# Most Equitable Voting Rules 

Lirong Xia<br>RPI<br>xialirong@gmail.com

#### Abstract

In social choice theory, anonymity (all agents being treated equally) and neutrality (all alternatives being treated equally) are widely regarded as "minimal demands" and "uncontroversial' axioms of equity and fairness. However, the ANR impossibility-there is no voting rule that satisfies anonymity, neutrality, and resolvability (always choosing one winner) -holds even in the simple setting of two alternatives and two agents. How to design voting rules that optimally satisfy anonymity, neutrality, and resolvability remains an open question. We address the optimal design question for a wide range of preferences and decisions that include ranked lists and committees. Our conceptual contribution is a novel and strong notion of most equitable refinements that optimally preserves anonymity and neutrality for any irresolute rule that satisfies the two axioms. Our technical contributions are twofold. First, we characterize the conditions for the ANR impossibility to hold under general settings, especially when the number of agents is large. Second, we propose the most-favorable-permutation (MFP) tie-breaking to compute a most equitable refinement and design a polynomial-time algorithm to compute MFP when agents' preferences are full rankings.

Keywords: Social choice, anonymity, neutrality, tie-breaking

## 1 Introduction

A major goal of social choice is to design a resolute voting rule $r: \mathcal{E}^{n} \rightarrow \mathcal{D}$ that maps $n$ agents' preferences, each of which is chosen from the preference space $\mathcal{E}$, to a single collective decision in the decision space $\mathcal{D}$. For example, in single-winner elections, each agent uses a linear order over the alternatives to represent his/her preferences, and the decision is a single alternative, i.e., the winner.

So how can we design the best voting rule? The answer depends on the measure of goodness. In axiomatic social choice, various normative measures of voting, called axioms, were proposed to evaluate and design voting rules [24]. While different axioms are desirable in different scenarios, the two equity/fairness axioms known as anonymity (all agents being treated equally) and neutrality (all alternatives being treated equally) are broadly viewed as "minimal demands" and "uncontroversial" $[28,22,3]$.

Indeed, it is easy to satisfy anonymity and neutrality if we allow ties by using an irresolute rule $\bar{r}: \mathcal{E}^{n} \rightarrow\left(2^{\mathcal{D}} \backslash \emptyset\right)$. For example, both axioms are satisfied by the irresolute rule that always chooses all decisions $\mathcal{D}$ regardless of agents' preferences, and by the majority rule with ties when there are two alternatives [20]. However, ties are not allowed in many scenarios, and in such cases a resolute rule must be used.

Consequently, it is natural and desirable to design voting rules that simultaneously satisfy anonymity, neutrality, and resolvability (i.e., the rule must be resolute). Such rules are called $A N R$ rules [14]. Unfortunately, no ANR rule exists even under the single-winner
election setting with two alternatives and two agents, as shown in the following simple proof.

## Proof: ANR impossibility

Let $\{1,2\}$ denote the two alternatives. Consider a "problematic" preference profile $P=$ $(1 \succ 2,2 \succ 1)$ and a permutation $\sigma$ that exchanges the names of the two alternatives. Suppose there exists an ANR rule $r$. W.l.o.g. suppose $r(P)=1$. Then, by neutrality $r(\sigma(P))=\sigma(r(P))=2$ and by anonymity $r(\sigma(P))=r(P)=1$, which is a contradiction.

This incompatibility between anonymity, neutrality, and resolvability is "among the most well-known results in social choice theory" [23] and is often presented as a first course when discussing fairness/equity in social choice, see, e.g., [22,28,18]. Perhaps because it is so fundament and the proof is so simple, it is often viewed as a folklore and doesn't have a name of its own. Following the convention [12,13,14], we call it the ANR impossibility in this paper. In fact, Moulin [21] proved that the ANR impossibility holds if and only if the number of alternatives $m$ can be represented as the sum of the number of agents $n$ 's non-trivial (i.e., > 1) divisors.

Surprisingly, despite the significance and desirability of anonymity and neutrality, our understanding of how to achieve them is still limited, and little is known beyond Moulin's characterization [21]. Specifically, when ANR rules exist for certain $m$ and $n$, it is unclear if any of them is polynomial-time computable. When ANR rules do not exist, it is unclear what is an informative measure of equity w.r.t. anonymity and neutrality. One natural approach is to consider the likelihood of ANR violations when agents' preferences are generated from some statistical model [27], yet how to choose an appropriate model and how to design rules with minimal likelihood of ANR violations still remains open.

Therefore, taking anonymity and neutrality as fundamental notions of equity, it is natural to ask how to optimally achieve equity in voting, i.e.:

## How can we design most equitable voting rules?

The same question also arises in other common social choice settings with various combinations of preference space and decision space. For example, in the Arrovian framework [8], an agent ranks all alternatives and the collective decision is a ranking over the alternatives. In rank aggregation [15], an agent ranks a subset of $\ell$ alternatives and the collective decision is a ranking over $k$ alternatives. In approval voting [2], each agent "approves" a set of $\ell$ alternatives and the collective decision is a single alternative. In multi-winner elections [19,17,18], an agent's preferences are represented by a ranking or a set of approved alternatives, and the collective decision is a set of $k$-committee that consists of $k$ alternatives. As a forth example, in the 2021 New York City Democratic mayoral primary election, an agent can rank up to 5 alternatives and the collective decision is a single alternative. Among these settings, the condition for the ANR impossibility to hold was only known when an agent's preferences and the decision are both linear orders over all alternatives, due to a characterization by Bubboloni and Gori [4]: the ANR impossibility holds if and only if $m \geq n$ 's smallest non-trivial divisor.

### 1.1 Our Contributions

We investigate general preference space $\mathcal{E}$ and decision space $\mathcal{D}$, with a focus on the Common Settings of $(\mathcal{E}, \mathcal{D})$ defined as follows, where the preferences and decisions are ranked lists or committees.

The Common Settings in this paper refer to

$$
(\mathcal{E}, \mathcal{D}) \in\left\{\mathcal{L}_{\ell}, \mathcal{M}_{\ell}: 1 \leq \ell \leq m\right\} \times\left\{\mathcal{L}_{k}, \mathcal{M}_{k}: 1 \leq k \leq m\right\}
$$

where $m$ is the number of alternatives; for any $i \leq m, \mathcal{L}_{i}$ is the set of all ranked lists over $i$ alternatives and $\mathcal{L}_{i}$ is the set of all $i$-committees (subsets of $i$ alternatives).

The Common Settings cover many common social choice settings discussed above, as shown in the following table.

| $\mathcal{E}$ | $\mathcal{L}_{k}$ | $\mathcal{M}_{k}$ |
| :---: | :---: | :---: |
| $\mathcal{L}_{\ell}$ | single-winner elections, <br> Arrovian framework [8] <br> rank aggregation [15] | multi-winner voting [17] |
| $\mathcal{M}_{\ell}$ | approval voting [2] | approval-based committee voting [18] |

Overall approach. We approach the optimal design problem via tie-breaking. More precisely, for any irresolute rule $\bar{r}$ that satisfies anonymity and neutrality, we aims at designing a refinement, which is a resolute voting rule $r$ that chooses a single co-winner of $\bar{r}$ as the sole winner, to optimally satisfy anonymity and neutrality (while resolvability is automatically satisfied). This approach is not only a natural common practice [28], but also without loss of generality, because any voting rule can be viewed as applying a tie-breaking mechanism to the irresolute rule $\bar{r}_{\mathcal{D}}$ that always chooses all decisions.

Our conceptual contribution is a novel notion of most equitable refinements for any irresolute rule $\bar{r}$ that satisfies anonymity and neutrality, especially $\bar{r}_{\mathcal{D}}$. This is a strong notion of optimality and is not guaranteed to exist by definition, because it requires that a most equitable refinement of $\bar{r}$ achieves the same or higher ANR satisfaction than every refinement of $\bar{r}$ at every preference profile. Consequently, a most equitable refinement of $\bar{r}$ also has the same or higher probability to satisfy ANR than every refinement of $\bar{r}$ under every distribution over agents' preferences. Surprisingly, most equitable refinements always exists (Lemma 1). We are not aware of a similar notion in the literature.

Our technical contributions are two-fold.
First: Characterizations of the ANR impossibility. It follows from the optimality of most equitable refinements that the ANR impossibility holds if and only if any most equitable refinement of $\bar{r}_{\mathcal{D}}$ satisfies anonymity and neutrality. Leveraging this observation, we characterize conditions on $m$ and $n$ for the ANR impossibility to hold under the Common Settings (Theorem 1): it holds if and only if a partition condition is met, i.e., there exists
an integer partition $\vec{m}$ of $m$ that satisfies a sub-vector constraint, and a change-making constraint, which requires that $n$ can be made up by coins whose denominations depend on $m$. This characterization not only resolves the open question on the ANR impossibility for Common Settings, but also provides a novel angle that unifies existing characterizations for $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{m}, \mathcal{L}_{1}\right)$ [21] and $\left(\mathcal{L}_{m}, \mathcal{L}_{m}\right)$ [4]. We also apply Theorem 1 to characterize at-large $A N R$ impossibility (Theorem 2), i.e., the ANR impossibility holds for every sufficiently large $n$, for up-to- $L$ lists and committees. As a corollary, the ANR impossibility holds for the 2021 New York City Democratic mayoral primary elections (Example 7).
Second: Computing most equitable refinements. We propose the most-favorablepermutation (MFP) tie-breaking mechanisms to obtain most equitable refinements, and design a polynomial-time algorithm (Algorithm 1) to compute them when $\mathcal{E}=\mathcal{L}_{m}$. A straightforward application of MFP tie-breaking to $\bar{r}_{\mathcal{D}}$ gives us a polynomial-time ANR rule when Moulin [21]'s condition or Bubboloni and Gori Bubboloni and Gori [6]'s condition is not satisfied, thus addressing computational challenges identified in previous work [7].

Technical innovations. Our work builds upon notation and principles of algebraic voting theory [11] and the group theoretic framework for analyzing anonymity and neutrality $[16,14]$. While most previous work focused on using the framework to characterize the conditions for the ANR impossibility to hold, we take a step further by developing the framework to investigate optimal refinements of irresolute rules for general preferences and decisions. As discussed above, our framework can naturally be used to obtain and extend previous characterizations of the ANR impossibility, as shown in Theorem 1. The key technical innovations in the proof of Theorem 1 are novel applications of the orbits-stabilizer theorem in group theory. Our Algorithm 1 addresses the computational challenge pointed out in previous work [7] by exploring a simple and efficient way to identify "representative" profiles. While the main text of the paper focuses on the Common Settings, our methodology naturally generalizes to even more general settings as discussed in Appendix E.

## 2 Preliminaries

Decisions. Let $\mathcal{A}=[m]=\{1, \ldots, m\}$ denote the set of $m \geq 2$ alternatives. For any $1 \leq k \leq m$, let $\mathcal{M}_{k}$ denote the set of all $k$-committees of $\mathcal{A}$, which are sets of $k$ alternatives in $\mathcal{A}$. That is, $\mathcal{M}_{k} \triangleq\{A \subseteq \mathcal{A}:|A|=k\}$. Let $\mathcal{L}_{k}$ denote the set of all $k$-lists, each of which is a linear order over $k$ alternatives. That is, $\mathcal{L}_{k} \triangleq\left\{\mathcal{L}(A): A \in \mathcal{M}_{k}\right\}$, where $\mathcal{L}(A)$ is the set of all linear orders over $A$. Let $\mathcal{D}$ denote the decision space. Common choices of $\mathcal{D}$ include $\mathcal{M}_{k}$ and $\mathcal{L}_{k}$ for some $k \leq m$.

Preferences. There are $n \in \mathbb{N}$ agents, each of which uses an element in the preference space $\mathcal{E}$ to represent his or her preferences, called a vote. Common choices of $\mathcal{D}$ include $\mathcal{M}_{\ell}$ and $\mathcal{L}_{\ell}$ for some $1 \leq \ell \leq m$. For example, when $m=5,\{1,5\} \in \mathcal{M}_{2}$ and $1 \succ 2 \succ 3 \in \mathcal{L}_{3}$, where $\succ$ reads "preferred to". We also consider up-to-L committees that consist of all $\ell \leq L$ committees, formally defined as $\mathcal{M}_{\leq L} \triangleq \bigcup_{\ell \leq L} \mathcal{M}_{\ell}$. The up-to- $L$ list $\mathcal{L}_{\leq L}$ is defined similarly. The vector of $n$ agents' votes, denoted by $P$, is called a (preference) profile, sometimes called an $n$-profile. Given $\mathcal{E}$, let $\operatorname{Hist}(P) \in \mathbb{Z}_{\geq 0}^{|\mathcal{E}|}$ denote the histogram of $P$,
which is the anonymized $P$ that contains the total number of times each element in $\mathcal{E}$ appears in $P$. Let $\mathbb{H}_{m, n}^{\mathcal{E}}$ denote the set of all histograms of $n$-profiles over $\mathcal{E}$.
Voting rules. An irresolute voting rule $\bar{r}: \mathcal{E}^{n} \rightarrow\left(2^{\mathcal{D}} \backslash \emptyset\right)$ maps a profile to a non-empty subset of $\mathcal{D}$. A resolute voting rule $r: \mathcal{E}^{n} \rightarrow \mathcal{D}$ can be viewed as an irresolute rule that always chooses a single decision. In this paper, we use - to indicate irresolute rules, meaning that it is possible, though not guaranteed, that there are two or more winners. We slightly abuse the notation by using $r(P)=d$ and $r(P)=\{d\}$ interchangeably. A voting rule $\bar{r}^{\prime}$ is a refinement of another voting rule $\bar{r}$ if for all profiles $P, \bar{r}^{\prime}(P) \subseteq \bar{r}(P)$.

Example 1 (Positional scoring rules). When $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{m}, \mathcal{L}_{1}\right)$, an irresolute positional scoring rule $\bar{r}_{\vec{s}}$ is characterized by a scoring vector $\vec{s}=\left(s_{1}, \ldots, s_{m}\right)$ with $s_{1} \geq s_{2} \geq$ $\ldots \geq s_{m}$ and $s_{1}>s_{m}$. For any alternative $a$ and any linear order $R \in \mathcal{L}(\mathcal{A})$, we let $\vec{s}(R, a) \triangleq s_{i}$, where $i$ is the rank of a in $R$. Given a profile $P$, let $\vec{s}(R, a) \triangleq \sum_{R \in P} \vec{s}(R, a)$ denote the total score of $a$. When $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{m}, \mathcal{M}_{k}\right), \bar{r}_{\vec{s}}$ chooses the set of all $k$-committees whose scores are not smaller than that of any other alternative. Special positional scoring rules include plurality, whose scoring vector is $(1,0, \ldots, 0)$, Borda, whose scoring vector is $(m-1, m-2, \ldots, 0)$, and veto, whose scoring vector is $(1, \ldots, 1,0)$.

