the two-scale system (2.5) as well as the initial value (2.12) determines a unique solution satisfying  $\|X(\tilde{t}, \tau)\|_{L^\infty_\tau(H^\nu)} \leq C$ . Furthermore, the first derivative of  $X(\tilde{t}, \tau)$ <sup>4</sup> w.r.t.  $\tilde{t}$  exists and is a function with value in  $H^{\nu-1}$ .

In what follows, we study the boundedness of the derivatives of  $X(\tilde{t}, \tau)$  w.r.t.  $t$  and hope to get a more rigorous result. To this end, we first consider the differential equation of the first derivative  $\partial_{\tilde{t}}X(\tilde{t}, \tau) := V(\tilde{t}, \tau)$  which reads

$$\partial_{\tilde{t}}V(\tilde{t}, \tau) + \frac{1}{\varepsilon}\partial_{\tau}V(\tilde{t}, \tau) = \partial_X G_\tau(X(\tilde{t}, \tau))V(\tilde{t}, \tau).$$

The initial date of this system is

$$\begin{aligned} V_0 &:= V(0, \tau) = \partial_{\tilde{t}}X(0, \tau) = G_\tau(X_0) - \frac{1}{\varepsilon}LX_0 \\ &= G_\tau(X_0) - L\kappa_1(\tau, \underline{X}^{[0]}) - \varepsilon L\kappa_2(\tau, \underline{X}^{[0]}) - \varepsilon^2 L\kappa_3(\tau, \underline{X}^{[0]}) \\ &= G_\tau(X_0) - G_\tau(\underline{X}^{[0]}) + \Pi G_\tau(\underline{X}^{[0]}) - \varepsilon L\kappa_2(\tau, \underline{X}^{[0]}) - \varepsilon^2 L\kappa_3(\tau, \underline{X}^{[0]}) \\ &= \Pi G_\tau(\underline{X}^{[0]}) + \varepsilon \partial_X G_\tau(\underline{X}^{[0]})AG_\tau(\underline{X}^{[0]}) + \varepsilon^2 \partial_X G_\tau(\underline{X}^{[0]})\kappa_2(\tau, \underline{X}^{[0]}) - \varepsilon L\kappa_2(\tau, \underline{X}^{[0]}) \\ &\quad - \varepsilon^2 L\kappa_3(\tau, \underline{X}^{[0]}) + \varepsilon^2 \frac{1}{2}\partial_U^2 G_\tau(\underline{X}^{[0]})(\kappa_1(\tau, \underline{X}^{[0]}), \kappa_1(\tau, \underline{X}^{[0]})) + \mathcal{O}_{\mathcal{X}^{\nu-1}}(\varepsilon^3). \end{aligned}$$

According to the expressions (2.11) of  $\kappa_1, \kappa_2, \kappa_3$ , one deduces that

$$\kappa_1 = \mathcal{O}_{\mathcal{X}^\nu}(\varepsilon), \quad \kappa_2 = \mathcal{O}_{\mathcal{X}^\nu}(\varepsilon^2), \quad \kappa_3 = \mathcal{O}_{\mathcal{X}^\nu}(\varepsilon^3)$$

and further  $V_0 = \mathcal{O}_{\mathcal{X}^{\nu-1}}(\varepsilon)$  based on  $G_\tau = \mathcal{O}_{\mathcal{X}^\nu}(\varepsilon)$ . Moreover, the nonlinear function satisfies

$$\|\partial_X G_\tau(X(\tilde{t}, \tau))V(\tilde{t}, \tau)\|_{H^{\nu-1}} \leq \varepsilon C_1 \|V(\tilde{t}, \tau)\|_{H^{\nu-1}}.$$

These results and Lemma 4.1 yield

$$\partial_{\tilde{t}}X(\tilde{t}, \tau) = \mathcal{O}_{\mathcal{X}^{\nu-1}}(\varepsilon).$$

For the second derivative  $\partial_{\tilde{t}}^2 X(\tilde{t}, \tau) := W(\tilde{t}, \tau)$ , the equation stands

$$\partial_{\tilde{t}}W(\tilde{t}, \tau) + \frac{1}{\varepsilon}\partial_{\tau}W(\tilde{t}, \tau) = \partial_X^2 G_\tau(X(\tilde{t}, \tau))(V(\tilde{t}, \tau), V(\tilde{t}, \tau)) + \partial_X G_\tau(X(\tilde{t}, \tau))W(\tilde{t}, \tau), \quad (4.3)$$

and the corresponding initial date is obtained by

$$\begin{aligned} W_0 &:= W(0, \tau) = \partial_{\tilde{t}}^2 X(0, \tau) = \partial_X^2 G_\tau(X_0)V_0 - \frac{1}{\varepsilon}LV_0 \\ &= \partial_X G_\tau(X_0)\Pi G_\tau(\underline{X}^{[0]}) + \varepsilon \partial_X G_\tau(\underline{X}^{[0]})\partial_X G_\tau(\underline{X}^{[0]})AG_\tau(\underline{X}^{[0]}) \\ &\quad - \varepsilon \partial_X G_\tau(\underline{X}^{[0]})L\kappa_2(\tau, \underline{X}^{[0]}) - L\partial_X G_\tau(\underline{X}^{[0]})AG_\tau(\underline{X}^{[0]}) \\ &\quad - \varepsilon L\partial_X G_\tau(\underline{X}^{[0]})\kappa_2(\tau, \underline{X}^{[0]}) + L^2 A\partial_X G_\tau(\underline{X}^{[0]})AG_\tau(\underline{X}^{[0]}) \\ &\quad - L^2 A^2 \partial_X G_\tau(\underline{X}^{[0]})\Pi G_\tau(\underline{X}^{[0]}) + \varepsilon L^2 \kappa_3(\tau, \underline{X}^{[0]}) \\ &\quad - \varepsilon \frac{1}{2}L\partial_X^2 G_\tau(\underline{X}^{[0]})(\kappa_1(\tau, \underline{X}^{[0]}), \kappa_1(\tau, \underline{X}^{[0]})) + \mathcal{O}_{\mathcal{X}^{\nu-2}}(\varepsilon^4). \end{aligned}$$

---

<sup>4</sup>In the following parts of this section, we omit the expression  $x$  for brevity.

We further simplify some parts of the above result and then  $W_0$  has the form

$$\begin{aligned} W_0 = & \Pi \partial_X G_\tau(\underline{X}^{[0]}) \Pi G_\tau(\underline{X}^{[0]}) + \varepsilon \partial_X^2 G_\tau(\underline{X}^{[0]}) (AG_\tau(\underline{X}^{[0]}), \Pi G_\tau(\underline{X}^{[0]})) \\ & + \varepsilon \partial_X G_\tau(\underline{X}^{[0]}) \partial_X G_\tau(\underline{X}^{[0]}) AG_\tau(\underline{X}^{[0]}) - \varepsilon \partial_X G_\tau(\underline{X}^{[0]}) L \kappa_2(\tau, \underline{X}^{[0]}) \\ & - \varepsilon L \partial_X G_\tau(\underline{X}^{[0]}) \kappa_2(\tau, \underline{X}^{[0]}) + \varepsilon L^2 \kappa_3(\tau, \underline{X}^{[0]}) \\ & - \varepsilon \frac{L}{2} \partial_X^2 G_\tau(\underline{X}^{[0]}) (\kappa_1(\tau, \underline{X}^{[0]}), \kappa_1(\tau, \underline{X}^{[0]})) + \mathcal{O}_{\mathcal{X}^{\nu-2}}(\varepsilon^4). \end{aligned}$$

