# VARIATION OF HODGE STRUCTURES FOR NON-KÄHLER MANIFOLDS 

WEI XIA

#### Abstract

In this note, we discuss variation of Hodge structures on non-Kähler manifolds. In particular, given a holomorphic family of $\partial \bar{\partial}$-manifolds the period map is shown to be holomorphic and transversal.

## 1. Introduction

The theory of variation of Hodge structures (VHS for short) is a extensively studied subject in complex geometry and mathematical physics [GGK13, CMSP17, KP16, CK99]. The purpose of this note is to extend some parts of Griffiths' classical theory of VHS [Gri68] to the non-Kähler setting. There are two motivations to do this, the first one is the works of Popovici and Anthes-Cattaneo-Rollenske-Tomassini [Pop19, ACRT18] where they showed local Torelli theorem holds for Clabi-Yau $\partial \bar{\partial}$-manifolds and $\partial \bar{\partial}$-complex symplectic manifolds, respectively; the second one is that we want to understand the proof of Voisin on a density criterion of complex projective manifolds [Voi05].

Given a holomorphic family of $\partial \bar{\partial}$-manifolds $\pi:(\mathcal{X}, X) \rightarrow(B, 0)$ and $0 \leq p \leq k \leq$ $n=: \operatorname{dim}_{\mathbb{C}} X$, the period map is defined as follows

$$
\begin{equation*}
\Phi^{p, k}: B \longrightarrow \operatorname{Grass}\left(f^{p, k}, H^{k}(X, \mathbb{C})\right), \quad t \longmapsto F^{p} H^{k}\left(X_{t}\right), \tag{1.1}
\end{equation*}
$$

where $f^{p, k}:=\operatorname{dim} F^{p} H^{k}(X)$ and

$$
F^{p} H^{k}\left(X_{t}\right):=\operatorname{im}\left(\oplus_{r \geq p} H_{B C}^{r, k-r}(X) \longrightarrow H^{k}(X, \mathbb{C})\right)
$$

Theorem 1.1 (=Theorem 4.4). Let $\pi:(\mathcal{X}, X) \rightarrow(B, 0)$ holomorphic family of $\partial \bar{\partial}-$ manifolds and assume $X$ is equipped with a fixed Hermitian metric.
(i) The period map $\Phi^{p, k}$ as defined in (1.1) is holomorphic;
(ii) Griffiths transversality: the tangent map

$$
\begin{aligned}
& \qquad d \Phi_{0}^{p, k}: T_{0} B \longrightarrow \operatorname{Hom}\left(F^{p} H^{k}(X), H^{k}(X, \mathbb{C}) / F^{p} H^{k}(X)\right) \\
& \text { has values in } \operatorname{Hom}\left(F^{p} H^{k}(X), F^{p-1} H^{k}(X) / F^{p} H^{k}(X)\right) .
\end{aligned}
$$

A main ingredient of this theorem is the fact that the exponential operator preserves Hodge structures, see Theorem 4.2.

## 2. The exponential operator

The exponential operator

$$
e^{i_{\phi(t)}}:=\sum_{k=0}^{\infty} \frac{i_{\phi(t)}^{k}}{k!}
$$

which first appear in the work of Todorov (see Remark 2.4.9. in [Tod89, pp.339]) turns out to be very useful for the studying of deformations of complex manifolds, see e.g. [Cle05, LSY09, LRY15, RZ18, Xia21b, LS20]. Let $\pi:(\mathcal{X}, X) \rightarrow(B, 0)$ be a complex analytic family in the sense of Kodaira-Spencer, that is, $\pi$ is a holomorphic submersion which is surjective and proper over the connected complex manifold $B$. Assume $B$ is a small polydisc (centered in 0 ) with coordinates $t=\left(t_{1}, t_{2}, \cdots\right)$, then by Ehresmann's theorem we have the following commutative diagram

where $F$ is a diffeomorphism. For any $t \in B$ set $f_{t}:=\left.F\right|_{X \times\{t\}}$, then $f_{t}$ is a diffeomorphism from $X$ to $X_{t}$. We use the isomorphism

$$
f_{t}^{*}: A^{\bullet}\left(X_{t}\right) \longrightarrow A^{\bullet}(X)
$$

to identify forms/cohomology on $X_{t}$ with forms/cohomology on $X$. Let $z^{1}, \cdots, z^{n}$ and $w^{1}, \cdots, w^{n}$ be holomorphic coordinates on $X$ and $X_{t}$ respectively, the Beltrami differential can be defined by

$$
\begin{equation*}
\phi(t):=\left(\frac{\partial w}{\partial z}\right)_{\alpha \gamma}^{-1} \frac{\partial w^{\gamma}}{\partial \bar{z}^{\beta}} d \bar{z}^{\beta} \otimes \frac{\partial}{\partial z^{\alpha}} \in A^{0,1}\left(X, T^{1,0}\right) \tag{2.1}
\end{equation*}
$$

