# The complexity of blocking (semi)total dominating sets with edge contractions 

Esther Galby ${ }^{1}$<br>${ }^{1}$ CISPA Helmholtz Center for Information Security, Saarbrücken, Germany

#### Abstract

We consider the problem of reducing the (semi)total domination number of graph by one by contracting edges. It is known that this can always be done with at most three edge contractions and that deciding whether one edge contraction suffices is an NP-hard problem. We show that for every fixed $k \in\{2,3\}$, deciding whether exactly $k$ edge contractions are necessary is NP-hard and further provide for $k=2$ complete complexity dichotomies on monogenic graph classes.

## 1 Introduction

A blocker problem asks whether given a graph $G$, a graph a parameter $\pi$, a set $\mathcal{O}$ of one or more graph operations and an integer $k \geq 1, G$ can be transformed into a graph $H$ such that $\pi(H) \leq \pi(G)-d$ for some threshold $d \geq 1$, by using at most $k$ operations from $\mathcal{O}$. These problems are so called because the set of vertices or edges involved can be seen as "blocking" the parameter $\pi$. Identifying such sets may provide important information on the structure of the input graph: for instance, if $\pi=\alpha, k=d=1$ and $\mathcal{O}=\{$ vertex deletion $\}$, then the problem is equivalent to testing whether the input graph contains a vertex which belongs to every maximum independent set [20]. While the set $\mathcal{O}$ generally consists of a single operation (namely vertex deletion, edge deletion, edge addition or edge contraction), a variety of parameters have been considered in the literature including the chromatic number [2, [5, 6, 19, 21], the stability number [1, 20], the clique number 16, 17], the matching number 3, 25], domination-like parameters [7, 9, 10, 11, 12, 18] and others [4, 13, 14, 22, 24]. In this paper, we focus on two well-known variants of the domination number, namely the total domination number and the semitotal domination number, let $\mathcal{O}$ consists of an edge contraction and set the threshold $d$ to one.

Formally, let $G$ be a graph. The contraction of an edge $x y \in E(G)$ removes vertices $x$ and $y$ from $G$ and replaces them with a new vertex that is made adjacent to precisely those vertices which were adjacent to $x$ or $y$ (without introducing self-loops nor multiple edges). For a parameter $\pi$, we denote by $c t_{\pi}(G)$ the minimum number of edge contractions required to modify $G$ into a graph $H$ such that $\pi(H)=\pi(G)-1$. A set $D \subseteq V(G)$ is a total dominating set of $G$ if every vertex in $V(G)$ has a neighbour in $D$, and the total domination number $\gamma_{t}(G)$ of $G$ is the size of a minimum total dominating set of $G$. A set $D \subseteq V(G)$ is a semitotal dominating set of $G$ if every vertex in $V(G) \backslash D$ has a neighbour in $D$ and every vertex in $D$ is at distance at most two from another vertex in $D$. The semitotal domination number $\gamma_{t 2}(G)$ of $G$ is the size of a minimum semitotal dominating set of $G$. We are interested in the following problem for $\pi \in\left\{\gamma_{t}, \gamma_{t 2}\right\}$.

Contraction $\operatorname{Number}(\pi, k)$
Instance: A graph $G$.
Question: Is $c t_{\pi}(G)=k$ ?
It is known 10, 12] that, contrary to other parameters such as the chromatic number, the stability number or the clique number $\frac{1}{1}$, $c t_{\pi}$ is bounded for $\pi \in\left\{\gamma_{t}, \gamma_{t 2}\right\}$, namely by three in

[^0]both cases. It follows that for $\pi \in\left\{\gamma_{t}, \gamma_{t 2}\right\}$ and $k>3$, every instance of the above problem is always negative. Similarly, for $\pi \in\left\{\gamma_{t}, \gamma_{t 2}\right\}$ and $k \geq 3$, deciding $c t_{\pi}(G) \leq k$ (the so-called $k$-Edge Contraction $(\pi)$ problem [9]) is trivial. In contrast, it was shown [10, 11] that for $\pi \in\left\{\gamma_{t}, \gamma_{t 2}\right\}$, 1-Edge Contraction $(\pi)$ (or, equivalently, Contraction $\operatorname{Number}(\pi, 1)$ ) is NPhard; the complexity status for $k=2,3$ remained open. In this paper, we settle these questions and show that for $\pi \in\left\{\gamma_{t}, \gamma_{t 2}\right\}$ and $k=2,3$, Contraction $\operatorname{Number}(\pi, k)$ is NP-hard. Thus, combined with [10, 11], the following dichotomy holds.

Theorem 1.1. For $\pi \in\left\{\gamma_{t}, \gamma_{t 2}\right\}$, Contraction $\operatorname{Number}(\pi, k)$ is $\operatorname{NP}$-hard if and only if $k \leq 3$.
Let us note that since for $\pi \in\left\{\gamma_{t}, \gamma_{t 2}\right\}$, a graph $G$ is a No-instance for Contraction $\operatorname{Number}(\pi, 3)$ if and only if $G$ is a Yes-instance for 2-Edge Contraction $(\pi)$, the above implies the following.

Theorem 1.2. For $\pi \in\left\{\gamma_{t}, \gamma_{t 2}\right\}$, $k$-Edge Contraction $(\pi)$ is (co)NP-hard if and only if $k \leq 2$.
It is, however, not difficult to find cases which are easy to solve: for instance, in any graph class closed under edge contraction and where $\pi$ can be efficiently computed, the Contraction $\operatorname{Number}(\pi, k)$ problem can efficiently be solved through a simple brute force approach. Based on this observation, a natural question is whether there are other efficiently solvable instances for which computing $\pi$ is in fact hard. Motivated by such questions, we consider these problems on monogenic graph classes (that is, graph classes excluding one graph as an induced subgraph) for which the complexity status of Total Domination and Semitotal Domination [8] is known: both problems are polynomial-time solvable on $H$-free graph if $H \subseteq_{i} P_{4}+t K_{1}$ for some $t \geq 0$, and NP-hard otherwise. This investigation led us to establish complete complexity dichotomies for $\pi \in\left\{\gamma_{t}, \gamma_{t 2}\right\}$ and $k=2$ on monogenic graph classes, which read as follows.

Theorem 1.3. Contraction $\operatorname{Number}\left(\gamma_{t}, 2\right)$ is polynomial-time solvable on $H$-free graphs if $H \subseteq_{i} P_{5}+t K_{1}$ for some $t \geq 0$ or $H \subseteq_{i} P_{4}+t P_{3}$ for some $t \geq 0$, and (co)NP-hard otherwise.

Theorem 1.4. Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ is polynomial-time solvable on $H$-free graphs if $H \subseteq_{i} P_{5}+t K_{1}$ for some $t \geq 0$ or $H \subseteq_{i} P_{3}+t P_{2}$ for some $t \geq 0$, and (co)NP-hard otherwise.

Related work. The study of the blocker problem for $\pi=\gamma_{t}$ and $\mathcal{O}=$ \{edge contraction $\}$ was initiated by Huang and Xu [12] who characterised for every $k \in[3]$, the graphs for which $c t_{\gamma_{t}}(G)=k$ in terms of the structure of their total dominating sets. More specifically, they proved the following theorem (see Section 2 for missing definitions).

Theorem 1.5 ([12]). For any graph $G$, the following holds.
(i) $c_{\gamma_{t}}(G)=1$ if and only if there exists a minimum total dominating set of $G$ that contains a (not necessarily induced) $P_{3}$.
(ii) $c_{\gamma_{t}}(G)=2$ if and only if no minimum total dominating set of $G$ contains a $P_{3}$ and there exists a total dominating set of $G$ of size $\gamma_{t}(G)+1$ that contains a (not necessarily induced) $P_{4}, K_{1,3}$ or $2 P_{3}$.

On the other hand, the algorithmic study of Contraction $\operatorname{Number}\left(\gamma_{t}, 1\right)$ was initiated in 11] where the following dichotomy theorem was established.

Theorem 1.6 ([11]). Contraction $\operatorname{Number}\left(\gamma_{t}, 1\right)$ is polynomial-time solvable on $H$-free graphs if $H \subseteq_{i} P_{5}+t K_{1}$ for some $t \geq 0$ or $H \subseteq_{i} P_{4}+t P_{3}$ for some $t \geq 0$, and (co)NP-hard otherwise.

Similarly to the total domination parameter, Galby et al. 10] later characterised for every $k \in[3]$ the graphs for which $c t_{\gamma_{t 2}}(G)=k$ in terms of the structure of their semitotal dominating sets, as follows (see Section 2 for missing definitions).

Theorem 1.7 ([10]). For any graph $G$, the following holds.
(i) $c t_{\gamma_{t 2}}(G)=1$ if and only if there exists a minimum semitotal dominating set of $G$ that contains a friendly triple.
(ii) $\operatorname{ct}_{\gamma_{t 2}}(G)=2$ if and only if no minimum semitotal dominating set of $G$ contains a friendly triple and there exists a semitotal dominating set of $G$ of size $\gamma_{t 2}(G)+1$ that contains a (not necessarily induced) ST-configuration.

Figure 1: The ST-configurations (the dashed lines indicate that the corresponding vertices are at distance two and the serpentine line indicates that the corresponding vertices can be identified).

In the same paper [10], the authors further established the following dichotomy theorem on monogenic graph classes.

Theorem 1.8. Contraction $\operatorname{Number}\left(\gamma_{t 2}, 1\right)$ is polynomial-time solvable for $H$-free graphs if $H \subseteq_{i} P_{5}+t K_{1}$ for some $t \geq 0$ or $H \subseteq_{i} P_{3}+t P_{2}$ for some $t \geq 0$, and (co)NP-hard otherwise.

The paper is organised as follows. In Section 2, we present the necessary definitions and notations, as well as some preliminary results. In Section 3 we study the complexity of Contraction $\operatorname{Number}\left(\gamma_{t}, k\right)$ for $k=2,3$, and in Section 4, that of Contraction $\operatorname{Number}\left(\gamma_{t 2}, k\right)$ for $k=2,3$. The proof of Theorem 1.3 can be found in Section 3.3 and that of Theorem 1.4 in Section 4.3 ,

## 2 Preliminaries

### 2.1 Definitions and notations

Throughout this paper, we only consider finite and simple graphs. Furthermore, since for any parameter $\pi$ and any $k \geq 0$, a non-connected graph $G$ is a Yes-instance for Contraction $\operatorname{Number}(\pi, k)$ if and only if at least one connected component of $G$ is a Yes-instance for Contraction $\operatorname{NUMBER}(\pi, k)$, we restrict our study to connected graphs.

For a graph $G$, we denote its vertex set by $V(G)$ and its edge set by $E(G)$. For any edge $e=\{x, y\} \in E(G)$, we call $x$ and $y$ the endvertices of $e$. We may also denote the edge $e$ by $x y$ instead of $\{x, y\}$. Given a set $S \subseteq V(G)$, we let $G[S]$ denote the graph induced by $S$, that is, the graph with vertex set $S$ and edge set $\{x y \in E(G) \mid x, y \in S\}$. A graph $H$ is an induced subgraph of $G$, which we denote by $H \subseteq_{i} G$, if there exists a set $S \subseteq V(G)$ such that $H$ is isomorphic to $G[S]$. The neighbourhood $N(x)$ of a vertex $x \in V(G)$ is the set $\{y \in V(G) \mid x y \in E(G)\}$ and the closed neighbourhood $N[x]$ of $x$ is the set $N(x) \cup\{x\}$. Similarly, for a set $X \subseteq V(G)$, the neighbourhood $N(X)$ of $X$ is the set $\{y \in V(G) \mid \exists x \in X$ s.t. $x y \in E(G)\} \backslash X$ and the closed neighbourhood $N[X]$ of $X$ is the set $N(X) \cup X$. The degree $d(x)$ of a vertex $x \in V(G)$ is the size of its neighbourhood. For any two vertices $x, y \in V(G)$, the distance between $x$ and $y$ is the number of edges in a shortest path from $x$ to $y$ and is denoted $d(x, y)$. Similarly, for any two sets $X, Y \subseteq V(G)$, the distance $d(X, Y)$ from $X$ to $Y$ is the number of edges in a shortest path from $X$ to $Y$, that is, $d(X, Y)=\min _{x \in X, y \in Y} d(x, y)$. If $X=\{x\}$, we may write $d(x, Y)$ instead of $d(\{x\}, Y)$. For any two sets $X, Y \subseteq V(G), X$ is complete (anticomplete, respectively) to $Y$, which we denote by $X-Y(X \cdots Y$, respectively) if every vertex in $X$ is adjacent (nonadjacent, respectively) to every vertex in $Y$.

For $n \geq 1$, we denote by $P_{n}$ the path on $n$ vertices and by $K_{1, n}$ the complete bipartite graph with partitions of size one and $n$. If $H$ is a graph and $k \in \mathbb{N}$, we denote by $k H$ the graph consisting of $k$ disjoint copies of $H$. The paw is the graph depicted in Figure2aland unless specified otherwise, the vertices of a paw $P$ will be denoted by $P(1), \ldots, P(4)$ (as indicated in Figure 2a) throughout the paper. The long paw is the graph depicted in Figure 2b and unless specified otherwise, the vertices of a long paw $P$ will be denoted by $P(1), \ldots, P(5)$ (as indicated in Figure 2b) throughout the paper.

Let $G$ be a graph with at least two vertices. A set $D \subseteq V(G)$ is dominating if every vertex in $V(G) \backslash D$ has a neighbour in $D$. A set $D \subseteq V(G)$ is a total dominating set (TD set for short) of $G$ if every vertex in $V(G)$ has a neighbour in $D$. The total domination number $\gamma_{t}(G)$ of $G$ is the size of a minimum total dominating set of $G$. Note that $\gamma_{t}(G) \geq 2$ by definition. For every $x \in V(G)$ and every neighbour $y \in N(x) \cap D$, we say that $y$ dominates $x$ or that $x$ is dominated by

(a) A paw $P$.

(b) A long paw $P$.

Figure 2: Some special graphs.
$y$. A set $D \subseteq V(G)$ is a semitotal dominating set (SD set for short) of $G$ if $D$ is dominating and every vertex in $D$ is at distance at most two from another vertex in $D$. The semitotal domination number $\gamma_{t 2}(G)$ is the size of a minimum semitotal dominating set of $G$. Note that $\gamma_{t 2}(G) \geq 2$ by definition. For every $x \in V(G)$ and every $y \in N[x] \cap D$, we say that $y$ dominates $x$ or that $x$ is dominated by $y$ (note that contrary to a total dominating set, $x$ can dominate itself). If $x, y \in D$ and $d(x, y) \leq 2$ then $y$ is called a witness for $x$. The set of witnesses of a vertex $x \in D$ is denoted by $w_{D}(x)$. Note that with this terminology, a semitotal dominating set $D$ is equivalently a dominating set where every vertex in $D$ has a witness. For every $x \in D$, we denote by $P N_{D}(x)=\{y \in V(G) \mid N(y) \cap D=\{x\}\}$ the private neighbourhood of $x$ with respect to $D$. A friendly triple is a subset of three vertices $x, y$ and $z$ such that $x y \in E(G)$ and $d_{G}(y, z) \leq 2$.

Finally, let us define the Positive Exactly 3-Bounded 1-In-3 3-Sat problem which will be used in several of our hardness reductions: it is an NP-hard [15] variant of the 3-SAT problem where given a formula $\Phi$ in which all literals are positive, every clause contains exactly three literals and every variable appears in exactly three clauses, the problem is to determine whether there exists a truth assignment for $\Phi$ such that each clause contains exactly one true literal.

### 2.2 Preliminary results

In this section, we present some useful technical results.
Lemma 2.1. Let $G$ be a graph such that $\gamma_{t}(G) \geq 3$. Then for any minimum $T D$ set $D$ of $G$, if there exist $x, y, z \in D$ such that $x y \in E(G)$ and $d(z,\{x, y\}) \leq 2$, then ct ${\gamma_{\gamma_{t}}}(G) \leq 2$.

Proof. Suppose that there exist three such vertices $x, y, z \in D$. If $d(z,\{x, y\})=1$, say $z$ is adjacent to $y$ without loss of generality, then $D$ contains the $P_{3} x y z$ and thus, $c t_{\gamma_{t}}(G)=1$ by Theorem 1.5 . Suppose next that $d(z,\{x, y\})=2$, say $d(z,\{x, y\})=d(z, y)$ without loss of generality, and let $t$ be a common neighbour of $y$ and $z$. If $t$ belongs to $D$ as well, then $D$ contains the $P_{3} y t z$ and we conclude as previously. Otherwise, $t \notin D$ in which case $D \cup\{t\}$ contains the $P_{4} x y t z$ and thus, $c t_{\gamma_{t}}(G) \leq 2$ by Theorem 1.5

Lemma 2.2. Let $G$ be a graph such that $\gamma_{t 2}(G) \geq 3$. If $G$ has a minimum $S D$ set $D$ such that one of the following holds:
(i) $D$ contains an edge, or
(ii) there exists $x \in D$ such that $\left|w_{D}(x)\right| \geq 2$,
then $c t_{\gamma_{t 2}}(G) \leq 2$.
Proof. Assume first that $G$ has a minimum SD set $D$ containing an edge $u v$. Let $w \in D \backslash\{u, v\}$ be a closest vertex from the edge $u v$, that is, $d(w,\{u, v\})=\min _{x \in D \backslash\{u, v\}} d(x,\{u, v\})$. Then $d(w,\{u, v\}) \leq 3$ : indeed, if $d(w,\{u, v\})>3$ then the vertex at distance two from $\{u, v\}$ on a shortest path from $\{u, v\}$ to $w$ is not dominated, by the choice of $w$. Now if $d(w,\{u, v\}) \leq 2$ then $u, v, w$ is a friendly triple of $D$ and thus, $c t_{\gamma_{t 2}}(G)=1$ by Theorem 1.7. Otherwise, $d(w,\{u, v\})=3$ in which case, denoting by $x$ the vertex at distance one from $\{u, v\}$ on a shortest path from $\{u, v\}$ to $w, D \cup\{x\}$ contains the $O_{4} u, v, x, w$ and thus, $c t_{\gamma_{t 2}}(G) \leq 2$ by Theorem 1.7 which proves item (i).

To prove item (ii), assume that $G$ has a minimum SD set $D$ such that there exists $x \in D$ where $\left|w_{D}(x)\right| \geq 2$, say $y, z \in w_{D}(x)$. If $d(x,\{y, z\})=1$ then we conclude as previously that $c t_{\gamma_{t 2}}(G) \leq 2$. Otherwise, $d(x, y)=d(x, z)=2$ in which case, denoting by $t$ a common neighbour of $x$ and $y, D \cup\{t\}$ contains the $O_{4} y, t, x, z$ and thus, $c t_{\gamma_{t 2}}(G) \leq 2$ by Theorem 1.7.

Lemma 2.3. Let $G$ be a graph such that $\operatorname{ct}_{\gamma_{t 2}}(G) \leq 2$ and for every minimum $S D$ set $D$ of $G$ the following hold.
(i) D contains no edge.
(ii) For every $x \in D,\left|w_{D}(x)\right|=1$.

Then every $S D$ set $D$ of $G$ of size $\gamma_{t 2}(G)+1$ containing an ST-configuration is either a minimal $S D$ set of $G$ or contains an $O_{6}$.

Proof. Let $D$ be an SD set of size $\gamma_{t 2}(G)+1$ containing an ST-configuration and suppose that $D$ is not minimal. Then there exists $x \in D$ such that $D_{x}=D \backslash\{x\}$ is a minimum SD set of $G$; in particular, $D_{x}$ contains no edge by item (i). It follows that $D$ contains no $O_{1}, O_{2}, O_{3}$ and $O_{7}$ : indeed, since these ST-configurations contain two vertex-disjoint edges, if $D$ contains one of them, then $D_{x}$ must contain at least one edge. Now if $D$ contains an $O_{4}$ on vertices $u, v, w, t$ where $u v, v w \in E(G)$ and $d(w, t)=2$, necessarily $x=v\left(D_{x}\right.$ would otherwise contain an edge); but then, $u, t \in w_{D_{x}}(w)$, a contradiction to item (ii). Similarly, if $D$ contains an $O_{5}$ on vertices $u, v, w, t$ where $t$ is the vertex of degree three, necessarily $x=t$ ( $D_{x}$ would otherwise contain an edge); but then, $u, v \in w_{D_{x}}(w)$, a contradiction to item (ii). Thus, $D$ contains an $O_{6}$.

Let us finally remark the following.
Observation 1. Let $\pi \in\left\{\gamma_{t}, \gamma_{t 2}\right\}$ and let $\mathcal{G}$ be a graph class where Contraction Number $(\pi, 3)$ is polynomial-time solvable. Then Contraction $\operatorname{Number}(\pi, 1)$ is $\operatorname{NP}$-hard on $\mathcal{G}$ if and only if Contraction $\operatorname{Number}(\pi, 2)$ is coNP-hard on $\mathcal{G}$.

## 3 Total Domination

In this section, we consider the Contraction $\operatorname{Number}\left(\gamma_{t}, k\right)$ problem for $k \in\{2,3\}$. In Section 3.1, we cover polynomial-time solvable cases and in Section 3.2, we examine hard cases. The proof of Theorem 1.3 can be found in Section 3.3.

### 3.1 Polynomial-time solvable cases

The algorithms for $\operatorname{Contraction~} \operatorname{Number}\left(\gamma_{t}, 2\right)$ and $\operatorname{Contraction~} \operatorname{Number}\left(\gamma_{t}, 3\right)$ outlined thereafter will rely on the following key result.

Lemma 3.1. For every $k \geq 0$, 2-Edge $\operatorname{Contraction~}\left(\gamma_{t}\right)$ is polynomial-time solvable on $\left(P_{6}+\right.$ $k P_{3}$ )-free graphs.

Proof. We prove the result by induction on $k$.
Base Case. $k=0$. Let $G$ be a $P_{6}$-free graph such that $\gamma_{t}(G) \geq 3$. We show that $c t_{\gamma_{t}}(G) \leq 2$, that is, $G$ is a Yes-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$. To this end, let $D$ be a minimum TD set of $G$. Consider two adjacent vertices $u, v \in D$ and let $w \in D \backslash\{u, v\}$ be a closest vertex from $\{u, v\}$, that is, $d(w,\{u, v\})=\min _{x \in D \backslash\{u, v\}} d(x,\{u, v\})$. Then $d(w,\{u, v\}) \leq 3$ : indeed, if $d(w,\{u, v\})>3$ then the vertex at distance two from $\{u, v\}$ on a shortest path from $\{u, v\}$ to $w$ is not dominated. Now if $d(w,\{u, v\}) \leq 2$ then $c t_{\gamma_{t}}(G) \leq 2$ by Lemma 2.1 thus, we assume henceforth that $d(w,\{u, v\})=3$, say $d(w,\{u, v\})=d(w, u)$ without loss of generality.

Let $P=u x y w$ be a shortest path from $u$ to $w$ and let $t \in D$ be a neighbour of $w$. Suppose first that $t$ is nonadjacent to $y$ (note that $t$ is nonadjacent to $x$ as $d(w,\{u, v\})=\min _{b \in D \backslash\{u, v\}} d(b,\{u, v\})$ $=3$ ). Then any neighbour $a$ of $t$ must be adjacent to $w, y$ or $x$, for atwyxv would otherwise induce a $P_{6}$ (note indeed that $a$ is nonadjacent to $v$ as $d(w,\{u, v\})=\min _{b \in D \backslash\{u, v\}} d(b,\{u, v\})=3$ ). But then, $(D \backslash\{t\}) \cup\{x, y\}$ is a TD set of $G$ of size $\gamma_{t}(G)+1$ containing the $P_{4}$ vxyw and thus, $c t_{\gamma_{t}}(G) \leq 2$ by Theorem 1.5. Second, suppose that $t$ is adjacent to $y$. If every neighbour of $v$ is adjacent to $x$ or $y$, then $(D \backslash\{v\}) \cup\{x, y\}$ is a TD set of $G$ of size $\gamma_{t}(G)+1$ containing the $P_{4}$ xywt and so, $c t_{\gamma_{t}}(G) \leq 2$ by Theorem 1.5. Thus, assume that $v$ has a neighbour $z$ which is nonadjacent to both $x$ and $y$. If $z=u$ then, by symmetry, we conclude as in the previous case. Suppose therefore that $z \neq u$. Then every neighbour $a$ of $w$ is adjacent to $z, x$ or $y$, for awyxvz would otherwise induce a $P_{6}$; and we conclude symmetrically that every neighbour of $t$ is adjacent to $z, x$ or $y$. It then follows that $(D \backslash\{w, t\}) \cup\{x, y, z\}$ is a TD set of $G$ of size $\gamma_{t}(G)+1$ containing
the $P_{4} y x v z$ and thus, $c t_{\gamma_{t}}(G) \leq 2$ by Theorem 1.5 ,
Inductive step. Let $G$ be a $\left(P_{6}+k P_{3}\right)$-free graph. We aim to show that if $G$ contains an induced $P_{6}+(k-1) P_{3}$ and $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$ then $\gamma_{t}(G)$ is bounded by some function $f$ of $k$ (and $k$ only). Assuming for now that this claim is correct, the following algorithm solves the 2-EdGE Contraction $\left(\gamma_{t}\right)$ problem on $\left(P_{6}+k P_{3}\right)$-free graphs.

1. If $G$ contains no induced $P_{6}+(k-1) P_{3}$ then use the algorithm for $\left(P_{6}+(k-1) P_{3}\right)$-free graphs to determine whether $G$ is a Yes-instance for 2-Edge $\operatorname{Contraction}\left(\gamma_{t}\right)$ or not.
2. Check whether there exists a TD set of $G$ of size at most $f(k)$.
2.1 If the answer is no then output Yes.
2.2 Check whether there exists a minimum TD set of $G$ containing a $P_{3}$, or a TD set of $G$ of size $\gamma_{t}(G)+1$ containing a $P_{4}, K_{1,3}$ or $2 P_{3}$ (see Theorem 1.5) and output the answer accordingly.

Now observe that checking whether $G$ is $\left(P_{6}+(k-1) P_{3}\right)$-free can be done in time $|V(G)|^{O(k)}$ and that step 2 can be done in time $|V(G)|^{O(f(k))}$ by simple brute force. Since 2-Edge Contrac$\operatorname{TION}\left(\gamma_{t}\right)$ is polynomial-time solvable on $\left(P_{6}+(k-1) P_{3}\right)$-free graphs by the induction hypothesis, the above algorithm indeed runs in polynomial time (for fixed $k$ ). The remainder of this proof is devoted to showing that $f(k)=k^{4}+4 k^{2}+21 k+19$.

Assume henceforth that $G$ contains an induced $P_{6}+(k-1) P_{3}$. Let $A \subseteq V(G)$ be a set of vertices such that $G[A]$ is isomorphic to $P_{6}+(k-1) P_{3}$, let $B \subseteq V(G) \backslash A$ be the set of vertices at distance one from $A$ and let $C=V(G) \backslash(A \cup B)$. Note that since $G$ is $\left(P_{6}+k P_{3}\right)$-free, $C$ is a disjoint union of cliques; we denote by $\mathcal{K}$ the set of maximal cliques in $C$. Now let $D$ be a minimum TD set of $G$ such that $|D \cap B|$ is maximum amongst all minimum TD set of $G$. Denote by $\mathcal{K}_{D} \subseteq \mathcal{K}$ the set of cliques $K \in \mathcal{K}$ such that $D \cap(N(K) \cap B) \neq \varnothing$, and set $\overline{\mathcal{K}_{D}}=\mathcal{K} \backslash \mathcal{K}_{D}$. We aim to upperbound $\left|D \cap N\left[\mathcal{K}_{D}\right]\right|$ and $\left|D \cap N\left[\overline{\mathcal{K}_{D}}\right]\right|$ when $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$. To this end, we first prove the following.

Claim 1. If $G$ is a No-instance for 2-Edge $\operatorname{Contraction~}\left(\gamma_{t}\right)$ then for every $K \in \mathcal{K}$, exactly one of the following holds.
(i) $D \cap V(K) \neq \varnothing$ and $D \cap N[K]=\{x, y\}$ for some edge $x y \in E(G)$.
(ii) $N[K] \cap D \subseteq B$.

Proof. Assume that $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$ and consider a clique $K \in \mathcal{K}$. Then $D \cap N[K] \neq \varnothing$ as the vertices of $K$ must be dominated. Now if $D \cap V(K) \neq \varnothing$, say $x \in D \cap V(K)$, then $x$ has a neighbour $y \in D$ as $x$ must be dominated; but then, $D \cap N[K]=\{x, y\}$ for otherwise $c t_{\gamma_{t}}(G) \leq 2$ by Lemma 2.1 (note indeed that every vertex in $N[K]$ is within distance at most two from $x$ ). Otherwise, $D \cap V(K)=\varnothing$ in which case $D \cap(N(K) \cap B) \neq \varnothing$.
Claim 2. If $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$ then $\left|D \cap N\left[\mathcal{K}_{D}\right]\right| \leq 4|A|$.
Proof. Assume that $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$ and suppose for a contradiction that $\left|D \cap N\left[\mathcal{K}_{D}\right]\right|>4|A|$. We contend that at least half of those vertices belong to $B$, that is, $\left|D \cap\left(N\left(\mathcal{K}_{D}\right) \cap B\right)\right|>2|A|$. Indeed, for every $x \in D \cap\left(N\left(\mathcal{K}_{D}\right) \cap B\right)$, denote by $\mathcal{K}_{D}^{x}$ the set of cliques $K \in \mathcal{K}_{D}$ such that $x \in N(K)$. Let us first show that for every $x \in D \cap\left(N\left(\mathcal{K}_{D}\right) \cap B\right)$, there exists at most one clique $K \in \mathcal{K}_{D}^{x}$ such that $D \cap V(K) \neq \varnothing$, and that furthermore, if such a clique exists then it in fact contains only one element of $D$. Consider $x \in D \cap\left(N\left(\mathcal{K}_{D}\right) \cap B\right)$. If $\left|\mathcal{K}_{D}^{x}\right|=1$ then the result readily follows from Claim 1 . Suppose therefore that $\left|\mathcal{K}_{D}^{x}\right| \geq 2$. Then for all but at most one of the cliques in $\mathcal{K}_{D}^{x}$, item (ii) of Claim 1 must hold: indeed, if there exist $K_{1}, K_{2} \in \mathcal{K}_{D}^{x}$ such that $K_{1}$ and $K_{2}$ both satisfy item (i) of Claim then $D$ contains the $P_{3} y_{1} x y_{2}$ where $y_{1} \in V\left(K_{1}\right)$ and $y_{2} \in V\left(K_{2}\right)$, a contradiction to Theorem 1.5 ,

Now observe that for any $x, y \in D \cap\left(N\left(\mathcal{K}_{D}\right) \cap B\right)$, if there exist $K_{x} \in \mathcal{K}_{D}^{x}$ and $K_{y} \in \mathcal{K}_{D}^{y}$ such that $D \cap V\left(K_{x}\right) \neq \varnothing$ and $D \cap V\left(K_{y}\right) \neq \varnothing$, then surely $K_{x} \neq K_{y}$ as otherwise $\left|D \cap N\left[K_{x}\right]\right| \geq 3$, a contradiction to Claim $\mathbb{1}$ (i). Since for every $K \in \mathcal{K}_{D}$, there exists $x \in D \cap\left(N\left(\mathcal{K}_{D}\right) \cap B\right)$ such that
$K \in \mathcal{K}_{D}^{x}$, by definition of $\mathcal{K}_{D}$, it follows that

$$
\begin{aligned}
\left|D \cap\left(N\left(\mathcal{K}_{D}\right) \cap B\right)\right| & \geq \sum_{x \in D \cap\left(N\left(\mathcal{K}_{D}\right) \cap B\right)}\left|D \cap \bigcup_{K \in \mathcal{K}_{D}^{x}} V(K)\right| \\
& \geq\left|D \cap \bigcup_{x \in D \cap\left(N\left(\mathcal{K}_{D}\right) \cap B\right)} \bigcup_{K \in \mathcal{K}_{D}^{x}} V(K)\right| \\
& \geq\left|D \cap \bigcup_{K \in \mathcal{K}_{D}} V(K)\right|
\end{aligned}
$$

But

$$
\left|D \cap N\left[\mathcal{K}_{D}\right]\right|=\left|D \cap\left(N\left(\mathcal{K}_{D}\right) \cap B\right)\right|+\left|D \cap \bigcup_{K \in \mathcal{K}_{D}} V(K)\right|
$$

and so, we conclude that

$$
2\left|D \cap\left(N\left(\mathcal{K}_{D}\right) \cap B\right)\right| \geq\left|D \cap N\left[\mathcal{K}_{D}\right]\right|>4|A|
$$

as claimed. It follows that there must exist at least three vertices $x, y, z \in D \cap\left(N\left(\mathcal{K}_{D}\right) \cap B\right)$ such that $x, y$ and $z$ have a common neighbour in $A$ : indeed, if no such three vertices exist then every vertex in $A$ has at most two neighbours in $D \cap\left(N\left(\mathcal{K}_{D}\right) \cap B\right)$ and so, $\left|D \cap\left(N\left(\mathcal{K}_{D}\right) \cap B\right)\right| \leq 2|A|$, a contradiction to the above. This implies, in particular, that for every $u, v \in\{x, y, z\}, d(u, v) \leq 2$; but $x$ must have a neighbour in $D$ (possibly $y$ or $z$ ) and so, $c t_{\gamma_{t}}(G) \leq 2$ by Lemma [2.1, a contradiction to our assumption. Therefore, $\left|D \cap N\left[\mathcal{K}_{D}\right]\right| \leq 4|A|$.