Therefore, one gets that  $W_0 = \mathcal{O}_{\mathcal{X}^{\nu-2}}(\varepsilon^2)$ . Concerning the nonlinear function, it is arrived that

$$\begin{aligned} & \left\| \partial_X^2 G_\tau(X(\tilde{t}, \tau))(V(\tilde{t}, \tau), V(\tilde{t}, \tau)) + \partial_X G_\tau(X(\tilde{t}, \tau))W(\tilde{t}, \tau) \right\|_{H^{\nu-2}} \\ & \leq \varepsilon C_1 \|V(\tilde{t}, \tau)\|_{H^{\nu-2}} + \varepsilon^3 C_2. \end{aligned}$$

By Lemma 4.1 again, one gets  $\partial_t^2 X(\tilde{t}, \tau) = \mathcal{O}_{\mathcal{X}^{\nu-2}}(\varepsilon^2)$ .

Consider  $\partial_t^3 X(\tilde{t}, \tau) := Y(\tilde{t}, \tau)$  and its equation reads

$$\begin{aligned} \partial_t Y(\tilde{t}, \tau) + \frac{1}{\varepsilon} \partial_\tau Y(\tilde{t}, \tau) = & \partial_X^3 G_\tau(X(\tilde{t}, \tau))(V(\tilde{t}, \tau), V(\tilde{t}, \tau), V(\tilde{t}, \tau)) \\ & + 3\partial_X^2 G_\tau(X(\tilde{t}, \tau))(V(\tilde{t}, \tau), W(\tilde{t}, \tau)) + \partial_X G_\tau(X(\tilde{t}, \tau))Y(\tilde{t}, \tau). \end{aligned}$$

The initial value  $Y_0 := Y(0, \tau)$  is extracted from (4.3)

$$\begin{aligned} Y_0 = & \partial_X^2 G_\tau(X_0)(V_0, V_0) + \partial_X G_\tau(X_0)W_0 - L \partial_X^2 G_\tau(\underline{X}^{[0]}) (AG_\tau(\underline{X}^{[0]}), \Pi G_\tau(\underline{X}^{[0]})) \\ & - L \partial_X G_\tau(\underline{X}^{[0]}) \partial_X G_\tau(\underline{X}^{[0]}) AG_\tau(\underline{X}^{[0]}) + L \partial_X G_\tau(\underline{X}^{[0]}) L \kappa_2(\tau, \underline{X}^{[0]}) \\ & + L^2 \partial_X G_\tau(\underline{X}^{[0]}) \kappa_2(\tau, \underline{X}^{[0]}) - L^3 \kappa_3(\tau, \underline{X}^{[0]}) \\ & + \frac{1}{2} L^2 \partial_X^2 G_\tau(\underline{X}^{[0]}) (\kappa_1(\tau, \underline{X}^{[0]}), \kappa_1(\tau, \underline{X}^{[0]})) + \mathcal{O}_{\mathcal{X}^{\nu-3}}(\varepsilon^3). \end{aligned}$$

Therefore, we obtain that  $Y_0 = \mathcal{O}_{\mathcal{X}^{\nu-3}}(\varepsilon^3)$  and in a same way  $\partial_t^3 X(\tilde{t}, \tau) = \mathcal{O}_{\mathcal{X}^{\nu-3}}(\varepsilon^3)$ .

This procedure can be proceeded in an analogous way for  $\partial_t^4 X(\tilde{t}, \tau) := K(\tilde{t}, \tau)$  and we get

$$\begin{aligned} \partial_t K(\tilde{t}, \tau) + \frac{1}{\varepsilon} \partial_\tau K(\tilde{t}, \tau) = & \partial_X^4 G_\tau(X(\tilde{t}, \tau))(V(\tilde{t}, \tau), V(\tilde{t}, \tau), V(\tilde{t}, \tau), V(\tilde{t}, \tau)) \\ & + 6\partial_X^3 G_\tau(X(\tilde{t}, \tau))(V(\tilde{t}, \tau), V(\tilde{t}, \tau), W(\tilde{t}, \tau)) + 4\partial_X^2 G_\tau(X(\tilde{t}, \tau))(V(\tilde{t}, \tau), Y(\tilde{t}, \tau)) \\ & + 3\partial_X^2 G_\tau(X(\tilde{t}, \tau))(W(\tilde{t}, \tau), W(\tilde{t}, \tau)) + \partial_X G_\tau(X(\tilde{t}, \tau))K(\tilde{t}, \tau) \end{aligned}$$

with the initial value

$$K(0, \tau) = \partial_X^3 G_\tau(X_0)(V_0, V_0, V_0) + 3\partial_X^2 G_\tau(X_0)(V_0, W_0) + \partial_X G_\tau(X_0)Y_0 - \frac{1}{\varepsilon} LY_0.$$

The only concern of this initial value comes from the factor  $\frac{1}{\varepsilon} LY_0$  and thus we collect the terms in the bound  $\mathcal{O}_{\mathcal{X}^{\nu-3}}(\varepsilon^3)$  of  $Y_0$ . In the light of the properties  $L\Pi = 0$ ,  $LA = I - \Pi$  and  $LA^2 = A$  given in (2.7), one can further derive that

$$\begin{aligned} L^3 A &= L^2(I - \Pi) = L^2, \quad L^2 A^2 = LA = I - \Pi, \\ L^3 A^2 &= L(I - \Pi) = L, \quad L^3 A^3 = LA = I - \Pi. \end{aligned}$$

With these results,  $Y_0$  can be simplified as

$$\begin{aligned} Y_0 = & \Pi \partial_X^2 G_\tau(\underline{X}^{[0]}) (\Pi G_\tau(\underline{X}^{[0]}), \Pi G_\tau(\underline{X}^{[0]})) \\ & + \Pi \partial_X G_\tau(\underline{X}^{[0]}) \Pi \partial_X G_\tau(\underline{X}^{[0]}) \Pi G_\tau(\underline{X}^{[0]}) + \mathcal{O}_{\mathcal{X}^{\nu-4}}(\varepsilon^5). \end{aligned}$$

Thus  $\frac{1}{\varepsilon} LY_0 = \mathcal{O}_{\mathcal{X}^{\nu-4}}(\varepsilon^4)$  and the initial condition  $K(0, \tau) = \mathcal{O}_{\mathcal{X}^{\nu-4}}(\varepsilon^4)$ . In a similar way, it is deduced that  $\partial_t^4 X(\tilde{t}, \tau) = \mathcal{O}_{\mathcal{X}^{\nu-4}}(\varepsilon^4)$ .

**III. Proof of Proposition 2.7 (local errors of exponential integrators).** Then we prove Proposition 2.7, where the local errors of our integrators for the transformed system are stated.

For all  $\tilde{h} \geq 0$ , it is true that  $\varphi_0(\tilde{h}M)$  and  $\varphi_i(\tilde{h}M)$  for  $i = 1, 2, 3$  are uniformly bounded w.r.t.  $\varepsilon$ . Therefore, the coefficients  $\bar{a}_{i\rho}(\tilde{h}M), \bar{b}_\rho(\tilde{h}M)$  for  $i, \rho = 1, 2, 3$  of exponential integrators are uniformly bounded.