where by abuse of notations, we write $w^{i}=f_{t}^{*} w^{i}=w^{i} \circ f_{t}$ for each $i=1,2, \cdots, n$. From

$$
\begin{equation*}
d w^{\beta}=\frac{\partial w^{\beta}}{\partial z^{\alpha}} d z^{\alpha}+\frac{\partial w^{\beta}}{\partial \bar{z}^{\alpha}} d \bar{z}^{\alpha}=\frac{\partial w^{\beta}}{\partial z^{\alpha}}\left(1+i_{\phi(t)}\right) d z^{\alpha}, \tag{2.2}
\end{equation*}
$$

and

$$
e^{i_{\phi(t)}}\left(d z^{i_{1}} \wedge \cdots \wedge d z^{i_{p}}\right)=\left(d z^{i_{1}}+i_{\phi(t)} d z^{i_{1}}\right) \wedge \cdots \wedge\left(d z^{i_{p}}+i_{\phi(t)} d z^{i_{p}}\right),
$$

We see that

$$
\begin{equation*}
e^{i_{\phi(t)}}: A^{p, 0}(X) \longrightarrow A^{p, 0}\left(X_{t}\right) . \tag{2.3}
\end{equation*}
$$

We will use the following formula (c.f. [Man04, LRY15, Xia19]):

$$
\begin{equation*}
d_{\phi(t)}:=e^{-i_{\phi(t)}} d e^{i_{\phi(t)}}=\partial+\bar{\partial}_{\phi(t)}=\partial+\bar{\partial}-\mathcal{L}_{\phi(t)}^{1,0}, \tag{2.4}
\end{equation*}
$$

where $\mathcal{L}_{\phi(t)}^{1,0}:=i_{\phi(t)} \partial-\partial i_{\phi(t)}$ is the Lie derivative. A remarkable property about the exponential operator (as observed in [FM06, FM09, WZ20]) is that while it does not preserve all the types of $(p, q)$-forms, it does map elements in a filtration on $X$ to elements in the corresponding filtration on $X_{t}$ :

$$
\begin{equation*}
e^{i_{\phi(t)}}: F^{p} A^{k}(X)=\oplus_{p \leq \lambda \leq n} A^{\lambda, k-\lambda}(X) \longrightarrow F^{p} A^{k}\left(X_{t}\right), \tag{2.5}
\end{equation*}
$$

where $n=\operatorname{dim}_{\mathbb{C}} X$. In fact, let $\varphi \in A^{\lambda, k-\lambda}(X)$ with $p \leq \lambda \leq k$, locally we write $\varphi=\varphi_{I J} d z^{I} \wedge d \bar{z}^{J}$ where $d z^{I}=d z^{i_{1}} \wedge \cdots \wedge d z^{i_{\lambda}}$ and $d \bar{z}^{J}=d \bar{z}^{j_{1}} \wedge \cdots \wedge d \bar{z}^{j_{k-\lambda}}$, then

$$
\begin{aligned}
& e^{i_{\phi(t)}} \varphi \\
= & \varphi_{I J}\left(e^{i_{\phi(t)}} d z^{I}\right) \wedge d \bar{z}^{J} \\
= & \varphi_{I J}\left(e^{i_{\phi(t)}} d z^{I}\right) \wedge\left(\frac{\partial \bar{z}^{j_{1}}}{\partial w^{l}} d w^{l}+\frac{\partial \bar{z}^{j_{1}}}{\partial \bar{w}^{l}} d \bar{w}^{l}\right) \wedge \cdots \wedge\left(\frac{\partial \bar{z}^{j_{k-\lambda}}}{\partial w^{l}} d w^{l}+\frac{\partial \bar{z}^{j_{k-\lambda}}}{\partial \bar{w}^{l}} d \bar{w}^{l}\right),
\end{aligned}
$$

which is clearly an element in $F^{p} A^{k}\left(X_{t}\right)$.

## 3. The canonical Bott-Chern deformation of $(p, q)$-forms

The Bott-Chern cohomology of $X$ is defined by

$$
H_{B C}^{\bullet \bullet \bullet}(X):=\frac{\operatorname{ker} d \cap A^{\bullet \bullet \bullet}(X)}{\operatorname{im} \partial \bar{\partial} \cap A^{\bullet \bullet \bullet}(X)} .
$$

3.1. Hodge decomposition for Bott-Chern cohomology. Let $X$ be a compact complex manifold equipped with a fixed Hermitian metric. The Bott-Chern Laplacian operator $\square_{B C}: A^{\bullet \bullet}(X) \rightarrow A^{\bullet \bullet}(X)$ is defined as

$$
\begin{equation*}
\square_{B C}:=(\partial \bar{\partial})(\partial \bar{\partial})^{*}+(\partial \bar{\partial})^{*}(\partial \bar{\partial})+\left(\bar{\partial}^{*} \partial\right)\left(\bar{\partial}^{*} \partial\right)^{*}+\left(\bar{\partial}^{*} \partial\right)^{*}\left(\bar{\partial}^{*} \partial\right)+\bar{\partial}^{*} \bar{\partial}+\partial^{*} \partial, \tag{3.1}
\end{equation*}
$$