Tie-breaking mechanisms. Many commonly studied resolute voting rules are defined as the result of a tie-breaking mechanism applied to the outcome of an irresolute rule. A tiebreaking mechanism $f$ is a mapping from a profile $P$ and a non-empty set $D \subseteq \mathcal{D}$ to a single decision in $D$. That is, $f: \mathcal{E}^{n} \times\left(2^{\mathcal{D}} \backslash \emptyset\right) \rightarrow \mathcal{D}$. For example, when $\mathcal{D}=\mathcal{A}$, the agenda tiebreaking breaks ties in favor of alternatives ranked higher w.r.t. a pre-defined ranking; and the fixed-voter tie-breaking breaks ties using a pre-defined agent's ranking. Let $f * \bar{r}$ denote the refinement of $\bar{r}$ by applying $f$. That is, for any profile $P,(f * \bar{r})(P)=\{f(P, \bar{r}(P))\}$.

Permutations. Let $\mathcal{S}_{\mathcal{A}}$ denote the set of all permutations over $\mathcal{A}$, called the permutation group. A permutation can be represented by its cycle form. For example, when $m=4$, $(1,3)(2,4)$ represents the permutation that exchanges 1 and 3 , and also exchanges 2 and 4. Any permutation $\sigma \in \mathcal{S}_{\mathcal{A}}$ can be naturally extended to $k$-committees, $k$-lists, profiles, and histograms over $\mathcal{A}$ as follows. For any $k$-committee $M=\left\{a_{1}, \ldots, a_{k}\right\}$, let $\sigma(M) \triangleq$ $\left\{\sigma\left(a_{1}\right), \ldots, \sigma\left(a_{k}\right)\right\}$; for any $k$-list $R=\left[a_{1} \succ \cdots \succ a_{k}\right]$, let $\sigma(R) \triangleq\left[\sigma\left(a_{1}\right) \succ \cdots \succ \sigma\left(a_{k}\right)\right]$; for any profile $P=\left(R_{1}, \ldots, R_{n}\right)$, let $\sigma(P) \triangleq\left(\sigma\left(R_{1}\right), \ldots, \sigma\left(R_{n}\right)\right)$; and for any histogram $\vec{h} \in \mathbb{H}_{m, n}^{\mathcal{E}}$, let $\sigma(\vec{h})$ be the histogram such that for every ranking $R,[\sigma(\vec{h})]_{R}=[\vec{h}]_{\sigma^{-1}(R)}$, where $[\sigma(\vec{h})]_{R}$ is the value of the $R$-component in $\sigma(\vec{h})$, i.e., the multiplicity of $R$-votes in $\sigma(\vec{h})$.

Example 2. Let $m=5, n=10$, and $P^{+}$denote any 10 -profile with the following histogram.

| Ranking | 13245 | 23145 | 34125 | 34215 | 43125 | 43215 |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: |
| \# in Hist $\left(P^{+}\right)$ | 2 | 2 | 2 | 2 | 1 | 1 |

In the table, 13245 represents the ranking $1 \succ 3 \succ 2 \succ 4 \succ 5$. Let $\sigma_{1}=(1,3)(2,4)$, which maps 34125 to 12345, and let $\sigma_{2}=(1,3,2,4)$, which maps 43125 to 12345. Then, $\sigma_{1}\left(\operatorname{Hist}\left(P^{+}\right)\right)$and $\sigma_{2}\left(\operatorname{Hist}\left(P^{+}\right)\right)$are:

| Ranking | 12345 | 12435 | 21345 | 21435 | 31425 | 32415 | 41325 | 42315 |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\#$ in Hist $\left(\sigma_{1}\left(P^{+}\right)\right)$ | 2 | 2 | 2 | 2 | 1 | 0 | 1 | 0 |
| $\#$ in Hist $\left(\sigma_{2}\left(P^{+}\right)\right)$ | 2 | 2 | 2 | 2 | 0 | 1 | 0 | 1 |

Anonymity, neutrality, and resolvability. For any rule $\bar{r}$ and any profile $P$, we define $\operatorname{ANo}(\bar{r}, P) \triangleq 1$ if for any profile $P^{\prime}$ with $\operatorname{Hist}\left(P^{\prime}\right)=\operatorname{Hist}(P), \bar{r}\left(P^{\prime}\right)=\bar{r}(P)$; otherwise $\operatorname{ANo}(\bar{r}, P) \triangleq 0$. We define $\operatorname{Nev}(\bar{r}, P) \triangleq 1$ if for every permutation $\sigma$ over $\mathcal{A}$, we have $\bar{r}(\sigma(P))=\sigma(\bar{r}(P))$; otherwise $\mathrm{NEU}(\bar{r}, P) \triangleq 0$. We define $\operatorname{RES}(\bar{r}, P) \triangleq 1$ if $|\bar{r}(P)|=1$; otherwise $\operatorname{REs}(\bar{r}, P) \triangleq 0$. Notice that a resolute rule outputs a single decision, which may not be a single alternative - for example when $\mathcal{D}=\mathcal{M}_{2}$, a decision is a set of two alternatives. If $\operatorname{Ano}(\bar{r}, P)=1$ (respectively, $\operatorname{Nev}(\bar{r}, P)=1$ or $\operatorname{Res}(\bar{r}, P)=1$ ), then we say that $\bar{r}$ satisfies anonymity (respectively, neutrality or resolvability) at $P$. We further define $\operatorname{ANR}(\bar{r}, P) \triangleq \operatorname{Ano}(\bar{r}, P) \times \operatorname{Nev}(\bar{r}, P) \times \operatorname{Res}(\bar{r}, P)$. That is, $\operatorname{ANR}(\bar{r}, P)=1(\bar{r}$ satisfies $A N R$ at $P$ ) if and only if $\bar{r}$ satisfies anonymity, neutrality, and resolvability at $P$. Given $n$, we say that $\bar{r}$ satisfies anonymity (respectively, neutrality, resolvability, or ANR) if and only if for all $n$-profiles $P$, we have $\operatorname{ANo}(\bar{r}, P)=1$ (respectively, $\operatorname{Nev}(\bar{r}, P)=1$, $\operatorname{Res}(\bar{r}, P)=1$, or $\operatorname{ANR}(\bar{r}, P)=1)$.

In this paper, the $A N R$ impossibility refers to the claim that no ANR rule exists given a certain combination of $(\mathcal{E}, \mathcal{D}), m$, and $n$.

## 3 Most Equitable Refinements

Before formally presenting the definition, let us first examine the following example of a "problematic" profile under veto, in which ANR fails under every refinement of veto.

Example 3 (A problematic profile under veto). Let $m=5$, $n=10,(\mathcal{E}, \mathcal{D})=$ $\left(\mathcal{L}_{m}, \mathcal{L}_{1}\right)$, and $P^{-}$be an arbitrary 10-profile whose histogram is:

| Ranking | 13245 | 23145 | 31254 | 32154 | 41253 | 42153 |
| ---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| \# in Hist $\left(P^{-}\right)$ | 2 | 2 | 2 | 2 | 1 | 1 |

We have $\operatorname{veto}\left(P^{-}\right)=\{1,2\}$. Let $\sigma$ denote the permutation that exchanges 1 and 2 while keeping all other alternatives the same. Suppose there exists a refinement $r$ of veto that satisfies ANR at $P^{-}$. If $r\left(P^{-}\right)=\{1\}$, then by neutrality, $r\left(\sigma\left(P^{-}\right)\right)=\{2\}$. On the other hand, notice that $\operatorname{Hist}\left(\sigma\left(P^{-}\right)\right)=\operatorname{Hist}\left(P^{-}\right)$. Therefore, by anonymity, $r\left(\sigma\left(P^{-}\right)\right)=r\left(P^{-}\right)=$ $\{1\}$, which is a contradiction. A similar contradiction happens if $r\left(P^{-}\right)=\{2\}$. Therefore, ANR is guaranteed to fail at $P^{-}$under every refinement of veto.

Other problematic profiles exist under veto when $m=5$ and $n=10$. Therefore, the best we could possibly achieve in a refinement is to preserve ANR at all non-problematic profiles. And if such a refinement exists, then we call it a most equitable refinement, formally defined as follows.

Definition 1 (Problematic profiles and most equitable refinements). For any irresolute rule $\bar{r}$ and any $n \geq 1$, let $\mathcal{P}_{\bar{r}}$ denote the set of problematic profiles $P$, such that for every refinements $r$ of $\bar{r}, \operatorname{ANR}(r, P)=0$. A refinement $r^{*}$ of $\bar{r}$ is called a most equitable refinement, if $\operatorname{ANR}\left(r^{*}, P\right)=1$ for every $P \notin \mathcal{P}_{\bar{r}}$.

A most equitable refinement may not exist by definition, because a refinement may satisfy ANR at one non-problematic profile but not at another. Therefore, most equitable refinements are a strong notion of optimality. Put in another way, a most equitable refinement has the same or higher likelihood of ANR satisfaction than any other refinement w.r.t. any distribution over the profile. It is surprising to see that they indeed exist according to the following lemma.

Lemma 1 (Existence of most equitable refinements). Under Common Settings, any anonymous and neutral rule has a most equitable refinement.

Proof sketch. At a high level, the proof proceeds in two steps. In Step 1, we provide a sufficient condition (i.e., (1)) for a profile to be problematic. Then in Step 2, we construct a most equitable refinement for any profile that does not satisfy this condition.
Step 1. To develop intuition behind the sufficient condition, let us revisit the proof of the ANR impossibility for $m=n=2$ in the Introduction. Indeed, the proof shows that $P=(1 \succ 2,2 \succ 1)$ is a problematic profile under $\bar{r}_{\mathcal{D}}$ - the irresolute rule that always outputs $\{1,2\}$, because any resolute rule $r$ (which refines $\bar{r}_{\mathcal{D}}$ ) fails anonymity or neutrality at $P$ no matter how winners of other profiles are chosen. Let $\{d\}=r(P)$. The reason behind such failure is the existence of a permutation $\sigma$ over $\mathcal{D}$ such that

$$
\begin{equation*}
\text { (i) } d \neq \sigma(d) \text {, and (ii) } \operatorname{Hist}(P)=\sigma(\operatorname{Hist}(P)) \tag{1}
\end{equation*}
$$

In group theoretic terms, (i) says that $d$ is not a fixed-point of $\sigma$ and (ii) says that $\operatorname{Hist}(P)$ is a fixed-point of $\sigma$. It is not hard to verify that for any profile and any rule $r$, if there exists a permutation that satisfies (i) and (ii), then ANR is guaranteed to fail at $P$ under $r$. In other words, the ANR impossibility holds if no decision is "good" at $P$. This notion of goodness is captured in the following definition, which defines "good" decisions.

Definition 2 (Fixed-point decisions). Given any $(\mathcal{E}, \mathcal{D})$ in the Common Settings, for any profile $P$, define fixed-point decisions at $P$ as:

$$
\operatorname{FPD}(P) \triangleq\left\{d \in \mathcal{D}: \forall \sigma \in \mathcal{S}_{\mathcal{A}} \text { s.t. } \operatorname{Hist}(\sigma(P))=\operatorname{Hist}(P), \sigma(d)=d\right\}
$$

A similar observation holds for general irresolute rule $\bar{r}$, with an additional constraint that $r$ must refine $\bar{r}$. Following the same logic, it is not hard to verify that a profile $P$ is problematic under $\bar{r}$ if for every $d \in \bar{r}(P)$, there exists a permutation that satisfies (1). Formally, if $\operatorname{FPD}(P) \cap \bar{r}(P)=\emptyset$, then $P$ is a problematic profile under $\bar{r}$.

Step 2. We explicitly construct a refinement $r^{*}$ that satisfies ANR at all profiles $P$ such that $\operatorname{FPD}(P) \cap \bar{r}(P) \neq \emptyset$. Notice that a necessary condition for $r^{*}$ is, for any profile $P$ and any profile $P^{\prime}$ that can be obtained from $P$ by applying a permutation over decisions and a permutation over the agents, $r^{*}\left(P^{\prime}\right)$ is determined by applying the same permutations to $r^{*}(P)$. Therefore, for each anonymous and neutral equivalence class (ANEC) [16]-profiles that can be obtained from each other by applying permutations over alternatives and over agents - either all profiles satisfy ANR or none of them satisfy ANR.

Then, we show that the non-problematic profiles ( $P$ 's such that $\operatorname{FPD}(P) \cap \bar{r}(P) \neq \emptyset)$ can be represented by unions of multiple ANECs. For each such ANEC, we first choose an
arbitrary profile $P^{*}$ as the "representative" profile of the ANEC, then choose an arbitrary winner in $\operatorname{FPD}\left(P^{*}\right) \cap \bar{r}\left(P^{*}\right)$, and finally extend the winner to all profiles in the ANEC in a consistent way. The full version of the lemma and its full proof can be found in Appendix B.2.

Following the proof of Lemma 1, we immediately have the following characterization: a profile is problematic if and only if none of its co-winners is a fixed point decision.

Proposition 1 (Characterization of problematic profiles). Given any $(\mathcal{E}, \mathcal{D})$ in the Common Settings and any irresolute rule $\bar{r}$ that satisfies anonymity and neutrality, for any profile $P$,

$$
P \text { is problematic } \Longleftrightarrow \operatorname{FPD}(P) \cap \bar{r}(P)=\emptyset .
$$

We emphasize that the notion of "most equitable" in this paper is w.r.t. anonymity and neutrality, following their wide recognition as fundamental and uncontroversial notions of equity and fairness discussed in the Introduction. Step 2 of the proof of Lemma 1 also characterizes all most equitable refinements, each of which uses different "representative" profiles and chooses different fixed point decisions.