Define the error functions by

$$e^n(\tau) := Z(\tilde{t}_n, \tau) - I_{\mathcal{M}}Z^n, \quad E^{ni}(\tau) := Z(\tilde{t}_n + c_i\tilde{h}, \tau) - I_{\mathcal{M}}Z^{ni},$$

and the projected errors as

$$e_{\mathcal{M}}^n(\tau) := P_{\mathcal{M}}Z(\tilde{t}_n, \tau) - Z_{\mathcal{M}}^n, \quad E_{\mathcal{M}}^{ni}(\tau) := P_{\mathcal{M}}Z(\tilde{t}_n + c_i\tilde{h}, \tau) - Z_{\mathcal{M}}^{ni},$$

where  $I_{\mathcal{M}}$  and  $P_{\mathcal{M}}$  are defined in (2.15). By the triangle inequality and estimates on projection error [38], one has

$$\begin{aligned} \|e^n\|_{H^{\nu-4}} &\leq \|e_{\mathcal{M}}^n\|_{H^{\nu-4}} + \|Z_{\mathcal{M}}^n - I_{\mathcal{M}}Z^n\|_{H^{\nu-4}} + \|Z(\tilde{t}_n, \tau) - P_{\mathcal{M}}Z(\tilde{t}_n, \tau)\|_{H^{\nu-4}} \\ &\lesssim \|e_{\mathcal{M}}^n\|_{H^{\nu-4}} + \delta_{\mathcal{F}}^\tau, \end{aligned}$$

and similarly  $\|E^{ni}\|_{H^{\nu-4}} \lesssim \|E_{\mathcal{M}}^{ni}\|_{H^{\nu-4}} + \delta_{\mathcal{F}}^\tau$ , where  $\delta_{\mathcal{F}}^\tau$  denotes the projection error in  $\tau$  brought by the Fourier pseudo-spectral method. Therefore, the estimations for  $e^n$  and  $E^{ni}$  could be converted to the estimations for  $e_{\mathcal{M}}^n$  and  $E_{\mathcal{M}}^{ni}$ .

Since the scheme (2.17) is implicit, iterative solutions are needed, and we consider pattern

$$\begin{aligned} (\widetilde{Z^{ni}})^{[0]} &= e^{c_i\tilde{h}M} \widetilde{Z^n} + \varepsilon\tilde{h} \sum_{\rho=1}^3 \bar{a}_{i\rho}(\tilde{h}M) \Gamma(\widetilde{Z^n}), \\ (\widetilde{Z^{ni}})^{[j+1]} &= e^{c_i\tilde{h}M} \widetilde{Z^n} + \varepsilon\tilde{h} \sum_{\rho=1}^3 \bar{a}_{i\rho}(\tilde{h}M) \Gamma((\widetilde{Z^{n\rho}})^{[j]}), \end{aligned}$$

for  $j = 0, 1, \dots, j^{\text{stopped}}$ . Then according to the property of  $e^{c_i\tilde{h}M}$  and the boundedness of the coefficients, the following result can be proved. That is, there exists a small constant  $0 < \tilde{h}_0 < 1$  such that when  $0 < \tilde{h} \leq \tilde{h}_0$  and  $\widetilde{Z^0} \in H^\nu$  with  $\|\widetilde{Z^0}\|_{H^\nu} \leq K_1$ , we can obtain  $\widetilde{Z^n} \in H^\nu$ ,  $(\widetilde{Z^{ni}})^{[j^{\text{stopped}}]} \in H^\nu$  as well as their bounds  $\|\widetilde{Z^n}\|_{H^\nu} \leq C_0$ ,  $\|(\widetilde{Z^{ni}})^{[j^{\text{stopped}}]}\|_{H^\nu} \leq C_0$ , where the constant  $C_0$  depends on  $T$  and  $K_1$ .

The error system of FS-F method is to find  $e_{\mathcal{M}}^n(\tau)$  and  $E_{\mathcal{M}}^{ni}(\tau)$  in the space  $Y_{\mathcal{M}}$ , i.e., we have

$$e_{\mathcal{M}}^{n+1}(\tau) = \sum_{k \in \mathcal{M}} (\widetilde{e_{\mathcal{M}}^{n+1}})_k e^{ik\tau}, \quad E_{\mathcal{M}}^{ni}(\tau) = \sum_{k \in \mathcal{M}} (\widetilde{E_{\mathcal{M}}^{ni}})_k e^{ik\tau},$$

where

$$\begin{aligned} \widetilde{e_{\mathcal{M}}^{n+1}} &= e^{\tilde{h}M} \widetilde{e_{\mathcal{M}}^n} + \tilde{h}\varepsilon \sum_{\rho=1}^3 \bar{b}_\rho(\tilde{h}M) \Delta \Gamma^{n\rho} + \widetilde{\delta^{n+1}}, \\ \widetilde{E_{\mathcal{M}}^{ni}} &= e^{c_i\tilde{h}M} \widetilde{e_{\mathcal{M}}^n} + \tilde{h}\varepsilon \sum_{\rho=1}^3 \bar{a}_{i\rho}(\tilde{h}M) \Delta \Gamma^{n\rho} + \widetilde{\Delta^{ni}}, \end{aligned} \tag{4.4}$$

and  $\widetilde{\Delta \Gamma^{n\rho}} := \Gamma(P_{\mathcal{M}}Z(\tilde{t}_n + c_\rho\tilde{h}, \tau)) - \Gamma(Z_{\mathcal{M}}^{n\rho})$ . Here the remainders  $\widetilde{\delta^{n+1}}, \widetilde{\Delta^{ni}}$  are bounded by inserting the exact solution of (2.16) into the numerical approximation, i.e.,

$$\begin{aligned} \widetilde{\mathbf{Z}(\tilde{t}_n + \tilde{h})} &= e^{\tilde{h}M} \widetilde{\mathbf{Z}(\tilde{t}_n)} + \varepsilon\tilde{h} \sum_{\rho=1}^3 \bar{b}_\rho(\tilde{h}M) \Gamma(\widetilde{\mathbf{Z}(\tilde{t}_n + c_\rho\tilde{h})}) + \widetilde{\delta^{n+1}}, \\ \widetilde{\mathbf{Z}(\tilde{t}_n + c_i\tilde{h})} &= e^{c_i\tilde{h}M} \widetilde{\mathbf{Z}(\tilde{t}_n)} + \varepsilon\tilde{h} \sum_{\rho=1}^3 \bar{a}_{i\rho}(\tilde{h}M) \Gamma(\widetilde{\mathbf{Z}(\tilde{t}_n + c_\rho\tilde{h})}) + \widetilde{\Delta^{ni}}. \end{aligned}$$