Now note that since for every $K \in \overline{\mathcal{K}_{D}}, D \cap(N(K) \cap B)=\varnothing$ by definition, the following ensues from Claim 1
Observation 2. If $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$ then for every $K \in \overline{\mathcal{K}_{D}}$, $|D \cap N[K]|=|D \cap V(K)|=2$.

For every $K \in \overline{\mathcal{K}_{D}}$, let us denote by $x_{K} y_{K} \in E(G)$ the edge contained in $V(K) \cap D$ when $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$. Observe that by Lemma 2.1 the following holds.

Observation 3. If $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$ then for every clique $K \in \overline{\mathcal{K}_{D}}, d\left(\left\{x_{K}, y_{K}\right\}, D \backslash\left\{x_{K}, y_{K}\right\}\right)>2$.
Claim 3. If $G$ is a No-instance for 2-Edge contraction $\left(\gamma_{t}\right)$ then for every $K \in \overline{\mathcal{K}_{D}}$, the following hold.
(i) For every $u \in\left\{x_{K}, y_{K}\right\}, P N_{D}(u) \neq \varnothing$.
(ii) For $u \in\left\{x_{K}, y_{K}\right\}$ and $v \in\left\{x_{K}, y_{K}\right\} \backslash\{u\}$, no vertex of $P N_{D}(u)$ is complete to $P N_{D}(v)$.

Proof. Assume that $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$ and consider a clique $K \in \overline{\mathcal{K}_{D}}$. Observe first the $P N_{D}\left(x_{K}\right) \cup P N_{D}\left(y_{K}\right) \subseteq B$ as $K$ is a clique. Furthermore, we may assume that $\left(N\left(x_{K}\right) \cup N\left(y_{K}\right)\right) \cap B \neq \varnothing$ for it otherwise suffices to consider, in place of $D$, the TD set $\left(D \backslash\left\{x_{K}\right\}\right) \cup\{x\}$, where $x \in V(K)$ has at least one neighbour in $B$. Now suppose that $P N_{D}(u)=\varnothing$ for some $u \in\left\{x_{K}, y_{K}\right\}$, say $P N_{D}\left(x_{K}\right)=\varnothing$ without loss of generality. Then $N\left(y_{K}\right) \cap B \neq \varnothing$ : if not, then $N\left(x_{K}\right) \cap B \neq \varnothing$ by the above, and since no vertex in $N\left(x_{K}\right) \cap B$ can be adjacent to another vertex in $D \backslash\left\{x_{K}, y_{K}\right\}$ by Observation 3, necessarily $N\left(x_{K}\right) \cap B \subseteq P N_{D}\left(x_{K}\right)$, a contradiction to our assumption. But then, letting $y \in B$ be a neighbour of $y_{K}$, the set $\left(D \backslash\left\{x_{K}\right\}\right) \cup\{y\}$ is a minimum TD set of $G$ containing strictly more vertices from $B$ than $D$, a contradiction to the choice of $D$. Thus, $P N_{D}(u) \neq \varnothing$ for every $u \in\left\{x_{K}, y_{K}\right\}$. Now if for some $u \in\left\{x_{K}, y_{K}\right\}$, there exists $y \in P N_{D}(u)$ such that $y$ is complete to $P N_{D}(v)$ where $v \in\left\{x_{K}, y_{K}\right\} \backslash\{u\}$, then the set $(D \backslash\{v\}) \cup\{y\})$ is a minimum TD set of $G$ containing strictly more vertices from $B$ than $D$, a contradiction to the choice of $D$.

Claim 4. If $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$ and there exists a set $S \subseteq \overline{\mathcal{K}_{D}}$ such that for every $K, K^{\prime} \in S, P N_{D}\left(x_{K}\right) \cup P N_{D}\left(y_{K}\right) \cdots P N_{D}\left(x_{K^{\prime}}\right) \cup P N_{D}\left(y_{K^{\prime}}\right)$ then $|S| \leq|A|$.

Proof. Assume that $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$ and there exists such a set $S \subseteq \overline{\mathcal{K}_{D}}$. Suppose for a contradiction that $|S|>|A|$. Then there must exist $u \in P N_{D}\left(x_{K}\right) \cup$ $P N_{D}\left(y_{K}\right)$ and $v \in P N_{D}\left(x_{K^{\prime}}\right) \cup P N_{D}\left(y_{K^{\prime}}\right)$ for two distinct cliques $K, K^{\prime} \in S$, such that $u$ and $v$ have a common neighbour $w \in A$. Then for all but at most $k-1$ cliques $K^{\prime \prime} \in S, w$ is complete to $P N_{D}\left(x_{K^{\prime \prime}}\right) \cup P N_{D}\left(y_{K^{\prime \prime}}\right)$ : indeed, if there exist at least $k$ cliques $K_{1}, \ldots, K_{k} \in S$ such that for every $i \in[k], w$ is nonadjacent to a vertex $u_{i} \in P N_{D}\left(x_{K_{i}}\right) \cup P N_{D}\left(y_{K_{i}}\right)$, then $\left\{x_{K}, y_{K}, u, w, v, x_{K^{\prime}}, y_{K^{\prime}}\right\} \cup \bigcup_{i \in[k]}\left\{u_{i}, x_{K_{i}}, y_{K_{i}}\right\}$ induces a $P_{7}+k P_{3}$, a contradiction. Since $|S|>$ $|A|=6+3(k-1)$, it follows that there are at least two cliques $K_{1}, K_{2} \in S \backslash\left\{K, K^{\prime}\right\}$ such that $w$ is complete to $P N_{D}\left(x_{K_{1}}\right) \cup P N_{D}\left(y_{K_{1}}\right)$ and to $P N_{D}\left(x_{K_{2}}\right) \cup P N_{D}\left(y_{K_{2}}\right)$. However, by Claim 3(i), $P N_{D}\left(y_{K_{1}}\right) \neq \varnothing$ and $P N_{D}\left(y_{K_{2}}\right) \neq \varnothing$ and so, the set $\left(D \backslash\left\{x_{K_{1}}, x_{K_{2}}\right\}\right) \cup\left\{w, u_{1}, u_{2}\right\}$ where $u_{1} \in P N_{D}\left(y_{K_{1}}\right)$ and $u_{2} \in P N_{D}\left(y_{K_{2}}\right)$, is a TD set of $G$ of size $\gamma_{t}(G)+1$ containing the $P_{4}$ $y_{K_{1}} u_{1} w u_{2}$, a contradiction to Theorem 1.5

Claim 5. Let $K, K^{\prime} \in \overline{\mathcal{K}_{D}}$. If there exist $u \in P N_{D}\left(x_{K}\right) \cup P N_{D}\left(y_{K}\right)$ and $v \in P N_{D}\left(x_{K^{\prime}}\right) \cup$ $P N_{D}\left(y_{K^{\prime}}\right)$ such that $u v \in E(G)$, then there exist a set $S_{u v} \subseteq \overline{\mathcal{K}_{D}} \backslash\left\{K, K^{\prime}\right\}$ and a set $T_{u v} \subseteq$ $\bigcup_{L \in S_{u v}} P N_{D}\left(x_{L}\right) \cup P N_{D}\left(y_{L}\right)$ such that the following hold.
(i) For every $L \in S_{u v}$, every vertex in $P N_{D}\left(x_{L}\right) \cup P N_{D}\left(y_{L}\right)$ is adjacent to at least one vertex of $T_{u v} \cup\{u, v\}$.
(ii) $\left|\overline{\mathcal{K}_{D}} \backslash S_{u v}\right| \leq 2+k(k-1) / 2$.

Proof. Assume that there exist $u \in P N_{D}\left(x_{K}\right) \cup P N_{D}\left(y_{K}\right)$ and $v \in P N_{D}\left(x_{K^{\prime}}\right) \cup P N_{D}\left(y_{K^{\prime}}\right)$ such that $u v \in E(G)$. Let $T \subseteq \bigcup_{L \in \overline{\mathcal{K}_{D}} \backslash\left\{K, K^{\prime}\right\}} P N_{D}\left(x_{L}\right) \cup P N_{D}\left(y_{L}\right)$ be a maximum size independent set such that $T \cdots\{u, v\}$ and for every $L \in \overline{\mathcal{K}_{D}},\left|T \cap\left(P N_{D}\left(x_{L}\right) \cup P N_{D}\left(y_{L}\right)\right)\right| \leq 1$. Further denote by $S=\left\{L \in \widehat{\mathcal{K}_{D}} \mid T \cap\left(P N_{D}\left(x_{L}\right) \cup P N_{D}\left(y_{L}\right)\right) \neq \varnothing\right\} \cup\left\{K, K^{\prime}\right\}$. Observe that since $\{u, v\} \cup T \cup \bigcup_{L \in S}\left\{x_{L}, y_{L}\right\}$ induces $P_{6}+|T| P_{3}$, necessarily $|T| \leq k-1$ and thus, $|S| \leq k+1$. Now consider the sequence of sets constructed according to the following procedure.

1. Initialise $i=1, T_{1}=T$ and $R_{1}=S_{1}=S$.
2. Increase $i$ by one.
3. Let $T_{i} \subseteq \bigcup_{L \in \overline{\mathcal{K}_{D}} \backslash S_{i-1}} P N_{D}\left(x_{L}\right) \cup P N_{D}\left(y_{L}\right)$ be a maximum size independent set such that $T_{i} \cdots\{u, v\}$ and for every $L \in \overline{\mathcal{K}_{D}} \backslash S_{i-1},\left|T_{i} \cap\left(P N_{D}\left(x_{L}\right) \cup P N_{D}\left(y_{L}\right)\right)\right| \leq 1$. Set $R_{i}=\{L \in$ $\left.\overline{\mathcal{K}_{D}} \mid T_{i} \cap\left(P N_{D}\left(x_{L}\right) \cup P N_{D}\left(y_{L}\right)\right) \neq \varnothing\right\}$ and $S_{i}=S_{i-1} \cup R_{i}$.
4. If $\left|T_{i}\right|=\left|T_{i-1}\right|$ then stop the procedure.
5. Return to step 2.

Consider the value of $i$ at the end of the procedure (note that $i \geq 2$ ). Let us show that we may take

$$
T_{u v}=T_{i-1} \cup T_{i}
$$

and

$$
S_{u v}= \begin{cases}\overline{\mathcal{K}_{D}} \backslash S_{i-2} & \text { if } i>2 \\ \overline{\mathcal{K}_{D}} \backslash\left\{K, K^{\prime}\right\} & \text { otherwise }\end{cases}
$$

Observe first that by construction, for every $L \in \overline{\mathcal{K}_{D}} \backslash S_{i}$ and every vertex $x \in P N_{D}\left(x_{L}\right) \cup P N_{D}\left(y_{L}\right)$, $x$ is adjacent to at least one vertex in $T_{i} \cup\{u, v\}$ for otherwise, the procedure would have output $T_{i} \cup\{x\}$ in place of $T_{i}$. Similarly, for every $L \in R_{i}$ and every vertex $x \in P N_{D}\left(x_{L}\right) \cup P N_{D}\left(y_{L}\right), x$ is adjacent to at least one vertex in $T_{i-1} \cup\{u, v\}$ for otherwise, the procedure would have output $T_{i-1} \cup\{x\}$ in place of $T_{i-1}$; and for $L \in R_{i-1}$ and every vertex $x \in P N_{D}\left(x_{L}\right) \cup P N_{D}\left(y_{L}\right), x$ is adjacent to at least one vertex in $T_{i} \cup\{u, v\}$ for otherwise, the procedure would have output $T_{i} \cup\{x\}$ in place of $T_{i-1}$ (recall that by construction $\left.\left|T_{i-1}\right|=\left|T_{i}\right|\right)$. In particular, every vertex in $T_{i}$ is adjacent to at least one vertex in $T_{i-1}$ and thus, item (i) holds true. Now for every $1 \leq p<q \leq i-1,\left|T_{q}\right|<\left|T_{p}\right|$ by construction; and since $\left|T_{1}\right| \leq k-1$, it follows that $i \leq k+1$ and for every $1 \leq p \leq i-1,\left|T_{p}\right| \leq k-p$. Thus, if $i>2$ then

$$
\left|S_{i-2}\right|=2+\sum_{1 \leq p \leq i-2}\left|T_{p}\right| \leq 2+\sum_{1 \leq p \leq i-2} k-p \leq 2+\frac{k(k-1)}{2}
$$

and so, item (ii) holds true.

In the following, for any $K, K^{\prime} \in \overline{\mathcal{K}_{D}}, u \in P N_{D}\left(x_{K}\right) \cup P N_{D}\left(y_{K}\right)$ and $v \in P N_{D}\left(x_{K^{\prime}}\right) \cup$ $P N_{D}\left(y_{K^{\prime}}\right)$ such that $u v \in E(G)$, we denote by $S_{u v} \subseteq \overline{\mathcal{K}_{D}}$ and $T_{u v} \subseteq B$ the two sets given by Claim 5 .
Claim 6. If there exist $K_{1}, K_{1}^{\prime}, K_{2}, K_{2}^{\prime} \in \overline{\mathcal{K}_{D}}$ such that
(i) $K_{2}, K_{2}^{\prime} \in S_{u_{1} u_{1}^{\prime}}$ for some $u_{1} \in P N_{D}\left(x_{K_{1}}\right) \cup P N_{D}\left(y_{K_{1}}\right)$ and $u_{1}^{\prime} \in P N_{D}\left(x_{K_{1}^{\prime}}\right) \cup P N_{D}\left(y_{K_{1}^{\prime}}\right)$ where $u_{1} u_{1}^{\prime} \in E(G)$, and
(ii) one of $K_{1}$ and $K_{1}^{\prime}$ belongs to $S_{u_{2} u_{2}^{\prime}}$ for some $u_{2} \in P N_{D}\left(x_{K_{2}}\right) \cup P N_{D}\left(y_{K_{2}}\right)$ and $u_{2}^{\prime} \in$ $P N_{D}\left(x_{K_{2}^{\prime}}\right) \cup P N_{D}\left(y_{K_{2}^{\prime}}\right)$ where $u_{2} u_{2}^{\prime} \in E(G)$,
then $\operatorname{ct}_{\gamma_{t}}(G) \leq 2$.
Proof. Assume that four such cliques $K_{1}, K_{1}^{\prime}, K_{2}, K_{2}^{\prime} \in \overline{\mathcal{K}_{D}}$ exist and let $u_{1}, u_{1}^{\prime}, u_{2}, u_{2}^{\prime}$ be the vertices given by items (i) and (ii). Then for every $z \in T_{u_{1} u_{1}^{\prime}}$, there exists, by construction, a clique $L_{z} \in S_{u_{1} u_{1}^{\prime}}$ such that $z$ is a private neighbour of $x_{L_{z}}$ or $y_{L_{z}}$ : let us denote by $w_{z} \in\left\{x_{L_{z}}, y_{L_{z}}\right\}$ the vertex such that $z$ is not a private neighbour of $w_{z}$. Similarly, for every $z \in T_{u_{2} u_{2}^{\prime}}$, there exists a clique $L_{z} \in S_{u_{2} u_{2}^{\prime}}$ such that $z$ is a private neighbour of $x_{L_{z}}$ or $y_{L_{z}}$ : let us denote by $w_{z} \in\left\{x_{L_{z}}, y_{L_{z}}\right\}$ the vertex such that $z$ is not a private neighbour of $w_{z}$. Now assume without loss of generality that for every $i \in[2], u_{i} \in P N_{D}\left(y_{K_{i}}\right)$ and $u_{i}^{\prime} \in P N_{D}\left(y_{K_{i}^{\prime}}\right)$, and that furthermore, $K_{1}^{\prime} \in S_{u_{2} u_{2}^{\prime}}$. We contend that the set $D^{\prime}=\left(D \backslash\left(\left\{w_{z} \mid z \in T_{u_{1} u_{1}^{\prime}} \cup T_{u_{2} u_{2}^{\prime}}\right\} \cup\left\{x_{K_{1}^{\prime}}, x_{K_{2}}, x_{K_{2}^{\prime}}\right\}\right)\right) \cup T_{u_{1} u_{1}^{\prime}} \cup T_{u_{2} u_{2}^{\prime}} \cup$ $\left\{u_{1}, u_{1}^{\prime}, u_{2}, u_{2}^{\prime}\right\}$ is a TD set of $G$. Indeed, by Claim $5(\mathrm{i})$, every vertex in $P N_{D}\left(w_{z}\right)$ for $z \in T_{u_{1} u_{1}^{\prime}}$, is adjacent to at least one vertex in $T_{u_{1} u_{1}^{\prime}} \cup\left\{u_{1}, u_{1}^{\prime}\right\}$; and similarly, every vertex in $P N_{D}\left(w_{z}\right)$ for $z \in T_{u_{2} u_{2}^{\prime}}$, is adjacent to at least one vertex in $T_{u_{2} u_{2}^{\prime}} \cup\left\{u_{2}, u_{2}^{\prime}\right\}$. Furthermore, by Claim 5 (i), since $K_{2}, K_{2}^{\prime} \in S_{u_{1} u_{1}^{\prime}}$ and $K_{1}^{\prime} \in S_{u_{2} u_{2}^{\prime}}$, every vertex in $P N_{D}\left(x_{K_{2}}\right) \cup P N_{D}\left(x_{K_{2}^{\prime}}\right)$ is adjacent to at least one vertex in $T_{u_{1} u_{1}^{\prime}} \cup\left\{u_{1}, u_{1}^{\prime}\right\}$, and every vertex in $P N_{D}\left(x_{K_{1}^{\prime}}\right)$ is adjacent to at least one vertex in $T_{u_{2} u_{2}^{\prime}} \cup\left\{u_{2}, u_{2}^{\prime}\right\}$. It follows that $D^{\prime}$ is indeed a TD set of $G$; and since $\left|D^{\prime}\right|=\gamma_{t}(G)+1$ and $D^{\prime}$ contains the $P_{4} y_{K_{1}} u_{1} u_{1}^{\prime} y_{K_{1}^{\prime}}^{\prime}$, we conclude by Theorem 1.5 that $c t_{\gamma_{t}}(G) \leq 2$.
Claim 7. If $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$ then $\left|\overline{\mathcal{K}_{D}}\right| \leq k^{2}(k(k-1) / 2+$ 2) $+|A|-1$.

Proof. Assume that $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$ and suppose to the contrary that $\left|\overline{\mathcal{K}_{D}}\right|>k^{2}(k(k-1) / 2+2)+|A|-1$. Let us show that there then exist four cliques in $\overline{\mathcal{K}_{D}}$ satisfying items (i) and (ii) of Claim 6, which would contradict the fact that $c t_{\gamma_{t}}(G)>2$. Let $K_{1}, K_{1}^{\prime} \in \overline{\mathcal{K}_{D}}$ be two cliques for which there exist $u_{1} \in P N_{D}\left(x_{K_{1}}\right) \cup P N_{D}\left(y_{K_{1}}\right)$ and $u_{1}^{\prime} \in P N_{D}\left(x_{K_{1}^{\prime}}\right) \cup P N_{D}\left(y_{K_{1}^{\prime}}\right)$ such that $u_{1} u_{1}^{\prime} \in E(G)$ (the existence of such cliques is guaranteed by Claim(4). We claim that the algorithm below always outputs four cliques of $\overline{\mathcal{K}_{D}}$ satisfying items (i) and (ii) of Claim 6.

1. Initialise $i=1$ and $C_{1}=S_{u_{1} u_{1}^{\prime}}$.
2. Increase $i$ by one.
3. If there exist $K, K^{\prime} \in C_{i-1}$ with $u \in P N_{D}\left(x_{K}\right) \cup P N_{D}\left(y_{K}\right)$ and $u^{\prime} \in P N_{D}\left(x_{K^{\prime}}\right) \cup P N_{D}\left(y_{K^{\prime}}\right)$ such that

- $u u^{\prime} \in E(G)$ and
- $K_{i-1} \in S_{u u^{\prime}}$ or $K_{i-1}^{\prime} \in S_{u u^{\prime}}$,
then output $K_{i-1}, K_{i-1}^{\prime}, K, K^{\prime}$.

4. If $\left|C_{i-1}\right| \geq|A|$ then let $K_{i}, K_{i}^{\prime} \in C_{i-1}$ be two cliques for which there exist $u_{i} \in P N_{D}\left(x_{K_{i}}\right) \cup$ $P N_{D}\left(y_{K_{i}}\right)$ and $u_{i}^{\prime} \in P N_{D}\left(x_{K_{i}^{\prime}}\right) \cup P N_{D}\left(y_{K_{i}^{\prime}}\right)$ such that $u_{i} u_{i}^{\prime} \in E(G)$; and set $C_{i}=C_{i-1} \cap$ $S_{u_{i} u_{i}^{\prime}}$.
5. If $\left|C_{i-1}\right|<|A|$ then set $C_{i}=C_{i-1}$.
6. Return to step 2.

Before showing correctness of the above algorithm, let us first note that for every $j \geq 1$ satisfying the condition in step 4 (that is, $\left|C_{j}\right| \geq|A|$ ), the existence of the cliques $K_{j}$ and $K_{j}^{\prime}$ is guaranteed by Claim 4. Now let us show that if the above algorithm terminates then its output is indeed as claimed. Assume that the algorithm terminates when the counter $i$ equals some value $j \geq 1$ and let $K_{j-1}, K_{j-1}^{\prime}, K, K^{\prime}$ be the output. Observe first that since the algorithm terminates, the condition in step 5 is never satisfied during its run (the algorithm would have otherwise looped indefinitely); in particular $C_{j-1}=\bigcap_{1 \leq \ell \leq j-1} S_{u_{\ell} u_{\ell}^{\prime}}$. Since by construction, $K$ and $K^{\prime}$ both belong to $C_{j-1}$,
they belong in particular to $S_{u_{j-1} u_{j-1}^{\prime}}$ and so, item (i) of Claim 6 indeed holds. Furthermore, by construction, there exist $u \in P N_{D}\left(x_{K}\right) \cup P N_{D}\left(y_{K}\right)$ and $u^{\prime} \in P N_{D}\left(x_{K^{\prime}}\right) \cup P N_{D}\left(y_{K^{\prime}}\right)$ with $u u^{\prime} \in E(G)$, such that $K_{j-1} \in S_{u u^{\prime}}$ or $K_{j-1}^{\prime} \in S_{u u^{\prime}}$, and thus, item (ii) of Claim 6 holds true as well.

There remains to show that the algorithm indeed terminates. To this end, let us first show by induction that for every $j \in\left[k^{2}+1\right]$, the condition in step 4 is always satisfied, that is, $\left|C_{j-1}\right| \geq|A|$. More specifically, we show that for every $j \in\left[k^{2}\right],\left|C_{j}\right| \geq\left(k^{2}-j\right)(k(k-1) / 2+2)+|A|$. For $j=1$, the result readily follows from the fact that $\left|\overline{\mathcal{K}_{D}}\right|=\left|C_{1}\right|+\left|\overline{\mathcal{K}_{D}} \backslash C_{1}\right| \geq k^{2}(k(k-1) / 2+2)+|A|$ by assumption and $\left|\overline{\mathcal{K}_{D}} \backslash C_{1}\right| \leq k(k-1) / 2+2$ by Claim 5(ii). For $j>1,\left|C_{j}\right|=\left|S_{u_{j} u_{j}^{\prime}} \cap C_{j-1}\right|$ by definition and so,

$$
\begin{aligned}
\left|C_{j}\right| & =\left|\overline{\mathcal{K}_{D}}\right|-\left|\overline{\mathcal{K}_{D}} \backslash C_{j}\right| \\
& =\left|\overline{\mathcal{K}_{D}}\right|-\left|\left(\overline{\mathcal{K}_{D}} \backslash S_{u_{j} u_{j}^{\prime}}\right) \cup\left(\overline{\mathcal{K}_{D}} \backslash C_{j-1}\right)\right| \\
& \geq\left|\overline{\mathcal{K}_{D}}\right|-\left(\left|\overline{\mathcal{K}_{D}} \backslash S_{u_{j} u_{j}^{\prime}}\right|+\left|\overline{\mathcal{K}_{D}} \backslash C_{j-1}\right|\right) \\
& =\left|C_{j-1}\right|-\left|\overline{\mathcal{K}_{D}} \backslash S_{u_{j} u_{j}^{\prime}}\right| .
\end{aligned}
$$

But $\left|C_{j-1}\right| \geq\left(k^{2}-(j-1)\right)(k(k-1) / 2+2)+|A|$ by the induction hypothesis and $\left|\overline{\mathcal{K}_{D}} \backslash S_{u_{j} u_{j}^{\prime}}\right| \geq$ $k(k-1) / 2+2$ by Claim 55(ii) and thus, $\left|C_{j}\right| \geq\left(k^{2}-j\right)(k(k-1) / 2+2)+|A|$ as claimed.

Now suppose to the contrary that the algorithm has not yet terminated by the time the counter $i$ reaches the value $t=k(k-1) / 4+3$. Then for every $j<t, K_{j}, K_{j}^{\prime} \notin S_{u_{t} u_{t}^{\prime}}$ : indeed, if there exist indices $j \in[t-1]$ such that one of $K_{j}$ and $K_{j}^{\prime}$ belongs to $S_{u_{t} u_{t}^{\prime}}$ then, letting $\ell$ be the smallest such index, we have $C_{t-1} \subseteq C_{\ell}$ and $K_{t}, K_{t}^{\prime} \in C_{t-1}$; but then, the algorithm would have terminated after setting the counter $i$ to $\ell+1$ and output $K_{\ell}, K_{\ell}^{\prime}, K=K_{t}, K^{\prime}=K_{t}^{\prime}$. It follows that $\left\{K_{j}, K_{j}^{\prime} \mid j \in[t-1]\right\} \subseteq \overline{\mathcal{K}_{D}} \backslash S_{u_{t} u_{t}^{\prime}} ;$ but $\left|\left\{K_{j}, K_{j}^{\prime} \mid j \in[t-1]\right\}\right|=2(t-1)=k(k-1) / 2+4$, a contradiction to Claim 5 (ii).

To conclude, assume that $G$ is a No-instance for 2 -Edge $\operatorname{Contraction}\left(\gamma_{t}\right)$. Then by Observation 2 and Claim 7

$$
\left|D \cap N\left[\overline{\mathcal{K}_{D}}\right]\right|=2\left|\overline{\mathcal{K}_{D}}\right| \leq k^{2}(k(k-1)+4)+2(|A|-1)
$$

and thus, combined with Claim 2, we conclude that

$$
|D \cap N[C]|=\left|D \cap N\left[\mathcal{K}_{D}\right]\right|+\mid D \cap N\left[\overline{\mathcal{K}_{D}}\left|\leq k^{2}(k(k-1)+4)+6\right| A \mid-2\right.
$$

Now observe that $D^{\prime}=D \backslash N[C]$ has size at most $|A|$ : indeed, since $D^{\prime}$ dominates (only) vertices from $A \cup B$, if $\left|D^{\prime}\right|>|A|$ then $\left(D \backslash D^{\prime}\right) \cup A$ is a TD set of $G$ of size strictly less than that of $D$, a contradiction. It follows that

$$
\gamma_{t}(G)=|D \cap N[C]|+|D \backslash N[C]| \leq k^{2}(k(k-1)+4)+7|A|-2
$$

and so, we may take $f(k)=k^{4}+4 k^{2}+21 k+19$ as claimed.
Since for any graph $G, G$ is a Yes-instance for 2-Edge Contraction $\left(\gamma_{t}\right)$ if and only if $G$ is a No-instance for Contraction $\operatorname{Number}\left(\gamma_{t}, 3\right)$, the following ensues from Lemma 3.1.

Corollary 3.2. For every $k \geq 0$, $\operatorname{Contraction~} \operatorname{Number}\left(\gamma_{t}, 3\right)$ is polynomial-time solvable on $\left(P_{6}+k P_{3}\right)$-free graphs.

Lemma 3.3. Contraction $\operatorname{Number}\left(\gamma_{t}, 2\right)$ is polynomial-time solvable on $H$-free graphs if $H \subseteq_{i}$ $P_{5}+t K_{1}$ for some $t \geq 0$, or $H \subseteq_{i} P_{4}+t P_{3}$ for some $t \geq 0$.
Proof. Assume that $H \subseteq_{i} P_{5}+t K_{1}$ for some $t \geq 0$ (the case where $H \subseteq_{i} P_{4}+t P_{3}$ for some $t \geq 0$ is handled similarly) and let $G$ be an $H$-free graph. Since $H$ is a fortiori an induced subgraph of $P_{6}+t P_{3}$, we may use the polynomial-time algorithm for $\left(P_{6}+t P_{3}\right)$-free graphs given by Corollary 3.2 to determine whether $G$ is a Yes-instance for Contraction Number $\left(\gamma_{t}, 3\right)$ or not. If the answer is yes then we output No; otherwise, we use the polynomial-time algorithm for $\left(P_{5}+t K_{1}\right)$-free graphs given by Theorem 1.6 to determine whether $G$ is a Yes-instance for $\operatorname{Contraction~} \operatorname{Number}\left(\gamma_{t}, 1\right)$ or not, and output the answer accordingly.

Figure 3: The variable gadget $G_{x}$ for a variable $x$ contained in clauses $c, c^{\prime}$ and $c^{\prime \prime}$ (a rectangle indicates that the corresponding set of vertices induces a clique).

(a) The graph $G_{c}^{T}$.

(b) The graph $G_{c}^{F}$.

Figure 4: The clause gadget $G_{c}$ for a clause $c=x \vee y \vee z$ is the disjoint union of $G_{c}^{T}$ and $G_{c}^{F}$ (a rectangle indicates that the corresponding set of vertices is a clique).

### 3.2 Hardness results

In this section, we show that Contraction $\operatorname{Number}\left(\gamma_{t}, 2\right)$ and $\operatorname{Contraction~} \operatorname{Number}\left(\gamma_{t}, 3\right)$ are NP-hard on a number of monogenic graph classes. We first consider the case $k=2$.

Lemma 3.4. Contraction $\operatorname{Number}\left(\gamma_{t}, 2\right)$ is NP-hard on $K_{1,3}$-free graphs.
Proof. We use the same construction as in [11, Theorem 6]. More precisely, we reduce from Positive Exactly 3-Bounded 1-In-3 3-Sat (see Section 2 for a precise definition of this problem): given an instance $\Phi$ of this problem, with variable set $X$ and clause set $C$, we construct an instance $G$ of $\operatorname{Contraction~} \operatorname{Number}\left(\gamma_{t}, 2\right)$ as follows. For every variable $x \in X$ appearing in clauses $c, c^{\prime}$ and $c^{\prime \prime}$, we introduce the gadget $G_{x}$ depicted in Figure 3 (where a rectangle indicates that the corresponding set of vertices is a clique). For every clause $c \in C$ containing variables $x, y$ and $z$, we introduce the gadget $G_{c}$ which is the disjoint union of the graph $G_{c}^{T}$ and the graph $G_{c}^{F}$ depicted in Figure 4 (where a rectangle indicates that the corresponding set of vertices is a clique) and further add for every $\ell \in\{x, y, z\}$, an edge between $t_{\ell}^{c}$ and $t_{c}^{\ell}$, and an edge between $f_{\ell}^{c}$ and $f_{c}^{\ell}$. We let $G$ be the resulting graph. Let us show that $\Phi$ is satisfiable if and only if $c t_{\gamma_{t}}(G)=2$. To do so, we will rely on the following key result shown in [11].
Claim 8 ([11]). The following statements are equivalent.
(i) $\Phi$ is satisfiable.
(ii) $\gamma_{t}(G)=14|X|+8|C|$.
(iii) $\operatorname{ct}_{\gamma_{t}}(G)>1$.