Define the Bott-Chern harmonic space by

$$
\begin{equation*}
\mathcal{H}_{B C}:=\operatorname{ker} \square_{B C}=\operatorname{ker} \partial \cap \operatorname{ker} \bar{\partial} \cap \operatorname{ker}(\partial \bar{\partial})^{*}, \tag{3.2}
\end{equation*}
$$

then the following orthogonal direct sum decomposition holds:

$$
\begin{equation*}
A^{\bullet \bullet}(X)=\operatorname{ker} \square_{B C} \oplus \operatorname{im} \partial \bar{\partial} \oplus\left(\operatorname{im} \partial^{*}+\operatorname{im} \bar{\partial}^{*}\right) \tag{3.3}
\end{equation*}
$$

which is equivalent to the existence of the Green operator $G_{B C}$ such that

$$
1=\mathcal{H}_{B C}+\square_{B C} G_{B C}
$$

where $\mathcal{H}_{B C}$ denotes the orthogonal projection operator to the Bott-Chern harmonic space.

### 3.2. Canonical Bott-Chern deformations. Recall the following

Definition 3.1. [Xia21b] Let $\pi:(\mathcal{X}, X) \rightarrow(B, 0)$ be a small deformation of a compact complex manifold $X$ over a small polydisc $B$ centered in 0 such that for each $t \in B$ the complex structure on $X_{t}$ is represented by Beltrami differential $\phi(t)$. Given $y \in \operatorname{ker} d \cap A^{p, q}(X)$ and $T \subseteq B$, which is a complex subspace (i.e. analytic subset) of $B$ containing 0, a Bott-Chern deformation of $y$ (w.r.t. $\pi:(\mathcal{X}, X) \rightarrow(B, 0))$ on $T$ is a family of $(p, q)$-forms $\sigma(t) \in A^{p, q}(X)$ such that

1. $\sigma(t)$ is holomorphic in $t \in T$ and $\sigma(0)=y$;
2. $d_{\phi(t)} \sigma(t)=0, \forall t \in T$.

We will always assume $X$ has been equipped with a fixed Hermitian metric. A BottChern deformation $\sigma(t)$ of $y$ on $T$ is called canonical if

$$
\sigma(t)=\sigma_{0}-G_{B C}\left(\bar{\partial}^{*} \partial \partial^{*}+\bar{\partial}^{*}\right) \partial i_{\phi(t)} \sigma(t), \quad \forall t \in T
$$

It can be shown that for any given $\sigma_{0} \in \mathcal{H}_{B C}^{p, q}(X)$, its canonical Bott-Chern deformation exists on an analytic subset of $B$ and is uniquely given by a convergent power series as follows,

$$
\sigma(t)=\sum_{k} \sigma_{k} \in A^{p, q}(X) \quad \text { and } \quad \sigma_{k}=-G_{B C}\left(\bar{\partial}^{*} \partial \partial^{*}+\bar{\partial}^{*}\right) \sum_{i+j=k} \partial i_{\phi_{j}} \sigma_{i}
$$

where $\phi(t)=\sum_{j} \phi_{j}$ and each $\phi_{j}, \sigma_{k}$ is a homogeneous polynomial of degree $k$ with coefficients in $A^{0,1}\left(X, T^{1,0}\right), A^{p, q}(X)$ respectively. Note that up to contraction to a smaller polydisc if possible we may assume the power series $\sigma(t)$ converges on $B$. It may happen that for some $t \in B, d_{\phi(t)} \sigma(t) \neq 0$ or $\sigma(t)$ is $d_{\phi(t)}$-exact. These are exactly the two facts which make $\operatorname{dim} H_{B C \phi(t)}^{p, q}(X)$ different from $\operatorname{dim} H_{B C}^{p, q}(X)$, where

$$
H_{B C \phi(t)}^{p, q}(X):=\frac{\operatorname{ker} d_{\phi(t)} \cap A^{p, q}(X)}{\operatorname{im} \partial \bar{\partial}_{\phi(t)} \cap A^{p, q}(X)}
$$

is the deformed Bott-Chern cohomology and

$$
\bar{\partial}_{\phi(t)}: A^{p, q}(X) \longrightarrow A^{p, q+1}(X),
$$

is the deformed Dolbeault operator defined by $\bar{\partial}_{\phi(t)}:=\bar{\partial}-\mathcal{L}_{\phi(t)}^{1,0}$ (c.f. [Xia22, Xia21a]) In fact, for any $t \in B$ and a vector subspace $V \subseteq \mathcal{H}_{B C}^{p, q}(X)$, we set

$$
V_{t}:=\left\{\sigma_{0} \in V \mid \sigma(t) \in \operatorname{ker} d_{\phi(t)}, \text { where } \sigma(t) \text { is the canonical deformation of } \sigma_{0}\right\} .
$$