By the Duhamel principle and Taylor expansions, the remainders  $\widetilde{\delta^{n+1}}$  can be represented as

$$\begin{aligned}\widetilde{\delta^{n+1}} &= \tilde{h}\varepsilon \int_0^1 e^{(1-z)\tilde{h}M} \sum_{\rho=1}^4 \frac{(z\tilde{h})^{\rho-1}}{(\rho-1)!} \frac{d^{\rho-1}}{dt^{\rho-1}} \widetilde{\Gamma(\tilde{t}_n)} dz \\ &\quad + \tilde{h}\varepsilon \sum_{j=1}^s \bar{b}_j(\tilde{h}M) \sum_{\rho=1}^4 \frac{c_j^{\rho-1} \tilde{h}^{\rho-1}}{(\rho-1)!} \frac{d^{\rho-1}}{d\tilde{t}^{\rho-1}} \widetilde{\Gamma(\tilde{t}_n)} + \widetilde{\delta_4^{n+1}} \\ &= \varepsilon \sum_{\rho=1}^4 \tilde{h}^\rho \psi_\rho(\tilde{h}M) \frac{d^{\rho-1}}{d\tilde{t}^{\rho-1}} \widetilde{\Gamma(\tilde{t}_n)} + \widetilde{\delta_4^{n+1}},\end{aligned}$$

where we take the notation  $\widetilde{\Gamma(\tilde{t})} := \Gamma(\widetilde{\mathbf{Z}(\tilde{t})})$ . With the bounds of the solution of the two-scale system proposed in Proposition 2.4, it is obtained that  $\frac{d^\rho}{d\tilde{t}^\rho} \widetilde{\Gamma(\tilde{t}_n)} = \mathcal{O}_{H^{\nu-\rho}}(\varepsilon^\rho)$  for  $\rho = 0, 1, \dots, 4$ . Thus we get for  $\zeta \in [0, 1]$

$$\widetilde{\delta^{n+1}} = \mathcal{O}_{H^{\nu-4}}\left(\varepsilon \tilde{h}^5 \frac{d^4}{d\tilde{t}^4} \widetilde{\Gamma(\tilde{t}_n + \zeta \tilde{h})}\right) = \mathcal{O}_{H^{\nu-4}}(\varepsilon^5 \tilde{h}^5).$$

Similarly, one has

$$\widetilde{\Delta^{ni}} = \varepsilon \sum_{\rho=1}^3 \tilde{h}^\rho \psi_{\rho,i}(\tilde{h}M) \frac{d^{\rho-1}}{d\tilde{t}^{\rho-1}} \widetilde{\Gamma(\tilde{t}_n)} + \widetilde{\Delta_3^{ni}}$$

with  $\widetilde{\Delta_3^{ni}} = \mathcal{O}_{H^{\nu-3}}(\varepsilon^4 \tilde{h}^4)$ . Then using the stiff order conditions presented in Proposition 2.7, we know that  $\widetilde{\Delta^{ni}} = \widetilde{\Delta_3^{ni}}$  and

$$\widetilde{\delta^{n+1}} = \varepsilon \tilde{h}^4 \psi_4(\tilde{h}M) \frac{d^3}{d\tilde{t}^3} \widetilde{\Gamma(\tilde{t}_n)} + \widetilde{\delta_4^{n+1}}.$$

The proof of Proposition 2.7 is immediately complete.

**IV. Proof of the global errors.** We are now in a position to derive the error bounds in a standard way. To make the analysis be more compact, here we only present the main points but without details.

For the error recursion (4.4), by Taylor series, one gets  $\widetilde{\Delta \Gamma^{n\rho}} = J_n \widetilde{E_{\mathcal{M}}^{n\rho}}$  with a matrix  $J_n$ . Then there exist bounded operators  $\mathcal{N}^{ni}(\widetilde{e_{\mathcal{M}}^n})$  such that

$$\widetilde{E_{\mathcal{M}}^{ni}} = \mathcal{N}^{ni}(\widetilde{e_{\mathcal{M}}^n}) \widetilde{e_{\mathcal{M}}^n} + \widetilde{\Delta^{ni}} + \tilde{h}^4 \varepsilon^4 \mathcal{R}^{ni}$$

with uniformly bounded remainders  $\mathcal{R}^{ni}$  in  $H^{\nu-4}$ . Now it is arrived at

$$\begin{aligned}\widetilde{e_{\mathcal{M}}^{n+1}} &= e^{\tilde{h}M} \widetilde{e_{\mathcal{M}}^n} + \tilde{h}\varepsilon \sum_{\rho=1}^3 \bar{b}_\rho(\tilde{h}M) J_n \mathcal{N}^{n\rho}(\widetilde{e_{\mathcal{M}}^n}) \widetilde{e_{\mathcal{M}}^n} \\ &\quad + \tilde{h}\varepsilon \sum_{\rho=1}^3 \bar{b}_\rho(\tilde{h}M) J_n \widetilde{\Delta^{n\rho}} + \varepsilon \tilde{h}^4 \psi_4(\tilde{h}M) \frac{d^3}{d\tilde{t}^3} \widetilde{\Gamma(\tilde{t}_n)} + \mathcal{O}_{H^{\nu-4}}(\varepsilon^5 \tilde{h}^5) \\ &= e^{\tilde{h}M} \widetilde{e_{\mathcal{M}}^n} + \tilde{h}\varepsilon \mathcal{N}^n(\widetilde{e_{\mathcal{M}}^n}) \widetilde{e_{\mathcal{M}}^n} + \varepsilon \tilde{h}^4 \psi_4(\tilde{h}M) \frac{d^3}{d\tilde{t}^3} \widetilde{\Gamma(\tilde{t}_n)} + \mathcal{O}_{H^{\nu-4}}(\varepsilon^5 \tilde{h}^5),\end{aligned}$$

where we use the notation  $\mathcal{N}^n(\widetilde{e_{\mathcal{M}}^n}) := \sum_{\rho=1}^3 \bar{b}_\rho(\tilde{h}M) J_n \mathcal{N}^{n\rho}(\widetilde{e_{\mathcal{M}}^n})$ . Solving this recursion leads to

$$\begin{aligned}\widetilde{e_{\mathcal{M}}^n} &= \tilde{h}\varepsilon \sum_{j=0}^{n-1} e^{(n-j-1)\tilde{h}M} \mathcal{N}^j(\widetilde{e_{\mathcal{M}}^j}) \widetilde{e_{\mathcal{M}}^j} \\ &\quad + \varepsilon \tilde{h}^4 \sum_{j=0}^{n-1} e^{(n-j-1)\tilde{h}M} \psi_4(\tilde{h}M) \frac{d^3}{d\tilde{t}^3} \widetilde{\Gamma(\tilde{t}_n)} + \mathcal{O}_{H^{\nu-4}}(\tilde{h}^4 \varepsilon^5).\end{aligned}$$

The order condition  $\psi_4(0) = 0$  shows that there exists bounded operator  $\tilde{\psi}_4(\tilde{h}M)$  with  $\psi_4(\tilde{h}M) = \tilde{h}M\tilde{\psi}_4(\tilde{h}M)$  and Lemma 4.8 of [32] contributes

$$\begin{aligned} \sum_{j=0}^{n-1} e^{(n-j-1)\tilde{h}M} \psi_4(\tilde{h}M) \frac{d^3}{dt^3} \widetilde{\Gamma(\tilde{t}_n)} &= \sum_{j=0}^{n-1} e^{(n-j-1)\tilde{h}M} \tilde{h}M \tilde{\psi}_4(\tilde{h}M) \frac{d^3}{dt^3} \widetilde{\Gamma(\tilde{t}_n)} \\ &= \mathcal{O}_{H^{\nu-4}} \left( \frac{d^3}{dt^3} \widetilde{\Gamma(\tilde{t}_n)} \right) = \mathcal{O}_{H^{\nu-4}}(\varepsilon^3). \end{aligned}$$