Now assume that $\Phi$ is satisfiable and consider a truth assignment satisfying $\Phi$. We construct a minimum TD set $D$ of $G$ as follows. For every variable $x \in X$ appearing in clauses $c, c^{\prime}$ and $c^{\prime \prime}$, if $x$ is true then we include $\left\{u_{x}, T_{x}\right\} \cup\left\{d_{x}^{p}, t_{x}^{p}, h_{x}^{p}, j_{x}^{p} \mid p \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}$ in $D$; otherwise, we include $\left\{u_{x}, F_{x}\right\} \cup\left\{b_{x}^{p}, d_{x}^{p}, j_{x}^{p}, f_{x}^{p} \mid p \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}$ in $D$. For every clause $c \in C$ containing variables $x, y$ and $z$, exactly one variable is true, say $x$ without loss of generality, in which case we include
$\left\{v_{c}, g_{c}^{x}\right\} \cup\left\{c_{c}^{x}, a_{c}^{x}\right\} \cup\left\{c_{c}^{t}, d_{c}^{t} \mid t \in\{y, z\}\right\}$ in $D$. It is not difficult to see that the constructed set $D$ is indeed a TD set and since $|D|=14|X|+8|C|$, we conclude by Claim 8 that $D$ is minimum. Now consider a clause $c \in C$ containing variables $x, y$ and $z$ and assume without loss of generality that $x$ is true (and thus $y$ and $z$ are false). Then $D \cup\left\{a_{c}^{y}\right\}$ contains the $P_{4} c_{c}^{x} a_{c}^{x} a_{c}^{y} c_{c}^{y}$ and thus, $c t_{\gamma_{t}}(G) \leq 2$ by Theorem 1.5 but $c t_{\gamma_{t}}(G)>1$ by Claim 8 and so, $c t_{\gamma_{t}}(G)=2$. Conversely, if $c t_{\gamma_{t}}(G)=2$ then $\Phi$ is satisfiable by Claim 8 . Since $G$ is $K_{1,3}$-free, the lemma follows.

Lemma 3.5. Contraction $\operatorname{Number}\left(\gamma_{t}, 2\right)$ is coNP-hard on $P_{6}$-free graphs.
Proof. If $G$ is a $P_{6}$-free graph then $c t_{\gamma_{t}}(G) \leq 2$ as shown in the proof of Lemma 3.1] and since Contraction $\operatorname{Number}\left(\gamma_{t}, 1\right)$ is $\operatorname{NP}$-hard on $P_{6}$-free graphs by Theorem 1.6 the lemma follows from Observation 1

Lemma 3.6. Contraction $\operatorname{Number}\left(\gamma_{t}, 2\right)$ is $\operatorname{NP}$-hard on $2 P_{4}$-free graphs.
Proof. We use the same reduction as in [11, Theorem 5]. More precisely, we reduce from 3-Sat: given an instance $\Phi$ of this problem, with variable set $X$ and clause set $C$, we construct an instance $G$ of Contraction $\operatorname{Number}\left(\gamma_{t}, 2\right)$ as follows. For every variable $x \in X$, we introduce the gadget $G_{x}$ consisting of a triangle on vertex set $\left\{x, \bar{x}, u_{x}\right\}$ and an additional vertex $v_{x}$ adjacent to $u_{x}$ (that is, $G_{x}$ is a paw); the vertices $x$ and $\bar{x}$ are referred to as literal vertices. For every clause $c \in C$, we introduce a clause vertex, denoted by $c$, and add an edge between $c$ and every literal vertex whose corresponding literal appears in the clause $c$. Finally, we add an edge between every two clause vertices so that the set of clause vertices induces a clique. We let $G$ be the resulting graph. We next show that $\Phi$ is satisfiable if and only if $c t_{\gamma_{t}}(G)=2$. To do so, we will rely on the following key results proved in [11].

Claim 9 (11]). The following statements are equivalent.
(i) $\Phi$ is satisfiable.
(ii) $\gamma_{t}(G)=2|X|$.
(iii) $\operatorname{ct}_{\gamma_{t}}(G)>1$.

Now assume that $\Phi$ is satisfiable and consider a truth assignment satisfying $\Phi$. We construct a minimum TD set $D$ of $G$ as follows. For every variable $x \in X$, if $x$ is true then we include $\left\{u_{x}, x\right\}$ in $D$; otherwise, we include $\left\{u_{x}, \bar{x}\right\}$ in $D$. It is not difficult to see that the constructed set $D$ is indeed a TD set of $G$ and since $|D|=2|X|$, we conclude by Claim 9 that $D$ is minimum. Now consider a clause $c \in C$ containing variables $x, y$ and $z$, and assume without loss of generality that $x$ and $y$ both appear positive in $c$. Then the set $\left(D \backslash\left(V\left(G_{x}\right) \cup V\left(G_{y}\right)\right)\right) \cup\left\{x, u_{x}, y, u_{y}, c\right\}$ is a TD set of $G$ of size $\gamma_{t}(G)+1$ containing the $P_{4} u_{x}, x, c, u_{y}$ and thus, $c t_{\gamma_{t}}(G) \leq 2$ by Theorem 1.5 but $c t_{\gamma_{t}}(G)>1$ by Claim 9 and so, $c t_{\gamma_{t}}(G)=2$. Conversely, if $c t_{\gamma_{t}}(G)=2$ then $\Phi$ is satisfiable by Claim 9. Since $G$ is readily seen to be $2 P_{4}$-free, the lemma follows.

Lemma 3.7. Contraction $\operatorname{Number}\left(\gamma_{t}, 2\right)$ is coNP-hard on $\left(P_{5}+P_{2}\right)$-free graphs.
Proof. Since $P_{5}+P_{2} \subseteq_{i} P_{6}+P_{3}$, Contraction $\operatorname{Number}\left(\gamma_{t}, 3\right)$ is polynomial-time solvable on $\left(P_{5}+P_{2}\right)$-free graphs by Corollary 3.2, but Contraction $\operatorname{Number}\left(\gamma_{t}, 1\right)$ is NP-hard on $\left(P_{5}+P_{2}\right)$ free graphs by Theorem 1.6 and thus, the lemma follows from Observation 1

Lemma 3.8. Let $G$ be a graph such that $\gamma_{t}(G) \geq 3$ and let $H$ be the graph obtained by 4-subdividing every edge of $G$. Then $c t_{\gamma_{t}}(G)=c t_{\gamma_{t}}(H)$.

Proof. It was shown in [11, Lemma 7] that $\gamma_{t}(H)=\gamma_{t}(G)+2|E(G)|$. Let us show how to construct from a TD set $D$ of $G$ a TD set $T(D)$ of $H$ of size $|D|+2|E(G)|$ (see Figure 5). For every edge $e=u v \in E(G)$, we will denote by $u e_{1} e_{2} e_{3} e_{4} v$ the $P_{6}$ in $H$ replacing the edge $e$. Firstly, we include in $T(D)$ every vertex of $D$. Then for every edge $e=u v \in E(G)$, if $D \cap\{u, v\}=\varnothing$, we further include $\left\{e_{2}, e_{3}\right\}$ in $T(D)$; if $|D \cap\{u, v\}|=1$, say $u \in D$ without loss of generality, we further include $\left\{e_{3}, e_{4}\right\}$ in $T(D)$; and if $u, v \in D$, we further include $\left\{e_{1}, e_{4}\right\}$ in $T(D)$. It is not difficult to see that the constructed set $T(D)$ is indeed a TD set of $H$ and that $|T(D)|=|D|+2|E(G)|$.

Conversely, given a TD set $D$ of $H$, let us show how to construct from $D$ a TD set $T^{-1}(D)$ of $G$ of size at most $|D|-2|E(G)|$. To this end, we show how, given a graph $F$, a graph $F^{\prime}$ obtained from $F$ by 4 -subdividing one edge $u v \in E(F)$ and a TD set $D_{F^{\prime}}$ of $F^{\prime}$, we can construct from

Figure 5: Constructing a total dominating set of $H$ from a total dominating set of $G$ (vertices in red belong to the corresponding total dominating set).
$D_{F^{\prime}}$ a TD set $D_{F}$ of $F$ of size at most $\left|D_{F^{\prime}}\right|-2$. Then by iterating this procedure on $H$, we will obtain the desired TD set $T^{-1}(D)$ of $G$.

Let $u e_{1} e_{2} e_{3} e_{4} v$ be the path in $F^{\prime}$ corresponding to the 4-subdivision of the edge $u v \in E(F)$. If $e_{1} \in D_{F^{\prime}}$ and $u \notin D_{F^{\prime}}$ then necessarily $e_{2} \in D_{F^{\prime}}$, for $e_{1}$ would otherwise not be dominated. Similarly, if $e_{4} \in D_{F^{\prime}}$ and $v \notin D_{F^{\prime}}$ then necessarily $e_{3} \in D_{F^{\prime}}$, for $e_{4}$ would otherwise not be dominated. Thus, if $e_{1}, e_{4} \in D_{F^{\prime}}$, we let $D_{F}=\left(D_{F^{\prime}} \backslash\left\{e_{1}, e_{2}, e_{3}, e_{4}\right\}\right) \cup\{u, v\}$. Suppose next that $e_{4} \notin D_{F^{\prime}}$. Then $e_{2} \in D_{F^{\prime}}$, for $e_{3}$ would otherwise not be dominated; and if $v \notin D_{F^{\prime}}$ then $e_{3} \in D_{F^{\prime}}$, for $e_{4}$ would otherwise not be dominated. Thus, if $e_{1} \in D_{F^{\prime}}$ and $e_{4} \notin D_{F^{\prime}}$, then either $v \in D_{F^{\prime}}$ in which case we let $D_{F}=D_{F^{\prime}} \backslash\left\{e_{1}, e_{2}, e_{3}, e_{4}\right\}$, or $v \in D_{F^{\prime}}$ in which case we let $D_{F}=\left(D_{F^{\prime}} \backslash\left\{e_{1}, e_{2}, e_{3}, e_{4}\right\}\right) \cup\{v\}$. We proceed symmetrically if $e_{1} \notin D_{F^{\prime}}$ and $e_{4} \in D_{F^{\prime}}$. Finally, if $e_{1}, e_{4} \notin D_{F^{\prime}}$ then $e_{2}, e_{3} \in D_{F^{\prime}}$ and so, we may take $D_{F}=D_{F^{\prime}} \backslash\left\{e_{1}, e_{2}, e_{3}, e_{4}\right\}$. Now let us observe that the TD set $T^{-1}(D)$ constructed as such satisfies the following property.
Observation 4. For every edge $e=u v \in E(G)$, if $e_{1} \in D\left(e_{4} \in D\right.$, respectively) then $v \in T^{-1}(D)$ ( $u \in T^{-1}(D)$, respectively).

We next show that $c t_{\gamma_{t}}(G)=c t_{\gamma_{t}}(H)$. As the following was shown in [11, Lemma 7], it in fact suffices to show that $c t_{\gamma_{t}}(G)=2$ if and only if $c t_{\gamma_{t}}(H)=2$.
Claim 10 (11]). $c t_{\gamma_{t}}(G)=1$ if and only if $c t_{\gamma_{t}}(H)=1$.
Assume first that $c t_{\gamma_{t}}(G)=2$ and let $D$ be a TD set of $G$ of size $\gamma_{t}(G)+1$ containing a $P_{4}$, a $2 P_{3}$ or a $K_{1,3}$ (see Theorem 1.5). Suppose first that $D$ contains a $P_{4}$ with edge set $e^{1}=u v$, $e^{2}=v w$ and $e^{3}=w t$. Then by construction, the TD set $T(D)$ of $G$ contains the $2 P_{3} e_{4}^{1} v e_{1}^{2}, e_{4}^{2} w e_{1}^{3}$. Second, suppose that $D$ contains a $2 P_{3}$ with edge set $e^{1}=u v, e^{2}=v w, e^{3}=x y$ and $e^{4}=y z$. Then by construction, the TD set $T(D)$ of $G$ contains the $2 P_{3} e_{4}^{1} v e_{1}^{2}, e_{4}^{3} y e_{1}^{4}$. Suppose finally that $D$ contains a $K_{1,3}$ on edge set $e^{1}=u v, e^{2}=w v$ and $e^{3}=t v$. Then by construction, the TD set $T(D)$ contains the $K_{1,3} v, e_{4}^{1}, e_{4}^{2}, e_{4}^{3}$. In all three cases, we conclude by Theorem 1.5 that $c t_{\gamma_{t}}(H) \leq 2$ and by Claim 10 that in fact $c t_{\gamma_{t}}(H)=2$.

Conversely assume that $c t_{\gamma_{t}}(H)=2$ and denote by $\mathcal{D}$ the set of TD sets of $H$ of size $\gamma_{t}(H)+1$ containing a $P_{4}$, a $2 P_{3}$ or a $K_{1,3}$ (note that $\mathcal{D} \neq \varnothing$ by Theorem 1.5). Observe that if there exists $D \in \mathcal{D}$ such that $T^{-1}(D)$ contains a $P_{4}$, a $2 P_{3}$ or a $K_{1,3}$, then since $c t_{\gamma_{t}}(G)>1$ by Claim 10, it must be that $\left|T^{-1}(D)\right|=\gamma_{t}(G)+1$ and thus, $c t_{\gamma_{t}}(G)=2$ by Theorem 1.5. Now if there exists $D \in \mathcal{D}$ such that $D$ contains a $K_{1,3} u, e_{1}^{1}, e_{1}^{2}, e_{1}^{3}$ where $u$ is the vertex of degree three and $e^{i}=u x_{i}$ for every $i \in[3]$, then by Observation 4$]$ the TD set $T^{-1}(D)$ contains the $K_{1,3} u, x_{1}, x_{2}, x_{3}$ and so, $c t_{\gamma_{t}}(G)=2$ by the above.

Assume henceforth that no TD set in $\mathcal{D}$ contains a $K_{1,3}$. We contend that there then exists a TD set in $\mathcal{D}$ containing a $2 P_{3}$. To prove this claim, let us first show that there exists $D \in \mathcal{D}$ such that for every edge $e \in E(G),\left\{e_{1}, e_{2}, e_{3}, e_{4}\right\} \nsubseteq D$. In the following, given a TD set $D \in \mathcal{D}$ and an edge $e \in E(G)$, if $\left\{e_{1}, e_{2}, e_{3}, e_{4}\right\} \subseteq D$ then $D$ is said to accommodate the edge $u v$. Consider a TD set $D \in \mathcal{D}$ accommodating the minimum number of edges amongst every TD set in $\mathcal{D}$, and suppose to the contrary that $D$ accommodates an edge $e=u v \in E(G)$. Let us show that $\mathcal{D} \backslash\{D\}$ contains a TD set accommodating fewer edges than $D$, which would contradict the choice of $D$. First note that one of $u$ and $v$ does not belong to $D$ : indeed, if $\{u, v\} \subseteq D$ then $D \backslash\left\{e_{3}\right\}$ is a minimum TD set of $H$ containing the $P_{3} u e_{1} e_{2}$, a contradiction to Theorem 1.5. Furthermore, since $\gamma_{t}(G) \geq 3$, at least one of $u$ and $v$ has degree at least two in $G$.

Suppose first that there exists $x \in\{u, v\} \backslash D$ such that $d_{G}(x) \geq 2$, say $x=v$ without loss of generality, and let $f=v w$ be an edge of $G$. Note that since $v \notin D$ by assumption, necessarily $f_{2} \in D$, for $f_{1}$ would otherwise not be dominated. Now if $f_{1} \notin D$ then $f_{3} \in D$ as $f_{2}$ should be dominated; but then, the TD set $\left(D \backslash\left\{e_{4}\right\}\right) \cup\left\{f_{1}\right\}$ belongs to $\mathcal{D}$ (note indeed that it contains $e_{1} e_{2} e_{3}$ and $f_{1} f_{2} f_{3}$ ) and accommodates fewer edges than $D$, a contradiction to the choice of $D$. Thus, it must be that $f_{1} \in D$; but then, the TD set $\left(D \backslash\left\{e_{3}\right\}\right) \cup\{v\}$ belongs to $\mathcal{D}$ (note indeed that it contains the $P_{4} e_{4} v f_{1} f_{2}$ ) and accommodates fewer edges than $D$, a contradiction to the choice of $D$.

Suppose second that for every $x \in\{u, v\} \backslash D, d_{G}(x)=1$. By the above, $\{u, v\} \backslash D \neq \varnothing$ and at least one of $u$ and $v$ has degree at least two in $G$ : let us assume without loss of generality that $u \notin D$ and $d_{G}(v) \geq 2$ (note that then $d_{G}(u)=1$ and $v \in D$ ). Observe that since $D \backslash\left\{e_{3}\right\}$ is a minimum TD set of $H$, it cannot contain a $P_{3}$ by Theorem 1.5. Now among the neighbours of $v$, there must be one of degree at least two, for $G$ is otherwise a star thereby contradicting the fact that $\gamma_{t}(G) \geq 3$. Thus, let $f=v w$ be an edge of $G$ such that $d_{G}(w) \geq 2$. Then since $f_{1} \notin D$ ( $D \backslash\left\{e_{3}\right\}$ would otherwise contain the $P_{3} e_{4} v f_{1}$ ), necessarily $f_{3} \in D$ as $f_{2}$ should be dominated; and since $f_{3}$ should be dominated but $D \backslash\left\{e_{3}\right\}$ cannot contain a $P_{3}$, necessarily $\left|D \cap\left\{f_{2}, f_{4}\right\}\right|=1$. Now if $f_{2} \in D$ then the TD set $\left(D \backslash\left\{e_{4}\right\}\right) \cup\left\{f_{1}\right\}$ belongs to $\mathcal{D}$ (note indeed that it contains the $P_{4}$ $v f_{1} f_{2} f_{3}$ ) and accommodates fewer edges than $D$ (recall that in this case $f_{4} \notin D$ ), a contradiction to the choice of $D$. Now if $f_{4} \in D$ then $w \notin D$, for $D \backslash\left\{e_{3}\right\}$ would otherwise contain the $P_{3} f_{3} f_{4} w$; but then, by considering the TD set $\left(D \backslash\left\{e_{3}, e_{4}\right\}\right) \cup\left\{f_{1}, f_{2}\right\}$ in place of $D$, we may argue as in the previous case (recall indeed that $w \notin D$ and $d_{G}(w) \geq 2$ ) and conclude similarly to a contradiction. Therefore, $D$ accommodates no edge.

Let us next show that among those TD sets of $\mathcal{D}$ accommodating no edge, there exists a TD set $D$ such that $D$ contains a $2 P_{3}$. Indeed, let $D \in \mathcal{D}$ be a TD set which accommodates no edge and suppose that $D$ contains no $2 P_{3}$. Let us show how obtain from $D$ a TD set with a $2 P_{3}$. Note that since $D$ contains no $2 P_{3}, D$ contains a $P_{4}$ by assumption. Now suppose first that $D$ contains a $P_{4}$ of the form $u e_{1} e_{2} e_{3}$, where $e=u v \in E(G)$. Since $D$ does not accommodate the edge $u v$, $e_{4} \notin D$ and so, there must exist $f=v w \in E(G)$ such that $f_{1} \in D$ ( $v$ would otherwise not be dominated). But then, either $v \notin D$ in which case $f_{2} \in D$ ( $f_{1}$ would otherwise not be dominated) and thus, the TD set $\left(D \backslash\left\{e_{3}\right\}\right) \cup\{v\}$ contains the $2 P_{3} u e_{1} e_{2}, v f_{1} f_{2}$; or $v \in D$ in which case the TD set $\left(D \backslash\left\{e_{3}\right\}\right) \cup\left\{e_{4}\right\}$ contains the $2 P_{3} u e_{1} e_{2}, e_{4} v f_{1}$. Second, suppose that $D$ contains a $P_{4}$ of the form $e_{4} v f_{1} f_{2}$, where $e=u v, f=v w \in E(G)$. Then we may assume that $f_{3} \notin D$ (we revert to the previous case otherwise) which implies that $w \in D$ for otherwise, $f_{4}$ would not be dominated. But then, either $f_{4} \in D$ in which case the TD set $\left(D \backslash\left\{f_{2}\right\}\right) \cup\left\{f_{3}\right\}$ contains the $2 P_{3}$ $e_{4} v f_{1}, f_{3} f_{4} w$; or $f_{4} \notin D$ in which case the TD set $\left(D \backslash\left\{f_{2}\right\}\right) \cup\left\{f_{4}\right\}$ contains the $2 P_{3} e_{4} v f_{1}, f_{4} w t$ where $t \in N_{H}(w) \cap D$.

Finally, let us show that among those TD sets in $\mathcal{D}$ accommodating no edge and containing a $2 P_{3}$, there exists a TD set $D$ such that (1) no $P_{3}$ in $D$ is of the form $e_{1} e_{2} e_{3}$ where $e \in E(G)$, and (2) if $D$ contains a $P_{3}$ of the form $u e_{1} e_{2}$, where $e=u v \in E(G)$, then $v$ has a neighbour $f_{1} \in D \backslash\left\{e_{4}\right\}$ where $f=v w \in E(G)$. To this end, let $D \in \mathcal{D}$ be a TD set accommodating no edge and containing a $2 P_{3}$. Suppose that $D$ contains a $P_{3}$ of the form $e_{1} e_{2} e_{3}$ where $e=u v \in E(G)$. Since $D$ does not accommodate the edge $u v, e_{4} \notin D$, which implies that $v$ must have a neighbour $f_{1} \in D$ where $f=v w \in E(G)$. But then, either $w \in D$ in which case we may consider the TD set $\left(D \backslash\left\{e_{3}\right\}\right) \cup\left\{e_{4}\right\}$ in place of $D$; or $w \notin D$ in which case $f_{2} \in D\left(f_{1}\right.$ would otherwise not be dominated) and we may consider the TD set $\left(D \backslash\left\{e_{3}\right\}\right) \cup\left\{e_{4}\right\}$ in place of $D$. By iterating this process, we eventually reach a TD set $D \in \mathcal{D}$ accommodating no edge, containing a $2 P_{3}$ and satisfying (1). Now suppose that this TD set $D$ contains a $P_{3}$ of the form $u e_{1} e_{2}$, where $e=u v \in E(G)$, and suppose that $N_{H}(v) \cap D=\left\{e_{4}\right\}$. Then since $D$ does not accommodate the edge $u v$, necessarily $e_{3} \notin D$ and so, $v \in D$ as $e_{4}$ would otherwise not be dominated. Thus, if there exists an edge $f=v w \in E(G)$, then we may consider the TD set $\left(D \backslash\left\{e_{4}\right\}\right) \cup\left\{f_{1}\right\}$ in place of $D$. Assume therefore that no such edge exists, that is, $d_{G}(v)=1$. Then surely, there exists an edge $f=u w \in E(G)$ since $\gamma_{t}(G) \geq 3$. But then, either $f_{1} \in D$ in which case we may consider the TD set $D^{\prime}=\left(D \backslash\left\{e_{2}\right\}\right) \cup\left\{e_{3}\right\}$ in place of $D$ (note indeed that the path $v e_{4} e_{3}$ in $D^{\prime}$ then satisfies (2) as $f_{1} \in D^{\prime}$ ); or $f_{1} \notin D$ in which case we may consider the TD set $\left(D \backslash\left\{e_{2}\right\}\right) \cup\left\{f_{1}\right\}$ (note that we here simply discard the path $u e_{1} e_{2}$ ). By iterating this process, we eventually reach a TD set in $\mathcal{D}$ accommodating no edge, containing a $2 P_{3}$ and satisfying both (1) and (2).

To conclude, let $D \in \mathcal{D}$ be a TD set accommodating no edge, containing a $2 P_{3}$ and satisfying

Figure 6: The variable gadget $G_{x}$ for a variable $x$ contained in clause $c, c^{\prime}$ and $c^{\prime \prime}$ (a rectangle indicates that the corresponding set of vertices induces a clique).
both (1) and (2). Then by (1), $D$ contains only $P_{3}$ s of the form $f_{4} v e_{1}$ where $f=u v, e=v w \in$ $E(G)$, or the form $u e_{1} e_{2}$ where $e=u v \in E(G)$. Now if $D$ contains a $P_{3}$ of the form $f_{4} v e_{1}$ where $f=u v, e=v w \in E(G)$, then $u v w$ is a $P_{3}$ of $T^{-1}(D)$ by Observation 4 Similarly, if $D$ contains a $P_{3}$ of the form $u e_{1} e_{2}$ where $e=u v \in E(G)$, then by (2), $v$ has a neighbour $f_{1} \in D \backslash\left\{e_{4}\right\}$ where $f=v w$, and thus, $u v w$ is a $P_{3}$ of $T^{-1}(D)$ by Observation 4 Since any two $P_{3} \mathrm{~s} u v w$ and $u^{\prime} v^{\prime} w^{\prime}$ in $T^{-1}(D)$ corresponding to two distinct $P_{3} \mathrm{~s}$ in $D$ have at most two common vertices (it may be indeed that $\{u, w\} \cap\left\{u^{\prime}, w^{\prime}\right\} \neq \varnothing$ ), we conclude that $T^{-1}(D)$ contains a $2 P_{3}$ if $\{u, w\} \cap\left\{u^{\prime}, w^{\prime}\right\}=\varnothing$, and a $P_{4}$ otherwise. Therefore, $c t_{\gamma_{t}}(G) \leq 2$ by Theorem 1.5 and since $c t_{\gamma_{t}}(G)>1$ by Claim 10 in fact $c t_{\gamma_{t}}(G)=2$.

By 4-subdividing an instance of Contraction $\operatorname{Number}\left(\gamma_{t}, k\right)$ sufficiently many times, the following ensues from Lemma 3.8.

Lemma 3.9. For every $k \in\{2,3\}$ and $\ell \geq 3$, Contraction $\operatorname{Number}\left(\gamma_{t}, k\right)$ is NP-hard on $\left\{C_{3}, \ldots, C_{\ell}\right\}$-free graphs.

The last result of this section concerns Contraction $\operatorname{Number}\left(\gamma_{t}, 3\right)$. Combining Lemma 3.8 with the following result, we obtain in particular that if Contraction $\operatorname{Number}\left(\gamma_{t}, 3\right)$ is polynomialtime solvable on $H$-free graphs, then $H$ must be a linear forest.

Lemma 3.10. Contraction $\operatorname{Number}\left(\gamma_{t}, 3\right)$ is $\operatorname{NP}$-hard on $K_{1,3}-$ free graphs.
Proof. We reduce from Positive Exactly 3-Bounded 1-In-3 3-Sat (see Section 2 for a precise definition of this problem): given an instance $\Phi$ of this problem, with variable set $X$ and clause set $C$, we construct an instance $G$ of Contraction $\operatorname{Number}\left(\gamma_{t}, 3\right)$ as follows. For every variable $x \in X$ appearing in clauses $c, c^{\prime}$ and $c^{\prime \prime}$, we introduce the gadget $G_{x}$ depicted in Figure 6 (where a rectangle indicates that the corresponding set of vertices is a clique). In the following, we denote by $P_{x}$ the paw induced by $\left\{T_{x}, F_{x}, v_{x}, u_{x}\right\}$ and we may refer to the vertices of $P_{x}$ as $P_{x}(1), \ldots, P_{x}(4)$ where $P_{x}(1)=T_{x}$ and $P_{x}(2)=F_{x}$. For every clause $c \in C$ containing variables $x, y$ and $z$, we introduce the gadget $G_{c}$ which is the disjoint union of the graphs $G_{c}^{T}$ and $G_{c}^{F}$ depicted un Figure 7 (where a rectangle indicates that the corresponding set of vertices is a clique) and further add for every $\ell \in\{x, y, x\}$, an edge between $P_{\ell, T}^{c}(1) t_{\ell}^{c}$, and an edge between $P_{x, F}^{c}(2)$ and $f_{\ell}^{c}$. In the following, we denote by $K_{c}^{T}$ the clique induced by $p_{c}^{x}, p_{c}^{y}$ and $p_{c}^{z}$, and by $K_{c}^{F}$ the clique induced by $q_{c}^{x}, q_{x}^{y}$ and $q_{c}^{z}$. We let $G$ be the resulting graph. We next show that $c t_{\gamma_{t}}(G)=3$ if and only if $\Phi$ is satisfiable through a series of claims.

Claim 11. For every $T D$ set $D$ of $G$, the following hold.
(i) For every clause $c \in C$ and for every $R \in\{T, F\},\left|D \cap V\left(G_{c}^{R}\right)\right| \geq 2$. Furthermore, $v_{c} \in D$.
(ii) For every variable $x \in X$ and every paw $P$ of $G_{x},|D \cap V(P)| \geq 2$ and $P(3) \in D$.

Proof. To prove (i), let $c \in C$ be a clause containing variables $x, y$ and $z$. Then since $u_{c}$ should be dominated, necessarily $v_{c} \in D$. Furthermore, $D \cap\left\{u_{c}, q_{c}^{x}, q_{c}^{y}, q_{c}^{z}\right\} \neq \varnothing$ as $v_{c}$ should be dominated. Thus, $\left|D \cap V\left(G_{c}^{F}\right)\right| \geq 2$. Now since every vertex of $K_{c}^{T}$ must be dominated, either $D \cap V\left(K_{c}^{T}\right)=\varnothing$

Figure 7: The clause gadget $G_{c}$ for a clause $c=x \vee y \vee z$ is the disjoint union of $G_{c}^{T}$ and $G_{c}^{F}$ (a rectangle indicates that the corresponding set of vertices is a clique).
in which case $\left\{t_{c}^{x}, t_{c}^{y}, t_{c}^{z}\right\} \subseteq D$; or $D \cap V\left(K_{c}^{T}\right) \neq \varnothing$, say $p_{c}^{x} \in D$ without loss of generality, in which case $D \cap\left\{t_{c}^{x}, p_{c}^{y}, p_{c}^{z}\right\} \neq \varnothing$ as $p_{c}^{x}$ should be dominated as well. In both cases, $\left|D \cap V\left(G_{c}^{T}\right)\right| \geq 2$.

To prove (ii), let $x \in X$ be a variable and let $P$ be a paw in $G_{x}$. Then since $P(4)$ should be dominated, necessarily $P(3) \in D$; and since $P(3)$ should be dominated, necessarily $D \cap$ $\{P(1), P(2), P(4)\} \neq \varnothing$. Thus, $|D \cap V(P)| \geq 2$.

The following is an immediate consequence of Claim 11(ii).
Observation 5. For every TD set $D$ of $G$ and every variable $x \in X$ contained in clauses $c, c^{\prime}$ and $c^{\prime \prime}$, if $\left|D \cap V\left(G_{x}\right)\right|=14$ then $D \cap\left\{q_{x}^{\ell}, p_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}=\varnothing$.

The following is an immediate consequence of Claim 11(i).
Observation 6. Let $D$ be a $T D$ set of $G$. If $\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ for some clause $c \in C$ containing variables $x, y$ and $z$, then $D \cap\left\{f_{c}^{x}, f_{c}^{y}, f_{c}^{z}\right\}=\varnothing$.
Claim 12. Let $D$ be a TD set of $G$ and let $x \in X$ be a variable appearing in clauses $c, c^{\prime}$ and $c^{\prime \prime}$. If $\left|D \cap V\left(G_{x}\right)\right|=14$ then the following hold.
(i) If there exists $\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}$ such that $P_{x, T}^{\ell}(1) \in D$ then $T_{x} \in D$.
(ii) It there exists $\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}$ such that $P_{x, F}^{\ell}(2) \in D$ then $F_{x} \in D$.

Proof. Assume that $\left|D \cap V\left(G_{x}\right)\right|=14$. If there exists $\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}$ such that $P_{x, T}^{\ell}(1) \in D$, then $P_{x, T}^{\ell}(2) \notin D$ by Claim11(i); and since $D \cap\left\{p_{x}^{c}, p_{x}^{c^{\prime}}, p_{x}^{c^{\prime \prime}}\right\}=\varnothing$ by Observation 5, necessarily $T_{x} \in D$ as $p_{x}^{\ell}$ should be dominated. Item (ii) follows by symmetry.

Claim 13. $\Phi$ is satisfiable if and only if $\gamma_{t}(G)=14|X|+4|C|$.
Proof. Assume first that $\Phi$ is satisfiable and consider a truth assignment satisfying $\Phi$. We construct a TD set $D$ of $G$ as follows. For every variable $x \in X$ appearing in clauses $c, c^{\prime}$ and $c^{\prime \prime}$, if $x$ is true then we include $\left\{v_{x}, T_{x}\right\} \cup\left\{P_{x, R}^{\ell}(1), P_{x, R}^{\ell}(3) \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right.$ and $\left.R \in\{T, F\}\right\}$ in $D$; otherwise, we include $\left\{v_{x}, F_{x}\right\} \cup\left\{P_{x, R}^{\ell}(2), P_{x, R}^{\ell}(3) \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right.$ and $\left.R \in\{T, F\}\right\}$ in $D$. For every clause $c \in C$ containing variables $x, y$ and $z$, exactly one variable is true, say $x$ without loss of generality, in which case we include $\left\{v_{c}, q_{c}^{x}\right\} \cup\left\{p_{c}^{y}, p_{c}^{z}\right\}$ in $D$. It is easy to see that the constructed set $D$ is indeed a TD set of $G$ and since $|D|=14|X|+4|C|$, we conclude by Claim 11 that $D$ is minimum.