## 4 The ANR Impossibilities

To motivate the statement of the main theorem of this section (Theorem 1), which characterizes the ANR impossibility under the Common Settings, let us revisit Moulin's condition [21] for the ANR impossibility under $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{m}, \mathcal{L}_{1}\right)$, and reveal an equivalent condition, which we call partition condition.

| Moulin's condition | Partition condition |
| :---: | :---: |
| $m$ is a sum of $n$ 's non-trivial divisors. | There exists a partition $\vec{m}$ of $m$ that satisfies <br> - sub-vector constraint: no sub-vector of $\vec{m}$ sum up to 1 , <br> - change-making constraint: $n$ is feasible by $\{\operatorname{lcm}(\vec{m})\}$, where $\operatorname{lcm}(\vec{m})$ is the least common multiplier of the elements in $\vec{m}$. |

The partition condition has two constraints. The first is on sub-vectors of $\vec{m}$. The second requires that the following change-making problem has a solution: $n$ can be represented as a non-negative integer combination of a certain set of denominations with infinite supplies of coins. The two conditions are equivalent because the sub-vector constraint is equivalent to no element of $\vec{m}$ being 1 , and the change-making constraint is equivalent to all elements of $\vec{m}$ being divisors of $n$.

Interestingly, Bubboloni and Gori [4]'s condition for the ANR impossibility under $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{m}, \mathcal{L}_{m}\right)$ also has an equivalent partition condition with a different sub-vector constraint.

| BG's condition |
| :--- |
| $m \geq n ' s ~ s m a l l e s t ~ n o n-~$ <br> trivial divisor. | | There exists a partition $\vec{m}$ of $m$ that satisfies <br> - sub-vector constraint: $\vec{m}$ contains less than $m 1$ 's, <br> - change-making constraint: $n$ is feasible by $\{\operatorname{lcm}(\vec{m})\}$. |
| :--- |

It turns out that, surprisingly, similar partition conditions characterize the ANR impossibility under the Common Settings. We now formally define the denominations that will be used in the change-making constraint. Given two vectors $\vec{m}$ and $\vec{\ell}$, we write $\vec{m} \geq \vec{\ell}$ or $\vec{\ell} \leq \vec{m}$, if $\vec{m}$ and $\vec{\ell}$ have the same length and $\vec{m}$ is larger than or equal to $\vec{\ell}$ element-wise.

Definition 3 (Coins ${ }^{\circledast}(\vec{m}, \ell)$ and Coins $\left.{ }^{\ominus}(\vec{m}, \ell)\right)$. For any pair of integers $\alpha \geq \beta \geq 0$, define

$$
\alpha \circledast \beta \triangleq\left\{\begin{array} { l l } 
{ \alpha } & { \text { if } \beta > 0 } \\
{ 1 } & { \text { otherwise } }
\end{array} \text { and } \alpha \oslash \beta \triangleq \left\{\begin{array}{ll}
\frac{\operatorname{lcm}(\alpha, \beta)}{\beta} & \text { if } \beta>0 \\
1 & \text { otherwise }
\end{array}\right.\right.
$$

Then, for any vector $\vec{m} \geq \overrightarrow{1}$ and $\ell \geq 1$, define

$$
\begin{aligned}
& \mathrm{Coins}^{\circledast}(\vec{m}, \ell) \triangleq\{\operatorname{lcm}(\vec{m} \circledast \vec{\ell}): \forall \overrightarrow{0} \leq \vec{\ell} \leq \vec{m} \text { and } \vec{\ell} \cdot \overrightarrow{1}=\ell\} \\
& \mathrm{Coins}^{\otimes}(\vec{m}, \ell) \triangleq\{\operatorname{lcm}(\vec{m} \oslash \vec{\ell}): \forall \overrightarrow{0} \leq \vec{\ell} \leq \vec{m} \text { and } \vec{\ell} \cdot \overrightarrow{1}=\ell\}
\end{aligned}
$$

where $\vec{m} \circledast \vec{\ell}$ and $\vec{m} \oslash \vec{\ell}$ are vectors obtained from element-wise applications of $\circledast$ and $\oslash$, respectively.

For simplicity, we assume that elements in $\vec{m}$ are sorted in non-increasing order. Elements in $\vec{\ell}$ are not sorted.
Example 4. $(6,4) \leq(8,6),(8,6) \circledast(6,4)=(8,6)$, and $(8,6) \oslash(6,4)=\left(\frac{\operatorname{lcm}(8,6)}{6}, \frac{\operatorname{lcm}(6,4)}{4}\right)=$ $(4,3)$. When $m=4, \ell=2$, and $\vec{m}=(2,2)$,

$$
\begin{aligned}
& \operatorname{Coins}^{\circledast}((2,2), 2)=\{\operatorname{lcm}((2,2) \circledast(2,0)), \operatorname{lcm}((2,2) \circledast(1,1)), \operatorname{lcm}((2,2) \circledast(0,2))\}=\{2\} \\
& \operatorname{Coins}^{\ominus}((2,2), 2)=\{\operatorname{lcm}((2,2) \oslash(2,0)), \operatorname{lcm}((2,2) \oslash(1,1)), \operatorname{lcm}((2,2) \oslash(0,2))\}=\{1,2\}
\end{aligned}
$$

Other partitions $\vec{m}$ of $m$, Coins $^{\circledast}(\vec{m}, 2)$, and $\operatorname{Coins}^{\ominus}(\vec{m}, 2)$ are summarized below.

| $\vec{m}$ | $=(4)$ | $(3,1)$ | $(2,2)$ | $(2,1,1)$ | $(1,1,1,1)$ |
| ---: | :--- | :---: | :---: | :---: | :---: | :---: |
| Coins $^{\circledast}(\vec{m}, 2)$ | $=\{4\}$ | $\{3\}$ | $\{2\}$ | $\{1,2\}$ | $\{1\}$ |
| Coins $^{\ominus}(\vec{m}, 2)$ | $=\{2\}$ | $\{3\}$ | $\{1,2\}$ | $\{1,2\}$ | $\{1\}$ |

Theorem 1 (ANR impossibility: Common Settings). For any $m \geq 2, n \geq 1,1 \leq$ $\ell \leq m, 1 \leq k \leq m$, and any $(\mathcal{E}, \mathcal{D})$ in the Common Settings, the ANR impossibility holds if and only if there exists a partition $\vec{m}$ of $m$ that satisfies

- sub-vector constraint: $\left\{\begin{array}{ll}\vec{m} \text { contains less than } k 1 \text { 's } & \text { if } \mathcal{D}=\mathcal{L}_{k} \\ \text { no sub-vector of } \vec{m} \text { sum up to } k & \text { if } \mathcal{D}=\mathcal{M}_{k}\end{array}\right.$, and
- change-making constraint: $n$ is feasible by $\begin{cases}\operatorname{Coins}^{\otimes}(\vec{m}, \ell) & \text { if } \mathcal{E}=\mathcal{L}_{\ell} \\ \operatorname{Coins}^{\otimes}(\vec{m}, \ell) & \text { if } \mathcal{E}=\mathcal{M}_{\ell}\end{cases}$

Theorem 1 naturally generalizes and strengthens previous characterizations. For example, when $\mathcal{E}=\mathcal{L}_{m}$, we have $\ell=m$ and the only partition $\vec{\ell}$ of $\ell$ such that $\vec{\ell} \leq \vec{m}$ is $\vec{\ell}=\vec{m}$, which means that Coins ${ }^{\circledast}(\vec{m}, m)=\operatorname{lcm}(\vec{m})$. Therefore, applications of Theorem 1
to $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{m}, \mathcal{L}_{1}\right)$ and $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{m}, \mathcal{L}_{m}\right)$ give us the partition conditions that are equivalent to Moulin [21]'s condition and Bubboloni and Gori [4]'s condition shown in the beginning of this section, respectively. See Example 12 in Appendix C. 1 for applications of Theorem 1 to $\mathcal{E}=\mathcal{M}_{m}$.

Let us look at another example where the preferences and decisions are both $\mathcal{L}_{2}$.
Example 5. Let $m=4$ and $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{2}, \mathcal{L}_{2}\right)$. The set of partitions $\vec{m}$ of $m=4$ that satisfy the sub-vector constraint in Theorem 1 is $\{(4),(3,1),(2,2)\}$. It follows from Theorem 1 and the table in Example 4 that the ANR impossibility holds if and only if $n$ is feasible by $\{4\}$, $\{3\}$, or $\{2\}$, or equivalently, $2 \mid n$ or $3 \mid n$. For example, the $A N R$ impossibility holds for $n=9$ but not for $n=7$.

Similarly, we can characterize the $A N R$ impossibility for other Common Settings with $\ell=k=2$, which are summarized in the table on the right.

| ANR Imp iff | $\mathcal{D}$ | $\mathcal{L}_{2}$ | $\mathcal{M}_{2}$ |
| :--- | :--- | :---: | :---: |
| $\mathcal{E}$ | $2 \mid n$ or $3\|n\| 3 \mid n$ or $4 \mid n$ |  |  |
| $\mathcal{L}_{2}$ | $2\|n\|$ | $n$ |  |
| $\mathcal{M}_{2}$ | every $n \in \mathbb{N}$ | $2 \mid n$ or $3 \mid n$ |  |

### 4.1 Proof Sketch of Theorem 1

The proof proceeds in three steps illustrated in Figure 1.

Fig. 1. Overview of the proof of Theorem 1.
In Step 1, we define the notion of problematic permutation group (Definition 4), which is a sub-group of $\mathcal{S}_{\mathcal{A}}$ (all permutations over $\mathcal{A}$ ), and proves that its existence is a necessary and sufficient for the ANR impossibility to hold (formally proved in Lemma 2 in Appendix C.2). In Step 2, we focus on $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{\ell}, \mathcal{L}_{k}\right)$ and establish connections between the two constraints in Definition 4 - the $\mathcal{D}$ constraint and the $\mathcal{E}$-histogram constraint - and the subvector constraint and the change-making constraint in the theorem statement, respectively (Claims 1 and 2) . Finally, in Step 3, we extend the connections to other preference and decision spaces in Claims 3 and 4, and combine Claims $1-4$ to prove Theorem 1 as shown in Figure 1.

Step 1: The "problematic" permutation group. It follows from Proposition 1 that the ANR impossibility holds if there exists a problematic profile $P$ under $\bar{r}_{\mathcal{D}}$, i.e., $\operatorname{FPD}(P)=\emptyset$.

For any problematic profile $P$, consider the set of all permutations $\sigma$ to which $\operatorname{Hist}(P)$ is invariant, i.e., $\sigma(\operatorname{Hist}(P))=\operatorname{Hist}(P)$. That is,

$$
G_{P}=\left\{\sigma \in \mathcal{S}_{\mathcal{A}}: \sigma(\operatorname{Hist}(P))=\operatorname{Hist}(P)\right\}
$$

It is not hard to verify that $G_{P}$ is a permutation group (i.e., a subgroup of $\mathcal{S}_{\mathcal{A}}$, the set of all permutations over $\mathcal{A}$ ). We call $G_{P}$ a problematic permutation group, because its existence (formally defined without referring to a problematic profile) is equivalent to the existence of a problematic profile as we will see soon. For any set $X$, let $\operatorname{Fixed}_{G}(X)$ denote the set of all fixed points of $G$ in $X$, i.e., all $x \in X$ such that $g(x)=x$ holds for all $g \in G$.

Definition 4 (Problematic permutation group). A permutation group $G$ is problematic if it satisfies

- the $\mathcal{D}$ constraint: $\operatorname{Fixed}_{G}(\mathcal{D})=\emptyset$,
- the $\mathcal{E}$-histogram constraint: $\operatorname{FIXED}_{G}\left(\mathbb{H}_{m, n}^{\mathcal{E}}\right) \neq \emptyset$.

Notice that the first constraint requires that $G$ has no fixed point in $\mathcal{D}$, while the second constraint requires that $G$ has a fixed point in the histogram space. To see why the existence of a problematic permutation group implies the ANR impossibility, consider any permutation group $G$ that satisfies the two conditions in Definition 4. Because of the $\mathcal{E}$-histogram constraint, there exists a profile $P$ whose histogram is invariant to all permutations in $G$, and because of the $\mathcal{D}$ constraint, for every decision in $d \in \mathcal{D}$, there exists a permutation $\sigma$ in $G$ that maps $d$ to a different decision. It follows that $\operatorname{FPD}(P)=\emptyset$, which means that $P$ is problematic, and therefore the ANR impossibility holds (Proposition 1 applied to $\bar{r}_{\mathcal{D}}$ ). The reverse direction also holds as proved in Lemma 2 in Appendix C.2.

Step 2: The $\left(\mathcal{L}_{\ell}, \mathcal{L}_{k}\right)$ case. We establish connections between the two constraints in Definition 4 and the sub-vector constraint and the change-making constraint in the theorem statement by considering the orbits of a permutation group $G$ on the set of alternatives $\mathcal{A}$. An orbit in $\mathcal{A}$ is a set of alternatives, each of which can be obtained from each other by applying a permutation in $G$.

Example 6 (An orbit in $\mathcal{A}$ ). Let $m=5$ and $G=\{I d,(1,2),(3,4),(1,2)(3,4)\}$. Then there are three orbits: $\{1,2\},\{3,4\},\{5\}$.

It follows that the orbits constitute a partition of $\mathcal{A}$, which means that the numbers of these orbits, called their sizes and are denoted by $\operatorname{Sizes}(\mathcal{A} / G)$ (formally defined in Definition 12), is a vector that partitions $m$. For example, $\operatorname{Sizes}(\mathcal{A} / G)=(2,2,1)$ in Example 6.

Then, we translate the two constraints in Definition 4 by analyzing the orbit sizes of a problematic permutation, and then construct a problematic permutation group when the constraints in the theorem statement are satisfied. For example, when $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{\ell}, \mathcal{L}_{k}\right)$, the connections are formally established by the following two claims.

Claim 1. $\left(\mathcal{D}=\mathcal{L}_{k}\right)$. For any permutation group $G$,

$$
\operatorname{Fixed}_{G}\left(\mathcal{L}_{k}\right)=\emptyset \Longleftrightarrow \operatorname{Sizes}(\mathcal{A} / G) \text { contains less than } k \text { 1's }
$$

Claim 2. $\left(\mathcal{E}=\mathcal{L}_{\ell}\right)$. For any permutation group $G$ and any partition $\vec{m}$ of $m$,
(i) $\operatorname{Fixed}_{G}\left(\mathbb{H}_{m, n}^{\mathcal{L}_{\ell}}\right) \neq \emptyset \Rightarrow n$ is feasible by $\operatorname{Coins}^{\circledast}(\operatorname{Sizes}(\mathcal{A} / G), \ell)$
(ii) $n$ is feasible by $\operatorname{Coins}^{\circledast}(\vec{m}, \ell) \Rightarrow \operatorname{FIXED}_{G_{\vec{m}}}\left(\mathbb{H}_{m, n}^{\mathcal{L}_{\ell}}\right) \neq \emptyset$.