Combined with the above results and using Gronwall inequality leads to  $\widetilde{e_{\mathcal{M}}^n} = \mathcal{O}_{H^{\nu-4}}(\tilde{h}^4 \varepsilon^4)$ . This result and the formulation of the scheme give the final convergence for the numerical solutions of the original system (1.1):

$$\begin{aligned} \|u(\cdot, n\tilde{h}) - u^n\|_{H^{\nu-3}} &\leq \|X(\cdot, n\tilde{h}, n\tilde{h}/\varepsilon) - I_{\mathcal{M}} Z^n\|_{H^{\nu-4}} \\ &\leq \|X(\cdot, n\tilde{h}, n\tilde{h}/\varepsilon) - Z(\tilde{t}, \tau)\|_{H^{\nu-4}} + \|Z(\tilde{t}, \tau) - I_{\mathcal{M}} Z^n\|_{H^{\nu-4}} \\ &\leq \delta_{\mathcal{F}}^x + \|P_{\mathcal{M}} Z(\tilde{t}_n, \tau) - Z_{\mathcal{M}}^n\|_{H^{\nu-4}} + \delta_{\mathcal{F}}^{\tau} \leq \delta_{\mathcal{F}} + C\varepsilon^4 \tilde{h}^4. \end{aligned}$$

and similarly

$$\|v(\cdot, n\tilde{h}) - v^n\|_{H^{\nu-4}} \leq \delta_{\mathcal{F}}^x + \frac{1}{\varepsilon^2} \|P_{\mathcal{M}} Z(\tilde{t}_n, \tau) - Z_{\mathcal{M}}^n\|_{H^{\nu-3}} + \delta_{\mathcal{F}}^{\tau} \leq \delta_{\mathcal{F}} + C\varepsilon^2 \tilde{h}^4.$$

The proof of Theorem 3.1 is complete.  $\square$

*Remark 4.2.* With the same arguments, the accuracy of the second-order method S2O2 can be studied. It is noted that S2O2 satisfies a stronger order condition, i.e.,  $\psi_2(\tilde{h}M) = 0$  instead of  $\psi_2(0) = 0$ , and thus the error brought by  $\sum_{j=0}^{n-1} e^{(n-j-1)\tilde{h}M} \psi_2(\tilde{h}M) \frac{d}{dt} \widetilde{\Gamma(\tilde{t}_n)}$  disappears in the analysis. Therefore, we obtain  $\widetilde{e_{\mathcal{M}}^n} = \mathcal{O}_{H^{\nu-2}}(\tilde{h}^2 \varepsilon^3)$  for S2O2 and its accuracy is improved as stated in Theorem 3.1.

## 5. PROOF OF LONG TIME ENERGY CONSERVATION (THEOREM 3.3)

Long time energy conservation is proved mainly based on the technology of modulated Fourier expansions, which was firstly developed in [27] and was used for the long-term analysis of many methods [18, 19, 20, 25, 29, 41, 42, 43]. The main differences and contributions of long term analysis given in this section involve in two aspects. We extend the technology of modulated Fourier expansions to multi-stage schemes and prove the long-time result for both two-stage and three-stage methods. This provides some developments for studying long-term behavior of various methods. Moreover, in contrast to the existing work, we neither assume bounded energy, nor assume small initial value for the considered system. In the proof, the result is derived for the methods applied to the energy unbounded system (1.1) with large initial value. Finite dimensional vector space and Euclidean norm are considered in the analysis.

*Proof.* The proof consists of three parts. The first two parts are given for S2O2 and the last one is devoted to the proof of S3O4.

### I. Modulated Fourier expansions.

**Lemma 5.1.** *With the notations introduced in Section 3.1 and under the conditions given in Theorem 3.3, the numerical result  $\widetilde{Z}^n$  (2.19) obtained from S2O2 can be expressed by the following modulated Fourier expansion at  $\tilde{t} = n\tilde{h}$*

$$\widetilde{Z}^n = \sum_{\mathbf{k} \in \mathcal{N}_N^*} e^{i(\mathbf{k} \cdot \boldsymbol{\omega})\tilde{t}} \alpha^{\mathbf{k}}(\tilde{t}) + R_{Z,N}(\tilde{t}), \quad (5.1)$$

where  $\alpha^{\mathbf{k}}$  are smooth coefficient functions for  $\tilde{t} = n\tilde{h}$ . These functions and their derivatives have the bounds

$$\begin{aligned} \alpha_{j,l}^{\langle j \rangle l}(\tilde{t}) &= \mathcal{O}_{abs}(\delta_0), \quad \dot{\alpha}_{j,l}^{\langle j \rangle l}(\tilde{t}) = \mathcal{O}_{abs}\left(\frac{\tilde{h}^2 \varepsilon^2}{\iota_1 \|\iota_3\|_{L^2}} \delta_0^3\right), \\ \alpha_{j,l}^{\mathbf{k}}(\tilde{t}) &= \mathcal{O}_{abs}\left(\frac{\tilde{h} \varepsilon}{\|\iota_3\|_{L^2}} \delta_0^{|\mathbf{k}|}\right), \quad \mathbf{k} \neq \langle j \rangle l, \end{aligned} \quad (5.2)$$

where  $j \in \{-N_\tau/2, -N_\tau/2 + 1, \dots, N_\tau/2\}$ ,  $l = 1, 2, \dots, 2\hat{d}$  and

$$\iota_1 := \frac{\tilde{h}^3 \omega_{j,l}^2}{4 \sin^2(\tilde{h} \omega_{j,l}/2)}, \quad \iota_2 := -i \tilde{h}^2 \Omega^2 \left( \tilde{h} \Omega - \cot \zeta + \cos \zeta \csc \zeta \right)^{-1}, \quad (5.3)$$

with  $\zeta := \frac{1}{2} \tilde{h}(\Omega - (\mathbf{k} \cdot \boldsymbol{\omega})I)$ . The remainder appeared in (5.1) is bounded by

$$R_{Z,N}(\tilde{t}) = \mathcal{O}_{L^2}(t \tilde{h}^2 \varepsilon^2 \delta_0^{N+1}), \quad (5.4)$$

where  $\mathcal{O}_{L^2}$  denotes the term bounded with the  $L^2$  norm. The constants symbolised by the notation  $\mathcal{O}$  are independent of  $h, \varepsilon$ , but depend on  $c_0, c_1$  appeared in the conditions of Theorem 3.3.

**Proof. Proof of (5.1).** We first derive the following modulated Fourier expansion of the numerical integrators, i.e., the numerical scheme S2O2 has the formal expansion:

$$\widehat{Z}^n = \Phi(\tilde{t}) := \sum_{\mathbf{k} \in \mathcal{N}_\infty^*} e^{i(\mathbf{k} \cdot \boldsymbol{\omega})\tilde{t}} \alpha^{\mathbf{k}}(\tilde{t}), \quad (5.5)$$

where  $\mathcal{N}_\infty^*$  denotes the set of  $\mathcal{N}_N^*$  with  $N = +\infty$ . With the same arguments of local errors, it can be shown that the error between  $\widehat{Z}^{ni}$  and  $\Phi(\tilde{t} + c_i \tilde{h})$  has the form  $\mathcal{O}_{L^2}(\varepsilon^3 \tilde{h}^2) \ddot{\Phi}(\tilde{t} + \theta \tilde{h})$  for some  $\theta \in [0, c_i]$ . Hence, one can assume that for  $i = 1, 2$

$$\widehat{Z}^{ni} = \Phi(\tilde{t} + c_i \tilde{h}) + C \varepsilon^3 \tilde{h}^2 \mathcal{D}^2 \Phi(\tilde{t} + c_i \tilde{h}),$$

where  $C$  is the error constant which is independent of  $\tilde{h}, \varepsilon$  and  $\mathcal{D}$  is referred to the differential operator (see [28]).