Conversely, assume that $\gamma_{t}(G)=14|X|+4|C|$ and let $D$ be a minimum TD set of $G$. Consider a clause $c \in C$ containing variables $x, y$ and $z$. Since $\left|D \cap V\left(G_{c}^{T}\right)\right|=2$ by Claim 11(i), at least one of $t_{c}^{x}, t_{c}^{y}$ and $t_{c}^{z}$ is not dominated by a vertex in $V\left(G_{c}^{T}\right)$, say $N\left(t_{c}^{x}\right) \cap D \subseteq V\left(G_{x}\right)$ without loss of generality. Then since $P_{x, T}^{c}(1) \in D$, it follows from Claim [12(i) that $T_{x} \in D$ and so, $F_{x} \notin D$ by Claim 11(ii). But then, $P_{x, F}^{c}(2) \notin D$ by Claim 12(ii) and since $f_{c}^{x} \notin D$ by Observation 6, necessarily $q_{c}^{x} \in D$ as $f_{c}^{x}$ should be dominated. It then follows from Claim 11(i) that $D \cap\left\{q_{c}^{y}, q_{c}^{z}, f_{c}^{y}, f_{c}^{z}\right\}=\varnothing$, which implies that $P_{y, F}^{c}(2), P_{z, F}^{c}(2) \in D$ (one of $f_{c}^{y}$ and $f_{c}^{z}$ would otherwise not be dominated) and so, $F_{y}, F_{z} \in D$ by Claim 12 (ii). Thus, the truth assignment obtained by setting a variable $x$ to true if $T_{x} \in D$ and to false otherwise, satisfies $\Phi$.

Claim 14. Let $D$ be a TD set of $G$. If there exists a clause $c \in C$ containing variables $x, y$ and $z$ such that $p_{c}^{\ell}, q_{c}^{\ell} \notin D$ for some $\ell \in\{x, y, z\}$, then $\left|D \cap V\left(G_{\ell}\right)\right|>14$.

Proof. Let $c \in C$ be a clause containing variables $x, y$ and $z$, and suppose that $p_{c}^{\ell}, q_{c}^{\ell} \notin D$ for some $\ell \in\{x, y, z\}$. Then $P_{\ell, T}^{c}(1), P_{\ell, F}^{c}(2) \in D$ since $t_{c}^{\ell}$ and $f_{c}^{\ell}$ should be dominated. Thus, if $\left|D \cap V\left(G_{\ell}\right)\right|=14$ then by Claim[12(i) and (ii), $T_{\ell}, F_{\ell} \in D$, a contradiction to Claim[11(ii).

Claim 15. Let $D$ be a TD set of $G$. If there exists a clause $c \in C$ such that $\left|D \cap V\left(G_{c}^{T}\right)\right|=$ $\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ and $t_{c}^{\ell} \in D$ for some variable $\ell$ contained in $c$, then there exists a variable $v \neq \ell$ contained in $c$ such that $\left|D \cap V\left(G_{v}\right)\right|>14$.

Proof. Let $c \in C$ be a clause containing variables $x, y$ and $z$, and assume that $\left|D \cap V\left(G_{c}^{T}\right)\right|=$ $\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ and $t_{c}^{\ell} \in D$ for some variable $\ell \in\{x, y, z\}$. Then $D \cap V\left(G_{c}^{T}\right)=\left\{t_{c}^{\ell}, p_{c}^{\ell}\right\}$ : indeed, $D \cap V\left(K_{c}^{T}\right) \neq \varnothing$ for one of $p_{c}^{x}$, $p_{c}^{y}$ and $p_{c}^{z}$ would otherwise not be dominated; and if $p_{c}^{v} \in D$ for some $v \neq \ell$, then $p_{c}^{v}$ is not dominated. Now by Claim 11(i), $\left|D \cap V\left(K_{c}^{F}\right)\right| \leq 1$ and so, there exists a variable $v \in\{x, y, z\} \backslash\{\ell\}$ such that $q_{c}^{v} \notin D$; and since $P_{c}^{v} \notin D$ by the above, the result then follows from Claim 14

Claim 16. ct $_{\gamma_{t}}(G)=3$ if and only if $\gamma_{t}(G)=14|X|+4|C|$.
Proof. Assume first that $c t_{\gamma_{t}}(G)=3$ and let $D$ be a minimum TD set of $G$. Let us show that $|D|=14|X|+4|C|$. To this end, consider first a variable $x \in X$ contained in clauses $c, c^{\prime}$ and $c^{\prime \prime}$. Since $D$ contains no $P_{3}$ by Theorem $1.5(\mathrm{i})$, it is clear that $|D \cap V(P)| \leq 2$ for every paw $P$ contained in $G_{x}$; and we conclude by Claim 11 that, in fact, equality holds. Now if there exists $\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}$ such that $p_{x}^{\ell} \in D$ then $\left(D \backslash V\left(P_{x, T}^{\ell}\right)\right) \cup\left\{P_{x, T}^{\ell}(1), P_{x, T}^{\ell}(2), P_{x, T}^{\ell}(3)\right\}$ is a TD set of $G$ of size $|D|+1=\gamma_{t}(G)+1$ containing the $P_{4} P_{x, T}^{\ell}(1) P_{x, T}^{\ell}(3) P_{x, T}^{\ell}(2) p_{x}^{\ell}$, a contradiction to Theorem 1.5 (ii). Thus, $D \cap\left\{p_{x}^{c}, p_{x}^{c^{\prime}}, p_{x}^{c^{\prime \prime}}\right\}=\varnothing$ and by symmetry, we conclude that $D \cap\left\{q_{x}^{c}, q_{x}^{c^{\prime}}, q_{x}^{c^{\prime \prime}}\right\}=\varnothing$ as well. Therefore, $\left|D \cap V\left(G_{x}\right)\right|=14$. Second, consider a clause $c \in C$ containing variables $x, y$ and $z$. Suppose to the contrary that there exists $\ell \in\{x, y, z\}$ such that $t_{c}^{\ell} \in D$. If $P_{\ell, T}^{c}(1) \in D$ as well, then $D$ contains the $P_{3} t_{c}^{\ell} P_{\ell, T}^{c}(1) P_{\ell, T}^{c}(3)$ by Claim 11(ii), a contradiction to Theorem 1.5(i). Thus, $P_{\ell, T}^{c}(1) \notin D$; but then, by Claim 11(ii), $D \cup\left\{P_{\ell, T}^{c}(1)\right\}$ contains the $P_{4} t_{c}^{\ell} P_{x, T}^{c}(1) P_{x, T}^{c}(3) w$ where $w \in D \cap\left\{P_{x, T}^{c}(2), P_{x, T}^{c}(4)\right\}$, a contradiction to Theorem 1.5. Thus, $D \cap\left\{t_{c}^{x}, t_{c}^{y}, t_{c}^{z}\right\}=\varnothing$. Now if there exists $\ell \in\{x, y, z\}$ such that $f_{c}^{\ell} \in D$, then either $P_{\ell, F}^{c}(2) \in D$ in which case $D$ contains the $P_{3} f_{c}^{\ell} P_{x, F}^{c}(2) P_{x, F}^{c}(3)$ by Claim 11(ii); or $P_{\ell, F}^{c}(2) \notin D$ in which case, by Claim 11(ii), $D \cup P_{\ell, F}^{c}(2)$ contains the $P_{4} f_{c}^{\ell} P_{\ell, F}^{c}(2) P_{\ell, F}^{c}(3) w$ where $t \in D \cap\left\{P_{\ell, F}^{c}(1), P_{\ell, F}^{c}(4)\right\}$, a contradiction in both cases to Theorem 1.5. Thus, $D \cap\left\{f_{c}^{x}, f_{c}^{y}, f_{c}^{z}\right\}=\varnothing$. Finally, since $D$ contains no $P_{3}$ by Theorem 1.5)(i), it is clear that $\left|D \cap V\left(K_{c}^{T}\right)\right| \leq 2$ and $\left|D \cap\left\{u_{c}, v_{c}, q_{c}^{x}, q_{c}^{y}, q_{c}^{x}\right\}\right| \leq 2$, and so, by Claim 11(i), $\left|D \cap V\left(G_{c}^{T}\right)\right|=\left|D \cap V\left(G_{c}^{F}\right)\right|=2$. Therefore, $\gamma_{t}(G)=|D|=14|X|+4|C|$.

Conversely, assume that $\gamma_{t}(G)=14|X|+4|C|$ and consider a minimum TD set $D$ of $G$. Let us show that $D$ contains no $P_{3}$, which by Theorem 1.5 (i), would imply that $c t_{\gamma_{t}}(G)>1$. Since for every clause $c \in C,\left|D \cap V\left(G_{c}^{T}\right)\right|=\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ by Claim11(i), clearly $D \cap V\left(G_{c}\right)$ contains no $P_{3}$. Similarly, for every variable $x \in X$ appearing in clauses $c, c^{\prime}$ and $c^{\prime \prime}, D \cap V\left(G_{x}\right)$ contains no $P_{3}$ : indeed, by Claim 11(ii), $|D \cap V(P)|=2$ for every paw $P$ of $G_{x}$ and $D \cap\left\{q_{x}^{\ell}, p_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}=\varnothing$ by Observation 5. Thus, if $D$ contains a $P_{3}$, then there must exist a clause $c \in C$ such that (1) $f_{c}^{\ell} \in D$ for some variable $\ell$ contained in $c$, or (2) $t_{c}^{\ell} \in D$ for some variable $\ell$ contained in $c$. However, by Observation 6 (1) cannot hold; and by Claim 15 (2) cannot hold. Thus, $D$ contains no $P_{3}$.

Now suppose for a contradiction that $G$ has a TD set $D$ of size $\gamma_{t}(G)+1$ containing a $P_{4}$, a $K_{1,3}$ or a $2 P_{3}$ (see Theorem 1.5(ii)). Then by Claim 11, there exists either a variable $x \in X$ such that $\left|D \cap V\left(G_{x}\right)\right|=15$ or a clause $c \in C$ such that $\left|D \cap V\left(G_{c}\right)\right|=5$. We next distinguish these two cases.

Case 1. There exists a variable $x \in X$ such that $\left|D \cap V\left(G_{x}\right)\right|=15$. Let $c, c^{\prime}, c^{\prime \prime} \in C$ be the three clauses in which $x$ is contained. First note that, since by Claim 11(ii), for every variable $v \in X \backslash\{x\},|D \cap V(P)|=2$ for every paw $P$ in $G_{x}$ and $q_{v}^{\ell}, p_{v}^{\ell} \notin D$ for every clause $\ell$ containing $v$, clearly $D \cap V\left(G_{v}\right)$ contains no $P_{4}, K_{1,3}$ or $2 P_{3}$. Similarly, for every clause $\ell \in C,\left|D \cap V\left(G_{\ell}^{T}\right)\right|=$ $\left|D \cap V\left(G_{\ell}^{F}\right)\right|=2$ by Claim 11(i), and so, $D \cap V\left(G_{\ell}\right)$ contains no $P_{4}, K_{1,3}$ or $2 P_{3}$. Since for every clause $\ell \in C \backslash\left\{c, c^{\prime}, c^{\prime \prime}\right\}$ and every variable $v \in X$ appearing in $\ell, f_{\ell}^{v}, t_{\ell}^{v} \notin D$ by Observation 6 and Claim [15, it follows that $D \cap\left(V\left(G_{\ell}\right) \cup V\left(G_{v}\right)\right)$ contains no $P_{4}, K_{1,3}$ or $2 P_{3}$. Now suppose that there exists a clause $\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}$ containing, apart from $x$, variables $y$ and $z$, such that $t_{\ell}^{v} \in D$
for some $v \in\{y, z\}$ (note that by Claim [15, $t_{\ell}^{x} \notin D$ ). We contend that $t_{\ell}^{v}$ cannot be part of a $P_{4}$, a $K_{1,3}$ or a $2 P_{3}$. To prove this claim, let us show that $P_{v, T}^{\ell}(1) \notin D$ (since $\left|D \cap V\left(G_{\ell}^{T}\right)\right|=2$, this would indeed imply our claim). Observe first that $D \cap V\left(G_{\ell}^{T}\right)=\left\{t_{\ell}^{v}, p_{\ell}^{v}\right\}$ : indeed, $D \cap V\left(K_{\ell}^{T}\right) \neq \varnothing$ for one of $p_{\ell}^{x}, p_{\ell}^{y}$ and $p_{\ell}^{z}$ would otherwise not be dominated; and if $p_{\ell}^{u} \in D$ for some $u \neq v$, then $p_{\ell}^{u}$ is not dominated, a contradiction. By Claim [14, it must then be that $q_{\ell}^{u} \in D$ for $u \in\{y, z\} \backslash\{v\}$, as $p_{\ell}^{u} \notin D$ and $\left|D \cap V\left(G_{u}\right)\right|=14$. It then follows from Claim 11(i) that $q_{\ell}^{v} \notin D$, which implies that $P_{v, F}^{\ell}(2) \in D$, as $f_{\ell}^{v}$ should be dominated. But then, $F_{\ell} \in D$ by Claim 12 (ii), and since then, $T_{\ell} \notin D$ by Claim 11(ii), $P_{v, T}^{\ell}(1) \notin D$ by Claim 12(i), as claimed. Since for every $\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}$, $f_{\ell}^{x} \notin D$ by Observation 6 and $t_{\ell}^{x} \notin D$ by Claim [15] it follows that any $P_{4}, K_{1,3}$ or $2 P_{3}$ of $D$ is in fact contained in $D \cap V\left(G_{x}\right)$.

Now suppose that $|D \cap V(P)|=3$ for some paw $P$ of $G_{x}$. Then by Claim 11(i), $D \cap\left\{p_{x}^{\ell}, q_{x}^{\ell} \mid \ell \in\right.$ $\left.\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}=\varnothing$ and $\left|D \cap V\left(P^{\prime}\right)\right|=2$ for any paw $P^{\prime} \neq P$ of $G_{x}$. Thus, $D \cap V\left(G_{x}\right)$ contains no $P_{4}$, $K_{1,3}$ or $2 P_{3}$. Suppose next that $D \cap\left\{p_{x}^{c}, p_{x}^{c^{\prime}}, p_{x}^{c^{\prime \prime}}\right\} \neq \varnothing$ (the case where $D \cap\left\{q_{x}^{c}, q_{x}^{c^{\prime}}, q_{x}^{c^{\prime \prime}}\right\} \neq \varnothing$ is symmetric). Then by Claim 11(ii), in fact $\left|D \cap\left\{p_{x}^{c}, p_{x}^{c^{\prime}}, p_{x}^{c^{\prime \prime}}\right\}\right|=1$; furthermore, $D \cap\left\{q_{x}^{c}, q_{x}^{c^{\prime}}, q_{x}^{c^{\prime \prime}}\right\}=\varnothing$ and $|D \cap V(P)|=2$ for every paw $P$ of $G_{x}$. Now assume without loss of generality that $p_{x}^{c} \in D$. If $T_{x} \notin D$, then it is easy to that $D$ at most one $P_{3}$ (namely $p_{x}^{c} P_{x, T}^{c}(2) P_{x, T}^{c}(3)$ if $\left.P_{x, T}^{c}(2) \in D\right)$. Similarly, if $P_{x, T}^{c}(2) \notin D$ then $D$ contains at most one $P_{3}$ (namely $p_{x}^{c} T_{x} v_{x}$ if $T_{x} \in D$ ). Thus, it must be that $T_{x}, P_{x, T}^{c}(2) \in D$ which by Claim 11(ii), implies that $F_{x}, P_{x, T}^{c}(1) \notin D$. Since $t_{c}^{x}$ should be dominated, it follows that $p_{c}^{x} \in D$. Furthermore, $P_{x, F}^{c}(2) \notin D$ by Claim 12(ii) and so, $q_{c}^{x} \in D$, as $f_{c}^{x}$ should be dominated. Since by Claim 11(i), $\left|D \cap V\left(G_{c}^{T}\right)\right|=\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ and $v_{c} \in D$, it follows that there exists a variable $v \neq x$ contained in $c$ such that $q_{c}^{v}, p_{c}^{v} \notin D$; but $\left|D \cap V\left(G_{v}\right)\right|=14$, a contradiction to Claim 14

Case 2. There exists a clause $c \in C$ such that $\left|D \cap V\left(G_{c}\right)\right|=5$. Let $x, y$ and $z$ be the variables contained in $c$. First note that, since by Claim 11(ii), for every variable $v \in X,|D \cap V(P)|=2$ for every paw $P$ of $G_{v}$ and $q_{v}^{\ell}, p_{v}^{\ell} \notin D$ for every clause $\ell$ containing $v$, clearly $D \cap V\left(G_{v}\right)$ contains no $P_{4}, K_{1,3}$ or $2 P_{3}$. Similarly, for every clause $\left.\ell \in C \backslash\{c\},\left|D \cap V\left(G_{\ell}^{T}\right)\right|=\mid D \cap V\left(G_{\ell}\right)^{F}\right) \mid=2$ by Claim11(i) and so, $D \cap V\left(G_{\ell}\right)$ contains no $P_{4}, K_{1,3}$ or $2 P_{3}$. Since for every clause $\ell \in C \backslash\{c\}$ and every variable $v \in X$ appearing in $\ell, f_{\ell}^{v}, t_{\ell}^{v} \notin D$ by Observation 6 and Claim 15, it follows that $D \backslash\left(V\left(G_{c}\right) \cup V\left(G_{x}\right) \cup V\left(G_{y}\right) \cup V\left(G_{z}\right)\right.$ contains no $P_{4}, K_{1,3}$ or $2 P_{3}$.

Suppose first that $\left|D \cap V\left(G_{c}^{F}\right)\right|=3$ (note that then $\left|D \cap V\left(G_{c}^{T}\right)\right|=2$ ). Suppose further that $D \cap\left\{t_{c}^{x}, t_{c}^{y}, t_{c}^{z}\right\} \neq \varnothing$, say $t_{c}^{x} \in D$ without loss of generality. We contend that $t_{c}^{x}$ cannot be part of a $P_{4}, K_{1,3}$ or $2 P_{3}$ in $D$. To prove this claim, let us show that $\left.P_{x, T}^{( } 1\right) \notin D$ (since $\left|D \cap V\left(G_{c}^{T}\right)\right|=2$, this would indeed prove our claim). Observe first that $D \cap V\left(G_{c}^{T}\right)=\left\{p_{c}^{x}, t_{c}^{x}\right\}$, for if $p_{c}^{x} \notin D$, then one of $p_{c}^{y}$ and $p_{c}^{z}$ is not dominated. Since $\left|D \cap V\left(K_{c}^{F}\right)\right| \leq 2$ by Claim11(i), it follows that either (1) $q_{c}^{v} \notin D$ for some $v \in\{y, z\}$, or (2) $q_{c}^{x} \notin D$. If (1) holds then $p_{c}^{v}, q_{c}^{v} \notin D$ by the above; but $\left|D \cap V\left(G_{v}\right)\right|=14$, a contradiction to Claim 14. Thus, (2) holds; in particular, $D \cap V\left(K_{c}^{F}\right)=\left\{q_{c}^{y}, q_{c}^{z}\right\}$. Since $v_{c} \in D$ by Claim11(i), it follows that $P_{x, F}^{c}(2) \in D$ as $f_{c}^{x}$ should be dominated. Then by Claim 12(ii), $F_{x} \in D$ which, by Claim11(ii), implies that $T_{x} \notin D$; and so, by Claim12(i), $P_{x, T}^{c}(1) \notin D$, as claimed. It follows that any $P_{4}, K_{1,3}$ or $2 P_{3}$ in $D$ is in fact contained in $V\left(G_{c}^{F}\right) \cup V\left(G_{x}\right) \cup V\left(G_{y}\right) \cup V\left(G_{z}\right)$. Since for any $\ell \in\{x, y, z\}, D \cap V\left(G_{\ell}\right)$ contains no $P_{3}$ by Claim 11(ii) and Observation 5 it follows that $D \cap\left\{f_{c}^{x}, f_{c}^{y}, f_{c}^{z}\right\} \neq \varnothing$; and since $v_{c} \in D$ by Claim 11(i) and $v_{c}$ should be dominated, in fact $\left|D \cap\left\{f_{c}^{x}, f_{c}^{y}, f_{c}^{z}\right\}\right|=1$. Assume without loss of generality that $f_{c}^{x} \in D$. Then $q_{c}^{x} \in D$ : indeed, if $q_{c}^{x} \notin D$ then $D \cap V\left(G_{c}^{F}\right)$ contains no $P_{3}$; and since for every $\ell \in\{x, y, z\}, D \cap V\left(G_{\ell}\right)$ contains no $P_{3}$ by Claim 11(ii) and Observation 5, clearly $D \cap\left(V\left(G_{c}^{F}\right) \cup V\left(G_{x}\right) \cup V\left(G_{y}\right) \cup V\left(G_{z}\right)\right)$ then contains no $P_{4}, K_{1,3}$ or $2 P_{3}$. Similarly, $P_{x, F}^{c}(2) \in D$ : indeed, if $P_{x, F}^{c}(2) \notin D$ then since for any $\ell \in\{x, y, z\}, D \cap V\left(G_{\ell}\right)$ contains no $P_{3}$, clearly $D \cap\left(V\left(G_{c}^{F}\right) \cup V\left(G_{x}\right) \cup V\left(G_{y}\right) \cup V\left(G_{z}\right)\right)$ then contains no $P_{4}, K_{1,3}$ or $2 P_{3}$. It then follows from Claim 12(ii) that $F_{x} \notin D$ which, by Claim11(ii), implies that $T_{x} \notin D$ and so, $P_{x, T}^{c}(1) \notin D$ by Claim $12(\mathrm{i})$. Since $t_{c}^{x}$ should be dominated, it follows that $p_{c}^{x} \in D$ which implies that $\left|D \cap\left\{p_{c}^{y}, p_{c}^{z}\right\}\right| \leq 1$, as $\left|D \cap V\left(G_{c}^{T}\right)\right|=2$. Since $D \cap\left\{q_{c}^{y}, q_{c}^{z}\right\}=\varnothing$ by the above, there then exists $v \in\{y, z\}$ such that $p_{c}^{v}, q_{c}^{v} \notin D$; but $\left|D \cap V\left(G_{v}\right)\right|=14$, a contradiction to Claim 14, Thus, $\left|D \cap V\left(G_{c}^{F}\right)\right|<3$.

Second, suppose that $\left|D \cap V\left(G_{c}^{T}\right)\right|=3$. Since then, $\left|D \cap V\left(G_{c}^{F}\right)\right|=2$, it follows from Observation 6 that $D \cap\left\{f_{c}^{x}, f_{c}^{y}, f_{c}^{z}\right\}=\varnothing$ and so, any $P_{4}, K_{1,3}$ or $2 P_{3}$ in $D$ is in fact contained in $D \cap\left(V\left(G_{c}^{T}\right) \cup V\left(G_{x}\right) \cup V\left(G_{y}\right) \cup V\left(G_{z}\right)\right.$. But then $D \cap\left\{t_{c}^{x}, t_{c}^{y}, t_{c}^{z}\right\} \neq \varnothing$ : indeed, if $D \cap\left\{t_{c}^{x}, t_{c}^{y}, t_{c}^{z}\right\}=\varnothing$, since for any $\ell \in\{x, y, z\}, D \cap V\left(G_{\ell}\right)$ contains no $P_{3}$ by Claim 11(ii) and Observation 5 clearly
$D \cap\left(V\left(G_{c}^{T}\right) \cup V\left(G_{x}\right) \cup V\left(G_{y}\right) \cup V\left(G_{z}\right)\right.$ then contains no $P_{4}, K_{1,3}$ or $2 P_{3}$. Assume without loss of generality that $t_{c}^{x} \in D$. Then $p_{c}^{x} \in D$ : indeed, if $p_{c}^{x} \notin D$ then $D \cap V\left(G_{c}^{T}\right)$ contains no $P_{3}$ and since for any $\ell \in\{x, y, z\}, D \cap V\left(G_{\ell}\right)$ contains no $P_{3}$, clearly $D \cap\left(V\left(G_{c}^{T}\right) \cup V\left(G_{x}\right) \cup V\left(G_{y}\right) \cup V\left(G_{z}\right)\right.$ contains no $P_{4}, K_{1,3}$ or $2 P_{3}$. Similarly, $P_{x, T}^{c}(1) \in D$ : if not, then since for any $\ell \in\{x, y, z\}$, $D \cap V\left(G_{\ell}\right)$ contains no $P_{3}$, clearly $D \cap\left(V\left(G_{c}^{T}\right) \cup V\left(G_{x}\right) \cup V\left(G_{y}\right) \cup V\left(G_{z}\right)\right.$ contains no $P_{4}, K_{1,3}$ or $2 P_{3}$. It then follows from Claim 12(i) that $T_{x} \in D$ which, by Claim 11(ii), implies that $F_{x} \notin D$ and so, $P_{x, F}^{c}(2) \notin D$ by Claim 12 (ii). Since $f_{c}^{x}$ should be dominated, necessarily $q_{c}^{x} \in D$ and so, $D \cap\left\{q_{c}^{y}, q_{c}^{z}\right\}=\varnothing$ by Claim $11\left(\right.$ i). Since $\left|D \cap\left\{p_{c}^{y}, p_{c}^{z}\right\}\right| \leq 1$ by the above, it follows that there exists $v \in\{y, z\}$ such that $p_{c}^{v}, q_{c}^{v} \notin D$; but $\left|D \cap V\left(G_{v}\right)\right|=14$, a contradiction to Claim 14 which concludes the proof.

Now by Claims 13 and 16 $\Phi$ is satisfiable if and only if $c t_{\gamma_{t}}(G)=3$; and since $G$ is easily seen to be $K_{1,3}$-free, the lemma follows.

### 3.3 Proof of Theorem 1.3

Let $H$ be a graph. If $H$ contains a cycle then Contraction $\operatorname{Number}\left(\gamma_{t}, 2\right)$ is NP-hard by Lemma 3.9. Assume henceforth that $H$ is a forest. If $H$ contains a vertex of degree at least three then $\operatorname{Contraction} \operatorname{Number}\left(\gamma_{t}, 2\right)$ is NP-hard on $H$-free graphs by Lemma 3.4. Suppose therefore that $H$ is a linear forest. If $H$ contains a connected component on at least six vertices then Contraction $\operatorname{Number}\left(\gamma_{t}, 2\right)$ is coNP-hard on $H$-free graphs by Lemma 3.5. Thus we may assume that every connected component of $H$ has size at most five. If $H$ contains at least two connected component on at least four vertices then Contraction $\operatorname{Number}\left(\gamma_{t}, 2\right)$ is NPhard on $H$-free graphs by Lemma [3.6. Assume therefore that $H$ contains at most one connected component of size at least four and at most five. Now if $H$ contains a $P_{5}$ and at least one other connected component on at least two vertices then Contraction $\operatorname{Number}\left(\gamma_{t}, 2\right)$ is coNP-hard on $H$-free graphs by Lemma 3.7] and if $H$ contains a $P_{5}$ and every other connected component has size one then $\operatorname{Contraction~} \operatorname{Number}\left(\gamma_{t}, 2\right)$ is polynomial-time solvable on $H$-free graphs by ??. Otherwise $H$ contains at most one connected component of size at most four while every other connected component has size at most three in which case Contraction Number $\left(\gamma_{t}, 2\right)$ is polynomial-time solvable on $H$-free graphs by Lemma 3.3.

## 4 Semitotal Domination

In this section, we consider the Contraction $\operatorname{Number}\left(\gamma_{t 2}, k\right)$ problem for $k=2,3$. In Section 4.1, we cover those polynomial-time solvable cases and in Section4.2, we examine hard cases. The proof of Theorem 1.4 can be found in Section 4.3.

### 4.1 Polynomial-time solvable cases

The algorithms for Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ and Contraction $\operatorname{Number}\left(\gamma_{t 2}, 3\right)$ outlined thereafter will rely on the following key result.

Lemma 4.1. Let $H$ be a graph. If 2-Edge Contraction $\left(\gamma_{t 2}\right)$ is polynomial-time solvable on $H$-free graphs then it is polynomial-time solvable on $\left(H+P_{3}\right)$-free graphs.

Proof. Let $G$ be an $\left(H+P_{3}\right)$-free graph. We aim to show that if $G$ contains an induced $H$ and $G$ is a No-instance for 2-EdGe Contraction $\left(\gamma_{t 2}\right)$, then $\gamma_{t 2}(G)$ is bounded by some function $f$ of $|V(H)|$ (and $|V(H)|$ only). Assuming for now that this claim is correct, the following algorithm solves the 2-Edge Contraction $\left(\gamma_{t 2}\right)$ problem on $\left(H+P_{3}\right)$-free graphs.

1. If $G$ contains no induced $H$ then use the algorithm for $H$-free graphs to determine whether $G$ is a Yes-instance for 2-Edge Contraction $\left(\gamma_{t 2}\right)$ or not.
2. Check whether there exists an SD set of $G$ of size at most $f(|V(H)|)$.
2.1 If the answer is no then output Yes.
2.2 Check whether there exists a minimum SD set of $G$ containing a friendly triple, or an SD set of $G$ of size $\gamma_{t 2}(G)+1$ containing an ST-configuration (see Theorem 1.7) and output the answer accordingly.

Now observe that checking whether $G$ is $H$-free can be done in time $|V(G)|^{O(|V(H)|)}$ and that step 2 can be done in time $|V(G)|^{O(f(|V(H)|)}$ by simple brute force. Since 2-Edge Contraction ( $\gamma_{t 2}$ ) is polynomial-time solvable on $H$-free graphs by assumption, the above algorithm indeed runs in polynomial time (for fixed $H$ ). We next show that $f(|V(H)|)=8|V(H)|$.

Assume henceforth that $G$ contains an induced $H$. Let $A \subseteq V(G)$ be a set of vertices such that $G[A]$ is isomorphic to $H$, let $B \subseteq V(G) \backslash A$ be the set of vertices at distance one from $A$ and let $C=V(G) \backslash(A \cup B)$. Note that since $G$ is $\left(H+P_{3}\right)$-free, $C$ is a disjoint union of cliques. In the following, we denote by $\mathcal{K}$ the set of maximal cliques in $C$.

Now observe that if $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t 2}\right)$, then no minimum SD set of $G$ contains an edge by Lemma 2.2 and thus, given a minimum SD set $D$ of $G, \mathcal{K}$ can be partitioned into two sets: $\mathcal{K}_{1}^{D}=\{K \in \mathcal{K}| | D \cap V(K) \mid=1\}$ and $\mathcal{K}_{0}^{D}=\{K \in \mathcal{K} \mid D \cap V(K)=\varnothing\}$.