In Claim 2, $G_{\vec{m}}$ is a special permutation group that is generated by the permutation that consists of cycles of alternatives whose sizes correspond to the elements in $\vec{m}$ (see Definition 13 in Appendix C.2). For example, when $m=5$ and $\vec{m}=(2,2,1)$, we have $G_{\vec{m}}=\{\operatorname{Id},(1,2)(3,4)\}$.

We are now ready to prove the $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{\ell}, \mathcal{L}_{k}\right)$ case of Theorem 1 by combining Claim 1 and Claim 2. To prove the "if" direction, suppose there exists a partition $\vec{m}$ of $m$ that satisfies the sub-vector constraint and the change-making constraint. Notice that $\operatorname{Sizes}\left(\mathcal{A} / G_{\vec{m}}\right)=\vec{m}$. Therefore, we have $\operatorname{FixED}_{G_{\vec{m}}}\left(\mathcal{L}_{k}\right)=\emptyset$ (the $\Leftarrow$ part of Claim 1) and $\operatorname{FIXED}_{G_{\vec{m}}}\left(\mathbb{H}_{m, n}^{\mathcal{L}_{\ell}}\right) \neq \emptyset$ (part (ii) of Claim 2). This means that there exists a permutation group (i.e., $G_{\vec{m}}$ ) that satisfies both constraints in Definition 4, which implies the ANR impossibility according to Lemma 2. To prove the "only if" direction, suppose the ANR impossibility holds. Then, by Lemma 2 , there exists a permutation group $G$ that satisfies both constraints in Definition 4. Then, $\operatorname{Sizes}(\mathcal{A} / G)$, which is a partition of $m$, satisfies the sub-vector constraint (the $\Rightarrow$ part of Claim 1) and the change-making constraint (part (i) of Claim 2).

A critical step in the proof of Claim 2 is the application of the orbit-stabilizer theorem (see, for example [26, Theorem 2.65] and (7) in Appendix C.2), which reveals a connection between the number of alternatives in an orbit and the number of stabilizers of the orbit (permutations in $G$, to each of which all alternatives in the orbit are invariant).

Step 3: Other Common Settings. We extend the proof in Step 2 to other Common Settings by proving Claim 3 (for $\mathcal{D}=\mathcal{M}_{k}$ ) and Claim 4 (for $\mathcal{E}=\mathcal{M}_{\ell}$ ), and combining Claims 1-4 in ways similar to Step 2, as shown in Figure 1. The proofs involve multiple novel applications of the orbit-stabilizer theorem. The full proof can be found in Appendix C.2.

### 4.2 At-Large ANR Impossibilities

In many applications, $(\mathcal{E}, \mathcal{D})$ is determined before $n$ is known, and $n$ is often large. Therefore, it is important to understand whether the ANR impossibility holds for every sufficiently large $n$. To this end, we introduce a notion called at-large ANR impossibility.

Definition 5 (At-large ANR impossibility). Given $(\mathcal{E}, \mathcal{D})$, we say that at-large ANR impossibility holds, if there exists $N$ such that the ANR impossibility holds for every $n>N$.

In other words, if at-large ANR impossibility does not hold, then there exist infinitely many $n$ 's such that ANR rules exist.

Theorem 2 (At-large ANR impossibility: up-to-L preferences). For any $(\mathcal{E}, \mathcal{D}) \in$ $\left\{\mathcal{L}_{\leq L}, \mathcal{M}_{\leq L}: 1 \leq L \leq m\right\} \times\left\{\mathcal{L}_{k}, \mathcal{M}_{k}: 1 \leq k \leq m\right\}$, at-large ANR impossibility holds if and only if

| $\mathcal{E}_{\mathcal{E}}^{\mathcal{D}}$ | $\mathcal{L}_{k}$ | $\mathcal{M}_{k}$ |
| :---: | :---: | :---: |
| $\mathcal{L}_{\leq L}$ | (i) $m=5$, or <br> (ii) $m \geq 7$, or <br> (iii) $k \geq 2$ | (i) $m=5$ and $k \leq m-1$, or <br> (ii) $m \geq 7$ and $k \leq m-1$, or <br> (iii) $2 \leq k \leq m-2$ |
| $\mathcal{M}_{\leq L}$ | (i) $m=5$, or <br> (ii) $m \geq 7$, or <br> (iii) $\max (L, k) \geq 2$, <br> except $(m, L, k) \in\{(2,1,2),(3,2,1)\}$ | (i) $m=5$ and $k \leq m-1$, or <br> (ii) $m \geq 7$ and $k \leq m-1$, or <br> (iii) $[L] \nsubseteq\{k, m-k\}$ and $k \leq m-1$ |

Moreover, under the conditions in the table, the ANR impossibility holds for every $n \geq$ $m^{2} / 2$.

Proof sketch. We prove the $\left(\mathcal{L}_{\leq L}, \mathcal{L}_{k}\right)$ case to illustrate the idea. The proof of other cases can be found in Appendix C.6. We first prove in Claim 7 in Appendix C. 6 that at-large ANR impossibility holds for any $L$ if and only if it holds for $L=1$, meaning that it suffices to focus on the $L=1$ case.

To prove the "if" direction, for each combination of $m$ and $k$ in the theorem statement, we specify a partition $\vec{m}$ of $m$ that satisfies the sub-vector constraint, and specify one or two $\vec{\ell}$ 's so that either a coin has value 1 or two coins are co-primes. When $k \geq 2$, let $\vec{m}=(m-1,1)$ and $\ell=(0,1)$. Then, $1 \in \operatorname{Coins}^{\circledast}(\vec{m}, 1)$. When $m=5$ and $k=1$, let $\vec{m}=(3,2)$ and $\vec{\ell} \in\{(0,1),(1,0)\}$. Then, $\{2,3\} \subseteq \operatorname{Coins}^{\circledast}(\vec{m}, 1)$. When $m \geq 7$ and $k=1$, let $\vec{m}$ be defined as in (2) and let $\ell \in\{(0,1),(1,0)\}$.

$$
\vec{m}=\left(m_{1}, m_{2}\right) \triangleq \begin{cases}\left(\frac{m+1}{2}, \frac{m-1}{2}\right) & 2 \nmid m  \tag{2}\\ \left(\frac{m}{2}+1, \frac{m}{2}-1\right) & 4 \mid m \\ \left(\frac{m}{2}+2, \frac{m}{2}-2\right) & 4 \nmid m \text { and } 2 \mid m\end{cases}
$$

Then Coins ${ }^{\circledast}(\vec{m}, 1)$ contains two co-prime numbers.
The "only if" direction covers the cases where $k=1$ and $m \in\{2,3,4,6\}$, and is proved by enumerating all $\vec{m}$ 's that satisfy the sub-vector constraint, which tell us all $n$ 's for which the ANR impossibility does not hold, as summarized below.

| $m$ | partitions satisfying the sub-vector constraint | ANR Imp does not hold for |
| ---: | :---: | :---: |
| 6 | $\{(6),(4,2),(3,3),(2,2,2)\}$ | $2 \nmid n$ and $3 \nmid n$ |
| 4 | $\{(4),(2,2)\}$ | $2 \nmid n$ |
| 3 | $\{(3)\}$ | $3 \nmid n$ |
| 2 | $\{(2)\}$ | $2 \nmid n$ |

Example 7 (NYC Democratic mayoral primary election). In this election, there were 13 qualified candidates. Each voter can rank up to five candidates. This corresponds to the setting where $m=13, n$ is close to a million, and $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{\leq 5}, \mathcal{L}_{1}\right)$. The ANR impossibility holds under this setting, because according to Theorem 2, at-large ANR impossibility holds. Notice that $n \geq m^{2} / 2$. Therefore, the ANR impossibility holds as well.

## 5 The Most-Favorable-Permutation Tie-Breaking

Lemma 1 only guarantees the existence of a most equitable refinement of $\bar{r}$. In this section, we propose a novel tie-breaking mechanism to obtain a most equitable refinement, and then design a polynomial-time algorithm to compute it when $\mathcal{E}=\mathcal{L}_{m}$.

The idea behind our tie-breaking mechanism is the following. As shown in the proof of Lemma 1, the key step in obtaining a most equitable refinement is to identify and fix a "representative" profile for each equivalent class. However, the number of equivalent classes is exponentially large in $m$, which means that pre-computing the representative profiles takes exponential time. This is the main challenge identified in previous work for $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{m}, \mathcal{L}_{1}\right)[7]$. To address this challenge, we define a priority order over the histograms by lexicographically extending a priority order $\triangleright$ over $\mathcal{A}$, and then choose a representative profile of an equivalent class to be one whose histogram has the highest priority in $\triangleright$.

Definition 6 (Lexicographic extensions of $\triangleright$ ). Let $\triangleright \in \mathcal{L}_{m}$. For any $i \leq m$, We extend $\triangleright$ to $\mathcal{L}_{i}$ (respectively, $\mathcal{M}_{i}$ ), such that $i$-lists (respectively, $i$-committees) are compared lexicographically w.r.t. their top-ranked alternatives, second-ranked alternatives (respectively, most-preferred alternative, second-most-preferred alternatives), etc. We extend $\triangleright$ to $\mathbb{H}_{m, n}^{\mathcal{E}}$, such the vectors in $\mathbb{H}_{m, n}^{\mathcal{E}}$ are compared lexicographically, favoring histograms with higher values in more important coordinates according to $\triangleright$.
W.l.o.g. we let $\triangleright=[1 \succ \cdots \succ m]$ in this paper. In all examples, the coordinates in $\mathbb{H}_{m, n}^{\mathcal{E}}$ are ordered in the increasing order according to $\triangleright$.
Example 8. Continuing the setting of Example 2, among the 8 types of rankings in $\sigma_{1}\left(P^{+}\right)$ and $\sigma_{2}\left(P^{+}\right)$, we have $12345 \triangleright 12435 \triangleright 21345 \triangleright 21435 \triangleright 31425 \triangleright 32415 \triangleright 41325 \triangleright 42315$. Therefore, $\sigma_{1}\left(P^{+}\right) \triangleright \sigma_{2}\left(P^{+}\right)$.

Next, for any profile $P$, we define a class of permutations that map $\operatorname{Hist}(P)$ to a histogram with the highest priority according to $\triangleright$.
Definition 7 (Most favorable permutations (MFPs)). For any profile $P$,

$$
\begin{equation*}
M F P(P) \triangleq \arg \max _{\sigma \in \mathcal{S}_{\mathcal{A}}}^{\triangleright} \operatorname{Hist}(\sigma(P)) \tag{3}
\end{equation*}
$$

Note that arg max maximizes the priority of $\operatorname{Hist}(\sigma(P))$ according $\triangleright$ instead of maximizing the rank number of $\operatorname{Hist}(\sigma(P))$ in $\triangleright$ (which corresponding to minimizing its priority). We are now ready to introduce the tie-breaking mechanism. The high-level idea is, for any profile $P$, we first find a "representative" histogram by applying a most favorable permutation $\sigma_{\mathrm{MFP}}$, then use $\triangleright$ to break ties among fixed-point decisions, and finally map the sole winner back via $\sigma_{\text {MFP }}^{-1}$. This is equivalent to choosing a fixed-point decision that has the highest priority in $\triangleright$ after applying $\sigma_{\mathrm{MFP}}$.
Definition 8 (MFP tie-breaking). Given a "backup" tie-breaking mechanism f, a profile $P$, and $D \subseteq \mathcal{D}$, let $\sigma_{M F P} \in \operatorname{MFP}(P)$ be an arbitrary most favorable permutation. Define

$$
M F P_{f}(P, D) \triangleq \begin{cases}\arg \max _{d \in \mathrm{FPD}(P) \cap D}^{\triangleright} \sigma_{M F P}(d) & \text { if } \operatorname{FPD}(P) \cap D \neq \emptyset  \tag{4}\\ f(P, D) & \text { otherwise }\end{cases}
$$

The following theorem confirms that $\mathrm{MFP}_{f}$ is well-defined, in the sense that the choice of $\sigma_{\mathrm{MFP}}$ does not matter, and $\mathrm{MFP}_{f}$ outputs a most equitable refinement.

Theorem 3. Under the Common Settings, for any anonymous and neutral rule $\bar{r}$ and any backup tie-breaking mechanism $f, M F P_{f}$ is well-defined and $\left(M F P_{f} * \bar{r}\right)$ is a most equitable refinement.

Proof sketch. The high-level idea naturally follows the idea in the proof of Lemma 1. For each profile $P$, we identify the representative profile in its ANEC by applying $\sigma_{\mathrm{MFp}}$. Then, $r(P)$ is determined by permuting the winner under $\sigma_{\mathrm{MFP}}(P)$ via $\sigma_{\mathrm{MFP}}^{-1}$. The full proof can be found in Appendix D.1.

Example $9\left(\mathbf{M F P}_{\boldsymbol{f}}\right)$. Continuing the setting of Examples 2 and let $\sigma_{1}^{*}=(1,4,2,3)$. Then, $\operatorname{MFP}\left(P^{+}\right)=\left\{\sigma_{1}, \sigma_{1}^{*}\right\}$ and $\sigma_{1}\left(P^{+}\right)=\sigma_{1}^{*}\left(P^{+}\right)$. Let $\bar{r}=$ veto. For any backup tie-breaking mechanism $f$, we have $\operatorname{MFP}_{f}\left(P^{+}\right.$, veto $\left.\left(P^{+}\right)\right)=\operatorname{MFP}_{f}\left(P^{+},\{1,2,3,4\}\right)=\{3\}$, because

$$
\sigma_{1}(3)=\sigma_{1}^{*}(3)=1 \triangleright 2=\sigma_{1}(4)=\sigma_{1}^{*}(4)
$$

Next, we present a polynomial-time algorithm (Algorithm 1) to compute $\mathrm{MFP}_{f}$ under the Common Settings where $\mathcal{E}=\mathcal{L}_{m}$. The main idea is that any MFP must map $R \in \mathcal{L}_{m}$ with the highest multiplicity in $\operatorname{Hist}(P)$ to the linear order with the highest priority w.r.t. $\triangleright$, which is $\triangleright$ itself (as a linear order in $\mathcal{L}_{m}$ ). Then, a MFP can be computed by exploring all such permutations and choosing the one that maps $P$ to the profile whose histogram has the highest priority in $\triangleright$.