Inserting (5.5) into (2.19) and defining the operators

$$\begin{aligned} \mathcal{L}_1(\tilde{h}\mathcal{D}) &:= (e^{\tilde{h}\mathcal{D}} - e^{\tilde{h}M}) (\bar{b}_1(\tilde{h}M) e^{c_1 \tilde{h}\mathcal{D}} + \bar{b}_2(\tilde{h}M) e^{c_2 \tilde{h}\mathcal{D}})^{-1}, \\ \mathcal{L}_2(\tilde{h}\mathcal{D}) &:= (e^{\tilde{h}\mathcal{D}} - e^{\tilde{h}M}) (\bar{b}_1(\tilde{h}M) (e^{c_1 \tilde{h}\mathcal{D}} + C \varepsilon^3 \tilde{h}^2 \mathcal{D}^2) \\ &\quad + \bar{b}_2(\tilde{h}M) (e^{c_2 \tilde{h}\mathcal{D}} + C \varepsilon^3 \tilde{h}^2 \mathcal{D}^2))^{-1} - \mathcal{L}_1(\tilde{h}\mathcal{D}), \\ \mathcal{L}(\tilde{h}\mathcal{D}) &:= \mathcal{L}_1(\tilde{h}\mathcal{D}) + \mathcal{L}_2(\tilde{h}\mathcal{D}), \end{aligned}$$

one has

$$\mathcal{L}(\tilde{h}\mathcal{D}) \Phi(\tilde{t}) = \tilde{h} \varepsilon \Gamma(\Phi(\tilde{t})).$$

Expanding the nonlinearity into its Taylor series yields

$$\mathcal{L}(\tilde{h}\mathcal{D}) \Phi(\tilde{t}) = h \varepsilon^1 \sum_{\mathbf{k} \in \mathcal{N}_\infty^*} e^{i(\mathbf{k} \cdot \boldsymbol{\omega})\tilde{t}} \sum_{m \geq 2} \frac{\Gamma^{(m)}(0)}{m!} \sum_{\mathbf{k}^1 + \dots + \mathbf{k}^m = \mathbf{k}} \left[ \alpha^{\mathbf{k}^1} \dots \alpha^{\mathbf{k}^m} \right](\tilde{t}).$$

We remark that the assumptions  $f(0) = 0$  and  $f'(0) = 0$  are used here. Inserting the ansatz (5.5) into these expressions and comparing the coefficients of  $e^{i(\mathbf{k} \cdot \boldsymbol{\omega})\tilde{t}}$ , we obtain

$$\mathcal{L}(\tilde{h}\mathcal{D} + i(\mathbf{k} \cdot \boldsymbol{\omega})\tilde{h}) \alpha^{\mathbf{k}}(\tilde{t}) = -\tilde{h} \varepsilon \mathcal{F} \mathcal{S} \sum_{m \geq 2} \frac{\Gamma^{(m)}(0)}{m!} \sum_{\mathbf{k}^1 + \dots + \mathbf{k}^m = \mathbf{k}} \left[ \alpha^{\mathbf{k}^1} \dots \alpha^{\mathbf{k}^m} \right](\tilde{t}).$$

This is the modulation system for the coefficients  $\alpha^{\mathbf{k}}(\tilde{t})$  of the modulated Fourier expansion.

In the light of the coefficients of S2O2, the Taylor expansions of  $\mathcal{L}_1(\tilde{h}\mathcal{D})$  are given by

$$\begin{aligned} \mathcal{L}_1(\tilde{h}\mathcal{D}) &= -\tilde{h} \Omega i + \tilde{h} \mathcal{D} - \frac{1}{2} \tilde{h} \Omega^{-1} (-2I + \tilde{h} \Omega \cot(\tilde{h} \Omega/2)) i \mathcal{D}^2 + \dots, \\ \mathcal{L}_1(\tilde{h}\mathcal{D} + i \tilde{h}(\mathbf{k} \cdot \boldsymbol{\omega})) &= -\tilde{h}^2 \Omega^2 \left( \tilde{h} \Omega - \cot \zeta + \cos \zeta \csc \zeta \right)^{-1} i + \dots, \end{aligned} \quad (5.6)$$

with  $\zeta := \frac{1}{2} \tilde{h}(\Omega - (\mathbf{k} \cdot \boldsymbol{\omega})I)$ . Some particular components we need are expressed as

$$\begin{aligned} (\mathcal{L}_1(\tilde{h}\mathcal{D} + i \tilde{h} \langle j \rangle_l \cdot \boldsymbol{\omega}))_{j,l} &= \frac{\tilde{h}^2 \omega_{j,l}^2}{4 \sin^2(\tilde{h} \omega_{j,l}/2)} \tilde{h} \mathcal{D} \\ &\quad - i \frac{\tilde{h}^2 \omega_{j,l}^2}{16 \sin^4(\tilde{h} \omega_{j,l}/2)} (\tilde{h} \omega_{j,l} - \sin(\tilde{h} \omega_{j,l})) (\tilde{h} \mathcal{D})^2 + \dots \end{aligned} \quad (5.7)$$

Similarly, we get  $\mathcal{L}_2(\tilde{h}\mathcal{D}) = -C\mathcal{D}^2(\mathcal{D} - i\Omega)\varepsilon^3\tilde{h}^3 + \dots$  and this demonstrates that the main part of  $\mathcal{L}(\tilde{h}\mathcal{D})$  comes from  $\mathcal{L}_1(\tilde{h}\mathcal{D})$ . With these Taylor expansions and in the spirit of Euler's derivation of the Euler-Maclaurin summation formula (see Chapter II. 10 of [30]), the following ansatz of the modulated Fourier functions  $\alpha^{\mathbf{k}}(\tilde{t})$  is derived (see [43] for the details of the derivation):

$$\begin{aligned}\dot{\alpha}_{j,l}^{(j)l}(\tilde{t}) &= \frac{\tilde{h}\varepsilon}{\iota_1}\Gamma_{j0}^1(\cdot) + \dots, \quad j = -\frac{N_\tau}{2}, -\frac{N_\tau}{2} + 1, \dots, \frac{N_\tau}{2}, \\ \alpha^{\mathbf{k}}(\tilde{t}) &= \frac{\tilde{h}\varepsilon}{\iota_2}(\Gamma_{j0}^{\mathbf{k}}(\cdot) + \dots), \quad \mathbf{k} \neq \langle j \rangle_l,\end{aligned}\tag{5.8}$$

where the dots mean the power series in  $\tilde{h}$  and  $\Gamma^{\mathbf{k}}$  and so on stand for formal series. We truncate the series after the  $\mathcal{O}_{L^2}(\tilde{h}^{N+N_0})$  terms for arbitrary positive integer  $N_0$  since they often diverge. The initial values for the differential equations appeared in the ansatz are determined by considering  $\Phi(0) = \widehat{Z}^0$ . We thus get  $\widehat{Z}_{j,l}^0 = \alpha_{j,l}^{(j)l}(0) + \mathcal{O}_{abs}(\tilde{h}\varepsilon^2\delta_0^2)$ , which yields  $\alpha_{j,l}^{(j)l}(0) = \mathcal{O}_{abs}(\delta_0)$ .