Claim 17. If $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t 2}\right)$ and $D$ is a minimum $S D$ set of $G$ then

$$
\left|\left(D \cap N\left[\mathcal{K}_{1}^{D}\right]\right) \cup w_{D}\left(D \cap N\left[\mathcal{K}_{1}^{D}\right]\right)\right| \leq 4|A|
$$

Proof. Assume that $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t 2}\right)$ and let $D$ be a minimum SD set of $G$. For every $K \in \mathcal{K}_{1}^{D}$, denote by $x_{K} \in V(K) \cap D$ the unique vertex in $K$ belonging to $D$. Observe that for every $K \in \mathcal{K}_{1}^{D}, N\left(x_{K}\right) \cap B \neq \varnothing$ : indeed, if $N\left(x_{K}\right) \cap B=\varnothing$ for some $K \in \mathcal{K}_{1}^{D}$, then there must exist $y \in V(K)$ such that $y$ is adjacent to the unique witness $z$ for $x_{K}$ (recall that by Lemma 2.2, $\left|w_{D}\left(x_{K}\right)\right|=1$ and $x_{K}$ is at distance exactly two from its witness); but then $\left(D \backslash\left\{x_{K}\right\}\right) \cup\{y\}$ is a minimum SD set of $G$ containing the edge $y z$, a contradiction to Lemma 2.2, We now contend that there exist no two cliques $K, K^{\prime} \in \mathcal{K}_{1}^{D}$ such that $d\left(x_{K}, x_{K^{\prime}}\right)=2$. Indeed, suppose to the contrary that there exist two such cliques $K, K^{\prime} \in \mathcal{K}_{1}^{D}$. Let $z \in B$ be a common neighbour of $x_{K}$ and $x_{K^{\prime}}$, and let $t \in A$ be a neighbour of $z$. Then $z \notin D\left(x_{K}, z, x_{K^{\prime}}\right.$ would otherwise be a friendly triple) which implies, in particular, that $t$ is not dominated by $z$. Since $t$ should be dominated nonetheless, it follows that either $t \in D$ in which case $D \cup\{z\}$ contains the $O_{5} z, x_{K}, x_{K^{\prime}}, t$; or $t$ has a neighbour $u \in D$ (note that $u \neq x_{K}, x_{K^{\prime}}$ by construction) in which case $D \cup\{z\}$ contains the $O_{6} x_{K}, z, x_{K^{\prime}}, u$, a contradiction in both cases to Theorem 1.7

It follows that for any clique $K \in \mathcal{K}_{1}^{D}$, any witness for $x_{K}$ can only belong to $A \cup B$ : let us denote by $W_{A}=A \cap w_{D}\left(\left\{x_{K} \mid K \in \mathcal{K}_{1}^{D}\right\}\right)$ and by $W_{B}=B \cap w_{D}\left(\left\{x_{K} \mid K \in \mathcal{K}_{1}^{D}\right\}\right)$. Further note that since by Lemma 2.2 $\left|w_{D}(x)\right|=1$ for any $x \in D$,

$$
\left|W_{B}\right|+\left|W_{A}\right|=\left|w_{D}\left(\left\{x_{K} \mid K \in \mathcal{K}_{1}^{D}\right\}\right)\right|=\left|\mathcal{K}_{1}^{D}\right| .
$$

Now if there exist two vertices $u, v \in W_{B}$ such that $u$ and $v$ have a common neighbour in $A$, then $d(u, v) \leq 2$, a contradiction to Lemma 2.2 as, by construction, $u$ and $v$ both have a witness in $\left\{x_{K} \mid K \in \mathcal{K}_{1}^{D}\right\}$. Thus, no two vertices in $W_{B}$ have a common neighbour in $A$, which implies that $\left|W_{B}\right| \leq|A|$. Since $\left|W_{A}\right| \leq|A|$, it follows that $\left|\left\{w_{K} \mid K \in \mathcal{K}_{1}^{D}\right\}\right| \leq 2|A|$. Now note that $\left|\left(D \cap N\left[\mathcal{K}_{1}^{D}\right]\right) \cup w_{D}\left(D \cap N\left[\mathcal{K}_{1}^{D}\right]\right)\right|=\left|\mathcal{K}_{1}^{D}\right|+\left|w_{D}\left(\left\{x_{K} \mid K \in \mathcal{K}_{1}^{D}\right\}\right)\right|$ : indeed, for every $K \in \mathcal{K}_{1}^{D}$, any vertex in $D \cap N[K]$ is at distance at most two from $x_{K}$, and by Lemma 2.2, $\left|w_{D}(x)\right|=1$ for every $x \in D$. Thus, the lemma follows.

Claim 18. If $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t 2}\right)$ and $D$ is a minimum $S D$ set of $G$, then

$$
\left|\left(D \cap N\left[\mathcal{K}_{0}^{D}\right]\right) \cup w_{D}\left(D \cap N\left[\mathcal{K}_{0}^{D}\right]\right)\right| \leq 2|A| .
$$

Proof. Assume that $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t 2}\right)$ and let $D$ be a minimum SD set of $G$. Since for every $K \in \mathcal{K}_{0}^{D}, D \cap V(K)=\varnothing$ by definition, necessarily $D \cap N\left[\mathcal{K}_{0}^{D}\right]=$ $D \cap N\left(\mathcal{K}_{0}^{D}\right) \subseteq B$; in particular, every vertex in $D \cap N\left(\mathcal{K}_{0}^{D}\right)$ has at least one neighbour in $A$. Since no two vertices $x, y \in D \cap N\left(\mathcal{K}_{0}^{D}\right)$ such that $y \notin w_{D}(x)$, have a common neighbour in $A$, and for every $x \in D,\left|w_{D}(x)\right|=1$ by Lemma 2.2, denoting by

$$
D_{1}=\left\{x \mid x \in D \cap N\left(\mathcal{K}_{0}^{D}\right) \text { and } w_{D}(x) \cap\left(D \cap N\left(\mathcal{K}_{0}^{D}\right)\right)=\varnothing\right\}
$$

and by

$$
D_{2}=\left\{\{x, y\} \mid x, y \in D \cap N\left(\mathcal{K}_{0}^{D}\right) \text { and } y \in w_{D}(x)\right\}
$$

it follows that $\left|D_{1}\right|+\left|D_{2}\right| \leq|A|$. But

$$
\left|\left(D \cap N\left(\mathcal{K}_{0}^{D}\right)\right) \cup w_{D}\left(D \cap N\left(\mathcal{K}_{0}^{D}\right)\right)\right|=2\left|D_{1}\right|+2\left|D_{2}\right|
$$

and thus, the upperbound follows.
To conclude, assume that $G$ is a No-instance for 2-Edge Contraction $\left(\gamma_{t 2}\right)$ and let $D$ be a minimum SD set of $G$. Then $D^{\prime}=D \backslash\left((D \cap N[\mathcal{K}]) \cup\left(w_{D}(D \cap N[\mathcal{K}])\right)\right)$ has size at most $2|A|$ : indeed, since $D^{\prime}$ dominates only vertices in $A \cup B$ and no vertex in $D \backslash D^{\prime}$ is witnessed by a vertex $D^{\prime}$ by Lemma 2.2 if $\left|D^{\prime}\right|>2|A|$ then $\left(D \backslash D^{\prime}\right) \cup\left(A \cup N_{A}\right)$ where $N_{A}$ contains one neighbour for each vertex in $A$, is an SD set of $G$ of size strictly smaller than that of $D$, a contradiction to the minimality of $D$. Since

$$
\left|(D \cap N[\mathcal{K}]) \cup\left(w_{D}(D \cap N[\mathcal{K}])\right)\right| \leq \sum_{i \in\{0,1\}}\left|\left(D \cap N\left[\mathcal{K}_{i}^{D}\right]\right) \cup\left(w_{D}\left(D \cap N\left[\mathcal{K}_{i}^{D}\right]\right)\right)\right| \leq 6|A|
$$

by Claims 17 and 18, we conclude that $\gamma_{t 2}(G)=|D| \leq 8|A|=8|V(H)|$, as claimed.
Lemma 4.2. If $G$ is a $P_{8}$-free graph then $c_{\gamma_{t 2}}(G) \leq 2$.
Proof. Let $G$ be a $P_{8}$-free graph and let $D$ be a minimum SD set of $G$. If $D$ contains an edge or there exists $x \in D$ such that $\left|w_{D}(x)\right| \geq 2$, then $c_{\gamma_{t 2}}(G) \leq 2$ by Lemma 2.2. Thus, assume that $D$ is an independent set and for every $x \in D,\left|w_{D}(x)\right|=1$. Let $u, v \in D$ be two vertices at distance two and further let $w \in D \backslash\{u, v\}$ be a closest vertex from $\{u, v\}$, that is, $d(w,\{u, v\})=$ $\min _{x \in D \backslash\{u, v\}} d(x,\{u, v\})$. Then $d(w,\{u, v\})>2$ by assumption, and since $d(w,\{u, v\}) \leq 3$ as shown in the proof of Lemma [2.2, in fact $d(w,\{u, v\})=3$. Now assume without loss of generality that $d(w,\{u, v\})=d(w, v)$, and let $t \in D$ be the witness for $w$. Note that if there exists $a \in$ $N(u) \cap N(v)$ and $b \in N(w)$ such that at $\in E(G)$, then $D \cup\{a\}$ contains the $O_{6} u, a, v, w$ and thus, $c t_{\gamma_{t 2}}(G) \leq 2$. Assume henceforth that no common neighbour of $u$ and $v$ is adjacent to a neighbour of $w$ (or $t$ ), and that, symmetrically, no common neighbour of $w$ and $t$ is adjacent to a neighbour of $u$ (or $v$ ). Let $P=v x y w$ be a shortest path from $v$ to $w$. Then by the aforementioned assumption, $u$ is nonadjacent to $x$, and $t$ is nonadjacent to $y$ (also note that $u$ is nonadjacent to $y$, and $t$ is nonadjacent to $x$, by minimality of the distance between $v$ and $w$ ). Let $a$ be a common neighbour of $u$ and $v$, and let $b$ be a common neighbour of $w$ and $t$. Then both $a$ and $x$ are nonadjacent to $b$ by assumption; and similarly, $y$ is nonadjacent to $a$. It follows that $a x \in E(G)$ or $b y \in E(G)$ for otherwise, uavxywbt would induce a $P_{8}$; we next distinguish two cases depending on these adjacencies.

Suppose first that $a x, b y \in E(G)$. Observe that if every private neighbour of $t$ is adjacent to $b$ or $y$, then $(D \backslash\{t\}) \cup\{b, y\}$ is an SD set of $G$ containing the $O_{4} b, w, y, v$ and thus, $c t_{\gamma_{t 2}}(G) \leq 2$ by Lemma 2.2. Assume therefore that $t$ has a private neighbour $c$ which is nonadjacent to both $b$ and $y$, and that, symmetrically, $u$ has a private neighbour $d$ which is nonadjacent to both $a$ and $x$. Let us show that then $G$ contains an induced $P_{8}$. Indeed, since by assumption $d$ is nonadjacent to $b$, and $c$ is nonadjacent to $a$, it must be that $d c \in E(G), d y \in E(G)$ or $c x \in E(G)$ for otherwise, dyaxybtc would induce a $P_{8}$. However, if $d c \in E(G)$ then vaudctbw induces a $P_{8}$. Thus, $d y \in E(G)$ or $c x \in E(G)$, say the latter holds without loss of generality, in which case wbtcxaud induces a $P_{8}$.

Second, suppose that either $a$ is nonadjacent to $x$, or $b$ is nonadjacent to $y$, say $a x \in E(G)$ and by $\notin E(G)$ (the other case is symmetric). As previously, we show that if $t$ has a private neighbour $c$ which is nonadjacent to both $b$ and $y$, and that $u$ has a private neighbour $d$ which is nonadjacent to both $a$ and $x$, then $G$ contains an induced $P_{8}$ (observe that if this does not hold, then $c t_{\gamma_{t 2}}(G) \leq 2$ as mentioned above). Since $c$ is nonadjacent to $a$ by assumption, $c$ must be adjacent to $x$ for otherwise, ctbwyxau would induce a $P_{8}$. But then, $c$ must be adjacent to $d$ for otherwise, wbtcxaud induces a $P_{8}$; however, if $d c \in E(G)$ then wbtcduav induces a $P_{8}$, a contradiction which concludes the proof.

Lemma 4.3. If $G$ is a $2 P_{4}$-free graph then $c t_{\gamma_{t 2}}(G) \leq 2$.
Proof. The proof is similar to that of Lemma 4.2. Let $G$ be a $2 P_{4}$-free graph and let $D$ be a minimum SD set of $G$. If $D$ contains an edge or there exists $x \in D$ such that $\left|w_{D}(x)\right| \geq 2$, then $c t_{\gamma_{t 2}}(G) \leq 2$ by Lemma 2.2. Thus, assume that $D$ is an independent set and for every $x \in D$,
$\left|w_{D}(x)\right|=1$. Let $u, v \in D$ be two vertices at distance two and further let $w \in D \backslash\{u, v\}$ be a closest vertex from $\{u, v\}$, that is, $d(w,\{u, v\})=\min _{x \in D \backslash\{u, v\}} d(x,\{u, v\})$. Then $d(w,\{u, v\})>2$ by assumption, and since $d(w,\{u, v\}) \leq 3$ as shown in the proof of Lemma 2.2 in fact $d(w,\{u, v\})=3$. Now assume without loss of generality that $d(w,\{u, v\})=d(w, v)$, and let $t \in D$ be the witness for $w$. Note that if there exists $a \in N(u) \cap N(v)$ and $b \in N(w)$ such that at $\in E(G)$, then $D \cup\{a\}$ contains the $O_{6} u, a, v, w$ and thus, $c_{\gamma_{t 2}}(G) \leq 2$ by Theorem 1.7. Assume henceforth that no common neighbour of $u$ and $v$ is adjacent to a neighbour of $w$ (or $t$ ), and that, symmetrically, no common neighbour of $w$ and $t$ is adjacent to a neighbour of $u$ (or $v$ ). Let $P=v x y w$ be a shortest path from $v$ to $w$. Then by the aforementioned assumption, $u$ is nonadjacent to $x$, and $t$ is nonadjacent to $y$ (also note that $u$ is nonadjacent to $y$, and $t$ is nonadjacent to $x$, by minimality of the distance between $v$ and $w$ ). Let $a$ be a common neighbour of $u$ and $v$, and let $b$ be a common neighbour of $w$ and $t$. Then $a$ and $x$ are nonadjacent to $b$ by assumption; and similarly, $y$ is nonadjacent to $a$. Now if $b$ is nonadjacent to $y$, then every private neighbour $p$ of $u$ must be adjacent to $a$ or $y$ for otherwise, puav and $y w b t$ would induce a $2 P_{4}$ (note that $p$ is nonadjacent to $b$ by assumption); but then, $(D \backslash\{u\}) \cup\{a, y\}$ is an SD set of $G$ containing the $O_{7} a, v, y, w$ and thus, $c t_{\gamma_{t 2}}(G) \leq 2$ by Theorem 1.7. Assume therefore that $b$ is adjacent to $y$. If every private neighbour of $u$ is adjacent to $a$, then $(D \backslash\{u\}) \cup\{a\}$ is a minimum SD set of $G$ containing an edge and thus, $c t_{\gamma_{t 2}}(G) \leq 2$ by Lemma [2.2. Thus, we may assume that $u$ has a private neighbour $p$ nonadjacent to $a$. Then every private neighbour $p^{\prime}$ of $t$ must be adjacent to $b$ or $p$ for otherwise, puav and $w b t p^{\prime}$ would induce a $2 P_{4}$ (note that $p$ is nonadjacent to $b$, and $p^{\prime}$ is nonadjacent to $a$ by assumption). By symmetry, we conclude that every private neighbour of $w$ is adjacent to $p$ or $b$. Now if, in fact, no private neighbour of $w$ is adjacent to $p$, then $D^{\prime}=(D \backslash\{w\}) \cup\{b\}$ is a minimum SD set of $G$, as every private neighbour of $w$ w.r.t. $D$ is then adjacent to $b$; but $D^{\prime}$ contains an edge and thus, $c t_{\gamma_{t 2}}(G) \leq 2$ by Lemma 2.2. Thus, we may assume that at least one private neighbour of $w$ is adjacent to $p$; in particular, $d(w, p)=2$. But then, $(D \backslash\{t\}) \cup\{p, b\}$ is an SD of $G$ containing the $O_{7} b, w, p, u$ and thus, $c t_{\gamma_{t 2}}(G) \leq 2$ by Theorem 1.7.

Since for any graph $G, G$ is a Yes-instance for 2-Edge Contraction $\left(\gamma_{t 2}\right)$ if and only if $G$ is a No-instance for Contraction $\operatorname{Number}\left(\gamma_{t 2}, 3\right)$, the following ensues from Lemmas 4.14 .2 and 4.3

Corollary 4.4. Contraction $\operatorname{Number}\left(\gamma_{t 2}, 3\right)$ is polynomial-time solvable on $H$-free graphs if $H \subseteq_{i} P_{8}+k P_{3}$ for some $k \geq 0$, or $H \subseteq 2 P_{4}+k P_{3}$ for some $k \geq 0$.

Lemma 4.5. Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ is polynomial-time solvable on $H$-free graphs if $H \subseteq_{i} P_{5}+t K_{1}$ for some $t \geq 0$, or $H \subseteq_{i} P_{3}+t P_{2}$ for some $t \geq 0$.

Proof. Assume that $H \subseteq_{i} P_{3}+t P_{2}$ for some $t \geq 0$ (the case where $H \subseteq_{i} P_{5}+t K_{1}$ for some $t \geq 0$ is handled similarly) and let $G$ be an $H$-free graph. Since $H$ is a fortiori an induced subgraph of $P_{8}+t P_{3}$, we may use the polynomial-time algorithm for $\left(P_{8}+t P_{3}\right)$-free graphs given by Corollary 4.4 to determine whether $G$ is a Yes-instance for Contraction Number $\left(\gamma_{t 2}, 3\right)$ or not. If the answer is yes then we output No; otherwise, we use the polynomial-time algorithm for $\left(P_{3}+t P_{2}\right)$-free graphs given by Theorem 1.8 to determine whether $G$ is a Yes-instance for Contraction $\operatorname{Number}\left(\gamma_{t 2}, 1\right)$ or not, and output the answer accordingly.

### 4.2 Hardness results

In this section, we show that Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ and $\operatorname{Contraction~} \operatorname{Number}\left(\gamma_{t 2}, 3\right)$ are NP-hard on a number of monogenic graph classes. We first consider the case $k=2$.

Firstly, since for any graph $G$ such that $c t_{\gamma_{t 2}}(G) \leq 2, G$ is a Yes-instance for Contraction $\operatorname{Number}\left(\gamma_{t 2}, 1\right)$ if and only if $G$ is a No-instance for $\operatorname{Contraction} \operatorname{Number}\left(\gamma_{t 2}, 2\right)$, the following ensues from Theorem 1.8 and Lemma 4.2

Lemma 4.6. Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ is (co)NP-hard on $P_{6}$-free graphs, $2 P_{3}$-free graphs and $\left(P_{4}+P_{2}\right)$-free graphs.

Lemma 4.7. Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ is NP-hard in $K_{1,3}$-free graphs.
Proof. We use the same construction as in [10, Theorem 7]. More precisely, we reduce from Positive Exactly 3-Bounded 1-In-3 3-Sat (see Section 2 for a precise definition of this

Figure 8: The gadget $G_{x}$ for a variable $x \in X$ contained in clauses $c, c^{\prime}$ and $c^{\prime \prime}$ (a rectangle indicates that the corresponding set of vertices induces a clique).

(a) The graph $G_{c}^{T}$.

(b) The graph $G_{c}^{F}$.

Figure 9: The gadget $G_{c}$ for a clause $c=x \vee y \vee z$ is the disjoint union of $G_{c}^{T}$ and $G_{c}^{F}$.
problem): given an instance $\Phi$ of this problem, with variable set $X$ and clause set $C$, we construct an instance $G$ of $\operatorname{Contraction~} \operatorname{Number}\left(\gamma_{t 2}, 2\right)$ as follows. For every variable $x \in X$ contained in clauses $c, c^{\prime}$ and $c^{\prime \prime}$, we introduce the gadget $G_{x}$ depicted in Figure 8 (where a rectangle indicates that the corresponding set of vertices is a clique). For every clause $c \in C$ containing variables $x, y$ and $z$, we introduce the gadget $G_{c}$, which is the disjoint union of the graph $G_{c}^{T}$ and the graph $G_{c}^{F}$ depicted in Figure 9, and further add the following edges.

- For every $p \in\{x, y, z\}$, we connect $P_{p, F}^{c}(2)$ to $f_{c}^{a b}$ if and only if $p \in\{a, b\}$.
- For every $p \in\{x, y, z\}$, we connect $P_{p, T}^{c}(1)$ to $t_{c}^{p}$ and further connect $P_{p, T}^{c}(1)$ to $w_{c}^{a b}$ if and only if $p \in\{a, b\}$.
We let $G$ be the resulting graph. Let us show that $\Phi$ is satisfiable if and only if $c t_{\gamma_{t 2}}(G)=2$. To do so, we will rely on the following key result shown in [10].
Claim 19 (10]). The following statements are equivalent.
(i) $\Phi$ is satisfiable.
(ii) $\gamma_{t 2}(G)=14|X|+|C|$.
(iii) $c t_{\gamma_{t 2}}(G)>1$.

Observe first that if $c t_{\gamma_{t 2}}(G)=2$ then $\Phi$ is satisfiable by Claim 19. Assume, conversely, that $\Phi$ is satisfiable and consider a truth assignment satisfying $\Phi$. Let us show how to construct a minimum SD set $D$ of $G$ given this assignment. For every variable $x \in X$ appearing in clauses $c, c^{\prime}$ and $c^{\prime \prime}$, if $x$ is true, we include $\left\{v_{x}, T_{x}\right\} \cup\left\{P_{x, R}^{p}(1), P_{x, R}^{p}(4) \mid R \in\{T, F\}\right.$ and $\left.p \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}$ in $D$; otherwise, we include $\left\{v_{x}, F_{x}\right\} \cup\left\{P_{x, R}^{p}(2), P_{x, R}^{p}(4) \mid R \in\{T, F\}\right.$ and $\left.p \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}$ in $D$. For every clause $c \in C$ containing variables $x, y$ and $z$, exactly one variable is set to true, say $x$ without loss of generality, in which case we add $t_{c}^{y}$ to $D$ (note that $w_{c}^{x z}, t_{c}^{x}$ and $w_{c}^{x y}$ are already dominated by $P_{x, T}^{c}(1)$, which also serves as a witness for $\left.t_{c}^{y}\right)$. It is not difficult to see that the constructed set $D$ is indeed an SD set of $G$ and since $|D|=14|X|+|C|$, we conclude by Claim 19 that $D$ is minimum. Now consider a clause $c \in C$ containing variables $x, y$ and $z$, and assume without loss of generality that $x$ is true and $t_{c}^{y} \in D$. Then $D \cup\left\{t_{c}^{x}\right\}$ is an SD set of $G$ of size $\gamma_{t 2}(G)+1$ containing the $O_{4} t_{c}^{y}, t_{c}^{x}, P_{x, T}^{c}(1), P_{x, T}^{c}(4)$ and thus, $c t_{\gamma_{t 2}}(G) \leq 2$ by Theorem 1.7. But $c t_{\gamma_{t 2}}(G)>1$ by Claim 19 and so, $c t_{\gamma_{t 2}}(G)=2$. Since $G$ is $K_{1,3}$-free, the lemma follows.

Lemma 4.8. Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ is $\operatorname{NP}$-hard on $\left\{C_{k} \mid k \geq 5\right\}$-free graphs.
Proof. The reduction is similar to that of Lemma 3.6. More precisely, we reduce from 3-Sat: given an instance $\Phi$ of this problem, with variable set $X$ and clause set $C$, we construct an instance $G$ of Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ as follows. For every variable $x \in X$, we introduce a long paw $G_{x}$ on vertex set $\left\{G_{x}(1)=x, G_{x}(2)=\bar{x}, G_{x}(3)=u_{x}, G_{x}(4)=v_{x}, G_{x}(5)=w_{x}\right\}$ and refer to the vertices $x$ and $\bar{x}$ as literal vertices. For every clause $c \in C$, we introduce a clause vertex, denoted by $c$, and add an edge between $c$ and every literal vertex whose corresponding literal appears in the clause $c$. Finally, we add an edge between every two clauses vertices so that the set of clause vertices induces a clique, denoted by $K$ in the following. We let $G$ be the resulting graph. We next show that $G$ is a Yes-instance for Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ if and only if $\Phi$ is satisfiable through a series of claims. Observe first that since for any variable $x \in X$, the vertex $w_{x}$ should be dominated and any witness for a vertex dominating $w_{x}$ can only belong to $G_{x}$, the following holds.

Observation 7. For any $S D$ set $D$ of $G$ and any variable $x \in X,\left|D \cap V\left(G_{x}\right)\right| \geq 2$.
Claim 20. $\Phi$ is satisfiable if and only if $\gamma_{t 2}(G)=2|X|$.
Proof. Assume first that $\Phi$ is satisfiable and consider a truth assignment satisfying $\Phi$. We construct an SD set $D$ of $G$ as follows. For every variable $x \in X$, if $x$ is true then we include $v_{x}$ and $x$ to $D$; otherwise, we include $v_{x}$ and $\bar{x}$ to $D$. It is easy to see that the constructed set $D$ is indeed an SD set of $G$ and since $|D|=2|X|$, we conclude by Observation 7 that $D$ is minimum.

Conversely assume that $\gamma_{t 2}(G)=2|X|$ and let $D$ be a minimum SD set of $G$. Then by Observation 7, $D \cap V(K)=\varnothing$ and thus, every clause vertex must have a neighbouring literal vertex in $D$. Therefore, the truth assignment obtained by setting a variable $x$ to true when $x \in D$ and to false otherwise, satisfies $\Phi$.

Claim 21. ct $_{\gamma_{t 2}}(G)=2$ if and only if $\gamma_{t 2}(G)=2|X|$.
Proof. Assume first that $c t_{\gamma_{t 2}}(G)=2$ and consider a minimum SD set $D$ of $G$. If there exists a variable $x \in X$ such that $\left|D \cap V\left(G_{x}\right)\right| \geq 3$, then $D \cap V\left(G_{x}\right)$ contains a friendly triple, a contradiction to Theorem 1.7. Thus, $\left|D \cap V\left(G_{x}\right)\right| \leq 2$ for every variable $x \in X$, and we conclude by Observation 7 that, in fact, equality holds. Now suppose that $D \cap V(K) \neq \varnothing$, say $c \in D \cap V(K)$, and let $x \in X$ be a variable occurring in $c$, say $x$ appears positive in $c$ without loss of generality. Then the set $\left(D \backslash V\left(G_{x}\right)\right) \cup\left\{x, v_{x}\right\}$ is a minimum SD set of $G$ containing the friendly triple $c, x, v_{x}$, a contradiction to Theorem 1.7. Thus, $D \cap V(K)=\varnothing$ and so, $\gamma_{t 2}(G)=|D|=2|X|$.

Conversely, assume that $\gamma_{t 2}(G)=2|X|$ and let $D$ be a minimum SD set of $G$. Then by Observation 7 $D \cap V(K)=\varnothing$ and $\left|D \cap V\left(G_{x}\right)\right|=2$ for every variable $x \in X$. Since for every variable $x \in X, w_{x}$ should be dominated, it follows that if for some variable $x \in X, D \cap V\left(G_{x}\right)$ contains an edge $e$, then $D \cap\{x, \bar{x}\}=\varnothing$; but then, $d(e, D \backslash e) \geq 3$ and thus, $e$ cannot be part of a friendly triple. Therefore, $D$ contains no friendly triple. Consider now a clause $c \in C$ and let $x, y \in X$ be two variables occurring in $c$, say $x$ and $y$ both appear positive in $c$ without loss of generality. Then the set $\left(D \backslash\left(V\left(G_{x}\right) \cup V\left(G_{y}\right)\right)\right) \cup\left\{c, x, v_{x}, y, v_{y}\right\}$ is an SD set of $G$ of size $\gamma_{t 2}(G)+1$ containing the $O_{4} x, c, y, v_{y}$ and thus, $c t_{\gamma_{t 2}}(G)=2$ by Theorem 1.7

Now Claims 20 and 21 $\Phi$ is satisfiable if and only if $c t_{\gamma_{t 2}}(G)=2$ if and only if $\Phi$ is satisfiable. Since $G$ is easily seen to contain no induced cycle of length at least five, the lemma follows.

Lemma 4.9. For every $\ell \in\{3,4\}$, Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ is NP-hard on $C_{\ell}$-free graphs.
Proof. We reduce from Positive Not-All-Equal 3-Sat which is a NP-complete variant [23] of the 3-Sat problem where given a formula in which all literals are positive, the problem is to determine whether there exists a truth assignment such that in no clause, all three literals have the same truth value. Given an instance $\Phi$ of this problem, with variable set $X$ and clause set $C$, we construct two instances $G_{3}$ and $G_{4}$ of $\operatorname{Contraction~} \operatorname{Number}\left(\gamma_{t 2}, 2\right)$, one $C_{3}$-free and the other $C_{4}$-free, respectively. For both graphs, we start as follows. For every variable $x \in X$, we introduce the gadget $G_{x}$ depicted in Figure 10, which has two distinguished truth vertices $T_{x}$ and $F_{x}$. For every clause $c \in C$ containing variables $x, y$ and $z$, we introduce two clause vertices $c$ and $\bar{c}$, and add for every $v \in\{x, y, z\}$, an edge between $c$ and $T_{v}$, and an edge between $\bar{c}$ and $F_{v}$. We

Figure 10: The variable gadget $G_{x}$.
denote by $V_{C}=\{c \mid c \in C\}$ the set of positive clause vertices, and by $V_{\bar{C}}=\{\bar{c} \mid c \in C\}$ the set of negated clause vertices. This concludes the construction of $G_{3}$. For the graph $G_{4}$, we further add edges so that $V_{C}$ is a clique and $V_{\bar{C}}$ is a clique.

We next show that for every $\ell \in\{3,4\}, c t_{\gamma_{t 2}}\left(G_{\ell}\right)=2$ if and only if $\Phi$ is satisfiable through a series of claims. Observe first that since for every variable $x \in X$, the vertex $r_{x}$ should be dominated and any witness for a vertex dominating $r_{x}$ can only belong to $G_{x}$, the following holds.

Observation 8. Let $\ell \in\{3,4\}$. Then for every $S D$ set $D$ of $G_{\ell}$ and every variable $x \in X$, $\left|D \cap V\left(G_{x}\right)\right| \geq 2$.
Claim 22. Let $\ell \in\{3,4\}$. Then $\Phi$ is satisfiable if and only if $\gamma_{t 2}\left(G_{\ell}\right)=2|X|$.
Proof. Assume first that $\Phi$ is satisfiable and consider a truth assignment satisfying $\Phi$. We construct an SD set $D$ for $G_{\ell}$. For every variable $x \in X$, if $x$ is true, then we include $w_{x}$ and $T_{x}$ in $D$; otherwise, we include $w_{x}$ and $F_{x}$ in $D$. It is not difficult to see that the constructed set $D$ is indeed an SD set for both $G_{\ell}$ and since $|D|=2|X|$, we conclude by Observation 8 that $D$ is minimum.

Conversely, assume that $\gamma_{t 2}\left(G_{\ell}\right)=2|X|$ and let $D$ be a minimum SD set of $G_{\ell}$. Then by Observation 8, $D \cap V_{C}=D \cap V_{\bar{C}}=\varnothing$ and thus, every (positive or negated) clause vertex must have a neighbouring truth vertex in $D$. Therefore, the truth assignment obtained by setting a variable $x$ to true when $T_{x} \in D$ and to false otherwise, satisfies $\Phi$.

Claim 23. Let $\ell \in\{3,4\}$. Then $c t_{\gamma_{t 2}}\left(G_{\ell}\right)=2$ if and only if $\gamma_{t 2}\left(G_{\ell}\right)=2|X|$.
Proof. Assume that $c t_{\gamma_{t 2}}\left(G_{\ell}\right)=2$ and let $D$ be a minimum SD set of $G_{\ell}$. If there exists a variable $x \in X$ such that $\left|D \cap V\left(G_{x}\right)\right| \geq 3$, then $D \cap V\left(G_{x}\right)$ contains a friendly triple, a contradiction to Theorem 1.7. Thus, $\left|D \cap V\left(G_{x}\right)\right| \leq 2$ for every variable $x \in X$ and we conclude by Observation 8 that, in fact, equality holds. Furthermore, we may assume that for every variable $x \in X, D \cap$ $\left\{F_{x}, T_{x}\right\} \neq \varnothing$ and $w_{x} \in D$, for it otherwise suffices to consider e.g. $\left(D \backslash V\left(G_{x}\right)\right) \cup\left\{F_{x}, w_{x}\right\}$ in place of $D$. Now suppose to the contrary that $D \cap V_{C} \neq \varnothing$. We distinguish cases depending on the value of $\ell$.

Case 1. $\ell=3$. Let $c \in V_{C}$ be a vertex in $D$ and let $x, y, z \in X$ be the three variables occurring in $c$. If there exists $v \in\{x, y, z\}$ such that $T_{v} \in D$, then $c, T_{v}, w_{v}$ is a friendly triple, a contradiction to Theorem 1.7. Thus, for every $v \in\{x, y, z\}, T_{v} \notin D$ and so, $F_{v} \in D$ by the aforementioned assumption. But then, $(D \backslash\{c\}) \cup\left\{T_{x}\right\}$ is a minimum SD of $G_{3}$ (recall that for $\ell=3, V_{C}$ is an independent set) containing the friendly triple $F_{x}, T_{x}, w_{x}$, a contradiction to Theorem 1.7 .

Case 2. $\ell=4$. Then $\left|D \cap V_{C}\right|=1$ : indeed, if there exist $c, c^{\prime} \in D \cap V_{C}$ then $d\left(\left\{c, c^{\prime}\right\}, D \backslash\right.$ $\left.\left\{c, c^{\prime}\right\}\right) \leq 2$ (recall that by assumption, $D \cap\left\{t_{v}, F_{v}\right\} \neq \varnothing$ for every variable $v \in X$ ) and so, $D$ contains a friendly triple, a contradiction to Theorem 1.7 Now if there exists a variable $x \in X$ such that $T_{x} \in D$ then letting $c \in C$ be a clause containing $x$, the set $\left(D \backslash V_{C}\right) \cup\{c\}$ is a minimum SD set of $G_{4}$ containing the friendly triple $c, T_{x}, w_{x}$, a contradiction to Theorem 1.7. It follows that for every variable $x \in X, F_{x} \in D$; but then, it suffices to consider, in place of $D$, the SD set $\left(D \backslash\left\{F_{x}\right\}\right) \cup\left\{T_{x}\right\}$ for some variable $x \in X$, and argue as previously.