Recall that for any profile $P$ and any ranking $R,[\operatorname{Hist}(P)]_{R}$ is the $R$-component of the histogram of $P$. Let $\operatorname{MPR}(P) \triangleq \arg \max _{R}[\operatorname{Hist}(P)]_{R}$ denote the set of all most popular rankings in $P$, i.e., the rankings with the highest multiplicity in $P$. Algorithm 1 stores $\operatorname{Hist}(P)$ as lists of linear orders that appear at least once in $P$ and their multiplicities.

```
ALGORITHM 1: (MFP tie-breaking) Compute \(\operatorname{MFP}_{f}(P, D)\) for \(P=\left(R_{1}, \ldots, R_{n}\right) \in\left(\mathcal{L}_{m}\right)^{n}\) and
\(D \subseteq \mathcal{D}\).
    1: Let \(\sigma_{j j^{\prime}}\) be the permutation such that \(\sigma_{j j^{\prime}}\left(R_{j}\right)=R_{j^{\prime}}\). Compute
        \(\operatorname{STAB}(\operatorname{Hist}(P))=\bigcap_{j \leq n}\left\{\sigma_{j j^{\prime}}: 1 \leq j^{\prime} \leq n\right.\) such that \(\left.[\operatorname{Hist}(P)]_{R_{j}}=[\operatorname{Hist}(P)]_{R_{j^{\prime}}}\right\}\)
    Compute \(\operatorname{FPD}(P)\), and if \(\operatorname{FPD}(P) \cap D=\emptyset\), then return \(f(P, D)\).
    for every most popular ranking \(R \in \operatorname{MPR}(P)\), compute \(\sigma_{R} \in \mathcal{S}_{\mathcal{A}}\) such that \(\sigma_{R}(R)=\triangleright\).
    Compute \(R^{*} \in \arg \max _{R \in \operatorname{MPR}(P)}^{\triangleright} \sigma_{R}(\operatorname{Hist}(P))\).
    return \(\arg \max _{d \in \operatorname{FPD}(P) \cap D}^{\triangleright} \sigma_{R^{*}}(d)\).
```

$\operatorname{Stab}(\operatorname{Hist}(P))$ in step 1 of Algorithm 1 is the set of stabilizers of $\operatorname{Hist}(P)$ in $\mathcal{S}_{\mathcal{A}}$, i.e., all permutations $\sigma$ such that $\sigma(\operatorname{Hist}(P))=\operatorname{Hist}(P)$.

Example 10 (Execution of Algorithm 1). We run Algorithm 1 on $P^{+}$and $\bar{r}=$ veto in the setting of Examples 2 and 9. In step 1, the right-hand side of Equation (5) for $j$ such that $R_{j}=43125$ is $\{I d,(1,2)\}$, because $\left[\operatorname{Hist}\left(P^{+}\right)\right]_{43125}=\left[\operatorname{Hist}\left(P^{+}\right)\right]_{43215}=1$. According to Equation (5), $\operatorname{StaB}\left(\operatorname{Hist}\left(P^{+}\right)\right)=\{I d,(1,2)\}$. In step 2, we have $\operatorname{FPD}\left(P^{+}\right) \cap$ veto $\left(P^{+}\right)=$
$\{3,4\}$. In step 3, $\operatorname{MPR}(P)=\{34125,34215,43125,43215\}$. Let $\sigma_{2}^{*} \triangleq(1,4)(2,3)$. We have $\sigma_{34125}=\sigma_{1}$ (defined in Example 2), $\sigma_{34215}=\sigma_{1}^{*}$ (defined in Example 9), $\sigma_{43125}=\sigma_{2}$ (defined in Example 2), and $\sigma_{43215}=\sigma_{2}^{*}$. Then in step 4, we have $\sigma_{1}\left(P^{+}\right)=\sigma_{1}^{*}\left(P^{+}\right)$ and $\sigma_{2}\left(P^{+}\right)=\sigma_{2}^{*}\left(P^{+}\right)$. Recall from Example 8 that $\sigma_{1}\left(P^{+}\right) \triangleright \sigma_{2}\left(P^{+}\right)$. Therefore, we can choose $R^{*}=34125$. Finally, in step $5, \sigma_{R^{*}}(3)=1 \triangleright 2=\sigma_{R^{*}}(4)$, which means that $\left(M F P_{f} *\right.$ veto $)\left(P^{+}\right)=\{3\}$.

The correctness and efficiency of Algorithm 1 are guaranteed by the following theorem, whose proof can be found in Appendix D.

Theorem 4. For any polynomially computable $f$ and any $\left(\mathcal{L}_{m}, \mathcal{D}\right)$ in the Common Settings, Algorithm 1 computes $M F P_{f}$ in polynomial time.

For any $(\mathcal{E}, \mathcal{D})$ in the Common Settings where $\mathcal{E} \neq \mathcal{L}_{m}$, computing a MFP of $P$ according to Equation (3) takes $O(m!\cdot \operatorname{poly}(m, n))$ time by enumerating all permutations $\sigma$, which means that computing $\mathrm{MFP}_{f}$ takes $O(m!\cdot \operatorname{poly}(m, n))$ time if $f$ is polynomial-time computable. This idea works for even more general settings and is formally presented as Algorithm 2 in Appendix E.4.

## 6 Related work and discussions

Circumventing the ANR impossibility. As commented by Zwicker [28], using tiebreaking mechanisms is a common approach towards circumventing the ANR impossibility. Most previous work focuses on $\mathcal{E}=\mathcal{L}_{m}$, while other settings have gain popularity recently. For example, the characterization of ANR impossibility is an open question for approval-based committee voting, where $(\mathcal{E}, \mathcal{D})=\left(\mathcal{M}_{\ell}, \mathcal{M}_{k}\right)$ [18, Chapter 3.1]. Our results contribute to the fundamental understandings of the tie-breaking approach: we now know how to break ties optimally (Lemma 1 and Theorem 3) and computationally efficiently (Theorem 4).

Characterizations of ANR rules. A series of previous work focused on (fully or partially) characterizing the existence of ANR rules by conditions on $m$ and $n$, mostly under certain Common Settings where $\mathcal{E}=\mathcal{L}_{m}$.

When $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{\boldsymbol{m}}, \mathcal{L}_{\mathbf{1}}\right)$, Moulin [21] proved that an ANR rule exists if and only if $m$ cannot be represented as a sum of $n$ 's non-trivial (i.e., $>1$ ) divisors. Moulin [21] also proved that an ANR rule that also satisfies Pareto efficiency exists if and only if $m$ is smaller than $n$ 's smallest non-trivial divisor, which is equivalent to $\operatorname{gcd}(m!, n)=1$, where gcd represents the greatest common divisor. Campbell and Kelly [9] pointed out that sometimes ANR comes at the cost of other desirable properties. Dogan and Giritligil [13] characterized ANR rules that also satisfy monotonicity. Ozkes and Sanver [23] investigated the existence of rules that satisfy anonymity, resolvability, and a weaker notion of neutrality.

When $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{m}, \mathcal{L}_{m}\right)$, Bubboloni and Gori [4] proved that an ANR rule exists if and only if $\operatorname{gcd}(m!, n)=1$. Bubboloni and Gori [5] considered a setting where voters are divided into groups and investigated a weaker notion of in-group anonymity.

When $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{\boldsymbol{m}}, \mathcal{M}_{\boldsymbol{k}}\right)$, Bubboloni and Gori [6] proved that an ANR rule that satisfies Pareto efficiency exists if and only if $\operatorname{gcd}(m!, n)=1$. Bubboloni and Gori [7]
provided sufficient conditions for the existence of ANR rules that satisfy weaker notions of anonymity and neutrality. However, the conditions for the ANR impossibility to hold under $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{m}, \mathcal{L}_{k}\right)$ as well as under other Common Settings not mentioned above remain open, which are resolved by our Theorem 1.

Other related works include the seminar work by May [20], which investigated anonymous and neutral rules for two alternatives where ties are allowed, and characterized the majority rule. Bartholdi et al. [1] proposed a new and weaker notion of equity in the same voting setting as May's setting [20] that justifies representative democracy.
Tie-breaking mechanisms. ANR is satisfied for any irresolute rule $\bar{r}$ at any profile $P$ under which there are no ties. Therefore, some previous work focused on designing tiebreak mechanisms to preserve as much ANR satisfaction as possible. When $(\mathcal{E}, \mathcal{D})=$ $\left(\mathcal{L}_{m}, \mathcal{L}_{1}\right)$, Dogan and Giritligil [13] proposed to use an ANR ranking rule to break ties when $\operatorname{gcd}(m!, n)=1$. Bubboloni and Gori $[6]$ characterized conditions for the existence of a tie-breaking mechanism to preserve weaker versions of anonymity and neutrality. Xia [27] showed that the agenda tie-breaking and the fixed-voter tie-breaking are far from being optimal under a large class of semi-random models, proposed a tie-breaking mechanism, and proved that it is asymptotically optimal for even $n$ 's. Our MFP tie-breakings are optimal as they computes most equitable refinements, which achieve highest ANR satisfaction regardless of the underlying distribution over profiles.

When $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{m}, \mathcal{L}_{m}\right)$ or $\left(\mathcal{L}_{m}, \mathcal{M}_{\boldsymbol{k}}\right)$, Bubboloni and Gori [7] proposed tiebreaking mechanisms for $k$-committees and rankings that are based on defining a system of "representatives" for each equivalent class of profiles. They also highlighted the computational challenges in their approach: (using our notation) "finding explicitly a system of representatives is in general a complex problem. However, that can be managed for small values of $m$ and $n$, that is, when the size $(m!)^{n}$ of $\left(\mathcal{L}_{m}\right)^{n}$ is not too large". It remained an open question of whether ANR can be optimally preserved by some polynomial-time tiebreaking mechanism when $\mathcal{E}=\mathcal{L}_{m}$, which is address by our MFP breakings (Algorithm 1 and Theorem 4).

## 7 Future Work

There are many directions for future work. For example, immediate open questions include characterizing conditions for the ANR impossibility for other commonly studied settings, such as partial orders; designing efficient algorithms for computing MFP; characterizing likelihood of ANR violations; analyzing randomized tie-breaking mechanisms; studying the likelihood of ANR violations under natural statistical models; verifying the likelihood of ANR violations on real-world data. Our general theory presented in Appendix E provides some useful tools for addressing these questions. More generally, how to extend the study to other desirable properties together with ANR (or other notions of fairness), such as Pareto efficiency and monotonicity, is another important direction for future work.

## A Additional Preliminaries

## A. 1 Commonly Studied Voting Rules

Weighted Majority Graphs. For any profile $P$ and any pair of alternatives $a, b$, let $P[a \succ b]$ denote the total weight of votes in $P$ where $a$ is preferred to $b$. Let WMG(P) denote the weighted majority graph of $P$, whose vertices are $\mathcal{A}$ and whose weight on edge $a \rightarrow b$ is $w_{P}(a, b)=P[a \succ b]-P[b \succ a]$.

A voting rule is said to be weighted-majority-graph-based (WMG-based) if its winners only depend on the WMG of the input profile. We consider the following commonly studied WMG-based rules. For each rule, we will define its $\mathcal{D}=\mathcal{L}_{k}$ version for $1 \leq k \leq m-1$, and its $\mathcal{M}_{k}$ version chooses all (unordered) alternatives involved in its $\mathcal{L}_{k}$ version. Recall that $\mathcal{D}=\mathcal{A}$ is a special case of $\mathcal{D}=\mathcal{L}_{k}$, where $k=1$; and $\mathcal{D}=\mathcal{L}(\mathcal{A})$ is a special case of $\mathcal{D}=\mathcal{L}_{k}$, where $k=m$.

- Copeland. The Copeland rule is parameterized by a number $0 \leq \alpha \leq 1$, and is therefore denoted by Copeland $\alpha_{\alpha}$, or $\mathrm{Cd}_{\alpha}$ for short. For any fractional profile $P$, an alternative $a$ gets 1 point for each other alternative it beats in their head-to-head competition, and gets $\alpha$ points for each tie. Copeland ${ }_{\alpha}$ for $\mathcal{D}=\mathcal{L}_{k}$ chooses all linear extensions of weak orders of top $k$ alternatives w.r.t. their Copeland scores. In other words, for any profile $P, a_{1} \succ \cdots \succ a_{k} \in \operatorname{Cd}_{\alpha}(P)$ if and only if (1) for any $k_{1}, k_{2} \leq k$ such that $a_{k_{1}} \succ a_{k_{2}}$, the Copeland score of $a_{k_{2}}$ is no more than the Copeland score of $k_{1}$; and (2) for any $k^{\prime}>k$, the Copeland score of $a_{k^{\prime}}$ is no more than the Copeland score of $k_{2}$.
- Maximin. For each alternative $a$, its min-score is defined to be $\min _{b \in \mathcal{A}} w_{P}(a, b)$. Maximin for $\mathcal{D}=\mathcal{L}_{k}$ chooses all linear extensions of weak orders of top $k$ alternatives w.r.t. their maximin scores.
- Ranked pairs. Given a profile $P$, we fix edges in $\mathrm{WMG}(P)$ one by one in a nonincreasing order w.r.t. their weights (and sometimes break ties), unless it creates a cycle with previously fixed edges. After all edges (with positive, 0 , or negative weights) are considered, the fixed edges represent a linear order over $\mathcal{A}$ and the ranked top- $k$ alternatives are chosen. We consider all tie-breaking methods to define the ranked top- $k$ alternatives. This is known as the parallel-universes tie-breaking (PUT) [10].
- Schulze. For any directed path in the WMG, its strength is defined to be the minimum weight on any single edge along the path. For any pair of alternatives $a, b$, let $s[a, b]$ be the highest weight among all paths from $a$ to $b$. Then, we write $a \succeq b$ if and only if $s[a, b] \geq s[b, a]$, and the strict version of this binary relation, denoted by $\succ$, is transitive [25]. The Schulze rule for $\mathcal{D}=\mathcal{L}_{k}$ chooses ranked top- $k$ alternatives in all linear extensions of $\succeq$.

STV. The single transferable vote (STV) rule has $m-1$ rounds. In each round, the alternative with the lowest plurality score is eliminated. STV for $\mathcal{D}=\mathcal{L}_{k}$ chooses ranked top- $k$ alternatives according to the inverse elimination order. Like ranked pairs, PUT is used to select the winning $k$-lists.