The following mapping

$$
\begin{aligned}
\tilde{f}_{t}: V_{t} & \longrightarrow \operatorname{ker}(\partial \bar{\partial})^{*} \cap \operatorname{ker} d_{\phi(t)} \cap A^{p, q}(X), \\
\sigma_{0} & \longmapsto \sigma(t)=\sum_{k} \sigma_{k}, \text { where } \sigma_{k}=-G_{B C}\left(\bar{\partial}^{*} \partial \partial^{*}+\bar{\partial}^{*}\right) \sum_{i+j=k} \partial i_{\phi_{j}} \sigma_{i}, \forall k \neq 0,
\end{aligned}
$$

is an isomorphism and

$$
\begin{aligned}
f_{t}: V_{t} & \longrightarrow \frac{\operatorname{ker}(\partial \bar{\partial})^{*} \cap \operatorname{ker} d_{\phi(t)} \cap A^{p, q}(X)}{\operatorname{ker}(\partial \bar{\partial})^{*} \cap \operatorname{im} \partial \bar{\partial}_{\phi(t)} \cap A^{p, q}(X)} \cong H_{B C \phi(t)}^{p, q}(X), \\
\sigma_{0} & \longmapsto\left[\tilde{f}_{t} \sigma_{0}\right] .
\end{aligned}
$$

is surjective with kernel equal to $\operatorname{ker}(\partial \bar{\partial})^{*} \cap \operatorname{im} \partial \bar{\partial}_{\phi(t)} \cap A^{p, q}(X)$. The following result give a precise description about the relation between the behavior of canonical Bott-Chern deformations and the changing of $\operatorname{dim} H_{B C \phi(t)}^{p, q}(X)$ (see Theorem 4.13 and Proposition 4.3 in [Xia21b]):

Theorem 3.2. Let $\pi:(\mathcal{X}, X) \rightarrow(B, 0)$ be a small deformation of a compact Hermitian manifold $X$ such that for each $t \in B$ the complex structure on $X_{t}$ is represented by a Beltrami differential $\phi(t)$. For each $(p, q) \in \mathbb{N} \times \mathbb{N}$, set

$$
v_{t}^{p, q}:=\operatorname{dim} H_{B C}^{p, q}(X)-\operatorname{dim} \operatorname{ker} d_{\phi(t)} \cap \operatorname{ker}(\partial \bar{\partial})^{*} \cap A^{p, q}(X) \geq 0,
$$

and

$$
u_{t}^{p, q}:=\operatorname{dim} H_{B C}^{p, q}(X)-\operatorname{dim} \operatorname{ker} \partial \bar{\partial}_{\phi(t)} \cap\left(\mathcal{H}_{B C}^{p, q}(X)+i m(\partial \bar{\partial})^{*}\right) \cap A^{p, q}(X) \geq 0,
$$

then we have

$$
\operatorname{dim} \operatorname{ker}(\partial \bar{\partial})^{*} \cap i m \partial \bar{\partial}_{\phi(t)} \cap A^{p, q}(X)=\operatorname{dim} u_{t}^{p-1, q-1}
$$

and

$$
\begin{equation*}
\operatorname{dim} H_{B C}^{p, q}(X)=\operatorname{dim} H_{B C \phi(t)}^{p, q}(X)+v_{t}^{p, q}+u_{t}^{p-1, q-1} . \tag{3.4}
\end{equation*}
$$

3.3. Bott-Chern deformations on $\partial \bar{\partial}$-manifold. Let $X$ be a compact complex manifold satisfying the $\partial \bar{\partial}$-lemma, see [DGMS75, Pop19, AT13] for more information. Such manifolds will be called a $\partial \bar{\partial}$-manifold.

Proposition 3.3. Let $\pi:(\mathcal{X}, X) \rightarrow(B, 0)$ be a deformation of a $\partial \bar{\partial}$-manifold $X$ (equipped with a fixed Hermitian metric) over a small polydisc $B$ such that for each $t \in B$ the complex structure on $X_{t}$ is represented by a Beltrami differential $\phi(t)$. Then for any $\sigma_{0} \in \mathcal{H}_{B C}^{p, q}(X)$ its canonical Bott-Chern deformation $\sigma(t)=\sum_{k} \sigma_{k}$ exists on $B$ and if $\sigma(t) \in$ im $\partial \bar{\partial}_{\phi(t)}$ then $\sigma_{0}=0$.