Thus, in both cases, $D \cap V_{C}=\varnothing$; and by symmetry, we conclude that $D \cap V_{\bar{C}}=\varnothing$ as well. Therefore, $\gamma_{t 2}\left(G_{\ell}\right)=|D|=2|X|$.

Conversely, assume that $\gamma_{t 2}\left(G_{\ell}\right)=2|X|$ and let $D$ be a minimum SD set of $G_{\ell}$. Then by Observation 8, $D \cap V_{C}=D \cap V_{\bar{C}}=\varnothing$ and $\left|D \cap V\left(G_{x}\right)\right|=2$ for every variable $x \in X$. Since for every variable $x \in X, r_{x}$ should be dominated, it follows that if for some variable $x \in X$, $D \cap V\left(G_{x}\right)$ contains an edge $e$, then $D \cap\left\{F_{x}, T_{x}\right\}=\varnothing$; but then, $d(e, D \backslash e) \geq 3$ and thus, $e$ cannot be part of a friendly triple. Therefore, $D$ contains no friendly triple. Now let us assume, for the following, that for every variable $x \in X, D \cap\left\{F_{x}, T_{x}\right\} \neq \varnothing$ and $w_{x} \in D$ (if this does

(a) The graph $G_{c}^{T}$.

(b) The graph $G_{c}^{F}$ (the rectangle indicates that the corresponding set of vertices is a clique).

Figure 11: The clause gadget $G_{c}$ for a clause $c=x \vee y \vee z$ is the disjoint union of $G_{c}^{T}$ and $G_{c}^{F}$.
not hold for a variable $x \in X$, we may consider e.g. $\left(D \backslash V\left(G_{x}\right)\right) \cup\left\{F_{x}, w_{x}\right\}$ in place of $\left.D\right)$. Consider a clause $c \in C$ and let $x, y, z \in X$ be the three variables occurring in $c$. By assumption, either $\left|D \cap\left\{T_{x}, T_{y}, T_{z}\right\}\right| \geq 2$ or $\left|D \cap\left\{F_{x}, F_{y}, F_{z}\right\}\right| \geq 2$, say $F_{x}, F_{y} \in D$ without loss of generality. Then the set $D \cup\{\bar{c}\}$ is an SD set of $G_{\ell}$ of size $\gamma_{t 2}(G)+1$ containing the $O_{4} F_{x}, \bar{c}, F_{y}, w_{y}$ and so, $c t_{\gamma_{t 2}}(G)=2$ by Theorem 1.7

Now by Claims 22 and 23, we conclude that for every $\ell \in\{3,4\}, c t_{\gamma_{t 2}}\left(G_{\ell}\right)=2$ if and only if $\Phi$ is satisfiable. Since for every $\ell \in\{3.4\}, G_{\ell}$ is easily seen to contain no induced $C_{\ell}$, the lemma follows.

The following now ensues from Lemmas 4.8 and 4.9
Corollary 4.10. For every $\ell \geq 3$, Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ is NP-hard on $C_{\ell}$-free graphs.
We next investigate the complexity of the Contraction $\operatorname{Number}\left(\gamma_{t 2}, 3\right)$ problem on several monogenic graph classes.
Lemma 4.11. Contraction $\operatorname{Number}\left(\gamma_{t 2}, 3\right)$ is $\operatorname{NP}$-hard on $K_{1,3}$-free graphs.
Proof. We reduce from Positive Exactly 3-Bounded 1-In-3 3-Sat (see Section 2 for a precise definition of this problem): given an instance $\Phi$ of this problem, with variable set $X$ and clause set $C$, we construct an instance $G$ of Contraction Number $\left(\gamma_{t 2}, 3\right)$ as follows. For every variable $x \in X$, we introduce the gadget $G_{x}$ depicted in Figure 8 (it is the same gadget as the one used in the proof of Lemma4.7). In the following, we denote by $P_{x}$ the long paw induced by $\left\{T_{x}, F_{x}, u_{x}, v_{x}, w_{x}\right\}$ and we may refer to the vertices of $P_{x}$ as $P_{x}(1), \ldots, P_{x}(5)$ where $P_{x}(1)=t_{x}$ and $P_{x}(2)=F_{x}$. For every clause $c \in C$ containing variables $x, y$ and $z$, we introduce the gadget $G_{c}$ which is the disjoint union of the graph $G_{c}^{T}$ and the graph $G_{c}^{F}$ depicted in Figure 11 (where a rectangle indicates that the corresponding set of vertices is a clique), and further add for every $v \in\{x, y, z\}$ an edge between $t_{c}^{v}$ and $P_{v, T}^{c}(1)$, and an edge between $f_{c}^{v}$ and $P_{v, F}^{c}(2)$. Note that $\left\{u_{c}^{x}, u_{c}^{y}, u_{c}^{z}, a_{c}\right\}$ and $\left\{v_{c}^{x}, v_{c}^{y}, v_{c}^{z}, b_{c}\right\}$ induce cliques; in particular, $G_{c}^{T}$ is $K_{1,3}$-free. We let $G$ be the resulting graph. We next show that $c t_{\gamma_{t 2}}(G)=3$ if and only if $\Phi$ is satisfiable through a series of claims.
Claim 24. For any $S D$ set $D$ of $G$, the following hold.
(i) For every variable $x \in X$ and every long paw $P$ contained in $G_{x},|D \cap V(P)| \geq 2$ and $D \cap\{P(4), P(5)\} \neq \varnothing$. In particular, $\left|D \cap V\left(G_{x}\right)\right| \geq 14$.
(ii) For every clause $c \in C$ containing variables $x, y$ and $z,\left|D \cap\left\{u_{c}, v_{c}, w_{c}, q_{c}^{x}, q_{c}^{y}, q_{c}^{z}\right\}\right| \geq 2$ and $\min \left(\left|D \cap\left\{u_{c}^{x}, u_{c}^{y}, u_{c}^{z}, a_{c}\right\}\right|,\left|D \cap\left\{v_{c}^{x}, v_{c}^{y}, v_{c}^{z}, b_{c}\right\}\right|\right) \geq 1$. In particular, $\left|D \cap V\left(G_{c}\right)\right| \geq 4$.
Proof. Let $D$ be an SD set of $G$. Since in a long paw $P$, the vertex $P(5)$ should be dominated and any witness for a vertex dominating $P(5)$ can only belong to $P$, item (i) follows. To prove (ii), consider a clause $c \in C$ containing variables $x, y$ and $z$. Since $w_{c}$ must be dominated and any witness for a vertex dominating $w_{c}$ can only belong to $\left\{u_{c}, v_{c}, w_{c}, q_{c}^{x}, q_{c}^{y}, q_{c}^{z}\right\}$, the first part of item (ii) follows. Now since $a_{c}$ should be dominated, $D \cap\left\{u_{c}^{x}, u_{c}^{y}, u_{c}^{z}, a_{c}\right\} \neq \varnothing$; and similarly, since $b_{c}$ should be dominated, $D \cap\left\{v_{c}^{x}, v_{c}^{y}, v_{c}^{z}, b_{c}\right\} \neq \varnothing$ which proves the second part of item (ii).

The following is an immediate consequence of Claim 24(i).

Observation 9. For every $S D$ set $D$ of $G$ and every variable $x \in X$ contained in clauses $c, c^{\prime}$ and $c^{\prime \prime}$, if $\left|D \cap V\left(G_{x}\right)\right|=14$ then $D \cap\left\{q_{x}^{\ell}, p_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}=\varnothing$.

Claim 25. Let $D$ be an $S D$ set of $G$ and let $c \in C$ be a clause containing variables $x, y$ and $z$. If $\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ then $D \cap\left\{f_{c}^{x}, f_{c}^{y}, f_{c}^{z}\right\}=\varnothing$. Similarly, if $\left|D \cap V\left(G_{c}^{T}\right)\right|=2$ then $D \cap\left\{t_{c}^{x}, t_{c}^{y}, t_{c}^{z}\right\}=\varnothing$.
Proof. If $\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ then by Claim 24(ii), $\left|D \cap V\left(G_{c}^{F}\right)\right|=\left|D \cap\left\{u_{c}, v_{c}, w_{c}, q_{c}^{x}, q_{c}^{y}, q_{c}^{z}\right\}\right|=2$ and thus, $D \cap\left\{f_{c}^{x}, f_{c}^{y}, f_{c}^{z}\right\}=\varnothing$. Now if $\left|D \cap V\left(G_{c}^{T}\right)\right|=2$ then by Claim 24(ii), $\left|D \cap\left\{u_{c}^{x}, u_{c}^{y}, u_{c}^{z}, a_{c}\right\}\right|=$ $\left|D \cap\left\{v_{c}^{x}, v_{c}^{y}, v_{c}^{z}, b_{c}\right\}\right|=1$ and thus, $D \cap\left\{t_{c}^{x}, t_{c}^{y}, t_{c}^{z}\right\}=\varnothing$.

Claim 26. Let $D$ be an $S D$ set of $G$. If for some variable $x \in X$ contained in clauses $c, c^{\prime}$ and $c^{\prime \prime},\left|D \cap V\left(G_{x}\right)\right|=14$ then the following hold.
(i) If there exists $\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}$ such that $P_{x, T}^{\ell}(1) \in D$ then $T_{x} \in D$.
(ii) If there exists $\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}$ such that $P_{x, F}^{\ell}(2) \in D$ then $F_{x} \in D$.

In particular, if $P_{x, T}^{\ell}(1) \in D$ for some $\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}$, then $D \cap\left\{P_{x, F}^{c}(2), P_{x, F}^{c^{\prime}}(2), P_{x, F}^{c^{\prime \prime}}(2)\right\}=\varnothing$. Similarly, if $P_{x, F}^{\ell}(2) \in D$ for some $\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}$, then $D \cap\left\{P_{x, T}^{c}(1), P_{x, T}^{c^{\prime}}(1), P_{x, T}^{c^{\prime \prime}}(1)\right\}=\varnothing$.
Proof. Let $x \in X$ be a variable such that $\left|D \cap V\left(G_{x}\right)\right|=14$ and let $c, c^{\prime}, c^{\prime \prime} \in C$ be the clauses in which $x$ appears. Then by Observation 9, $D \cap\left\{p_{x}^{\ell}, q_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}=\varnothing$ and by Claim [24(i), $|D \cap\{P(1), P(2)\}| \leq 1$ for every long paw $P$ of $G_{x}$. Thus if $P_{x, T}^{\ell}(1) \in D$ for some $\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}$, then $T_{x} \in D$ as $p_{x}^{\ell}$ should be dominated; but then, $F_{x} \notin D$ which implies that $\left\{P_{x, F}^{c}(1), P_{x, F}^{c^{\prime}}(1), P_{x, F}^{c^{\prime \prime}}(1)\right\} \subseteq D$ (one of $q_{x}^{c}, q_{x}^{c^{\prime}}$ and $q_{x}^{c^{\prime \prime}}$ would otherwise not be dominated) and so, $D \cap\left\{P_{x, F}^{c}(2), P_{x, F}^{c^{\prime}}(2), P_{x, F}^{c^{\prime \prime}}(2)\right\}=\varnothing$. Item (ii) follows by symmetry.

Claim 27. $\Phi$ is satisfiable if and only if $\gamma_{t 2}(G)=14|X|+4|C|$.
Proof. Assume first that $\Phi$ is satisfiable and consider a truth assignment satisfying $\Phi$. We construct an SD set $D$ of $G$ as follows. For every variable $x \in X$ contained in clauses $c, c^{\prime}$ and $c^{\prime \prime}$, if $x$ is true then we include $\left\{v_{x}, T_{x}\right\} \cup\left\{P_{x, R}^{\ell}(1), P_{x, R}^{\ell}(4) \mid R \in\{T, F\}\right.$ and $\left.\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}$ in $D$; otherwise we include $\left\{v_{x}, F_{x}\right\} \cup\left\{P_{x, R}^{\ell}(2), P_{x, R}^{\ell}(4) \mid R \in\{T, F\}\right.$ and $\left.\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}$ in $D$. For every clause $c \in C$ containing variables $x, y$ and $z$, exactly one variable is true, say $x$ without loss of generality, in which case we include $\left\{w_{c}, q_{c}^{x}\right\} \cup\left\{v_{c}^{y}, u_{c}^{z}\right\}$ in $D$. Now it is not difficult to see that the constructed set $D$ is indeed an SD set of $G$ and since $|D|=14|X|+4|C|$, we conclude by Claim 24 that $D$ is minimum.

Conversely, assume that $\gamma_{t 2}(G)=14|X|+4|C|$ and let $D$ be a minimum SD set of $G$. Consider a clause $c \in C$ and let $x, y, z \in X$ be the variables contained in $c$. Then $\left|D \cap\left\{q_{c}^{x}, q_{c}^{y}, q_{c}^{z}\right\}\right| \leq 1$ : indeed, $D \cap\left\{w_{c}, v_{c}\right\} \neq \varnothing$ as $w_{c}$ should be dominated, and $\left|D \cap\left\{u_{c}, v_{c}, w_{c}, q_{c}^{x}, q_{c}^{y}, q_{c}^{z}\right\}\right|=2$ by Claim 24(i). Since $D \cap\left\{f_{c}^{x}, f_{c}^{y}, f_{c}^{z}\right\}=\varnothing$ by Claim[25, it follows that at least two vertices amongst $f_{c}^{x}, f_{c}^{y}$ and $f_{c}^{z}$ are not dominated by a vertex in $G_{c}^{F}$, say $f_{c}^{y}$ and $f_{c}^{z}$ without loss of generality. Then $P_{y, F}^{c}(2), P_{z, F}^{c}(2) \in D$ as $f_{c}^{y}$ and $f_{c}^{z}$ should be dominated, and so $F_{y}, F_{z} \in D$ by Claim 26(ii). It then follows from Claim[24(i) that $T_{y}, T_{z} \notin D$ which, by Claim[26(i), implies that $P_{y, T}^{c}(1), P_{z, T}^{c}(1) \notin D$; in particular, $t_{c}^{y}$ and $t_{c}^{z}$ must be dominated by vertices in $G_{c}^{T}$. But then, $D \cap\left\{t_{c}^{x}, v_{c}^{x}, u_{c}^{x}\right\}=\varnothing$ : indeed, since $\left|D \cap V\left(G_{c}^{T}\right)\right|=2$ by assumption, if $D \cap\left\{t_{c}^{x}, v_{c}^{x}, u_{c}^{x}\right\} \neq \varnothing$ then one of $t_{c}^{y}$ and $t_{c}^{z}$ is not dominated. Since $t_{c}^{x}$ should be dominated nonetheless, it follows that $P_{x, T}^{c}(1) \in D$ and thus, $T_{x} \in D$ by Claim 26(i). Therefore, the truth assignment obtained by setting a variable $x$ to true when $T_{x} \in D$ and to false otherwise, satisfies $\Phi$.

Claim 28. Let $D$ be an $S D$ set of $G$ and let $c \in C$ be a clause containing variables $x, y$ and $z$. If $\left|D \cap V\left(G_{c}\right)\right|=4$ and $\left|D \cap V\left(G_{\ell}\right)\right|=14$ for every $\ell \in\{x, y, z\}$ then $D \cap V\left(G_{c}^{T}\right)$ is an independent set.

Proof. Assume that $\left|D \cap V\left(G_{c}\right)\right|=4$ and $\left|D \cap V\left(G_{\ell}\right)\right|=14$ for every $\ell \in\{x, y, z\}$ (note that then $\left|D \cap V\left(G_{c}^{T}\right)\right|=\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ by Claim[24(ii)). Suppose to the contrary that $D \cap V\left(G_{c}^{T}\right)$ contains an edge $u v$. Then $\{u, v\}=\left\{u_{c}^{\ell}, v_{c}^{\ell}\right\}$ for some $\ell \in\{x, y, z\}$ : indeed, $\{u, v\} \cap\left\{u_{c}^{x}, u_{c}^{y}, u_{c}^{z}, a_{c}\right\} \neq$ $\varnothing$ and $\{u, v\} \cap\left\{v_{c}^{x}, v_{c}^{y}, v_{c}^{z}, b_{c}\right\} \neq \varnothing$ by Claim 24(ii), and any edge between $\left\{u_{c}^{x}, u_{c}^{y}, u_{c}^{z}, a_{c}\right\}$ and $\left\{v_{c}^{x}, v_{c}^{y}, v_{c}^{z}, b_{c}\right\}$ connect vertices with the same superscript. Assume without loss of generality that $\{u, v\}=\left\{u_{c}^{x}, v_{c}^{x}\right\}$. Then $P_{y, T}^{c}(1), P_{z, T}^{c}(1) \in D$ as $t_{c}^{y}$ and $t_{c}^{z}$ should be dominated, which, by Claim [26] implies that $P_{y, F}^{c}(2), P_{z, F}^{c}(2) \notin D$. By Claim [25], it must then be that $q_{c}^{y}, q_{c}^{z} \in D$ for
one of $f_{c}^{y}$ and $f_{c}^{z}$ would otherwise not be dominated; but $\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ and thus, $w_{c}$ is not dominated.

Claim 29. Let $D$ be an $S D$ set of $G$ and let $c \in C$ be a clause containing variables $x, y, z \in X$. If $\left|D \cap V\left(G_{c}\right)\right|=4$ and $\left|D \cap V\left(G_{\ell}\right)\right|=14$ for every $\ell \in\{x, y, z\}$ then $D \cap V\left(G_{c}^{F}\right)$ is an independent set.

Proof. Assume that $\left|D \cap V\left(G_{c}\right)\right|=4$ and $\left|D \cap V\left(G_{\ell}\right)\right|=14$ for every $\ell \in\{x, y, z\}$ (note that then $\left|D \cap V\left(G_{c}^{T}\right)\right|=\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ by Claim 24(ii)). Suppose for a contradiction that $D \cap V\left(G_{c}^{F}\right)$ contains an edge $u v$. Then, since $w_{c}$ should be dominated, $\{u, v\} \subseteq\left\{u_{c}, v_{c}, w_{c}\right\}$; in particular $D \cap\left\{q_{c}^{\ell}, f_{c}^{\ell} \mid \ell \in\{x, y, z\}\right\}=\varnothing$ by Claims 24(ii) and 25. But then, $\left\{P_{\ell, F}^{c}(2) \mid \ell \in\{x, y, z\}\right\} \subseteq D$ as $f_{c}^{x}, f_{c}^{y}$ and $f_{c}^{z}$ should be dominated, which, by Claim[26, implies that $\left\{P_{\ell, T}^{c}(1) \mid \ell \in\{x, y, z\}\right\} \subseteq D$. But $\left|D \cap V\left(G_{c}^{T}\right)\right|=2$ and so, one of $t_{c}^{x}, t_{c}^{y}$ and $t_{c}^{z}$ is not dominated.

Claim 30. Let $D$ be an $S D$ set of $G$ and let $x \in X$ be a variable. If $\left|D \cap V\left(G_{x}\right)\right|=14$ and $D \cap V\left(G_{x}\right)$ contains an edge uv then $\{u, v\}=\{P(3), P(4)\}$ for some long paw $P$ of $G_{x}$.

Proof. Assume that $\left|D \cap V\left(G_{x}\right)\right|=14$ and $D \cap V\left(G_{x}\right)$ contains an edge $u v$. Then by Observation 9 $u, v \in V(P)$ for some long paw $P$ of $G_{x}$. But $|D \cap V(P)|=2$ and $D \cap\{P(4), P(5)\} \neq \varnothing$ by Claim [24(i) and so, $D \cap V(P)=\{u, v\} \subseteq\{P(3), P(4), P(5)\}$. Now suppose for a contradiction that $P(3) \notin D$. If $P=P_{x}$ then both $T_{x}$ and $F_{x}$ are not dominated since by Observation 9 $q_{x}^{\ell}, p_{x}^{\ell} \notin D$ for every clause $\ell$ containing $x$. If $P=P_{x, T}^{\ell}$ for some clause $\ell$ containing $x$, then $P_{x, T}^{\ell}(2)$ is not dominated since $p_{x}^{\ell} \notin D$ by Observation 9. Finally if $P=P_{x, F}^{\ell}$ for some clause $\ell$ containing $x$, then $P_{x, F}^{\ell}(1)$ is not dominated since $q_{x}^{\ell} \notin D$ by Observation 9 Thus, $P(3) \in D$ and so, $\{u, v\}=\{P(3), P(4)\}$.

Claim 31. Let $D$ be an $S D$ set of $G$ and let $c \in C$ be a clause containing variables $x, y$ and $z$. If $\left|D \cap V\left(G_{c}\right)\right|=4$ and $\left|D \cap V\left(G_{\ell}\right)\right|=14$ for every $\ell \in\{x, y, z\}$, then for every $\ell \in\{x, y, z\}$, the following hold.
(i) $D \cap\left\{u_{c}^{\ell}, v_{c}^{\ell}\right\}=\varnothing$ if and only if $P_{\ell, T}^{c}(1) \in D$.
(ii) $q_{c}^{\ell} \notin D$ if and only if $P_{\ell, F}^{c}(2) \in D$.
(iii) $P_{\ell, F}^{c}(2) \in D$ if and only if $P_{\ell, T}^{c}(1) \notin D$

Proof. Assume that $\left|D \cap V\left(G_{c}\right)\right|=4$ and $\left|D \cap V\left(G_{\ell}\right)\right|=14$ for every $\ell \in\{x, y, z\}$. Now consider $\ell \in\{x, y, z\}$ and let us first prove (i). If $D \cap\left\{u_{c}^{\ell}, v_{c}^{\ell}\right\}=\varnothing$ then since $t_{c}^{\ell} \notin D$ by Claim 25, necessarily $P_{\ell, T}^{c}(1) \in D$ as $t_{c}^{\ell}$ should be dominated. Conversely, assume that $P_{\ell, T}^{c}(1) \in D$ and suppose for a contradiction that $D \cap\left\{u_{c}^{\ell}, v_{c}^{\ell}\right\} \neq \varnothing$. Then since $\left|D \cap V\left(G_{c}^{T}\right)\right|=2$ by Claim 24(ii), it must be that $D \cap\left\{u_{c}^{p}, v_{c}^{p}\right\}=\varnothing$ for some $p \neq \ell$; and since $t_{c}^{p} \notin D$ by Claim 25, necessarily $P_{p, T}^{c}(1) \in D$ as $t_{c}^{p}$ should be dominated. Then $P_{\ell, F}^{c}(2), P_{p, F}^{c}(2) \notin D$ by Claim 26 and since $f_{c}^{\ell}, f_{c}^{p} \notin D$ by Claim 25, it follows that $q_{c}^{\ell}, q_{c}^{p} \in D$ as $f_{c}^{\ell}$ and $f_{c}^{p}$ should be dominated. But $\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ by Claim 24] and thus, $w_{c}$ is not dominated.

To prove (ii), observe that if $q_{c}^{\ell} \notin D$ then since $f_{c}^{\ell} \notin D$ by Claim 25 necessarily $P_{\ell, F}^{c}(2) \in D$ for $f_{c}^{\ell}$ would otherwise not be dominated. Conversely, assume that $P_{\ell, F}^{c}(2) \in D$ for some $\ell \in\{x, y, z\}$, and suppose for a contradiction that $q_{c}^{\ell} \in D$. Then since $\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ by Claim 24(ii) and $w_{c}$ must be dominated, $q_{c}^{p} \notin D$ for every $p \neq \ell$; and since by Claim 25, $f_{c}^{p} \notin D$ for every $p \neq \ell$, necessarily $P_{p, F}^{c}(2) \in D$ for every $p \neq \ell\left(f_{c}^{p}\right.$ would otherwise not be dominated). It then follows from Claim 26 that $D \cap\left\{P_{x, T}^{c}(1), P_{y, T}^{c}(1), P_{z, T}^{c}(1)\right\}=\varnothing$; but $\left|D \cap V\left(G_{c}^{T}\right)\right|=2$ by Claim 24(ii) and so, one of $t_{c}^{x}, t_{c}^{y}$ and $t_{c}^{z}$ is not dominated.

Let us finally prove (iii). If $P_{\ell, F}^{c}(2) \in D$ then by Claim 26, $P_{\ell, T}^{c}(1) \notin D$. Conversely, assume that $P_{\ell, T}^{c}(1) \notin D$. Then by item (i), $D \cap\left\{u_{c}^{\ell}, v_{c}^{\ell}\right\} \neq \varnothing$ which implies that $D \cap\left\{u_{c}^{p}, v_{c}^{p}\right\}=\varnothing$ for some $p \neq \ell$, since $\left|D \cap V\left(G_{c}^{T}\right)\right|=2$ by Claim 24(ii). It then follows from item (i) that $P_{p, T}^{c}(1) \in D$ and so, $P_{p, F}^{c}(2) \notin D$ by Claim[26. Thus, by item (ii), $q_{c}^{p} \in D$; but $\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ by Claim[24(ii) and $w_{c}$ must be dominated, and so $q_{c}^{\ell} \notin D$ which, by item (ii), implies that $P_{\ell, F}^{c}(2) \in D$.
Claim 32. Let $D$ be an $S D$ set of $G$ and let $x \in X$ be a variable contained in clauses $c, c^{\prime}$ and $c^{\prime \prime}$. If $\left|D \cap V\left(G_{\ell}\right)\right|=4$ for every $\ell \in\left\{c, c^{\prime \prime} c^{\prime \prime}\right\}$ and $\left|D \cap V\left(G_{v}\right)\right|=14$ for every variable $v$ appearing in $c, c^{\prime}$ or $c^{\prime \prime}$, then $D \cap V\left(G_{x}\right)$ is an independent set.

Proof. Assume that $\left|D \cap V\left(G_{\ell}\right)\right|=4$ for every $\ell \in\left\{c, c^{\prime \prime} c^{\prime \prime}\right\}$ and $\left|D \cap V\left(G_{v}\right)\right|=14$ for every variable $v$ appearing in $c, c^{\prime}$ or $c^{\prime \prime}$. Suppose for a contradiction that $D \cap V\left(G_{x}\right)$ contains an edge $u v$. Then by Claim 30, $\{u, v\}=\{P(3), P(4)\}$ for some long paw $P$ of $G_{x}$. If $P=P_{x}$ then since $D \cap\left\{q_{x}^{\ell}, p_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}=\varnothing$ by Observation 9, necessarily $P_{x, T}^{c}(2), P_{x, F}^{c}(1) \in D$ (one of $p_{x}^{c}$ and $q_{x}^{c}$ would otherwise not be dominated); but then by Claim 24(i), $P_{x, T}^{c}(1), P_{x, F}^{c}(2) \notin D$, a contradiction to Claim 31(iii). Thus $P=P_{x, R}^{\ell}$ for some $\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}$ and $R \in\{T, F\}$. Assume that $R=T$ (the case where $R=F$ is symmetric). Then since $D \cap\left\{q_{x}^{\ell}, p_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}=\varnothing$ by Observation 9, necessarily $T_{x} \in D$ ( $p_{x}^{\ell}$ would otherwise not be dominated) and so, $F_{x} \notin D$ by Claim 24(i). But then by Claim 26(ii), $P_{x, F}^{\ell}(2) \notin D$, a contradiction to Claim 31(ii) as $P_{x, T}^{\ell}(1) \notin D$.

Claim 33. If $\gamma_{t 2}(G)=14|X|+4|C|$ then for every minimum $S D$ set $D$ of $G$, the following hold.
(i) $D$ is an independent set.
(ii) For every $u \in D,\left|w_{D}(u)\right|=1$.

Proof. Assume that $\gamma_{t 2}(G)=14|X|+4|C|$ and let $D$ be a minimum SD set of $G$. Then by Claims 25, 28, 29and 32, $D$ contains no edge. Let us next show that for every $u \in D,\left|w_{D}(u)\right|=1$. Consider first a clause $c \in C$ containing variables $x, y, z \in X$ and let $u \in D \cap V\left(G_{c}\right)$. Note that since $\left|D \cap V\left(G_{c}^{T}\right)\right|=\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ by Claim[24(ii), if $\left|w_{D}(u)\right| \geq 2$ then $d\left(u, D \backslash V\left(G_{c}\right)\right) \leq 2$. Now if $u \in\left\{u_{c}^{\ell}, v_{c}^{\ell}\right\}$ for some $\ell \in\{x, y, z\}$, then by Claim 31(i), $P_{\ell, T}^{c}(1) \notin D$ and thus, $d\left(u, D \backslash V\left(G_{c}\right)\right)>$ 2. Similarly, if $u=q_{c}^{\ell}$ for some $\ell \in\{x, y, z\}$, then by Claim 31(ii), $P_{\ell, F}^{c}(2) \notin D$ and thus, $d\left(u, D \backslash V\left(G_{c}\right)\right)>2$. Since $u \notin\left\{f_{c}^{\ell}, t_{c}^{\ell} \mid \ell \in\{x, y, z\}\right\}$ by Claim 25 and $d\left(w, D \backslash V\left(G_{c}\right)\right) \geq 3$ for every $w \in\left\{a_{c}, b_{c}\right\}$, it follows that $\left|w_{D}(u)\right|=1$. Consider next a variable $x \in X$ contained in clauses $c, c^{\prime}, c^{\prime \prime} \in C$, and suppose to the contrary that there exists a vertex $u \in D \cap V\left(G_{x}\right)$ such that $\left|w_{D}(u)\right| \geq 2$. Since $|D \cap V(P)|=2$ for ever long paw $P$ in $G_{x}$ and $D \cap\left\{q_{x}^{\ell}, p_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right.$, necessarily $u \in\{P(1), P(2)\}$ for some long paw $P$ of $G_{x}$. Suppose first that $u=T_{x}$ (the case where $u=F_{x}$ is symmetric). Then by Observation 9 there must exist $\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}$ such that $P_{x, T}^{\ell}(2) \in$ $D$; in particular, $P_{x, T}^{\ell}(1) \notin D$ by Claim 24(i). But $F_{x} \notin D$ by Claim 24(i) and so, $P_{x, F}^{\ell}(2) \notin D$ by Claim 26(ii), a contradiction to Claim 31(iii). Suppose next that $u \in\left\{P_{x, R}^{\ell}(1), P_{x, R}^{\ell}(2)\right\}$ for some $\ell \in\left\{c, c^{\prime}, c^{\prime}\right\}$ and $R \in\{T, F\}$. Assume that $R=F$ (the case where $R=T$ is symmetric). Then $u$ must have a witness in $D \cap V\left(G_{\ell}^{F}\right)$ : indeed, if $u$ had two witnesses in $D \cap V\left(G_{x}\right)$ then one of them would be $F_{x}$ and so, $\left|w_{D}\left(F_{x}\right)\right| \geq 2$ which is excluded by the previous case. However, $f_{\ell}^{x} \notin D$ by Claim [25], and if $q_{\ell}^{x} \in D$ then $P_{x, F}^{\ell}(2) \notin D$ by Claim 31(ii); thus $d\left(u, D \cap V\left(G_{\ell}^{F}\right)\right)>2$, a contradiction. Therefore, every vertex in $D \cap V\left(G_{x}\right)$ has a unique witness.

Claim 34. Let $D$ be an $S D$ set of $G$ and let $x \in X$ be a variable. If $\left|D \cap V\left(G_{x}\right)\right|=14$ then for every clause $c \in C$ containing $x$, the following hold.
(i) If $D \cap\left\{P_{x, T}^{c}(1), P_{x, T}^{c}(3)\right\} \neq \varnothing$ then $P_{x, F}^{c}(2) \notin D$.
(ii) If $D \cap\left\{P_{x, F}^{c}(2), P_{x, F}^{c}(3)\right\} \neq \varnothing$ then $P_{x, T}^{c}(1) \notin D$.

Proof. Assume that $\left|D \cap V\left(G_{x}\right)\right|=14$ and let $c \in C$ be a clause containing $x$. Suppose that $D \cap\left\{P_{x, T}^{c}(1), P_{x, T}^{c}(3)\right\} \neq \varnothing$. Then by Claim [24(i), $P_{x, T}^{c}(2) \notin D$ which, by Observation 9 implies that $T_{x} \in D$ ( $p_{x}^{c}$ would otherwise not be dominated); but then $F_{x} \notin D$ by Claim 24(i) and so, $P_{x, F}^{c}(2) \notin D$ by Claim[26(ii). Item (ii) follows by symmetry.