## A. 2 Group Theory

Let $|G|$ denote the number of elements in $G$, also called the order of $G$. A group $H$ is a subgroup of another group $G$, denoted by $H \leqslant G$, if $H \subseteq G$ and the operation for $H$ is the restriction of the operation for $G$ on $H$.

For any $g \in G$ in a group and any $K \in \mathbb{N}$, we let $g^{K} \triangleq \underbrace{g \circ \cdots \circ g}_{K}$. The symmetric group over $\mathcal{A}=[m]$, denoted by $\mathcal{S}_{\mathcal{A}}$, is the set of all permutations over $\mathcal{A}$. A permutation $\sigma$ that maps each $a \in \mathcal{A}$ to $\sigma(a)$ can be represented in two ways.

- Two-line form: $\sigma$ is represented by a $2 \times m$ matrix, where the first row is $(1,2, \ldots, m)$ and the second row is $(\sigma(1), \sigma(2), \ldots, \sigma(m))$.
- Cycle form: $\sigma$ is represented by non-overlapping cycles over $\mathcal{A}$, where each cycle $\left(a_{1}, \cdots, a_{K}\right)$ represent $a_{i+1}=\sigma\left(a_{i}\right)$ for all $i \leq K-1$, and with $a_{1}=\sigma\left(a_{K}\right)$.

For example, all permutations in $S_{3}$ are represented in two-line form and cycle form respective in the Table 1.

| Two-line | $\left(\begin{array}{lll}1 & 2 & 3 \\ 1 & 2 & 3\end{array}\right)$ | $\left(\begin{array}{lll}1 & 2 & 3 \\ 2 & 1 & 3\end{array}\right)$ | $\left(\begin{array}{lll}1 & 2 & 3 \\ 1 & 3 & 2\end{array}\right)$ | $\left(\begin{array}{lll}1 & 2 & 3 \\ 3 & 2 & 1\end{array}\right)$ | $\left(\begin{array}{lll}1 & 2 & 3 \\ 2 & 3 & 1\end{array}\right)$ | $\left(\begin{array}{lll}1 & 2 & 3 \\ 3 & 1 & 2\end{array}\right)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Cycle | () or Id | $(1,2)$ | $(2,3)$ | $(1,3)$ | $(1,2,3)$ | $(1,3,2)$ |
| Table 1. $\mathcal{S}_{\mathcal{A}}$ with $m=3$ |  |  |  |  |  |  |

A permutation group $G$ over $\mathcal{A}$ is a subgroup of $\mathcal{S}_{\mathcal{A}}$, i.e., $G \leqslant \mathcal{S}_{\mathcal{A}}$. For any vector $\vec{d}$ of non-negative integers that sum up to $m$, we define a special permutation $\sigma_{\vec{d}}$ and a permutation group $G_{\vec{d}}$ generated by $\sigma_{\vec{d}}$ as follows.

## B Materials for Section 3

## B. 1 Group-Theoretic Definition of Fixed-Point Decisions

Definition 9 (Fixed-point decisions). Given any $(\mathcal{E}, \mathcal{D})$ in the Common Settings, for any profile $P \in \mathcal{E}^{n}$ and any set of decisions $D \subseteq \mathcal{D}$, define

Stabilizers of $\operatorname{Hist}(\boldsymbol{P}): \operatorname{StaB}(\operatorname{Hist}(P)) \triangleq\left\{\sigma \in \mathcal{S}_{\mathcal{A}}: \operatorname{Hist}(\sigma(P))=\operatorname{Hist}(P)\right\}$,
Fixed-point decisions:

$$
\operatorname{FPD}(P) \triangleq \operatorname{FixED}_{\mathrm{Stab}(\operatorname{Hist}(P))}(\mathcal{D}) \triangleq\left\{\sigma \in \mathcal{S}_{\mathcal{A}}: \operatorname{Hist}(\sigma(P))=\operatorname{Hist}(P)\right\}
$$

In words, a stabilizer of $\operatorname{Hist}(P)$ is a permutation $\sigma$ under which $\operatorname{Hist}(P)$ is invariant. A fixed point of $\operatorname{STAB}(\operatorname{Hist}(P))$ in $\mathcal{D}$ is a decision that is invariant under all stabilizers of $\operatorname{Hist}(P)$. And a fixed-point decision is simply a decision in $D$ that is also a fixed point of $\operatorname{Stab}(\operatorname{Hist}(P))$. For example, in the setting of Example 3, $\operatorname{STAB}\left(\operatorname{Hist}\left(P^{-}\right)\right)=$ $\left\{\operatorname{Id}, \sigma_{(1,2)}\right\}$, where Id is the identity permutation that does not change any alternative, $\operatorname{FixED}_{\operatorname{Stab}\left(\operatorname{Hist}\left(P^{-}\right)\right)}=\{3,4,5\}, \operatorname{FPD}\left(P^{-}, \operatorname{veto}\left(P^{-}\right)\right)=\{3,4,5\} \cap\{1,2\}=\emptyset$.

## B. 2 Lemma 1 and Its Proof

Lemma 1. (Existence of most equitable refinements). Under Common Settings, any anonymous and neutral irresolute rule has a most equitable refinement. Moreover, for every most equitable refinement $r^{*}$ and every $P \notin \mathcal{P}_{\bar{r}}, r^{*}(P) \subseteq \operatorname{FPD}(P) \cap \bar{r}(P)$.

Proof. The lemma is proved in the following two steps.
Step 1: any profile $\boldsymbol{P}$ such that $\operatorname{FPD}(\boldsymbol{P}) \cap \overline{\boldsymbol{r}}(\boldsymbol{P})=\emptyset$ is in $\mathcal{P}_{\overline{\boldsymbol{r}}}$. The proof is similar to the reasoning in Example 3. Suppose for the sake of contradiction that there exists $P$ with $\operatorname{FPD}(P) \cap \bar{r}(P)=\emptyset$ and a refinement $r$ of $\bar{r}$ such that $\operatorname{ANR}(r, P)=1$. Let $r(P)=\{d\}$. Then, $d$ is not a fixed point of $\operatorname{Stab}(\operatorname{Hist}(P))$, which means that there exists a permutation $\sigma \in \operatorname{Stab}(\operatorname{Hist}(P))$ such that $\sigma(d) \neq d$. Because $\operatorname{Hist}(\sigma(P))=\sigma(\operatorname{Hist}(P))=\operatorname{Hist}(P)$, by anonymity, we have $r(\sigma(P))=r(P)=\{d\}$, but by neutrality, we have $r(\sigma(P))=$ $\sigma(r(P))=\{\sigma(d)\} \neq\{d\}$, which is a contradiction.

Step 2: there exists a refinement $r^{*}$ such that for all profiles $P$ such that $\operatorname{FPD}(\boldsymbol{P}) \cap \overline{\boldsymbol{r}}(\boldsymbol{P}) \neq \emptyset, \operatorname{ANR}\left(\boldsymbol{r}^{*}, \boldsymbol{P}\right)=\mathbf{1}$. The proof is constructive and is similar to the idea in the following example.

Example 11 (Non-problematic profile). Let $P^{+}$be the profile in Example 2. We have veto $\left(P^{+}\right)=\{1,2,3,4\}$ and $\operatorname{Stab}\left(H i s t\left(P^{+}\right)\right)=\left\{I d, \sigma_{(1,2)}\right\}$, which means that $\operatorname{FixED}_{\operatorname{STAB}\left(H i s t\left(P^{+}\right)\right)}(\mathcal{D})=$ $\{3,4,5\}$. Hence $\operatorname{FPD}\left(P^{+}\right) \cap \operatorname{veto}\left(P^{+}\right)=\{3,4\}$. Let $r$ be a refinement such that $r\left(P^{+}\right)=$ $\{3\}$, and for every permutation $\sigma$ and every profiles $P$ such that $\operatorname{Hist}(P)=\operatorname{Hist}\left(\sigma\left(P^{+}\right)\right)$, let $r(P)=\{\sigma(3)\}$. Then, we have $\operatorname{ANR}\left(r, P^{+}\right)=1$. A similar construction works if we choose $r\left(P^{+}\right)=\{4\}$, but if $r\left(P^{+}\right) \subseteq\{1,2\}$, then $\operatorname{ANR}\left(r, P^{+}\right)=0$ by considering $\sigma_{(1,2)}$ as in Example 3.

Formally, Step 2 consists of the following three steps.
Step 2.1. Define an equivalence relationship. Let $\sim$ denote the equivalence relationship in $\mathbb{H}_{m, n}^{\mathcal{E}}$, such that for any pair of profiles $P_{1}, P_{2}, P_{1} \sim P_{2}$ if and only if there exists a permutation $\sigma$ such that $\operatorname{Hist}\left(P_{1}\right)=\operatorname{Hist}\left(\sigma\left(P_{2}\right)\right)$.

Step 2.2. Choose "representative" profiles. For each equivalent class (of $n$-profiles) according to $\sim$, we arbitrarily choose a "representative" profile $P$, fix it throughout the proof, and define $r^{*}(P)$ to be an arbitrary but fixed decision in $\operatorname{FPD}(P) \cap \bar{r}(P)$.

Step 2.3. Extend to other profiles. For any "representative" profile $P$ and any $P^{\prime} \sim P$, let $\sigma$ denote the permutation such that $\operatorname{Hist}\left(P^{\prime}\right)=\sigma(\operatorname{Hist}(P))$. We define $r^{*}(P)=$ $\sigma\left(r^{*}(P)\right)$.

It follows that for every $P$ such that $\operatorname{FPD}(P) \cap \bar{r}(P) \neq \emptyset, \operatorname{ANR}\left(r^{*}, P\right)=1$. Moreover, if there exits a most equitable refinement $r^{*}$ and $P \notin \mathcal{P}_{\bar{r}}$ such that $r^{*}(P)=\{d\} \nsubseteq \operatorname{FPD}(P) \cap$ $\bar{r}(P)$, then $d$ is not a fixed point under $\operatorname{Stab}(\operatorname{Hist}(P))$, which means that there exists a permutation $\sigma \in \operatorname{Stab}(\operatorname{Hist}(P))$ such that $\sigma(d) \neq d$. Notice that $\sigma(\operatorname{Hist}(P))=\operatorname{Hist}(P)$. Therefore, anonymity or neutrality is violated at $P$ under $r^{*}$, which is a contradiction.

## C Materials for Section 4

## C. 1 Notation and Examples

Definition 10 (Feasible numbers). Given a set $\mathcal{C}=\left\{n_{1}, \ldots, n_{T}\right\}$ of positive integers, we let $\operatorname{Feas}(\mathcal{C})$ denote the set of all positive integers that can be represented as non-negative linear combinations of elements in $\mathcal{C}$. That is, let $\vec{n}=\left(n_{1}, \ldots, n_{T}\right)$, define

$$
\operatorname{Feas}(\mathcal{C}) \triangleq\left\{\vec{\alpha} \cdot \vec{n}: \vec{\alpha} \in \mathbb{Z}_{\geq 0}^{T} \text { and } \vec{\alpha} \neq \overrightarrow{0}\right\}
$$

In other words, $n \in \operatorname{Feas}(\mathcal{C})$ if and only if $n$ is feasible by $\mathcal{C}$.
Next, we define $\mathcal{D} \mathcal{L}_{k}(m)$ and $\mathcal{D} \mathcal{M}_{k}(m)$ to be the two sets of partitions of $m$ that satisfy the sub-vector constraint for $\mathcal{D}=\mathcal{L}_{k}$ and $\mathcal{D}=\mathcal{M}_{k}$ in the statement of Theorem 1, respectively. Let $\mathcal{E} \mathcal{L}_{\ell}(m, n)$ and $\mathcal{E} \mathcal{M}_{\ell}(m, n)$ denote the partitions of $m$ that satisfy the change-making constraint for $n$ for $\mathcal{E}=\mathcal{L}_{\ell}$ and $\mathcal{E}=\mathcal{M}_{\ell}$ in the statement of Theorem 1, respectively. More precisely, we have the following definition.

Definition 11. Given any $m, n, \ell$, and $k$, we define

$$
\begin{aligned}
\mathcal{D} \mathcal{L}_{k}(m) & \triangleq\left\{\vec{m}: \vec{m} \text { contains less than } k 1^{\prime} s\right\} \\
\mathcal{D} \mathcal{M}_{k}(m) & \triangleq\{\vec{m}: \text { no sub-vector of } \vec{m} \text { sum up to } k\} \\
\mathcal{E} \mathcal{L}_{\ell}(m, n) & \triangleq\left\{\vec{m}: n \text { is feasible by } \operatorname{Coins}^{\circledast}(\vec{m}, \ell)\right\} \\
\mathcal{E} \mathcal{M}_{\ell}(m, n) & \triangleq\left\{\vec{m}: n \text { is feasible by } \operatorname{Coins}^{\otimes}(\vec{m}, \ell)\right\}
\end{aligned}
$$

We assume that all vectors are represented in non-increasing order of their components. For example, $\mathcal{D L}_{2}(4)=\{(4),(3,1),(2,2)\}$.

Example 12. When $\mathcal{E}=\mathcal{M}_{m}$, i.e., $\ell=m$, for any partition $\vec{m}$ of $m$, we have $\operatorname{Coins}^{\ominus}(\vec{m}, \ell)=$ Coins ${ }^{\otimes}(\vec{m}, m)=\{1 \mathrm{~cm}(\vec{m} \oslash \vec{m})\}=\{1\}$. Therefore, the ANR impossibility holds (for any $n$ ) if and only if there exists an $\vec{m}$ that satisfies the sub-vector constraint.

That is, according to Theorem 1, for all $\left(\mathcal{M}_{m}, \mathcal{D}\right)$ in the Common Settings, except $\mathcal{D}=\mathcal{M}_{m}$, the $A N R$ impossibility holds for all $n \geq 1$. It is not hard to verify that this is true because all voters can only cast the same vote $(\mathcal{A})$, and when $\mathcal{D} \neq \mathcal{M}_{m}$, for any decision, there exists a permutation that maps it to a different decisions, which proves that the ANR impossibility holds.

When $(\mathcal{E}, \mathcal{D})=\left(\mathcal{M}_{m}, \mathcal{M}_{m}\right)$, according to Theorem 1, the ANR impossibility theorem does not hold. It is easy to verify that this is true because there is only one decision $\mathcal{A}$, and any permutation maps it to itself.