Under the above analysis, the numerical result obtained from S2O2 can be expressed by (5.1). From the construction of the coefficient functions, it follows that it is reasonable to assume  $\alpha_{0,l}^{\mathbf{k}} = 0$  if  $\mathbf{k} \neq \langle 0 \rangle_l$  and  $\alpha_{:,m}^{\mathbf{k}} = 0$  if  $|\mathbf{k}_{:,l}| > 0$  and  $l \neq m$ . Considering the fact  $\widehat{Z}^n \in \mathbb{R}^D$  yields that  $\alpha_{-,j}^{-\mathbf{k}} = \overline{\alpha_{l,j}^{\mathbf{k}}}$ .

**Proof of (5.2).** In what follows, we derive the bounds of the coefficient functions  $\alpha^{\mathbf{k}}(\tilde{t})$ . By the first formula of (5.8), we obtain a coarse estimate as  $\dot{\alpha}_{j,l}^{(j)l}(\tilde{t}) = \mathcal{O}_{abs}\left(\frac{\tilde{h}\varepsilon}{\iota_1}\right)\mathcal{O}_{L^2}(\Gamma^1) = \mathcal{O}_{abs}\left(\frac{\tilde{h}\varepsilon}{\iota_1}\right)$  and by further considering the bound of  $\alpha_{j,l}^{(j)l}(0)$ ,  $\alpha_{j,l}^{(j)l}(\tilde{t}) = \mathcal{O}_{abs}(\delta_0)$ . Based on this estimate, it is deduced that  $\Gamma^{\mathbf{k}} = \mathcal{O}_{L^2}(\delta_0^{|\mathbf{k}|})$ . Therefore,  $\alpha_{j,l}^{\mathbf{k}}(\tilde{t})$  is bounded as  $\alpha_{j,l}^{\mathbf{k}}(\tilde{t}) = \mathcal{O}_{abs}\left(\frac{\tilde{h}\varepsilon}{\|\iota_2\|_{L^2}}\delta_0^{|\mathbf{k}|}\right)$  by the second formula of (5.8). According to these estimates, a finer bound of  $\Gamma^1$  is determined by  $\sum_{\mathbf{k}^1 + \dots + \mathbf{k}^m = \langle j \rangle_l} \left[ \eta_{j,l}^{\mathbf{k}^1} \dots \eta_{j,l}^{\mathbf{k}^m} \right]$ , which yields  $\Gamma^1 = \mathcal{O}_{L^2}\left(\frac{\tilde{h}\varepsilon}{\iota_2}\delta_0^3\right)$ . Thence,  $\dot{\alpha}_{j,l}^{(j)l}(\tilde{t}) = \mathcal{O}_{abs}\left(\frac{\tilde{h}^2\varepsilon^2}{\iota_1\|\iota_2\|_{L^2}}\delta_0^3\right)$ . Therefore, the bounds presented in (5.2) are derived.

**Proof of (5.4).** Finally, we show the bound of remainder (5.4). First insert  $\Phi(\tilde{t})$  into the numerical scheme (2.19) and then the corresponding discrepancies are (here we omit  $(\tilde{h}M)$  for conciseness)

$$\begin{aligned}d_1(\tilde{t}) &= \Phi(\tilde{t} + c_1\tilde{h}) - e^{c_1\tilde{h}M}\Phi(\tilde{t}) - \tilde{h}\varepsilon(\bar{a}_{11}\Gamma(\Phi(\tilde{t} + c_1\tilde{h})) + \bar{a}_{12}\Gamma(\Phi(\tilde{t} + c_2\tilde{h}))), \\ d_2(\tilde{t}) &= \Phi(\tilde{t} + c_2\tilde{h}) - e^{c_2\tilde{h}M}\Phi(\tilde{t}) - \tilde{h}\varepsilon(\bar{a}_{21}\Gamma(\Phi(\tilde{t} + c_1\tilde{h})) + \bar{a}_{22}\Gamma(\Phi(\tilde{t} + c_2\tilde{h}))), \\ d_3(\tilde{t}) &= \Phi(\tilde{t} + \tilde{h}) - e^{\tilde{h}M}\Phi(\tilde{t}) - \tilde{h}\varepsilon(\bar{b}_1\Gamma(\Phi(\tilde{t} + c_1\tilde{h})) + \bar{b}_2\Gamma(\Phi(\tilde{t} + c_2\tilde{h}))).\end{aligned}$$

There are two aspects in the bounds of these discrepancies:  $\mathcal{O}_{L^2}\left(\frac{\tilde{h}\varepsilon}{\iota_2}\delta_0^{N+1}\right) = \mathcal{O}_{L^2}(\tilde{h}\varepsilon^2\delta_0^{N+1})$  in the truncation of modulated Fourier expansions and  $\mathcal{O}_{L^2}(\tilde{h}^{N+N_0})$  in the truncation of the ansatz (5.8). Therefore, discrepancies are bounded by  $d_j(\tilde{t}) = \mathcal{O}_{L^2}(\tilde{h}^{N+N_0}) + \mathcal{O}_{L^2}(\tilde{h}^2\varepsilon^2\delta_0^{N+1}) = \mathcal{O}_{L^2}(\tilde{h}^2\varepsilon^2\delta_0^{N+1})$  for  $j = 1, 2, 3$  on the basis of the arbitrarily large  $N_0$ . Then define the errors  $e_n^Z = \widehat{Z}^n - \Phi(\tilde{t}_n)$ ,  $E_{ni}^Z = \widehat{Z}^{ni} - \Phi(\tilde{t}_n + c_i\tilde{h})$ . They satisfy the error recursion

$$\begin{aligned}E_{ni}^Z &= e^{c_i\tilde{h}M}e_n^Z + \tilde{h}\varepsilon \sum_{\rho=1}^2 \bar{a}_{i\rho}(\tilde{h}M)(\Gamma(\widehat{Z}^{n\rho}) - \Gamma(\Phi(\tilde{t}_n + c_\rho\tilde{h}))) + d_i(\tilde{t}_n), \quad i = 1, 2, \\ e_{n+1}^Z &= e^{\tilde{h}M}e_n^Z + \tilde{h}\varepsilon \sum_{\rho=1}^2 \bar{b}_\rho(\tilde{h}M)(\Gamma(\widehat{Z}^{n\rho}) - \Gamma(\Phi(\tilde{t}_n + c_\rho\tilde{h}))) + d_3(\tilde{t}_n).\end{aligned}$$

Taking the Lipschitz condition into account, we obtain

$$\left\| \Gamma(\widehat{Z}^{n\rho}) - \Gamma(\Phi(\tilde{t}_n + c_\rho\tilde{h})) \right\|_{L^2} \leq L \|E_{n\rho}^Z\|_{L^2}.$$

The application of the Gronwall inequality now shows the bound of the defect (5.4).  $\square$

**II. Almost-invariant.** We have derived the modulated Fourier expansion (5.1) of S2O2 integrator and its long time energy conservation will be studied on the basis of an almost-invariant of the coefficient functions of (5.1). Using the same arguments of [43], the almost-invariant can be derived as follows.