Claim 35. ct $_{\gamma_{t 2}}(G)=3$ if and only if $\gamma_{t 2}(G)=14|X|+4|C|$.
Proof. Assume first that $c t_{\gamma_{t 2}}(G)=3$ and let $D$ be a minimum SD set of $G$. Consider a variable $x \in X$ contained in clauses $c, c^{\prime}$ and $c^{\prime \prime}$. If $|D \cap V(P)| \geq 3$ for some long paw $P$ of $G_{x}$ then $D \cap V(P)$ contains a friendly triple, a contradiction to Theorem 1.7. Thus $|D \cap V(P)| \leq 2$ for every long paw $P$ of $G_{x}$ and we conclude by Claim 24(i) that, in fact, equality holds. Let us assume, in the following, that for every long paw $P$ of $G_{x}, D \cap\{P(1), P(2)\} \neq \varnothing$ and $P(4) \in D$ (if this does not hold for a long paw $P$ then it suffices to consider, e.g., $(D \backslash V(P)) \cup\{P(1), P(4)\}$ in place of $D)$. Now suppose that $D \cap\left\{p_{x}^{c}, p_{x}^{c^{\prime}}, p_{x}^{c^{\prime \prime}}\right\} \neq \varnothing$, say $p_{x}^{c} \in D$ without loss of generality. Then $T_{x} \notin D$ ( $D$ would otherwise contain the friendly triple $\left.p_{x}^{c}, T_{x}, v_{x}\right)$ and so, $\left(D \backslash\left\{p_{x}^{c}\right\}\right) \cup\left\{T_{x}\right\}$ is a minimum SD set of $G$ containing the friendly triple $T_{x}, F_{x}, w_{x}$, a contradiction to Theorem 1.7 Thus $D \cap\left\{p_{x}^{c}, p_{x}^{c^{\prime}}, p_{x}^{c^{\prime \prime}}\right\}=\varnothing$ and by symmetry, we conclude that $D \cap\left\{q_{x}^{c}, q_{x}^{c^{\prime}}, q_{x}^{c^{\prime \prime}}\right\}=\varnothing$ as well. Therefore, $\left|D \cap V\left(G_{x}\right)\right|=14$.

Next, consider a clause $c \in C$ and let $x, y, z \in X$ be the variables contained in $c$. Then $\mid D \cap$ $\left\{u_{c}, v_{c}, w_{c}, q_{c}^{x}, q_{c}^{y}, q_{c}^{z}\right\} \mid \leq 2$ for $D \cap\left\{u_{c}, v_{c}, w_{c}, q_{c}^{x}, q_{c}^{y}, q_{c}^{z}\right\}$ would otherwise contain a friendly triple; and we conclude by Claim[24]that, in fact, equality holds. Now suppose that $D \cap\left\{f_{c}^{x}, f_{c}^{y}, f_{c}^{z}\right\} \neq \varnothing$, say $f_{c}^{x} \in D$ without loss of generality. Then $q_{c}^{x} \notin D$ : indeed, $D$ would otherwise contain the friendly triple $f_{c}^{x}, q_{c}^{x}$, , where $t \in D \cap\left\{u_{c}, v_{c}, w_{c}, q_{c}^{y}, q_{c}^{z}\right\}$, a contradiction to Theorem 1.7 But by assumption, $P_{x, F}^{c}(2)$ is not a private neighbour of $f_{c}^{x}$ and the vertex in $D \cap\left\{P_{x, F}^{c}(1), P_{x, F}^{c}(2)\right\}$ is witnessed by $P_{x, F}^{c}(4)$, which implies that $D^{\prime}=\left(D \backslash\left\{f_{c}^{x}\right\}\right) \cup\left\{q_{c}^{x}\right\}$ is a minimum SD set of $G$ where $\left|D^{\prime} \cap\left\{u_{c}, v_{c}, w_{c}, q_{c}^{x}, q_{c}^{y}, q_{c}^{z}\right\}\right| \geq 3$, a contradiction to the above. Thus, $D \cap\left\{f_{c}^{x}, f_{c}^{y}, f_{c}^{z}\right\}=\varnothing$ and so, $\left|D \cap V\left(G_{c}^{F}\right)\right|=2$. Suppose next that $\left|D \cap V\left(G_{c}^{T}\right)\right| \geq 3$. If $D \cap\left\{t_{c}^{x}, t_{c}^{y}, t_{c}^{z}\right\}=\varnothing$, say $t_{c}^{x} \in D$ without loss of generality, then surely one of $u_{c}^{x}$ and $v_{c}^{x}$ does not belong to $D$ ( $D$ would otherwise contain the friendly triple $t_{c}^{x}, u_{c}^{x}, v_{c}^{x}$ ), say $u_{c}^{x} \notin D$ without loss of generality. Since by assumption, $P_{x, T}^{c}(1)$ is not a private neighbour of $t_{c}^{x}$ and the vertex in $D \cap\left\{P_{x, T}^{c}(1), P_{x, T}^{c}(2)\right\}$ is witnessed by $P_{x, T}^{c}(4)$, the set $D^{\prime}=\left(D \backslash\left\{t_{c}^{x}\right\} \cup\left\{u_{c}^{x}\right\}\right.$ is a minimum SD of $G$ (note that $u_{c}^{x}$ is within distance two of every vertex in $D \cap V\left(G_{c}^{T}\right)$ ). By repeating this argument if necessary, we obtain a minimum SD set $D^{\prime \prime}$ of $G$ such that $D^{\prime \prime} \cap\left\{t_{c}^{x}, t_{c}^{y}, t_{c}^{z}\right\}=\varnothing$ and $\left|D^{\prime \prime} \cap V\left(G_{c}^{T}\right)\right| \geq 3$; but then, it is easy to see that $D^{\prime \prime} \cap\left(\left\{a_{c}, b_{c}\right\} \cup\left\{u_{c}^{\ell}, v_{c}^{\ell} \mid \ell \in\{x, y, z\}\right\}\right.$ contains a friendly triple, a contradiction to Theorem 1.7 Thus, $\left|D \cap V\left(G_{c}^{T}\right)\right| \leq 2$ and we conclude by Claim 24(ii) that, in fact, equality holds. Therefore, $\left|D \cap V\left(G_{c}\right)\right|=4$ and thus, $\gamma_{t 2}(G)=|D|=14|X|+4|C|$.

Conversely, assume that $\gamma_{t 2}(G)=14|X|+4|C|$. Observe first that since by Claim 33, every minimum SD set of $G$ is an independent set, no minimum SD set of $G$ contains a friendly triple; thus by Theorem 1.7(i), $c t_{\gamma_{t 2}}(G)>1$. Now suppose to the contrary that $c t_{\gamma_{t 2}}(G)=2$ and let $D$ be an SD set of size $\gamma_{t 2}(G)+1$ containing an ST configuration (see Theorem 1.7(ii)). Then by Claim [24, there exists either a clause $c \in C$ such that $\left|D \cap V\left(G_{c}\right)\right|=5$ or a variable $x \in X$ such that $\left|D \cap V\left(G_{x}\right)\right|=15$. We next distinguish these two cases.

Case 1. There exists a clause $c \in C$ such that $\left|D \cap V\left(G_{c}\right)\right|=5$. Let $x, y, z \in X$ be the three variables appearing in $c$. Then for any clause $\ell \in C \backslash\{c\}, D \cap V\left(G_{\ell}\right)$ contains no edges by Claims 28 and 29] and for any variable $v \in X \backslash\{x, y, z\}, D \cap V\left(G_{v}\right)$ contains no edge by Claim 32, Thus by Claim [25, $D \backslash\left(V\left(G_{c}\right) \cup V\left(G_{x}\right) \cup V\left(G_{y}\right) \cup V\left(G_{z}\right)\right)$ contains no edge and a fortiori, no ST-configurations. Further observe if for some $\ell \in\{x, y, z\}, D \cap V\left(G_{\ell}\right)$ contains an edge $u v$ then by Claim 30, $\{u, v\}=\{P(3), P(4)\}$ for some long paw $P$ in $G_{\ell}$. Now if $P \neq P_{\ell, T}^{c}, P_{\ell, F}^{c}$ then by Observation 9 and Claim [25, $d(\{u, v\}, D \backslash\{u, v\}) \geq 3$ and so $u v$ cannot be part of an STconfiguration in $D$.; and if $P=P_{\ell, T}^{c}$ (resp. $\left.P=P_{\ell, F}^{c}\right)$ then $d(\{u, v\}, D \backslash\{u, v\}) \geq 3$ unless $t_{c}^{\ell} \in D$ (resp. $f_{c}^{\ell} \in D$ ). Thus any edge $u v$ of an ST-configuration in $D$ satisfies one of the following.
(aT) $\{u, v\}=\left\{P_{\ell, T}^{c}(3), P_{\ell, T}^{c}(4)\right\}$ for some $\ell \in\{x, y, z\}$ and $t_{c}^{\ell} \in D$.
(aF) $\{u, v\}=\left\{P_{\ell, F}^{c}(3), P_{\ell, F}^{c}(4)\right\}$ for some $\ell \in\{x, y, z\}$ and $f_{c}^{\ell} \in D$.
(bT) $\left.\{u, v\}=\left\{P_{\ell, T}^{( } 1\right), t_{c}^{\ell}\right\}$ for some $\ell \in\{x, y, z\}$.
(bF) $\left.\{u, v\}=\left\{P_{\ell, F}^{( } 2\right), f_{c}^{\ell}\right\}$ for some $\ell \in\{x, y, z\}$.
(cT) $u, v \in V\left(G_{c}^{T}\right)$.
(cF) $u, v \in V\left(G_{c}^{F}\right)$.
Note that since for any $\ell \in\{x, y, z\}$ and any $R \in\{T, F\},\left|D \cap\left\{P_{\ell, R}^{c}(1), P_{\ell, R}^{c}(2), P_{\ell, R}^{c}(3)\right\}\right| \leq 1$ by Claim 24(i), if there is an edge satisfying (aR) and an edge satisfying (bR), then these two edges are vertex-disjoint. We now distinguish cases depending on whether $\left|D \cap V\left(G_{c}^{T}\right)\right|=3$ or $\left|D \cap V\left(G_{c}^{F}\right)\right|=3$.

Case 1.a. $\left|D \cap V\left(G_{c}^{T}\right)\right|=3$. Then $D \cap\left\{f_{c}^{x}, f_{c}^{y}, f_{c}^{z}\right\}=\varnothing$ by Claim 25, which implies that no edge of an ST-configuration in $D$ satisfies (aF) or (bF). Now if $D \cap V\left(G_{c}^{F}\right)$ contains an edge $u v$ then $\{u, v\} \subseteq\left\{w_{c}, v_{c}, u_{c}\right\}$ as $w_{c}$ should be dominated; but then $d(\{u, v\}, D \backslash\{u, v\}) \geq 3$ and so, $u v$ cannot be part of an ST-configuration in $D$. Thus no edge of an ST-configuration in $D$ satisfies (cF). Further note that since $\left|D \cap\left\{t_{c}^{x}, t_{c}^{y}, t_{c}^{z}\right\}\right| \leq 1$ by Claim[24(ii), there is at most one edge of an ST-configuration in $D$ satisfying (aT) or (bT).

Suppose first that $D \cap V\left(G_{c}^{T}\right)$ is an independent set and let $u v$ be an edge of an ST-configuration in $D$. If $u v$ satisfies (aT) for some $\ell \in\{x, y, z\}$, then $\left.D \cap\left\{P_{\ell, T}^{( } 1\right), P_{\ell, T}^{c}(2)\right\}=\varnothing$ by Claim 24(i) and so, $u v$ cannot be part of a $P_{3}$. Similarly, if $u v$ satisfies (bT) for some $\ell \in\{x, y, z\}$, then
$D \cap\left\{P_{\ell, T}^{c}(2), P_{\ell, T}^{c}(3)\right\}=\varnothing$ by Claim 24(i) and so, $u v$ cannot be part of a $P_{3}$. It follows that $D$ contains no $P_{3}$, which implies that $D$ must contain an $O_{3}$ or an $O_{7}$; in particular, $D$ contains two vertex-disjoint edges. However, any such edge would satisfy (aT) or (bT), a contradiction to the above.

Suppose next that $D \cap V\left(G_{c}^{T}\right)$ contains an edge. We claim that there exists at most one variable $\ell \in\{x, y, z\}$ such that $D \cap\left\{P_{\ell, T}^{c}(1), P_{\ell, T}^{c}(3)\right\} \neq \varnothing$. Indeed, suppose for a contradiction that there are two such variables, say $x$ and $y$ without loss of generality. Then $P_{x, F}^{c}(2), P_{y, F}^{c}(2) \notin D$ by Claim 34, which implies that $\left|D \cap\left\{q_{c}^{x}, q_{c}^{y}, f_{c}^{x}, f_{c}^{y}\right\}\right| \geq 2$ as $f_{c}^{x}$ and $f_{c}^{y}$ should be dominated; but $\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ and so, $w_{c}$ is not dominated, a contradiction. Thus assume, without loss of generality, that $D \cap\left\{P_{x, T}^{c}(1), P_{x, T}^{c}(3)\right\}=D \cap\left\{P_{y, T}^{c}(1), P_{y, T}^{c}(3)\right\}=\varnothing$ (note that $D \cap\left(\left\{t_{c}^{x}\right\} \cup V\left(P_{x, T}^{c}\right)\right)$ and $D \cap\left(\left\{t_{c}^{y}\right\} \cup V\left(P_{y, T}^{c}\right)\right)$ can then contain no edge). Since $t_{c}^{x}$ and $t_{c}^{y}$ should be dominated, necessarily $D \cap\left\{t_{c}^{x}, u_{c}^{x}, v_{c}^{x}\right\} \neq \varnothing$ and $D \cap\left\{t_{c}^{y}, u_{c}^{y}, v_{c}^{y}\right\} \neq \varnothing$. Now if $D \cap\left\{t_{c}^{z}, u_{c}^{z}, v_{c}^{z}\right\} \neq \varnothing$ then since $D \cap V\left(G_{c}^{T}\right)$ contains an edge by assumption, it must be that $u_{c}^{a}, u_{c}^{b} \in D$ or $v_{c}^{a}, v_{c}^{b} \in D$ for two variables $a, b \in\{x, y, z\}$. In the first case, since $D \cap\left\{v_{c}^{x}, v_{c}^{y}, v_{c}^{z}\right\} \neq \varnothing$ by Claim 24(ii), necessarily $D \cap\left\{t_{c}^{x}, t_{c}^{y}, t_{c}^{z}\right\}=\varnothing$; and in the second case, since $D \cap\left\{u_{c}^{x}, u_{c}^{y}, u_{c}^{z}\right\} \neq \varnothing$ by Claim [24(ii), necessarily $D \cap\left\{t_{c}^{x}, t_{c}^{y}, t_{c}^{z}\right\}=\varnothing$. Thus, in both cases, we conclude that $D$ contains no edge satisfying (aT) or (bT); but then $D$ contains only one edge, a contradiction. Thus $D \cap\left\{t_{c}^{z}, v_{c}^{z}, v_{c}^{z}\right\}=$ $\varnothing$ which implies, in particular, $D \cap\left(\left\{t_{c}^{z}\right\} \cup V\left(P_{z, T}^{c}\right)\right)$ contains no edge. Since by assumption $\left\{t_{c}^{x}\right\} \cup V\left(P_{x, T}^{c}\right)$ and $\left\{t_{c}^{y}\right\} \cup V\left(P_{y, T}^{c}\right)$ contain no edge as well, it follows that $D \cap V\left(G_{c}^{T}\right)$ must contain a $P_{3}$ ( $D$ would otherwise contain only one edge). However, since $D \cap\left\{t_{c}^{x}, u_{c}^{x}, v_{c}^{x}\right\} \neq \varnothing$ and $D \cap\left\{t_{c}^{y}, u_{c}^{y}, v_{c}^{y}\right\} \neq \varnothing$, any such $P_{3}$ must then be contained in $\left\{u_{c}^{x}, v_{c}^{x}, u_{c}^{y}, v_{c}^{y}\right\}$ by Claim [24(ii); but $d\left(\left\{u_{c}^{x}, v_{c}^{x}, u_{c}^{y}, v_{c}^{y}\right\}, D \backslash V\left(G_{c}^{T}\right)\right) \geq 3$, a contradiction.

Case 1.b. $\left|D \cap V\left(G_{c}^{F}\right)\right|=3$. Then $D \cap\left\{t_{c}^{x}, t_{c}^{y}, t_{c}^{z}\right\}=\varnothing$ by Claim 25] which implies that no edge of an ST-configuration satisfies (aT) or (bT). Let us next show that no edge of an STconfiguration in $D$ satisfies (cT). Suppose that $D \cap V\left(G_{c}^{T}\right)$ contains an edge uv. Then by ??(ii), $\{u, v\}=\left\{u_{c}^{\ell}, v_{c}^{\ell}\right\}$ for some $\ell \in\{x, y, z\}$, say $x$ without loss of generality. If $P_{x, T}^{c}(1) \notin D$ then $d(\{u, v\}, D \backslash\{u, v\} \geq 3$ and so, $u v$ cannot be part of an ST-configuration in $D$. Thus suppose that $P_{x, T}^{c}(1) \in D$. Since $t_{c}^{y}$ and $t_{c}^{z}$ should be dominated and $D \cap\left\{t_{c}^{y}, u_{c}^{y}, v_{c}^{y}, t_{c}^{z}, u_{c}^{z}, v_{c}^{z}\right\}=\varnothing$, necessarily $P_{y, T}^{c}(1), P_{z, T}^{c}(1) \in D$. Then $D \cap\left\{P_{x, F}^{c}(2), P_{y, F}^{c}(2), P_{z, F}^{c}(2)\right\}=\varnothing$ by Claim 34 and so, $\left|D \cap\left\{f_{c}^{\ell}, q_{c}^{\ell} \mid \ell \in\{x, y, z\}\right\}\right| \geq 3$ as $f_{c}^{x}, f_{c}^{y}$ and $f_{c}^{z}$ should be dominated. But $\left|D \cap V\left(G_{c}^{F}\right)\right|=3$ and so, $w_{c}$ is not dominated, a contradiction. Thus no edge of an ST-configuration satisfies (cT). Now observe that $\left|D \cap\left\{f_{c}^{x}, f_{c}^{y}, f_{c}^{z}\right\}\right| \leq 1$ : indeed, if, say, $t_{c}^{x}, t_{c}^{y} \in D$ then $D \cap\left\{u_{c}, q_{c}^{x}, q_{c}^{y}, q_{c}^{z}, f_{c}^{z}\right\} \neq \varnothing$ as $q_{c}^{z}$ should be dominated; but then $D \cap\left\{w_{c}, v_{c}\right\}=\varnothing$ and so, $w_{c}$ is not dominated, a contradiction. This implies, in particular, that there is at most one edge of an ST-configuration in $D$ satisfying (aF) or (bF).

Now suppose that $D \cap V\left(G_{c}^{F}\right)$ is an independent set and let $u v$ be an edge of an ST-configuration in $D$. If $u v$ satisfies (aF) for some $\ell \in\{x, y, z\}$, then $\left.D \cap\left\{P_{\ell, F}^{( } 1\right), P_{\ell, F}^{c}(2)\right\}=\varnothing$ by Claim 24(i) and so, $u v$ cannot be part of a $P_{3}$. Similarly, if $u v$ satisfies (bF) for some $\ell \in\{x, y, z\}$, then $D \cap\left\{P_{\ell, T}^{c}(1), P_{\ell, T}^{c}(3)\right\}=\varnothing$ by Claim 24(i) and so, $u v$ cannot be part of a $P_{3}$. It follows that $D$ contains no $P_{3}$, which implies that $D$ must contain an $O_{3}$ or an $O_{7}$; in particular, $D$ contains two vertex-disjoint edges. However, any such edge would satisfy (aF) or (bF), a contradiction to the above.

Suppose next that $D \cap V\left(G_{c}^{F}\right)$ contains an edge. We claim that there exists at least one variable $\ell \in\{x, y, z\}$ such that $D \cap\left\{P_{\ell, F}^{c}(2), P_{\ell, F}^{c}(3)\right\}=\varnothing$. Indeed, if there is no such variable then by Claim [34, $D \cap\left\{P_{x, T}^{c}(1), P_{y, T}^{c}(1), P_{z, T}^{c}(1)\right\}=\varnothing$; but $\left|D \cap V\left(G_{c}^{T}\right)\right|=2$ and so, one of $t_{c}^{x}, t_{c}^{y}$ and $t_{c}^{z}$ is not dominated.Thus assume, without loss of generality, that $D \cap\left\{P_{x, F}^{c}(2), P_{x, F}^{c}(3)\right\}=\varnothing$ (note that $D \cap\left(\left\{f_{c}^{x}\right\} \cup V\left(P_{x, F}^{c}\right)\right)$ can then contain no edge). Since $f_{c}^{x}$ should be dominated, necessarily $D \cap\left\{q_{c}^{x}, f_{c}^{x}\right\} \neq \varnothing$. Now if $q_{c}^{x}, f_{c}^{x} \in D$ then since $\left|D \cap\left\{w_{c}, v_{c}\right\}\right|=1, D \cap V\left(G_{c}^{F}\right)$ contains only one edge and so, $D$ contains no ST-configuration, a contradiction. Suppose next that $f_{c}^{x} \in D$. Since $D \cap\left\{w_{c}, v_{c}\right\} \neq \varnothing$ and $D \cap V\left(G_{c}^{F}\right)$ contains an edge by assumption, it must then be that $D \cap\left\{q_{c}^{y}, f_{c}^{y}, q_{c}^{z}, f_{c}^{z}\right\}=\varnothing$; but then $D \cap V\left(G_{c}^{F}\right)$ contains only one edge and so, $D$ contains no ST-configuration, a contradiction. Suppose finally that $q_{c}^{x} \in D$. Since $D \cap\left\{w_{c}, v_{c}\right\} \neq \varnothing$ and $D \cap V\left(G_{c}^{F}\right)$ contains an edge, necessarily $D \cap\left\{f_{c}^{y}, f_{c}^{z}\right\}=\varnothing$. Now if $D \cap\left\{q_{c}^{y}, q_{c}^{z}\right\} \neq \varnothing$ in which case $D \cap V\left(G_{c}^{F}\right)$ contains only one edge and so, $D$ contains no ST-configuration. Thus it must be that $\left|D \cap\left\{w_{c}, v_{c}, u_{c}\right\}\right|=2$; but then $d\left(D \cap V\left(G_{c}^{F}\right), D \backslash V\left(G_{c}^{F}\right)\right) \geq 3$ and so, $D$ contains no

ST-configuration.
Case 2. There exists a variable $x \in X$ such that $\left|D \cap V\left(G_{x}\right)\right|=15$. Let $c, c^{\prime}, c^{\prime \prime} \in C$ be the three clauses in which $x$ appears. If for some variable $\ell \neq x$ appearing in $c, c^{\prime}$ or $c^{\prime \prime}, D \cap V\left(G_{\ell}\right)$ contains an edge $u v$ then by Claim 30, $\{u, v\}=\{P(3), P(4)\}$ for some long paw $P$ of $G_{\ell}$. But then $d(\{u, v\}, D \backslash\{u, v\}) \geq 3$ by Claim 25 and so, $u v$ cannot be part of an ST-configuration in $D$. Now for any clause $\ell \in C \backslash\left\{c, c^{\prime}, c^{\prime \prime}\right\}, D \cap V\left(G_{\ell}\right)$ contains no edges by Claims 28 and 29, and for any variable $\ell \in X$ not appearing in $c, c^{\prime}$ or $c^{\prime \prime}, D \cap V\left(G_{v}\right)$ contains no edge by Claim 32. Thus by Claim 25, any ST-configuration in $D$ is in fact contained in $D \cap\left(V\left(G_{x}\right) \cup V\left(G_{c}\right) \cup V\left(G_{c^{\prime}}\right) \cup V\left(G_{c^{\prime \prime}}\right)\right)$.

Now suppose that for some clause $\ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}, D \cap V\left(G_{\ell}\right)$ contains an edge $u v$. If $u, v \in V\left(G_{\ell}^{F}\right)$ then, since $w_{\ell}$ must be dominated, necessarily $\{u, v\} \subseteq\left\{w_{c}, v_{c}, u_{c}\right\}$. But then $d(\{u, v\}, D \backslash$ $\{u, v\}) \geq 3$ and so, $u v$ cannot be part of an ST-configuration in $D$. Thus assume that $u, v \in V\left(G_{\ell}^{T}\right)$ and let $y, z \in X$ be the other two variables appearing in $\ell$. Then by Claim[24(ii), $\{u, v\}=\left\{u_{\ell}^{a}, v_{\ell}^{a}\right\}$ for some variable $a \in\{x, y, z\}$. Now if $P_{a, T}^{\ell}(1) \notin D$ then $d(\{u, v\}, D \backslash\{u, v\}) \geq 3$ and so, $u v$ cannot be part of an ST-configuration in $D$. Thus suppose that $P_{a, T}^{\ell}(1) \in D$. Since for every $b \neq a, t_{\ell}^{b}$ should be dominated, it follows that $P_{b, T}^{\ell}(1) \in D$ as well. Then by Claim 34] $P_{y, F}^{\ell}(2), P_{z, F}^{\ell}(2) \notin D$ and so $\left|D \cap\left\{q_{\ell}^{y}, f_{\ell}^{y}, q_{\ell}^{z}, f_{\ell}^{z}\right\}\right| \geq 2$ since $f_{\ell}^{y}$ and $f_{\ell}^{z}$ should be dominated, But $\left|D \cap V\left(G_{\ell}^{F}\right)\right|=2$ and so, $w_{c}$ is not dominated, a contradiction. Thus no edge of an ST-configuration in $D$ is contained in $D \cap\left(V\left(G_{c}\right) \cup V\left(G_{c^{\prime}}\right) \cup V\left(G_{c^{\prime \prime}}\right)\right.$. By Claim [25] it follows that every edge of an ST-configuration in $D$ is contained in $G_{x}$. We next distinguish cases depending on whether $D \cap\left\{q_{x}^{\ell}, p_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\} \neq \varnothing$ or $|D \cap V(P)|=3$ for some long paw $P$ of $G_{x}$.

Case 2.a. $D \cap\left\{q_{x}^{\ell}, p_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\} \neq \varnothing$. Then by Claim 24(i), $\mid D \cap\left\{q_{x}^{\ell}, p_{x^{\prime \prime}}^{\ell} \mid \ell \in\right.$ $\left.\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\} \mid=1$. Now suppose that $D \cap\left\{q_{x}^{c}, q_{x}^{c^{\prime}}, q_{x}^{c^{\prime \prime}}\right\} \neq \varnothing$ (the case where $D \cap\left\{p_{x}^{c}, p_{x}^{c^{\prime}}, p_{x}^{c^{\prime \prime}}\right\} \neq \varnothing$ is symmetric), say $q_{x}^{c} \in D$ without loss of generality. Suppose first that $F_{x} \in D$. Since $f_{c}^{x} \notin D$ by ?? and $P_{x, F}^{c}(2)$ must be dominated, $D \cap\left\{P_{x, F}^{c}(1), P_{x, F}^{c}(2), P_{x, F}^{c}(3)\right\} \neq \varnothing$ and so, by Claim 24(i), $D^{\prime}=D \backslash\left\{q_{x}^{c}\right\}$ is an SD set of $G$. Now since $D^{\prime}$ is in fact minimum, it follows from Claim 33 that every vertex in $D^{\prime}$ has a unique witness; in particular, $D^{\prime} \cap\left\{P_{x, F}^{c}(1), P_{x, F}^{c^{\prime}}(1), P_{x, F}^{c^{\prime \prime}}(1)\right\}=\varnothing$ as $F_{x} \in D$. On the other hand, since $D$ is not minimal, $D$ must contain an $O_{6}$ by Lemma 2.3 and Claim 33) in particular, $D \cap V\left(G_{x}\right)$ contains a $P_{3} Q$. Now since $|D \cap V(P)|=2$ for every long paw $P$ of $G_{x}$ and $D \cap\left\{q_{x}^{c^{\prime}}, q_{x}^{c^{\prime \prime}}, p_{x}^{c}, p_{x}^{c^{\prime}}, p_{x}^{c^{\prime \prime}}\right\}=\varnothing$, necessarily $q_{x}^{c} \in V(Q)$. However $N\left(q_{x}^{c}\right) \cap D=\left\{F_{x}\right\}$; and since $D \cap\left\{v_{x}, w_{x}\right\} \neq \varnothing$ by Claim[24(i), we also have that $N\left(F_{x}\right) \cap D=\left\{q_{c}^{x}\right\}$, a contradiction.

Second, suppose that $F_{x} \notin D$. Then $D \cap V\left(G_{c}\right)$ contains no $P_{3}$ : indeed, by Claim [24(i), $D \cap\left\{F_{x}, q_{x}^{c^{\prime}}, q_{x}^{c^{\prime \prime}}, p_{x}^{c}, p_{x}^{c^{\prime}}, p_{x}^{c^{\prime \prime}}\right\}=\varnothing$ and for every long paw $P$ of $G_{x},|D \cap\{P(4), P(5)\}| \geq 1$ and $|D \cap\{P(1), P(2), P(3)\}| \leq 1$. It follows that $D$ contains an $O_{3}$ or an $O_{7}$; in particular, $D \cap V\left(G_{x}\right)$ contains two vertex-disjoint edges. Now suppose that some long paw $P$ of $G_{x}$ contains an edge $u v$. Then since $D \cap\{P(4), P(5)\} \neq \varnothing$ by Claim 24(i), necessarily $\{u, v\} \subseteq$ $\{P(3), P(4), P(5)\}$. Thus, if $P \neq P_{x}, P_{x, F}^{c}$ then $d(\{u, v\}, D \backslash\{u, v\}) \geq 3$ by Claim 25] and so, $u v$ cannot be part of an ST-configuration in $D$. It follows that $D \cap V\left(P_{x}\right)$ must contain an edge, as $D \cap\left(\left\{q_{x}^{c}\right\} \cup V\left(P_{x, F}^{c}\right)\right)$ can contain at most one edge of an ST-configuration in $D$; in particular, $D \cap V\left(P_{x}\right)=\left\{v_{x}, u_{x}\right\}$. Note that since $p_{x}^{c}$ should be dominated and $T_{x} \notin D, P_{x, T}^{c}(2) \in D$ and so, $P_{x, T}^{c}(1) \notin D$. Now, similarly, $D \cap\left(\left\{q_{x}^{c}\right\} \cup V\left(P_{x, F}^{c}\right)\right)$ must contain an edge $u v$; and either $q_{x}^{c} \in\{u, v\}$ in which case $\left.D \cap\left\{P_{x, F}^{c}(1), P_{x, F}^{c}(2), P_{x, F}^{( } 3\right)\right\}=\left\{P_{x, F}^{c}(1)\right\}$, or $u, v \in V\left(P_{x, F}^{c}\right)$ in which case $D \cap V\left(P_{x}\right)=\left\{P_{x, F}^{c}(3), P_{x, F}^{c}(4)\right\}$. In both cases, we conclude that $P_{x, F}^{c}(2) \notin D$. Since, as shown above, $P_{x, T}^{c}(1) \notin D$ as well, it follows from Claim 25 that $q_{c}^{x} \in D$ and $D \cap\left\{u_{c}^{x}, v_{c}^{x}\right\} \neq \varnothing$ as $f_{c}^{x}$ and $t_{c}^{x}$ should be dominated, respectively. Now $\left|D \cap V\left(G_{c}^{T}\right)\right|=\left|D \cap V\left(G_{c}^{F}\right)\right|=2$ and so, by Claim24(ii), there must exist a variable $\ell \neq x$ contained in $c$ such that $D \cap\left\{q_{c}^{\ell}, u_{c}^{\ell}, v_{c}^{\ell}\right\}=\varnothing$. But $f_{c}^{\ell}$ and $t_{c}^{\ell}$ should be dominated and so, by Claim 25, $P_{\ell, F}^{c}(2), P_{\ell, T}^{c}(1) \in D$, a contradiction to Claim 26 ,

Case 2.b. $|D \cap V(P)|=3$ for some long paw $P$ of $G_{x}$. Suppose first that $P=P_{x}$. If $D \cap V(P)=\{P(3), P(4), P(5)\}$ then $D \backslash\{P(3)\}$ is an SD set of $G$ and so, by Lemma 2.3 and Claim [33, $D$ must contain an $O_{6}$; in particular, $D \cap V\left(G_{x}\right)$ contains a $P_{3} Q$. Since $D \cap$ $\left\{q_{x}^{\ell}, p_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}=\varnothing$ and for any long paw $P^{\prime} \neq P,\left|D \cap V\left(P^{\prime}\right)\right|=2$, necessarily $Q=P(3), P(4), P(5)$; but then, by Claim 25 and because $D \cap\left\{q_{x}^{\ell}, p_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}=\varnothing$, $d(P(4), D \backslash\{P(3), P(4), P(5)\}) \geq 3$, a contradiction. Suppose next that $|D \cap\{P(3), P(4), P(5)\}|=$ 2. If $P(4), P(5) \in D$ then $D \backslash\{P(5)\}$ is an SD set of $G$ and so, by Lemma 2.3 and Claim 33, $D$

Figure 12: The graph $H_{c}$ (a rectangle indicates that the corresponding set of vertices is a clique).
must contain an $O_{6}$; but $D$ contains no $P_{3}$ in this case, a contradiction. Now suppose that $D \cap\{P(3), P(4), P(5)\}=\{P(3), P(4)\}$ and assume that $P(1) \in D$ (the case where $P(2) \in$ $D$ is symmetric). Then $D^{\prime}=D \backslash\{P(3)\}$ is a minimum SD set of $G$ and so, $D$ must contain an $O_{6}$ by Lemma 2.3 and Claim 33] in particular, $D \cap V\left(G_{c}\right)$ contains a $P_{3} Q$. Since $D \cap\left\{q_{x}^{\ell}, p_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}=\varnothing$ and for any long paw $P^{\prime} \neq P,\left|D \cap V\left(P^{\prime}\right)\right|=2$, necessarily $Q=P(1), P(3), P(4)$. However, by Claim 33(ii), $w_{D^{\prime}}(P(1))=\{P(4)\}$ and so $d(P(3), D \backslash$ $\{P(1), P(3), P(4)\}) \geq d\left(P(1), D^{\prime} \backslash\{P(1), P(4)\}\right) \geq 3$, a contradiction. Suppose finally that $D \cap\{P(3), P(4), P(5)\}=\{P(3), P(5)\}$ and assume that $P(1) \in D$ (the case where $P(2) \in D$ is symmetric). Then, since $D \cap\left\{q_{x}^{\ell}, p_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}=\varnothing$ and for every long paw $P^{\prime} \neq P$, $\left|D \cap V\left(P^{\prime}\right)\right|=2, D \cap V\left(G_{x}\right)$ contains no $P_{3}$. It follows that $D$ contains an $O_{3}$ or $O_{6}$; in particular, $D \cap V\left(G_{x}\right)$ must contain an edge $u v$ distinct from $P(1) P(3)$. Now $u v$ can only be contained in some long paw $P^{\prime} \neq P$; and since $\left|D \cap\left\{P^{\prime}(4), P^{\prime}(5)\right\}\right| \geq 1$ and $\left|D \cap\left\{P^{\prime}(1), P^{\prime}(2), P^{\prime}(3)\right\}\right| \leq 1$ by Claim $24(\mathrm{i})$, in fact $\{u, v\} \subseteq\left\{P^{\prime}(3), P^{\prime}(4), P^{\prime}(5)\right\}$. But then, by Claim 25 and because $D \cap\left\{q_{x}^{\ell}, p_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}=\varnothing, d(\{u, v\}, D \backslash\{u, v\}) \geq 3$, a contradiction. Thus, it must be that $|D \cap\{P(3), P(4), P(5)\}|=1$; and since $P(5)$ must be dominated and any vertex dominating $P(5)$ must have a witness, in fact $D \cap\{P(3), P(4), P(5)\}=P(4)$. Since $D \cap\left\{q_{x}^{\ell}, p_{x}^{\ell} \mid \ell \in\left\{c, c^{\prime}, c^{\prime \prime}\right\}\right\}=\varnothing$ and for every long paw $P^{\prime} \neq P,\left|D \cap V\left(P^{\prime}\right)\right|=2$, it follows that $D$ contains no $P_{3}$ and so, $D$ contains an $O_{3}$ or an $O_{6}$. In particular, $D$ must contain an edge $u v$ distinct from $P(1) P(2)$; but then, we conclude, as in the previous case, that $\{u, v\} \subseteq\left\{P^{\prime}(3), P^{\prime}(4), P^{\prime}(5)\right\}$ for some long paw $P^{\prime} \neq P$ and $d(\{u, v\}, D \backslash\{u, v\}) \geq 3$, a contradiction which concludes the proof.