## C. 2 Proof of Theorem 1

Theorem 1 (ANR impossibility: Common Settings). For any $m \geq 2, n \geq 1$, $1 \leq \ell \leq m, 1 \leq k \leq m$, and any $(\mathcal{E}, \mathcal{D})$ in the Common Settings, the ANR impossibility holds if and only if there exists a partition $\vec{m}$ of $m$ that satisfies

- sub-vector constraint: $\left\{\begin{array}{ll}\vec{m} \text { contains less than } k 1 \text { 's } & \text { if } \mathcal{D}=\mathcal{L}_{k} \\ \text { no sub-vector of } \vec{m} \text { sum up to } k & \text { if } \mathcal{D}=\mathcal{M}_{k}\end{array}\right.$, and
- change-making constraint: $n$ is feasible by $\begin{cases}\operatorname{Coins}^{\circledast}(\vec{m}, \ell) & \text { if } \mathcal{E}=\mathcal{L}_{\ell} \\ \operatorname{Coins}^{\oslash}(\vec{m}, \ell) & \text { if } \mathcal{E}=\mathcal{M}_{\ell}\end{cases}$

Proof. Overview. In Step 1, we introduce the notion of problematic permutation groups, which are permutation groups that satisfy two group theoretic constraints (Definition 4) and prove that the existence of a problematic permutation group characterizes the ANR impossibility. Then in Step 2, we show that the two constraints are equivalent to the subvector constraint and the change-making constraint under Common Settings, respectively. We present the full proof for $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{\ell}, \mathcal{L}_{k}\right)$, where the equivalences are shown in Claim 1 (for $\mathcal{D}=\mathcal{L}_{k}$ ) and Claim 2 (for $\mathcal{E}=\mathcal{L}_{\ell}$ ), respectively. Finally, other Common Settings are handled in Step 3.
Step 1: Group theoretic constraints. As discussed in the beginning of Section 4, the ANR impossibility holds if and only if there exists a problematic $n$-profile $P$ under $\bar{r}_{\mathcal{D}}$, and by Lemma 1,

$$
\begin{equation*}
\operatorname{FPD}\left(P, \bar{r}_{\mathcal{D}}(P)\right)=\mathcal{D} \cap \operatorname{FixED}_{\operatorname{Stab}(\operatorname{Hist}(P))}(\mathcal{D})=\operatorname{FixED}_{\operatorname{Stab}(\operatorname{Hist}(P))}(\mathcal{D})=\emptyset \tag{6}
\end{equation*}
$$

Notice that $\operatorname{Stab}(\operatorname{Hist}(P))$ is a subgroup of $\mathcal{S}_{\mathcal{A}}$ with two properties. First, as (6) shows, $\operatorname{Stab}(\operatorname{Hist}(P))$ does not have a fixed point in $\mathcal{D}$. Second, $\operatorname{Stab}(\operatorname{Hist}(P))$ has at least one fixed point, e.g., Hist $(P)$, in $\mathbb{H}_{m, n}^{\mathcal{E}}$. This motivates us to define the following condition and prove that it characterizes the ANR impossibility. We recall that FIXED ${ }_{G}(X)$ consists of fixed points of $G$ in $X$, i.e., all $x \in X$ such that $g(x)=x$ holds for all $g \in G$. (Also see Definition 19 in Appendix E. 4 for its formal definition.)

Recall from Definition 4 that a problematic permutation group is characterized by the following two constraints:

- the $\mathcal{D}$ constraint: $\operatorname{FiXED}_{G}(\mathcal{D})=\emptyset$,
- the $\mathcal{E}$-histogram constraint: $\operatorname{FIXED}_{G}\left(\mathbb{H}_{m, n}^{\mathcal{E}}\right) \neq \emptyset$.

Lemma 2. The ANR impossibility holds if and only if there exists a problematic permutation group.

Proof. We have already proved the "only if" part by letting $G=\operatorname{StaB}(\operatorname{Hist}(P))$, where $P$ is a problematic profile. To prove the "if" direction, let $G$ denote the permutation group that satisfies both constraints in Definition 4 and let $P$ denote any profile such that Hist $(P)$ satisfies the $\mathcal{E}$-histogram constraint for $G$. It follows that $G \subseteq \operatorname{STAB}(\operatorname{Hist}(P))$, which means that $\operatorname{FixED}_{\text {Stab }(\operatorname{Hist}(P))}(\mathcal{D}) \subseteq \operatorname{FixED}_{G}(\mathcal{D})=\emptyset$ (due to the $\mathcal{D}$ constraint for $G$ ).

The remainder of the proof establishes the equivalence between the two constraints in Definition 4 and the sub-vector constraint and the change-making constraint in the theorem statement under the Common Settings. This is achieved by a group theoretic approach that analyzes the sizes of orbits in $\mathcal{A}$ under $G$, formally defined as follows, where $G \leqslant \mathcal{S}_{\mathcal{A}}$ means that $G$ is a subgroup of $\mathcal{S}_{\mathcal{A}}$.

Definition 12 (Orbit sizes). For any $G \leqslant \mathcal{S}_{\mathcal{A}}$ and any set $X$ that permutations over $\mathcal{A}$ can be naturally applied (formal defined as "acts on" in Definition 17 in Appendix E.1), the orbit of $x \in X$ under $G$ is defined to be $\operatorname{OrBit}_{G}(x) \triangleq\{g(x): g \in G\}$. Let $\operatorname{Sizes}(X / G)$ denote the vector that represents the sizes of non-overlapping orbits in $\mathcal{A}$ under $G$ in nonincreasing order.

Because $\mathcal{A}$ can be partitioned to orbits under $G, \operatorname{Sizes}(\mathcal{A} / G)$ is a partition of $m$.
Example 13 (Orbit sizes). Let $m=4, n=2,(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{1}, \mathcal{L}_{2}\right)$, and $G=\{I d,(1,2)(3,4)\}$. We have $\operatorname{Sizes}(\mathcal{D} / G)=\operatorname{Sizes}\left(\mathcal{L}_{2} / G\right)=(2,2,2,2,2,2)$, because $\mathcal{L}_{2}$ can be partitioned into the following 6 orbits under $G$ :

$$
\begin{aligned}
\mathcal{L}_{2}=\{1 \succ 2,2 \succ 1\} & \cup\{1 \succ 3,2 \succ 4\} \cup\{1 \succ 4,2 \succ 3\} \cup\{3 \succ 1,4 \succ 2\} \\
& \cup\{3 \succ 2,4 \succ 1\} \cup\{3 \succ 4,4 \succ 3\}
\end{aligned}
$$

$\operatorname{Sizes}\left(\mathbb{H}_{m, n}^{\mathcal{E}} / G\right)=(2,2,2,2,1,1)$, because $\mathbb{H}_{m, n}^{\mathcal{E}}$ can be partitioned into 6 orbits under $G$, i.e., $O_{1}, \ldots, O_{6}$ in the table below. Each column after the first represents a histogram, where 0 entries are omitted:

| $\mathcal{D}=\mathcal{L}_{1}$ | $\mathbb{H}_{m, n}^{\mathcal{E}}$ |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 2 |  | $1{ }_{1}$ | 1 |  |  |
| 2 | 12 |  |  | '1 | 1 |  |
| 3 | 1 |  |  | 1 |  | 1 |
| 4 | , | '2 |  | '1 |  |  |
|  | $O_{1}$ | $\mathrm{O}_{2}$ | $\mathrm{O}_{3}$ | $\mathrm{O}_{4}$ | $O_{5}$ | $O_{6}$ |

For example, $O_{1}=\{(2,0,0,0),(0,2,0,0)\}$. Sizes $\left(\mathcal{L}_{1} / G\right)=(2,2)$, because $\mathcal{A}=\mathcal{L}_{1}$ is partitioned into two orbits: $\mathcal{L}_{1}=\{1,2\} \cup\{3,4\}$.

Step 2: the $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{\ell}, \mathcal{L}_{k}\right)$ case. The proof proceeds in three steps. First, for $\mathcal{D}=\mathcal{L}_{k}$, we reveal a relationship (Claim 1) between the $\mathcal{D}$ constraint in Definition 4 and the sub-vector constraint in the statement of the theorem. Second, for $\mathcal{E}=\mathcal{L}_{\ell}$, we reveal a relationship (Claim 2) between the $\mathcal{E}$-histogram constraint in Definition 4 and the changemaking constraint in the statement of the theorem. Finally, we combine the two claims to prove the theorem.

Claim $1\left(\mathcal{D}=\mathcal{L}_{k}\right)$. For any $G \leqslant \mathcal{S}_{\mathcal{A}}$ and any $1 \leq k \leq m$,

$$
\operatorname{FixeD}_{G}\left(\mathcal{L}_{k}\right)=\emptyset \Longleftrightarrow \operatorname{Sizes}(\mathcal{A} / G) \text { contains less than } k \text { 1's }
$$

Proof. We first prove the " $\Leftarrow$ " direction. Suppose $\operatorname{Sizes}(\mathcal{A} / G)$ contains less than $k$ 1's and suppose for the sake of contradiction that $G$ has a fixed point in $R \in \mathcal{L}_{k}$, and suppose $R$ is a linear order over $A \subseteq \mathcal{A}$ with $|A|=k$. Then, for every $a \in A$ and every $\sigma \in G$, we have $\sigma(a)=a$, or in other words, every $a \in A$ is a fixed point of $G$ on $\mathcal{A}$, which means that $\operatorname{Sizes}(\mathcal{A} / G)$ contains at least $k$ 1's (corresponding to the alternatives in $A$ ), which is a contradiction.

The " $\Rightarrow$ " direction proved by proving its contraposition: if $\operatorname{Sizes}(\mathcal{A} / G)$ contains at least $k$ 1's, then $\operatorname{Fixed}_{G}\left(\mathcal{L}_{k}\right) \neq \emptyset$. Let $A \subseteq \mathcal{A}$ denote any set of $k$ alternatives whose
corresponding components in $\operatorname{Sizes}(\mathcal{A} / G)$ are 1's, or equivalently, for every $a \in A$, we have $\left|\operatorname{Orbit}_{G}(a)\right|=1$. Let $R$ denote an arbitrary ranking over $A$. It follows that $R \in \mathcal{L}_{k}$ and for all $\sigma \in G, \sigma(R)=R$, which means that $R$ is a fixed point under $G$ and therefore, $\operatorname{Fixed}_{G}\left(\mathcal{L}_{k}\right) \neq \emptyset$.

For $\mathcal{E}=\mathcal{L}_{\ell}$, the relationship between the $\mathcal{E}$-histogram constraint in Definition 4 and the change-making constraint is weaker than Claim 1, in the sense that the $\Leftarrow$ direction only holds for a special type of permutation groups $G_{\vec{m}}$ defined as follows.
Definition 13. Given any partition $\vec{m}=\left(m_{1}, \ldots, m_{T}\right)$ of $m$, define

$$
\begin{gathered}
\sigma_{\vec{m}} \triangleq(\underbrace{1, \ldots, m_{1}}_{m_{1}})(\underbrace{m_{1}+1, \ldots, m_{1}+m_{2}}_{m_{2}}) \cdots(\underbrace{m-m_{T}+1, \ldots, m}_{m_{T}}) \\
G_{\vec{m}} \triangleq\left\{\left(\sigma_{\vec{m}}\right)^{K}: K \in \mathbb{N}\right\}
\end{gathered}
$$

That is, $\sigma_{\vec{m}}$ consists of cyclic permutations among groups of alternatives whose sizes are $m_{1}, \ldots, m_{T}$, respectively. $G_{\vec{m}}$ is the cyclic group generated by $\sigma_{\vec{m}}$. We have $\left|G_{\vec{m}}\right|=\operatorname{lcm}(\vec{m})$.

Claim $2\left(\mathcal{E}=\mathcal{L}_{\ell}\right)$. For any $G \leqslant \mathcal{S}_{\mathcal{A}}$, any $1 \leq \ell \leq m$, and any partition $\vec{m}$ of $m$,
(i) $\operatorname{FixED}_{G}\left(\mathbb{H}_{m, n}^{\mathcal{L}}\right) \neq \emptyset \Rightarrow n$ is feasible by $\operatorname{Coins}^{\circledast}(\operatorname{Sizes}(\mathcal{A} / G), \ell)$
(ii) $n$ is feasible by $\operatorname{Coins}^{\circledast}(\vec{m}, \ell) \Rightarrow \operatorname{FIXED}_{G_{\vec{m}}}\left(\mathbb{H}_{m, n}^{\mathcal{L}_{\ell}}\right) \neq \emptyset$.

Proof. Part (i). Choose any $\vec{h} \in \operatorname{Fixed}_{G}\left(\mathbb{H}_{m, n}^{\mathcal{L}_{\ell}}\right)$. Let $O_{1}, \ldots, O_{T}$ denote the orbits in $\mathcal{L}_{\ell}$ under $G$ such that each $\ell$-list in each orbit appears at least once in $\vec{h}$. That is,

$$
\forall 1 \leq t \leq T, \forall R \in O_{t},[\vec{h}]_{R}>0
$$

Because $\vec{h}$ is a fixed point of $G$, the $\ell$-lists in the same obit $O_{t}$ appear the same number of times in $\vec{h}$. For every $1 \leq t \leq T$, fix an arbitrary $\ell$-list $R_{t}^{*} \in O_{t}$. We have $\sum_{t=1}^{T}\left|O_{t}\right| \times[\vec{h}]_{R_{t}^{*}}=$ $n$. Therefore, $n$ is feasible by $\left\{\left|O_{1}\right|, \ldots,\left|O_{T}\right|\right\}$.

To prove that $n$ is feasible by $\operatorname{Coins}^{\circledast}(\operatorname{Sizes}(\mathcal{A} / G), \ell)$, it suffices to prove that each number in $\left\{\left|O_{1}\right|, \ldots,\left|O_{T}\right|\right\}$ is coarser than some denomination $\operatorname{lcm}(\operatorname{Sizes}(\mathcal{A} / G) \circledast \vec{\ell})$ in Coins ${ }^{\circledast}(\operatorname{Sizes}(\mathcal{A} / G), \ell)$. That is, we will prove that for every $t \leq T$, there exist a sub-vector $\vec{m}_{t}$ of $\operatorname{Sizes}(\mathcal{A} / G)$ that satisfies
constraint (a): $\vec{m}_{t} \cdot \overrightarrow{1} \geq \ell$,
constraint (b): $\operatorname{lcm}\left(\vec{m}_{t}\right)$ is a divisor of $\left|O_{t}\right|$.
If such $\vec{m}_{t}$ exists, then we let $\vec{\ell}_{t}$ denote an arbitrary partition of $\ell$ whose elements are positive only if they correspond to elements in $\vec{m}_{t}$. It follows that $\operatorname{lcm}\left(\operatorname{Sizes}(\mathcal{A} / G) \circledast \vec{\ell}_{t}\right)$ is a divisor of $\operatorname{lcm}\left(\vec{m}_{t}\right)$, which is a divisor of $\left|O_{t}\right|$.