Proof. First, since $X$ satisfies the $\partial \bar{\partial}$-lemma, we have that $X_{t}$ satisfies the $\partial_{t} \bar{\partial}_{t}$-lemma [Wu06, AT13] and also the $\partial \bar{\partial}_{\phi(t)}$-lemma holds for each $t \in B$ (see [Xia21b, Coro. 5.5]) which implies that

$$
\operatorname{dim} H_{B C \phi(t)}^{p, q}(X)=\operatorname{dim} H_{\bar{\partial}_{t}}^{p, q}\left(X_{t}\right)=\operatorname{dim} H_{B C}^{p, q}\left(X_{t}\right)=\operatorname{dim} H_{B C}^{p, q}(X), \quad \forall t \in B,
$$

where in the last equality we have used the deformation invariance of Hodge numbers for $\partial \bar{\partial}$-manifolds. Now by Theorem 3.2 we have

$$
v_{t}^{p, q}=\operatorname{dim} H_{B C}^{p, q}(X)-\operatorname{dim} \operatorname{ker} d_{\phi(t)} \cap \operatorname{ker}(\partial \bar{\partial})^{*} \cap A^{p, q}(X)=0,
$$

and

$$
u_{t}^{p-1, q-1}=\operatorname{dim} \operatorname{ker}(\partial \bar{\partial})^{*} \cap \operatorname{im} \partial \bar{\partial}_{\phi(t)} \cap A^{p, q}(X)=0 .
$$

The former equality says that for $V=\mathcal{H}_{B C}^{p, q}(X)$, the mapping

$$
\tilde{f}_{t}: \mathcal{H}_{B C}^{p, q}(X) \rightarrow \operatorname{ker}(\partial \bar{\partial})^{*} \cap \operatorname{ker} d_{\phi(t)} \cap A^{p, q}(X)
$$

defined as above is an isomorphism which shows that for any $\sigma_{0} \in \mathcal{H}_{B C}^{p, q}(X)$ its canonical Bott-Chern deformation $\sigma(t)=\sum_{k} \sigma_{k}$ is $d_{\phi(t)}$-closed for any $t \in B$. The latter equality implies that if $\sigma(t) \in \operatorname{im} \partial \bar{\partial}_{\phi(t)}$ then $\sigma_{0}=0$ in view of the mapping $f_{t}$.

## 4. Deformations of Hodge filtration

On a $\partial \bar{\partial}$-manifold $X$, there is a natural Hodge decomposition given by ${ }^{1}$

$$
\begin{equation*}
H^{k}(X, \mathbb{C})=\oplus_{p+q=k} H_{B C}^{p, q}(X), \quad \text { with } H_{B C}^{p, q}(X):=\frac{\operatorname{ker} d \cap A^{p, q}(X)}{\operatorname{im} \partial \bar{\partial} \cap A^{p, q}(X)} \tag{4.1}
\end{equation*}
$$

[^0]Together with $H^{k}(X, \mathbb{Z}) /$ Tor, where Tor denotes the torsion subgroup of $H^{k}(X, \mathbb{Z})$, (4.1) define an integral Hodge structure of weight $k$. Equivalently, this Hodge structure can be determined by the Hodge filtration

$$
\begin{equation*}
H^{k}(X, \mathbb{C})=F^{0} H^{k}(X) \supseteq \cdots \supseteq F^{k} H^{k}(X)=H^{k, 0}(X) \tag{4.2}
\end{equation*}
$$

where

$$
F^{p} H^{k}\left(X_{t}\right):=\operatorname{im}\left(\oplus_{r \geq p} H_{B C}^{r, k-r}(X) \longrightarrow H^{k}(X, \mathbb{C})\right)
$$

Lemma 4.1. Let $X$ be a $\partial \bar{\partial}$-manifold. If $\sigma \in F^{p} A^{k}(X) \cap \operatorname{ker} d$, then there exists $x \in A^{k-1}(X)$ and $\beta^{r, k-r} \in A^{r, k-r}(X) \cap$ ker $d$ for each $r \geq p$ such that

$$
\sigma=d x+\sum_{r \geq p} \beta^{r, k-r} .
$$

Proof. Since $X$ is a $\partial \bar{\partial}$-manifold, we have $[\sigma] \in H^{k}(X, \mathbb{C})=\oplus_{p+q=k} H_{B C}^{p, q}(X)$ which implies that there exists $x \in A^{k-1}(X)$ and $\beta^{r, k-r} \in A^{r, k-r}(X) \cap \operatorname{ker} d$ for each $r \geq 0$ such that

$$
\sigma=d x+\sum_{r \geq 0} \beta^{r, k-r}
$$

Now because $\sigma \in F^{p} A^{k}(X)$, we have

$$
\sigma=\sum_{r \geq p} \partial x^{r-1, k-r}+\sum_{r \geq p} \bar{\partial} x^{r, k-r-1}+\sum_{r \geq p} \beta^{r, k-r},
$$

where $x=\sum_{r \geq 0} x^{r, k-r}$ with $x^{r, k-r} \in A^{r, k-r}(X)$. Rearranging this identity, we get

$$
\sigma=d \sum_{r \geq p+1} x^{r-1, k-r}+\partial x^{p-1, k-p}+\sum_{r \geq p} \beta^{r, k-r}
$$

which shows that $\partial x^{p-1, k-p} \in A^{p, k-p}(X) \cap$ ker $d$. Hence $\partial x^{p-1, k-p}=\partial \bar{\partial} y^{p-1, k-p-1}$ for some $y^{p-1, k-p-1} \in A^{p-1, k-p-1}(X)$ by the $\partial \bar{\partial}$-lemma. The conclusion follows.