Now by Claims 27 and 35, $\Phi$ is satisfiable if and only if $c t_{\gamma_{t 2}}(G)=3$; and since $G$ is $K_{1,3}$-free, the lemma follows.

Lemma 4.12. Contraction $\operatorname{Number}\left(\gamma_{t 2}, 3\right)$ is $\operatorname{NP}$-hard on $3 P_{4}$-free graphs.
Proof. We reduce from Positive Exactly 3-Bounded 1-In-3 3-Sat (see Section 2 for a precise definition of this problem): given an instance $\Phi$ of this problem, with variable set $X$ and clause set $C$, we construct an instance $G$ of $\operatorname{Contraction~} \operatorname{Number}\left(\gamma_{t 2}, 3\right)$ as follows. For every clause $c \in C$, we introduce the gadget $G_{c}$ which is constructed as follows. Let $x, y, z \in X$ be the variables appearing in $c$. For every $\ell \in\{x, y, z\}$, denote by $a_{\ell}$ and $b_{\ell}$ the two other clauses in $C$ in which $\ell$ appears. To construct the gadget $G_{c}$ for $c$, we first construct the auxiliary graph $H_{c}$ depicted in Figure 12 (where a rectangle indicates that the corresponding set is a clique). More precisely, $H_{c}$ consists of two cliques $V_{c}=\left\{p_{c}, q_{c}, v_{c}^{x}, v_{c}^{y}, v_{c}^{z}\right\}$ and $K_{c}=\left\{u_{c}^{\ell, a_{\ell}}, u_{c}^{\ell, b_{\ell}} \mid \ell \in\right.$ $\{x, y, z\}\} \cup\left\{t_{c}^{x, y}, t_{c}^{x, z}, t_{c}^{y, z}\right\}$, and the following edges.

- For every $\ell \in\{x, y, z\}, u_{c}^{\ell}$ is complete to $\left\{u_{c}^{\ell, a_{\ell}}, u_{c}^{\ell, b_{\ell}}\right\}$.
- For every $\ell \in\{x, y, z\}, u_{c}^{\ell}$ is adjacent to $t_{c}^{a, b}$ if and only if $\ell \in\{a, b\}$.

The gadget $G_{c}$ then consists of two disjoint copies of $H_{c}$, denoted by $H_{c, 1}$ and $H_{c, 2}$, with the following additional edges. For $i \in[2]$, let us denote by $\left\{p_{c, i}, q_{c, i}, v_{c, i}^{x}, v_{c, c}^{y}, v_{c, i}^{z}\right\} \cup\left\{u_{c, i}^{\ell, a_{\ell}}, u_{c, i}^{\ell, b_{\ell}} \mid \ell \in\right.$ $\{x, y, z\}\} \cup\left\{t_{c, i}^{x, y}, t_{c, i}^{x, z}, t_{c, i}^{y, z}\right\}$ the vertex set of $H_{c, i}$, and by $K_{c, i}$ (resp. $V_{c, i}$ ) the copy of $K_{c}$ (resp. $V_{c}$ ) in $H_{c, i}$.
(1) For every $\ell \in\{x, y, z\}, v_{c, 1}^{\ell}$ is adjacent to $t_{c, 2}^{a, b}$ if and only if $\ell \notin\{a, b\}$.
(2) For every $\ell \in\{x, y, z\}, v_{c, 2}^{\ell}$ is adjacent to $t_{c, 1}^{a, b}$ if and only if $\ell \notin\{a, b\}$.
(3) $p_{c, 1}$ is complete to $V_{c, 2} \backslash\left\{p_{c, 2}\right\}$.
(4) $p_{c, 2}$ is complete to $V_{c, 1} \backslash\left\{p_{c, 1}\right\}$.

Figure 13: The graph $G_{c}$ (a rectangle indicates that the corresponding set of vertices is a clique, and thick edges between a vertex and a rectangle indicates that the vertex is complete to the corresponding set).

This completes the construction of $G_{c}$ (see Figure 13 for an illustration - the edges of (1) and (2) have been omitted for clarity).

To complete the construction of $G$, we proceed as follows. For every two clauses $a, b \in C$ containing a same variable $u \in X$, we further add edges between $G_{a}$ and $G_{b}$ as described below.

- $v_{a, 1}^{u}$ is adjacent to $u_{b, 2}^{v, a}$, for every variable $v \neq u$ appearing in $b$.
- $v_{a, 2}^{u}$ is adjacent to $u_{b, 1}^{v, a}$, for every variable $v \neq u$ appearing in $b$.
- $v_{b, 1}^{u}$ is adjacent to $u_{a, 2}^{v, b}$, for every variable $v \neq u$ appearing in $a$.
- $v_{b, 2}^{u}$ is adjacent to $u_{a, 1}^{v, b}$, for every variable $v \neq u$ appearing in $a$.

Finally, we add edges so that $K_{1}=\bigcup_{c \in C} K_{c, 1}$ is a clique and $K_{2}=\bigcup_{c \in C} K_{c, 2}$ is a clique. We let $G$ be the resulting graph. We next show that $\Phi$ is satisfiable if and only if $c t_{\gamma_{t 2}}(G)=3$.

Before turning to the proof, let us briefly explain the idea behind the construction. In a clause gadget $G_{c}$, the vertices $v_{c, 1}^{\ell}$ and $v_{c, 2}^{\ell}$ should be seen as representing the variable $\ell$. As we will show, for any minimum SD set $D$ of $G, D \cap V\left(G_{c}\right)$ contains only one vertex from $V_{c, 1} \backslash\left\{p_{c, 1}, q_{c, 1}\right\}$ and one vertex from $V_{c, 2} \backslash\left\{p_{c, 2}, q_{c, 2}\right\}$, both corresponding to the same variable $\ell$. This variable $\ell$ can then be set to true to satisfy $c$. To ensure that the choice in every clause gadget is consistent (that is, if $\ell$ is chosen in $G_{c}$ then $\ell$ should be chosen in $G_{a}$, for every clause $a$ containing $\ell$ ), we make use of the vertices $u_{c, i}^{v, a}$, which should be seen as representing the clause $a$ in $G_{c}$. By construction, $u_{c, i}^{v, a}$ is adjacent to only $v_{c, i}^{v}$ (representing $v$ ) and $v_{a,(i+1) \bmod 2}^{u}$ (representing $u$ ), for $u \neq v$. Thus, if $v_{c, i}^{v}$ is not in the SD set then $v_{a, i}^{v}$ is not in the SD set either, as $u_{c, i}^{v, a}$ would otherwise not be dominated.

Claim 36. For any $S D D$ of $G$ and any clause $c \in C,\left|D \cap\left(V_{c, 1} \cup V_{c, 2}\right)\right| \geq 2$.
Proof. Let $D$ be an SD set of $G$ and let $c \in C$ be a clause. Since $q_{c, 1}$ should be dominated, $D \cap\left(V_{c, 1} \cup\left\{p_{c, 2}\right\} \neq \varnothing\right.$; and similarly, since $q_{c, 2}$ should be dominated, $D \cap\left(V_{c, 2} \cup\left\{p_{c, 1}\right\}\right) \neq \varnothing$. Suppose first that $p_{c, 1} \in D$. Then $D \cap\left(V_{c, 2} \cup V_{c, 1} \backslash\left\{p_{c, 1}\right\}\right) \neq \varnothing$, as $p_{c, 2}$ should be dominated, and so $\left|D \cap\left(V_{c, 1} \cup V_{c, 2}\right)\right| \geq 2$. We conclude symmetrically if $p_{c, 2} \in D$. Otherwise, $D \cap\left\{p_{c, 1}, p_{c, 2}\right\}=\varnothing$ and so, $D \cap\left(V_{c, i} \backslash\left\{p_{c, i}\right\}\right) \neq \varnothing$ for every $i \in[2]$.

Claim 37. If $\gamma_{t 2}(G)=2|C|$ then for every minimum $S D$ set $D$ of $G$ and every clause $c \in C$, $D \cap V\left(G_{c}\right)=\left\{v_{c, 1}^{\ell}, v_{c, 2}^{\ell}\right\}$ for some variable $\ell$ appearing in $c$.

Proof. Assume that $\gamma_{t 2}(G)=2|C|$ and let $D$ be a minimum SD set of $G$. Consider a clause $c \in C$ containing variables $x, y$ and $z$. We contend that $D \cap\left\{p_{c, 1}, q_{c, 1}, p_{c, 2}, q_{c, 2}\right\}=\varnothing$. Indeed, observe first that by Claim 36, $\left|D \cap\left\{p_{c, 1}, q_{c, 1}, p_{c, 2}, q_{c, 2}\right\}\right| \leq 2$. Now if $\left|D \cap\left\{p_{c, 1}, q_{c, 1}, p_{c, 2}, q_{c, 2}\right\}\right|=2$ then the vertices in $\left\{t_{c, i}^{x, y}, t_{c, i}^{x, z}, t_{c, i}^{y, z} \mid i \in[2]\right\}$ are not dominated, as $D \cap\left(K_{1} \cup K_{2}\right)=\varnothing$ by Claim36. Similarly, if $\left|D \cap\left\{p_{c, 1}, q_{c, 1}, p_{c, 2}, q_{c, 2}\right\}\right|=1$ then by Claim 36] $\left|D \cap\left\{v_{c, i}^{x}, v_{c, i}^{y}, v_{c, i}^{z} \mid i \in[2]\right\}\right|=1$, say $v_{c, i}^{\ell} \in D$, and so the vertex $t_{c, i}^{a, b}$ with $\ell \notin\{a, b\}$, is not dominated. Thus, $D \cap\left\{p_{c, 1}, q_{c, 1}, p_{c, 2}, q_{c, 2}\right\}=\varnothing$ which by Claim [36. implies that $\left|D \cap\left\{v_{c, i}^{x}, v_{c, i}^{y}, v_{c, i}^{z} \mid i \in[2]\right\}\right|=2$; and since $q_{c, 1}$ and $q_{c, 2}$ should be dominated, in fact $\left|D \cap\left\{v_{c, 1}^{x}, v_{c, 1}^{y}, v_{c, 1}^{z}\right\}\right|=\left|D \cap\left\{v_{c, 2}^{x}, v_{c, 2}^{y}, v_{c, 2}^{z}\right\}\right|=1$. Now if $v_{c, 1}^{u}, v_{c, 2}^{v} \in D$ for
two distinct variables $u, v \in\{x, y, z\}$, then the vertex $t_{c, 1}^{v, w}$ where $w \in\{x, y, z\} \backslash\{u, v\}$, is not dominated. Thus, $D \cap V\left(G_{c}\right)=\left\{v_{c, 1}^{\ell}, v_{c, 2}^{\ell}\right\}$ for some variable $\ell \in\{x, y, z\}$.

Claim 38. $\Phi$ is satisfiable if and only if $\gamma_{t 2}(G)=2|C|$.
Proof. Assume first that $\Phi$ is satisfiable and consider a truth assignment satisfying $\Phi$. We construct an SD set $D$ of $G$ as follows: for every clause $c \in C$, exactly one variable in $c$ is true, say $\ell$, in which case we add $v_{c, 1}^{\ell}$ and $v_{c, 2}^{\ell}$ to $D$. Let us show that the constructed set $D$ is indeed an SD set of $G$. Consider a clause $c \in C$ containing variables $x, y$ and $z$, and assume without loss of generality that $x$ is true. For every $\ell \in\{x, y, z\}$, let $a_{\ell}$ and $b_{\ell}$ be the two other clauses in which $\ell$ appears. Note that since by construction, $D \cap V\left(G_{c}\right)=\left\{v_{c, 1}^{x}, v_{c, 2}^{x}\right\}$ and $d\left(v_{c, 1}^{x}, v_{c, 2}^{x}\right)=2, v_{c, 1}^{x}$ and $v_{c, 2}^{x}$ witness each other. Now it is clear that every vertex in $V_{c, 1} \cup V_{c, 2} \cup\left\{u_{c, i}^{x, a_{x}}, u_{c, i}^{x, b_{x}} \mid i \in[2]\right\} \cup\left\{t_{c, i}^{x, y}, t_{c, i}^{x, z} \mid i \in[2]\right\}$ is dominated. Furthermore, by construction, $v_{c, 1}^{x}$ is adjacent to $t_{c, 2}^{y, z}$, and $v_{c, 2}^{x}$ is adjacent to $t_{c, 1}^{y, z}$, and thus, these two vertices are dominated as well. There remains to show that for every $i \in[2]$ and every $\ell \neq x$, the vertices $u_{c, i}^{\ell, a_{\ell}}$ and $u_{c, i}^{\ell, b_{\ell}}$ are dominated. But this readily holds true: for every $\ell \in\{y, z\}$ and every $c_{\ell} \in\left\{a_{\ell}, b_{\ell}\right\}$, since $\ell$ is false, $D \cap V\left(G_{c_{\ell}}\right)=\left\{v_{c_{\ell}, 1}^{v}, v_{c_{\ell}, 2}^{v}\right\}$ for some variable $v \neq \ell$ appearing in $c_{\ell}$; and by construction, $v_{c_{\ell, 1}}^{v}$ is adjacent to $u_{c, 2}^{\ell, c_{\ell}}$ and $v_{c_{\ell, 2}}^{v, 2}$ is adjacent to $u_{c, 1}^{\ell, c_{\ell}}$. Thus, $D$ is an SD set of $G$ and since $|D|=2|C|$, we conclude by Claim 36 that $D$ is minimum.

Conversely, assume that $\gamma_{t 2}(G)=2|C|$ and let $D$ be a minimum SD set of $G$. Then by Claim 37, $D \cup\left(K_{1} \cup K_{2}\right)=\varnothing$ and for every clause $c \in C, D \cap V\left(G_{c}\right)=\left\{v_{c, 1}^{\ell}, v_{c, 2}^{\ell}\right\}$ for some variable $\ell$ contained in $c$. We claim that if $a, b \in C$ are two clauses containing a same variable $\ell$ and $D \cap V\left(G_{a}\right)=$ $\left\{v_{a, 1}^{\ell}, v_{a, 2}^{\ell}\right\}$, then $D \cap V\left(G_{b}\right)=\left\{v_{b, 1}^{\ell}, v_{b, 2}^{\ell}\right\}$. Indeed, suppose for a contradiction that $D \cap V\left(G_{b}\right)=$ $\left\{v_{b, 1}^{v}, v_{b, 2}^{v}\right\}$ for some variable $v \neq \ell$, and let $p, q \in X$ be the other two variables appearing in $a$. Then $u_{b, 1}^{\ell, a}$ and $u_{b, 2}^{\ell, a}$ are not dominated: indeed, $N\left(u_{b, 1}^{\ell, a}\right) \backslash\left(K_{1} \cup K_{2}\right)=\left\{v_{b, 1}^{\ell}, v_{a, 2}^{p}, v_{a, 2}^{q}\right\}$ and $N\left(u_{b, 2}^{\ell, a}\right) \backslash\left(K_{1} \cup K_{2}\right)=\left\{v_{b, 2}^{\ell}, v_{a, 1}^{p}, v_{a, 1}^{q}\right\}$, and so $D \cap N\left(u_{b, 1}^{\ell, a}\right)=D \cap N\left(u_{b, 2}^{\ell, a}\right)=\varnothing$. Thus, $V\left(G_{b}\right)=$ $\left\{v_{b, 1}^{\ell}, v_{b, 2}^{\ell}\right\}$ as claimed. It follows that the truth assignment obtained by setting a variable $\ell$ to true if $v_{c, 1}^{\ell} \in D$ for some clause $c$ containing $\ell$, and to false otherwise, satisfies $\Phi$.

Claim 39. $\operatorname{ct}_{\gamma_{t 2}}(G)=3$ if and only if $\gamma_{t 2}(G)=2|C|$.
Proof. Assume first that $c t_{\gamma_{t 2}}(G)=3$ and let $D$ be a minimum SD set of $G$. If there exists a clause $c \in C$ such that $\left|D \cap\left(V_{c, 1} \cup V_{c, 2}\right)\right| \geq 3$ then $D \cap\left(V_{c, 1} \cup V_{c, 2}\right)$ contains a friendly triple, a contradiction to Theorem 1.7 Thus, $\left|D \cap\left(V_{c, 1} \cup V_{c, 2}\right)\right| \leq 2$ for every clause $c \in C$, and we conclude by Claim 36 that, in fact, equality holds. Now suppose that $D \cap K \neq \varnothing$, say $u \in D \cap\left(K_{c, 1} \cup K_{c, 2}\right.$ for some clause $c \in C$. If $u$ has a neighbour $v \in D \cap\left(V_{c, 1} \cup V_{c, 2}\right)$, then $u, v, w$ where $w \in D \cap\left(V_{c, 1} \cup V_{c, 2} \backslash\{v\}\right)$, is a friendly triple, a contradiction to ??. Thus, $N(u) \cap\left(D \cup\left(V_{c, 1} \cup V_{c, 2}\right)\right)=\varnothing$. Now let $v \in V_{c, 1} \in V_{c, 2}$ be a neighbour of $u$, and let $w_{1}, w_{2} \in D \cap\left(V_{c, 1} \cup V_{c, 2}\right)$. Then the vertices in $\left\{v, w_{1}, w_{2}\right\}$ are pairwise at distance at most two, and at least two of them must be adjacent. However, if $w_{1} w_{2} \in E(G)$ then $D \cup\{v\}$ contains the $O_{7} u, v, w_{1}, w_{2}$; and if $v w_{i} \in E(G)$ for some $i \in[2]$, then $D \cup\{v\}$ contains the $O_{4} u, v, w_{1}, w_{2}$, a contradiction in both cases to Theorem 1.7 Thus, $D \cap K=\varnothing$ and so, $\gamma_{t 2}(G)=|D|=2|C|$.

Conversely, assume that $\gamma_{t 2}(G)=2|C|$ and let $D$ be a minimum SD set of $G$. Then by Claim 37, $D \cap\left(K_{1} \cup K_{2}\right)=\varnothing$ and for every clause $c \in C, D \cap V\left(G_{c}\right)=\left\{v_{c, 1}^{\ell}, v_{c, 2}^{\ell}\right\}$ for some variable $\ell$ contained in $c$. Since for every clause $c \in C$ and every variable $v \in X$ contained in $c$, $d\left(v_{c, 1}^{v}, v_{c, 2}^{v}\right)=2$, it follows that $D$ is an independent set and thus, $D$ contains no friendly triple. Furthermore, as shown in the proof of Claim 38, if two clauses $a, b \in C$ contain a same variable $\ell$ and $D \cap V\left(G_{a}\right)=\left\{v_{a, 1}^{\ell}, v_{a, 2}^{\ell}\right\}$, then $D \cap V\left(G_{b}\right)=\left\{v_{b, 1}^{\ell}, v_{b, 2}^{\ell}\right\}$. It follows that for any two clauses $a, b \in C$ containing a same variable, $d\left(D \cap V\left(G_{a}\right), D \cap V\left(G_{b}\right)\right) \geq 3$; and since for any two clauses $a, b \in C$ with no common variable, $d\left(V_{a, 1} \cup V_{a, 2}, V_{b, 1} \cup V_{b, 2}\right) \geq 3$, every vertex in $D$ has a unique witness. Thus, the following hold.

Observation 10. If $\gamma_{t 2}(G)=2|C|$ then for every minimum $S S$ set $D$ of $G$, the following hold.
(i) $D$ is an independent set.
(ii) For every $x \in D,\left|w_{D}(x)\right|=1$.

Now suppose for a contradiction that $G$ has an SD set $D$ of size $\gamma_{t 2}(G)+1$ containing an ST-configuration (see Theorem 1.7). Then by Claim [36, either there exists a clause $c \in C$ such that $\left|D \cap\left(V_{c, 1} \cup V_{c, 2}\right)\right|=3$, or $\left|D \cap\left(K_{1} \cup K_{2}\right)\right|=1$. We next distinguish these two cases.

Case 1. There exists a clause $c \in C$ such that $\left|D \cap\left(V_{c, 1} \cup V_{c, 2}\right)\right|=3$. Let us first show that for every clause $a \in C \backslash\{c\}, D \cap\left(V_{a, 1} \cup V_{a, 2}\right)$ contains no edge. Suppose for a contradiction that there exists a clause $a \in C \backslash\{a\}$ such that $D \cap\left(V_{a, 1} \cup V_{a, 2}\right)$ contains an edge, and let $x, y, z \in X$ be the three variables appearing in $a$. Since by Claim [36, $\left|D \cap\left(V_{a, 1} \cup V_{a, 2}\right)\right|=2$, necessarily $D \cap\left\{q_{a, i}, v_{a, i}^{x}, v_{a, i}^{y}, v_{a, i}^{z}\right\}=\varnothing$ for some $i \in[2]$. But $D \cap K_{i}=\varnothing$ and $\left|D \cap\left\{v_{a, j}^{x}, v_{a, j}^{y}, v_{a, j}^{z}\right\}\right| \leq 2$ for $j \neq i$ and so, one at least of $t_{a, i}^{x, y}, t_{a, i}^{x, z}$ and $t_{a, i}^{y, z}$ is not dominated, a contradiction.

Now let $x, y, z \in X$ be the three variables appearing in $c$. We contend that for every $i \in[2]$, $D \cap\left\{v_{c, i}^{x}, v_{c, i}^{y}, v_{c, i}^{z}\right\} \neq \varnothing$. Indeed, suppose for a contradiction that $D \cap\left\{v_{c, i}^{x}, v_{c, i}^{y}, v_{c, i}^{z}\right\}=\varnothing$ for some $i \in[2]$, say $i=1$ without loss of generality. Then since every vertex in $\left\{t_{c, 1}^{x, y}, t_{c, 1}^{x, z}, t_{c, 1}^{y, z}\right\}$ must be dominated and $D \cap K_{1}=\varnothing$, necessarily $v_{c, 2}^{\ell} \in D$ for every $\ell \in\{x, y, z\}$. But then, $D \cap\left(V_{c, 1} \cup V_{c, 2}\right)=\left\{v_{c, 2}^{x}, v_{c, 2}^{y}, v_{c, 2}^{z}\right\}$ and so, $q_{c, 1}$ is not dominated, a contradiction. It follows that $D \cap\left\{p_{c, 1}, p_{c, 2}\right\} \neq \varnothing$ : indeed, if $p_{c, 1}, p_{c, 2} \notin D$ then $D \cap\left(V_{c, 1} \cup V_{c, 2}\right)$ contains only one edge; and since $D \backslash V_{c, 1} \cup V_{c, 2}$ ) contains no edge, as shown above, $D$ contains no ST-configuration, a contradiction to our assumption. Now assume without loss of generality that $p_{c, 1} \in D$, and for $i \in[2]$, let $w_{i} \in D \cap\left\{v_{c, i}^{x}, v_{c, i}^{y}, v_{c, i}^{z}\right\}$. Then since $D \backslash\left\{p_{c, 1}\right\}$ is an SD set of $G$, it follows from Lemma 2.3 and Observation 10 that $D$ contains an $O_{6}$; but $w_{1} p_{c, 1} w_{2}$ is the only $P_{3}$ contained in $D$ and $d\left(p_{c, 1}, D \backslash\left\{w_{1}, w_{2}, p_{c, 1}\right\}\right) \geq 3$, a contradiction.

Case 2. $\left|D \cap\left(K_{1} \cup K_{2}\right)\right|=1$. Assume without loss of generality that $D \cap K_{1} \neq \varnothing$. Let us first show that for every clause $c \in C,\left|D \cap\left(V_{c, 1} \backslash\left\{p_{c, 1}\right\}\right)\right|=D \cap\left(V_{c, 2} \backslash\left\{p_{c, 2}\right\} \mid=1\right.$. Suppose for a contradiction that there exists a clause $c \in C$ such that $D \cap\left(V_{c, i} \backslash\left\{p_{c, i}\right\}\right)=\varnothing$ for some $i \in[2]$, and let $x, y, z \in X$ be the three variables appearing in $c$. Then $i \neq 2$ : indeed, since $D \cap K_{2}=\varnothing$ and $\left|D \cap\left\{v_{c, 1}^{\prime} v_{c, 1}^{y}, v_{c, 1}^{z}\right\}\right| \leq 2$, if $i=2$ then one of $t_{c, 2}^{x, y}, t_{c, 2}^{x, z}, t_{c, 2}^{y, z}$ is not dominated. Thus, it must be that $i=1$; but then, $D \cap\left\{p_{c, 1}, p_{c, 2}\right\} \neq \varnothing$ as $q_{c, 1}$ should be dominated, which implies that $\left|D \cap\left\{q_{c, 2}, v_{c, 2}^{x}, v_{c, 2}^{y}, v_{c, 2}^{z}\right\}\right| \leq 1$, and so, one of $t_{c, 2}^{x, y}, t_{c, 2}^{x, z}$ and $t_{c, 2}^{y, z}$ is not dominated, a contradiction. Thus, $\left|D \cap\left(V_{c, 1} \backslash\left\{p_{c, 1}\right\}\right)\right|=D \cap\left(V_{c, 2} \backslash\left\{p_{c, 2}\right\} \mid=1\right.$ for every clause $c \in C$; in particular, $D \cap\left(V_{c, 1} \cup V_{c, 2}\right)$ contains no edge.

Now let $u \in D \cap K_{1}$, say $u \in K_{c, 1}$ for some clause $c \in C$. Then $|N(u) \cap D|>1$ : if not then $u$ is the endvertex of at most one edge in $D$; and since $D \backslash\{u\}$ contains no edge, as shown above, $D$ then contains no ST-configuration. Suppose first that $u \in\left\{t_{c, 1}^{x, y}, t_{c, 1}^{x, z}, t_{c, 1}^{y, z}\right\}$, say $u=t_{c, 1}^{x, y}$ without loss of generality. Then since $\left|D \cap\left\{v_{c, 1}^{\prime} v_{c, 1}^{y}, v_{c, 1}^{z}\right\}\right| \leq 1$ as shown above, it must be that $D \cap\left\{v_{c, 1}^{x}, v_{c, 1}^{y}\right\} \neq \varnothing$ and $v_{c, 2}^{z} \in D$ ( $u$ would otherwise has at most one neighbour in $D$ ); but then, $t_{c, 2}^{x, y}$ is not dominated, a contradiction. Second, suppose that $u \in K_{c, 1} \backslash\left\{t_{c, 1}^{x, y}, t_{c, 1}^{x, z}, t_{c, 1}^{y, z}\right\}$, say $u=u_{c, 1}^{x, a}$ where $a \neq c$ is a clause containing $x$. Then since $N\left(u_{c, 1}^{x, a} \subseteq V_{c, 1} \cup V_{a, 2}\right.$ and $\left|D \cap V_{c, 1}\right|=\left|D \cap V_{a, 2}\right|=1$ as shown above, it must be that $D \cap V_{c, 1}=\left\{v_{c, 1}^{x}\right\}$ and $D \cap V_{a, 2}=\left\{v_{a, 2}^{\ell}\right\}$ for some variable $\ell \neq x$ contained in $a$; but then, $u_{a, 2}^{x, c}$ is not dominated, a contradiction which concludes the proof.

Now by Claims 38 and 39, $\Phi$ is satisfiable if and only if $c t_{\gamma_{t 2}}(G)=3$. There remains to show that $G$ is $3 P_{4}$-free. To see this, observe that for any clause $c \in C, G\left[V_{c, 1} \cup V_{c, 2}\right]$ is $P_{4}$-free. Thus, if $G$ contains a $P_{4} P$, then $V(P) \cap\left(K_{1} \cup K_{2}\right) \neq \varnothing$; but $K_{1}$ are $K_{2}$ are both cliques and so, $G$ contains no induced $3 P_{4}$.

### 4.3 Proof of Theorem 1.4

Let $H$ be a graph. If $H$ contains a cycle then Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ is NP-hard on $H$-free graphs by Corollary 4.10. Assume henceforth that $H$ is a forest. If $H$ contains a vertex of degree at least three then $\operatorname{Contraction} \operatorname{Number}\left(\gamma_{t 2}, 2\right)$ is NP-hard on $H$-free graphs by Lemma 4.7. Suppose therefore that $H$ is a linear forest. If $H$ has a connected component on at least six vertices then Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ is $(c o) N P$-hard on $H$-free graphs by Lemma 4.6. Thus we may assume that every connected component of $H$ has size at most five. Now suppose that $H$ has a connected component on at least four vertices, Then if every other connected component of $H$ has size one, Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ is polynomial-time solvable on $H$-free graphs by Lemma 4.5 otherwise Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ is (co)NP-hard on $H$-free graphs by

Lemma 4.6. Assume finally that every connected component of $H$ has at most three vertices. If $H$ has at least two connected component of size three then Contraction Number $\left(\gamma_{t 2}, 2\right)$ is (co)NP-hard on $H$-free graphs by Lemma 4.6. Otherwise $H$ has at most one connected component of size three in which case Contraction $\operatorname{Number}\left(\gamma_{t 2}, 2\right)$ is polynomial-time solvable on $H$-free graphs by Lemma 4.5 which concludes the proof.