**Lemma 5.2.** Define the almost-invariant  $\mathcal{H} := \frac{1}{\varepsilon^2}\mathcal{I} + \mathcal{H}_1$ , which satisfies

$$\varepsilon^2\mathcal{H}(\tilde{t}) = \varepsilon^2\mathcal{H}(0) + \mathcal{O}_{abs}(\tilde{t}\varepsilon^2\delta_0^{N+1}).$$

Here  $\mathcal{I}$  and  $\mathcal{H}_1$  are expressed as

$$\begin{aligned}\mathcal{I}(\tilde{t}) &= \sum_{l=1}^{\tilde{d}} \sum_{j=-N_\tau/2}^{N_\tau/2} \left( \Omega_{l,l}^2 \left| \alpha_{j,l}^{(j)} \right|^2 (\tilde{t}) + \left| \alpha_{j,l+\tilde{d}}^{(j)} \right|^2 (\tilde{t}) \right) + \mathcal{O}_{abs}(\varepsilon^4\delta_0^4), \\ \mathcal{H}_1(\tilde{t}) &= \mathcal{V}(\vec{\alpha}) + \mathcal{O}_{abs}(\varepsilon^3\delta_0^4),\end{aligned}$$

with  $\vec{\alpha} = (\alpha^{\mathbf{k}})_{\mathbf{k} \in N^*}$  and the potential

$$\mathcal{V}(\vec{\alpha}) := \sum_{m=1}^N \frac{H_1^{(m+1)}(0)}{(m+1)!} \sum_{\mathbf{k}^1 + \dots + \mathbf{k}^{m+1} = \mathbf{0}} \left( \alpha_h^{\mathbf{k}^1} \dots \alpha_h^{\mathbf{k}^{m+1}} \right) (t).$$

Here we use the notation  $\alpha_h^{\mathbf{k}}(\tilde{t}) = e^{i(\mathbf{k} \cdot \boldsymbol{\omega})t} \alpha^{\mathbf{k}}(\tilde{t})$  and the potential  $H_1$  given in (1.2). Moreover, the relationship between this almost-invariant and the result  $H$  of the numerical method is derived as

$$\varepsilon^2\mathcal{H}(\tilde{t}_n) = \varepsilon^2 H(u^n, v^n) + \mathcal{O}_{abs}(\varepsilon^4\delta_0^4) + \mathcal{O}_{abs}(\delta_{\mathcal{F}}).$$

With the above results, it is easy to get

$$\begin{aligned}\varepsilon^2 H(\tilde{q}^n, \tilde{p}^n) &= \varepsilon^2 \mathcal{H}(\tilde{t}_n) + \mathcal{O}_{abs}(\varepsilon^4\delta_0^4) + \mathcal{O}_{abs}(\delta_{\mathcal{F}}) \\ &= \varepsilon^2 \mathcal{H}(\tilde{t}_{n-1}) + h\mathcal{O}_{abs}(\tilde{t}\varepsilon^2\delta_0^{N+1}) + \mathcal{O}_{abs}(\varepsilon^4\delta_0^4) + \mathcal{O}_{abs}(\delta_{\mathcal{F}}) \\ &= \dots = \varepsilon^2 H(u^0, v^0) + \mathcal{O}_{abs}(\varepsilon^4\delta_0^4) + \mathcal{O}_{abs}(\delta_{\mathcal{F}})\end{aligned}$$

as long as  $n\tilde{h}^2\varepsilon^2\delta_0^{N+1} \leq \varepsilon^4\delta_0^4$ . Then using the connection of  $H_2$  with  $H$  completes the proof of Theorem 3.3 for S2O2.

**III. Proof for S3O4.** For the integrator S3O4, it follows from its coefficients that  $\widehat{Z^{nj}} = \Phi(\tilde{t} + c_j\tilde{h}) + C\varepsilon^5\tilde{h}^4\mathcal{D}^4\Phi(\tilde{t} + c_j\tilde{h})$  for  $j = 1, 2, 3$  with the error constant  $C$ . We define the operator

$$\begin{aligned}\mathcal{L}_{S3}(\tilde{h}\mathcal{D}) &:= (e^{\tilde{h}\mathcal{D}} - e^{\tilde{h}M}) \left( \bar{b}_1(\tilde{h}M)(e^{c_1\tilde{h}\mathcal{D}} + C\varepsilon^5\tilde{h}^4\mathcal{D}^4) \right. \\ &\quad \left. + \bar{b}_2(\tilde{h}M)(e^{c_1\tilde{h}\mathcal{D}} + C\varepsilon^5\tilde{h}^4\mathcal{D}^4) + \bar{b}_3(\tilde{h}M)(e^{c_1\tilde{h}\mathcal{D}} + C\varepsilon^5\tilde{h}^4\mathcal{D}^4) \right)^{-1}\end{aligned}$$

for S3O4. Then the rest proceeds similarly to that stated above for S2O2. It should be noted that the bounds of the coefficients in modulated expansion have the same expression as S2O2. For S3O4, the notations  $\iota_1, \iota_2, \iota_2$  appeared in the above proof (5.3) become

$$\iota_1 := \frac{\tilde{h}^4\omega_{j,l}^3}{\sin^3(\tilde{h}\omega_{j,l}/4)(64\cos(\tilde{h}\omega_{j,l}/4)+16\tilde{h}\omega_{j,l}\sin(\tilde{h}\omega_{j,l}/4))}, \quad \iota_2 := \mathcal{O}_{abs}(\tilde{h})\Omega,$$

based on the Taylor expansion of  $\mathcal{L}_{S3}$ . Therefore, the energy at S3O4 has the following relation with the almost-invariant  $\mathcal{H}$ :  $\varepsilon^2\mathcal{H}(\tilde{t}_n) = \varepsilon^2 H(u^n, v^n) + \mathcal{O}_{abs}(\varepsilon^4\delta_0^4) + \mathcal{O}_{abs}(\delta_{\mathcal{F}})$ . This result yields the estimate of S3O4 given in Theorem 3.3.  $\square$

## 6. CONCLUSION

In this paper, we have designed and analyzed symmetric integrators for the nonlinear relativistic Klein–Gordon equation with a dimensionless parameter  $0 < \varepsilon \ll 1$ . Using three transformations of the original system, two-scale formulation approach, spectral semi-discretisation and symmetric  $s$ -stage exponential integrators, a class of large-stepsize highly accurate integrators was formulated as the numerical approximation of (1.1) with large initial data. Stiff order conditions and symmetric property were used in the construction of practical methods. The proposed integrators were shown to have not only improved uniform accuracy but also good long-term energy conservation. The numerical results of a numerical experiment supported the properties of the obtained integrators.

Last but not least, we point out that the main contribution of this paper is that we have established a new framework to design improved uniform higher-order integrators with long time behavior for solving highly oscillatory differential equations with strong nonlinearity. We believe that the methodology presented in this paper can be extended to a range of nonlinear Hamiltonian PDEs such as the Dirac equation and Schrödinger equation. The rigorous analysis on this topic

will be considered in our next work. Another issue for future exploration is the study of uniform higher-order integrators with exact structure conservation such as symplecticity and energy.