Theorem 4.2. Let $\pi:(\mathcal{X}, X) \rightarrow(B, 0)$ be a deformation of a $\partial \bar{\partial}$-manifold $X$ (equipped with a fixed Hermitian metric) over a small polydisc $B$ such that for each $t \in B$ the complex structure on $X_{t}$ is represented by a Beltrami differential $\phi(t)$. For any $t \in B$ and $p \leq k$, the exponential operator induces the following isomorphism of vector spaces (still denoted by $e^{i \phi(t)}$ )

$$
\begin{equation*}
e^{i_{\phi(t)}}: H^{k}(X, \mathbb{C}) \longrightarrow H^{k}\left(X_{t}, \mathbb{C}\right):\left[\sigma_{0}\right] \longmapsto\left[e^{i_{\phi(t)}} \sigma(t)\right] \tag{4.3}
\end{equation*}
$$

so that

$$
e^{i_{\phi(t)}} F^{p} H^{k}(X)=F^{p} H^{k}\left(X_{t}\right),
$$

where $\sigma(t)$ is the canonical Bott-Chern deformation of $\sigma_{0}$.
Proof. First of all, note that (4.3) is the composition of the following two mappings

$$
\begin{equation*}
H^{k}(X, \mathbb{C}) \longrightarrow H_{d_{\phi(t)}}^{k}(X):\left[\sigma_{0}\right] \longmapsto[\sigma(t)], \tag{4.4}
\end{equation*}
$$

where $\sigma(t)$ is the canonical Bott-Chern deformation of $\sigma_{0}$ and

$$
\begin{equation*}
H_{d_{\phi(t)}}^{k}(X) \longrightarrow H^{k}\left(X_{t}, \mathbb{C}\right):[\sigma] \longmapsto\left[e^{i_{\phi(t)}} \sigma\right], \tag{4.5}
\end{equation*}
$$

where $H_{d_{\phi(t)}}^{k}(X):=\frac{\operatorname{ker} d_{\phi(t)} \cap A^{k}(X)}{\operatorname{im} d_{\phi(t)} \cap A^{k}(X)}$. Since $X$ is a $\partial \bar{\partial}$-manifold, it follows from Proposition 3.3 that (4.4) is well-defined. To show (4.3) is an isomorphism we only need to show (4.4) is injective because (4.5) is clearly an isomorphism and $\operatorname{dim} H^{k}(X, \mathbb{C})=$ $\operatorname{dim} H^{k}\left(X_{t}, \mathbb{C}\right)$. Let $\sigma_{0} \in \mathcal{H}_{B C}^{r, k-r}(X) \subset H^{k}(X, \mathbb{C})$ be a Bott-Chern harmonic form, if $[\sigma(t)]=0 \in H_{d_{\phi(t)}}^{k}(X)$ then by the $\partial \bar{\partial}_{\phi(t)}$-lemma [Xia21b, Coro. 5.5] we know that $\sigma(t) \in \operatorname{im} \partial \bar{\partial}_{\phi(t)}$. Thus we must have $\sigma_{0}=0$ by Proposition 3.3. This shows that (4.3) is an isomorphism.

It is left to show the image of the subspace $F^{p} H^{k}(X) \subseteq H^{k}(X, \mathbb{C})$ under $e^{i_{\phi}(t)}$ is exactly $F^{p} H^{k}\left(X_{t}\right) \subseteq H^{k}\left(X_{t}, \mathbb{C}\right)$. Indeed, let $\sigma_{0} \in \mathcal{H}_{B C}^{r, k-r}(X)$ be a Bott-Chern harmonic form with $r \geq p$, then it follows from (2.5) that $e^{i_{\phi(t)}} \sigma(t) \in F^{p} A^{k}\left(X_{t}\right) \cap \operatorname{ker} d$. Since $X_{t}$ is also a $\partial \bar{\partial}$-manifold, we have that $\left[e^{i_{\phi(t)}} \sigma(t)\right] \in F^{p} H^{k}\left(X_{t}\right)$ by Lemma 4.1. This shows $e^{i \phi(t)} F^{p} H^{k}(X) \subseteq F^{p} H^{k}\left(X_{t}\right)$. On the other hand, since $\operatorname{dim} H_{B C}^{\bullet \bullet \bullet}(X)$ is deformation invariant for $\partial \bar{\partial}$-manifolds, we have

$$
\operatorname{dim} F^{p} H^{k}(X)=\sum_{r \geq p} \operatorname{dim} H_{B C}^{r, k-r}(X)=\sum_{r \geq p} \operatorname{dim} H_{B C}^{r, k-r}\left(X_{t}\right)=\operatorname{dim} F^{p} H^{k}\left(X_{t}\right)
$$

The proof is complete.
Remark 4.3. Note that the mapping (4.3) may depend on the choices of the Hermitian metric on $X$.

In the context of Theorem 4.2, the period map can be defined as follows

$$
\begin{equation*}
\Phi^{p, k}: B \longrightarrow \operatorname{Grass}\left(f^{p, k}, H^{k}(X, \mathbb{C})\right), \quad t \longmapsto F^{p} H^{k}\left(X_{t}\right) \tag{4.6}
\end{equation*}
$$

where $f^{p, k}:=\operatorname{dim} F^{p} H^{k}(X)$. The period map $\Phi^{p, k}$ has the following properties (c.f. [Voi02, Chp. 10] for case of Kähler manifolds),

Theorem 4.4. Let $X$ be a $\partial \bar{\partial}$-manifold equipped with a fixed Hermitian metric.
(i) The period map $\Phi^{p, k}$ is holomorphic;
(ii) Griffiths transversality: the tangent map

$$
d \Phi_{0}^{p, k}: T_{0} B \longrightarrow \operatorname{Hom}\left(F^{p} H^{k}(X), H^{k}(X, \mathbb{C}) / F^{p} H^{k}(X)\right)
$$

has values in $\operatorname{Hom}\left(F^{p} H^{k}(X), F^{p-1} H^{k}(X) / F^{p} H^{k}(X)\right)$;
(iii) The following diagram is commutative:

$\operatorname{Hom}\left(\mathcal{H}_{B C}^{r, k-r}(X), H_{B C}^{r-1, k-r+1}(X) \oplus H_{B C}^{r, k-r}(X)\right) \longleftarrow_{\iota} \mathcal{H}_{\vec{\partial}}^{0,1}\left(X, T_{X}^{1,0}\right)$,
where $\kappa$ is the Kodaira-Spencer map, $\mathcal{H}_{\bar{\partial}}$ is the $\bar{\partial}$-harmonic projection map and $\iota$ is defined as follows: for any $\varphi \in \mathcal{H}_{\bar{\partial}}^{0,1}\left(X, T_{X}^{1,0}\right)$,

$$
\begin{aligned}
\iota(\varphi): \mathcal{H}_{B C}^{r, k-r}(X) & \longrightarrow H_{B C}^{r-1, k-r+1}(X) \oplus H_{B C}^{r, k-r}(X) \\
x & \longmapsto\left(i_{\varphi} x-\bar{\partial}(\partial \bar{\partial})^{*} G_{B C} \partial i_{\varphi} x\right)-\mathcal{H}_{B C}^{r, k-r} \partial(\partial \bar{\partial})^{*} G_{B C} \partial i_{\varphi} x .
\end{aligned}
$$

Proof. These statements can be deduced from Theorem 4.2. In fact, for any $t \in B$ we now have

$$
\Phi^{p, k}(t)=F^{p} H^{k}\left(X_{t}\right)=\mathbb{C}\left\{e^{i}{ }_{\phi(t)} \sigma^{l}(t)\right\}_{l=1}^{f p, k},
$$

where $\left\{\sigma_{0}^{l}\right\}_{l=1}^{f^{p, k}}$ is a basis of $\bigoplus_{r \geq p} \mathcal{H}_{B C}^{r, k-r}(X)$ such that for each $q \geq p$,

$$
\mathbb{C}\left\{\sigma_{0}^{l} \mid 1+\sum_{r=p}^{q-1} \operatorname{dim} \mathcal{H}_{B C}^{r, k-r}(X) \leq l \leq \sum_{r=p}^{q} \operatorname{dim} \mathcal{H}_{B C}^{r, k-r}(X)\right\}=\mathcal{H}_{B C}^{q, k-q}(X)
$$

and $\sigma^{l}(t)$ is the canonical deformation of $\sigma_{0}^{l}$. This shows $\Phi^{p, k}$ is holomorphic because both $\phi(t)$ and each $\sigma^{l}(t)$ are holomorphic. This is $(i)$.
Next, let $\sigma(t)$ be the canonical deformation of some $\sigma_{0} \in \mathcal{H}_{B C}^{r, k-r}(X)$ with $r \geq p$. Without loss of generality assume $\operatorname{dim} B=1$ and we can write $\phi(t)=\sum_{j \geq 1} \phi_{j} t^{j}$, $\sigma(t)=\sum_{k \geq 0} \sigma_{k} t^{k}$, where $\sigma_{k}=-G_{B C}\left(\bar{\partial}^{*} \partial \partial^{*}+\bar{\partial}^{*}\right) \sum_{i+j=k} \partial i_{\phi_{j}} \sigma_{i}$. So we have

$$
\left.\frac{\partial}{\partial t}\right|_{t=0} \sigma(t)=\sigma_{1}=-G_{B C}\left(\bar{\partial}^{*} \partial \partial^{*}+\bar{\partial}^{*}\right) \partial i_{\phi_{1}} \sigma_{0}
$$

Now if we differentiate $e^{i \phi(t)} \sigma(t)$ with respect to $t$ at $t=0$, we get

$$
\begin{equation*}
\left.\frac{\partial}{\partial t}\right|_{t=0}\left[e^{i_{\phi(t)}} \sigma(t)\right]=\left[i_{\phi_{1}} \sigma_{0}-G_{B C}\left(\bar{\partial}^{*} \partial \partial^{*}+\bar{\partial}^{*}\right) \partial i_{\phi_{1}} \sigma_{0}\right] . \tag{4.7}
\end{equation*}
$$

Notice that since $\left(i_{\phi_{1}} \sigma_{0}-G_{B C}\left(\bar{\partial}^{*} \partial \partial^{*}+\bar{\partial}^{*}\right) \partial i_{\phi_{1}} \sigma_{0}\right) \in \operatorname{ker} d$, it follows that for $y:=$ $G_{B C}\left(\bar{\partial}^{*} \partial \partial^{*}+\bar{\partial}^{*}\right) \partial i_{\phi_{1}} \sigma_{0} \in A^{r, k-r}(X)$, we have

$$
\partial y=0=\bar{\partial} i_{\phi_{1}} \sigma_{0} \quad \text { and } \quad \partial i_{\phi_{1}} \sigma_{0}=\bar{\partial} y
$$

which by the $\partial \bar{\partial}$-lemma implies that there exists $u \in A^{r-1, k-r}(X), \tau \in A^{r-1, k-r+1}(X) \cap$ ker $\partial$ and $\mu \in A^{r, k-r}(X) \cap \operatorname{ker} \bar{\partial}$ such that

$$
i_{\phi_{1}} \sigma_{0}=\bar{\partial} u+\tau \quad \text { and } \quad y=-\partial u+\mu
$$

From which we may observe that $\tau \in A^{r-1, k-r+1}(X) \cap \operatorname{ker} d$ and $\mu \in A^{r, k-r}(X) \cap \operatorname{ker} d$. Hence, we have the following equality in $H^{k}(X, \mathbb{C})$ :

$$
\left[i_{\phi_{1}} \sigma_{0}-y\right]=[\tau]-[\mu] \in F^{p-1} H^{k}(X) .
$$

This is (ii).
For (iii), since

$$
[\tau]=\left[i_{\phi_{1}} \sigma_{0}-\bar{\partial} u\right] \in H_{B C}^{r-1, k-r+1}(X),
$$

and

$$
[\mu]=\left[\mathcal{H}_{B C}^{r, k-r}(y+\partial u)\right]=\left[\mathcal{H}_{B C}^{r, k-r} \partial u\right] \in H_{B C}^{r, k-r}(X),
$$

by using the Hodge decomposition $H^{k}(X, \mathbb{C})=\oplus_{p+q=k} H_{B C}^{p, q}(X)$, we have the following equality in $H^{k}(X, \mathbb{C})$ :

$$
\left[i_{\phi_{1}} \sigma_{0}-y\right]=[\tau]-[\mu]=\left[i_{\phi_{1}} \sigma_{0}-\bar{\partial} u\right]-\left[\mathcal{H}_{B C}^{r, k-r} \partial u\right] \in H_{B C}^{r-1, k-r+1}(X) \oplus H_{B C}^{r, k-r}(X) .
$$

Since $u \in A^{r-1, k-r}(X)$ is a solution of $\partial \bar{\partial} u=\partial i_{\phi_{1}} \sigma_{0}$, we may set $u=(\partial \bar{\partial})^{*} G_{B C} \partial i_{\phi_{1}} \sigma_{0}$.

Note that $\left\{e^{i_{\phi(t)}} \sigma^{l}(t)\right\}_{l=1}^{f^{p, k}}$ is a holomorphic frame of the Hodge bundle $\mathcal{F}^{p}:=$ $\bigcup_{t \in B} F^{p} H^{k}\left(X_{t}\right)$ (c.f.[LS18]).

[^0]:    ${ }^{1}$ We could also use the pure type de Rham cohomology $H_{d}^{p, q}(X):=\frac{\operatorname{ker} d \cap A^{p, q}(X)}{\operatorname{im} d \cap A^{p, q}(X)}$ in this decomposition. Here we prefer to adopt the Bott-Chern cohomology because later we need to apply the deformation theory of Bott-Chern classes established in [Xia21b]. Moreover, since $\partial \bar{\partial}$-lemma holds on $X$ the natural map $H_{B C}^{p, q}(X) \rightarrow H^{k}(X, \mathbb{C})$ is injective, so we can regard $H_{B C}^{p, q}(X)$ as a subspace of $H^{k}(X, \mathbb{C})$.