We explicitly construct $\vec{m}_{t}$ as follows. Let $R_{t} \in O_{t}$ denote an arbitrary $\ell$-list. For every orbit $O$ in $\mathcal{A}$ under $G$, if any alternative in $O$ appears in $R_{t}$, then $\vec{m}_{t}$ has a component $|O|$. More precisely, let $O_{1}^{t}, O_{2}^{t}, \ldots, O_{S}^{t}$ denote the orbits in $\mathcal{A}$ under $G$ that touches $R_{t}$. W.l.o.g., suppose $\left|O_{1}^{t}\right| \geq \cdots \geq\left|O_{S}^{t}\right|$. Then, $\vec{m}_{t}=\left(\left|O_{1}^{t}\right|, \ldots,\left|O_{S}^{t}\right|\right)$.

By construction, $\vec{m}_{t} \cdot \overrightarrow{1}$ is at least the number of alternatives that appear in $R_{t}$, which is $\ell$. This means that $\vec{m}_{t}$ satisfies constraint (a). To see that $\vec{m}_{t}$ satisfies constraint (b),
it suffices to prove that for every $1 \leq s \leq S,\left|O_{s}^{t}\right|$ is a divisor of $\left|O_{t}\right|$. Let $a_{s}$ denote an alternative that appears in both $R_{t}$ and $\left|O_{s}^{t}\right|$. We will prove constraint (b) by applying the orbit-stabilizer theorem (see, e.g., [26, Theorem 2.65]) twice, one to the orbit $O_{s}^{t}$ of $a_{t}$ under $G$ and the other to the orbit $O_{t}$ of $R_{t}$ under $G$.

Orbit-stabilizer theorem. For any $x$ in the set that $G$ acts on,

$$
\begin{equation*}
|G|=\left|\operatorname{StaB}_{G}(x)\right| \times\left|\operatorname{OrBIT}_{G}(x)\right| \tag{7}
\end{equation*}
$$

Notice that $O_{s}^{t}=\operatorname{Orbit}_{G}\left(a_{t}\right)=\left\{g\left(a_{t}\right): g \in G\right\}$ and $\operatorname{Stab}_{G}\left(a_{t}\right)=\left\{g \in G: g\left(a_{t}\right)=a_{t}\right\}$ is the set of stabilizers of $a_{t}$. Therefore, by the orbit-stabilizer theorem, we have $|G|=$ $\left|\operatorname{Stab}_{G}\left(a_{t}\right)\right| \times\left|O_{s}^{t}\right|$. Also notice that $O_{t}=\operatorname{Orbit}_{G}\left(R_{t}\right)$ is the orbit of $R_{t}$ under $G$ and $\operatorname{STAB}_{G}\left(R_{t}\right) \leq G$ is the set of stabilizers of $R_{t}$. Therefore, by the orbit-stabilizer theorem, we have $|G|=\left|\operatorname{StaB}_{G}\left(R_{t}\right)\right| \times\left|O_{t}\right|$. Then,

$$
\begin{equation*}
|G|=\left|\operatorname{StaB}_{G}\left(a_{t}\right)\right| \times\left|O_{s}^{t}\right|=\left|\operatorname{StaB}_{G}\left(R_{t}\right)\right| \times\left|O_{t}\right| \tag{8}
\end{equation*}
$$

Notice that any stabilizer $\sigma \in \operatorname{StaB}_{G}\left(R_{t}\right)$ maps every alternative that appear in $R_{t}$, particularly $a_{t}$, to itself. Therefore, $\sigma \in \operatorname{StaB}_{G}\left(a_{t}\right)$, which means that $\operatorname{StaB}_{G}\left(R_{t}\right)$ is a subgroup of $\operatorname{StaB}_{G}\left(a_{t}\right)$. By Lagrange's theorem, $\left|\operatorname{StaB}_{G}\left(R_{t}\right)\right|$ is a divisor of $\operatorname{StaB}_{G}\left(a_{t}\right)$. This observation, combined with (8), implies that $\left|O_{s}^{t}\right|$ is a divisor of $\left|O_{t}\right|$. Therefore, $\vec{m}_{t}$ satisfies constraint (b).

Part (ii). We will explicitly construct a profile $P \in\left(\mathcal{L}_{\ell}\right)^{n}$ whose histogram is a fixed point of $G_{\vec{m}}$. Let $\vec{m}=\left(m_{1}, \ldots, m_{T}\right)$ be the partition of $m$ such that $n$ is feasible by Coins $^{\circledast}(\vec{m}, \ell)$. Let $\mathcal{A}=A_{1} \cup A_{2} \cdots \cup A_{T}$ denote a partition of $\mathcal{A}$ such that for every $t \leq T$, $\left|A_{t}\right|=m_{t}$. Moreover, let $\vec{\ell}_{1}, \ldots, \vec{\ell}_{S}$ be non-negative partitions of $\ell$ such that $n$ is feasible by $\left\{\operatorname{lcm}\left(\vec{m} \circledast \vec{\ell}_{s}\right): s \leq S\right\}$. More precisely, let $\alpha_{1}, \ldots, \alpha_{S}$ be non-negative integers such that $n=\sum_{s=1}^{S} \alpha_{s} \cdot \operatorname{lcm}\left(\vec{m} \circledast \vec{\ell}_{s}\right)$.

Next, we define the $\ell$-lists that will be used to construct the profile $P$. For every $s \leq S$, let $R_{s}$ denote an arbitrary $\ell$-list over an arbitrary subset of $\ell$ alternatives of

$$
\begin{equation*}
\bigcup_{t \leq T:\left[\vec{\ell}_{s}\right]_{t} \neq 0} A_{t} \tag{9}
\end{equation*}
$$

That is, $R_{s}$ involves alternatives in the union of $A_{t}$ 's for all $t$ such that the $t$-th element of $\vec{\ell}_{s}$ is strictly positive. $R_{s}$ is well-defined, because $\vec{\ell}_{s} \cdot \overrightarrow{1}=\ell$ and $\vec{\ell}_{s} \leq \vec{m}$.

Consider the orbits of $R_{1}, \ldots, R_{S}$ under $G_{\vec{m}}$. It follows that for every $s \leq S,\left|\operatorname{OrBIT}_{G_{\vec{m}}}\left(R_{s}\right)\right|$ divides $\operatorname{lcm}\left(\vec{m} \circledast \vec{\ell}_{s}\right)$, because for every alternative $a$ in (9), suppose $a \in A_{t}$, then we have $\left(\sigma_{\vec{m}}\right)^{\left|A_{t}\right|}(a)=a$. Notice that $\left|A_{t}\right|$ divides $\operatorname{lcm}\left(\vec{m} \circledast \vec{\ell}_{s}\right)$. Therefore, $\left(\sigma_{\vec{m}}\right)^{\operatorname{lcm}\left(\vec{m} \circledast \vec{\ell}_{s}\right)}(a)=a$, which means that $\left(\sigma_{\vec{m}}\right)^{1 \mathrm{~cm}\left(\vec{m} \circledast \vec{\ell}_{s}\right)}\left(R_{s}\right)=R_{s}$.

Finally, we define the following profile

$$
P \triangleq \bigcup_{s=1}^{S}\left(\alpha_{s} \cdot \frac{\operatorname{lcm}\left(\vec{m} \circledast \vec{\ell}_{s}\right)}{\left|\operatorname{OrBIT}_{G_{\vec{m}}}\left(R_{s}\right)\right|}\right) \times \operatorname{ORBIT}_{G_{\vec{m}}}\left(R_{s}\right)
$$

Example 14. Let $m=5, n=7, \ell=2, \vec{m}=(3,2), \vec{\ell}_{1}=(2,0)$ and $\vec{\ell}_{2}=(0,2)$. Then, $n=7=\operatorname{lcm}\left(\vec{m} \circledast \vec{\ell}_{1}\right)+2 \times \operatorname{lcm}\left(\vec{m} \circledast \vec{\ell}_{1}\right) . \sigma_{\vec{m}}=(1,2,3)(4,5)$, and we can let
$\mathcal{A}=\underbrace{\{1,2,3\}}_{A_{1}} \cup \underbrace{\{4,5\}}_{A_{2}}, R_{1}=[1 \succ 2]$ and $R_{2}=[4 \succ 5]$. Then, $\operatorname{OrBIT}_{G_{\vec{m}}}\left(R_{1}\right)=\{1 \succ 2,2 \succ$ $3,3 \succ 1\}$ and $\operatorname{ORBIT}_{G_{\vec{m}}}\left(R_{2}\right)=\{4 \succ 5,5 \succ 4\} . P=\{1 \succ 2,2 \succ 3,3 \succ 1\} \cup 2 \times\{4 \succ 5,5 \succ$ $4\}$.

Then, for every $s \leq S$ and every $\sigma \in G_{\vec{m}}, \operatorname{Hist}\left(\sigma\left(\operatorname{Orbit}_{G_{\vec{m}}}\left(R_{s}\right)\right)\right)=\operatorname{Hist}\left(\operatorname{OrBit}_{G_{\vec{m}}}\left(R_{s}\right)\right)$. Therefore, $\operatorname{Hist}(P)$ is a fixed point of $G_{\vec{m}}$, which completes the proof.

We are now ready to prove the $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{\ell}, \mathcal{L}_{k}\right)$ case of Theorem 1 by combining Claim 1 and Claim 2. To prove the "if" direction, suppose there exists a partition $\vec{m}$ of $m$ that satisfies the sub-vector constraint and the change-making constraint. Notice that $\operatorname{Sizes}\left(\mathcal{A} / G_{\vec{m}}\right)=\vec{m}$. Therefore, we have $\operatorname{FixED}_{G_{\vec{m}}}\left(\mathcal{L}_{k}\right)=\emptyset$ (the $\Leftarrow$ part of Claim 1) and $\operatorname{FIXED}_{G_{\vec{m}}}\left(\mathbb{H}_{m, n}^{\mathcal{L}_{\ell}}\right) \neq \emptyset$ (part (ii) of Claim 2). This means that there exists a permutation group (i.e., $G_{\vec{m}}$ ) that satisfies both constraints in Definition 4, which implies the ANR impossibility according to Lemma 2. To prove the "only if" direction, suppose the ANR impossibility holds. Then, by Lemma 2, there exists a permutation group $G$ that satisfies both constraints in Definition 4. Then, $\operatorname{Sizes}(\mathcal{A} / G)$, which is a partition of $m$, satisfies the sub-vector constraint (the $\Rightarrow$ part of Claim 1) and the change-making constraint (part (i) of Claim 2).

Step 3: Other $(\mathcal{E}, \mathcal{D})$ settings. For $\mathcal{E}=\mathcal{M}_{\ell}$ and $\mathcal{D}=\mathcal{M}_{k}$, we prove the following counterparts to Claim 1 and Claim 2, respectively.

Claim $3\left(\mathcal{D}=\mathcal{M}_{\boldsymbol{k}}\right)$. For any $G \leqslant \mathcal{S}_{\mathcal{A}}$ and any $1 \leq k \leq m$,

$$
\operatorname{Fixed}_{G}\left(\mathcal{M}_{k}\right)=\emptyset \Longleftrightarrow \operatorname{Sizes}(\mathcal{A} / G) \text { has no sub-vector that sum up to } k
$$

Claim $4\left(\mathcal{E}=\mathcal{M}_{\ell}\right)$. For any $G \leq \mathcal{S}_{\mathcal{A}}$, any $1 \leq \ell \leq m$, and any partition $\vec{m}$ of $m$,
(i) $\operatorname{Fixed}_{G}\left(\mathbb{H}_{m, n}^{\mathcal{M}}\right) \neq \emptyset \Rightarrow n$ is feasible by $\operatorname{Coins}^{\ominus}(\operatorname{Sizes}(\mathcal{A} / G), \ell)$
(ii) $n$ is feasible by $\operatorname{Coins}^{\ominus}(\vec{m}, \ell) \Rightarrow \operatorname{FIXED}_{G_{\vec{m}}}\left(\mathbb{H}_{m, n}^{\mathcal{M}}\right) \neq \emptyset$.

The proof of Claim 3 is similar to the proof of Claim 1 while the proof of Claim 4 is more complicated and involves multiple novel applications of the orbits-stabilizer theorem. The full proofs can be found in Appendix C. 3 and Appendix C.4, respectively. Then, other $(\mathcal{E}, \mathcal{D})$ settings in Theorem 1 are proved in a similar way as the $\left(\mathcal{L}_{\ell}, \mathcal{L}_{k}\right)$ case, using combinations of Claims 1, 2, 3, and 4 shown in the following table.

| Proved by | $\mathcal{D}$ | $\mathcal{L}_{k}$ | $\mathcal{M}_{k}$ |
| :---: | :---: | :---: | :---: |
| $\mathcal{E}$ | Claims 2\&1 | Claims 2\&3 |  |
| $\mathcal{L}_{\ell}$ | Claims 4\&1 | Claims 4\&3 |  |
| $\mathcal{M}_{\ell}$ |  |  |  |

## C. 3 Proof of Claim 3

Claim 3. $\left(\mathcal{D}=\mathcal{M}_{\boldsymbol{k}}\right)$. For any $G \leqslant \mathcal{S}_{\mathcal{A}}$ and any $1 \leq k \leq m$,

$$
\operatorname{Fixed}_{G}\left(\mathcal{M}_{k}\right)=\emptyset \Longleftrightarrow \operatorname{Sizes}(\mathcal{A} / G) \text { has no sub-vector that sum up to } k
$$

Proof. We first prove the " $\Leftarrow$ " direction. Suppose $\operatorname{Sizes}(\mathcal{A} / G)$ does not contain a sub-vector whose elements sum up to $k$. Suppose for the sake of contradiction that $G$ has a fixed point in $\mathcal{M}_{k}$, denoted by $A \subseteq \mathcal{A}$ with $|A|=k$. Because $A$ cannot be represented as the union of multiple orbits of $G$ in $\mathcal{A}$, there exists $a \in A$ and $\sigma \in G$ such that $\sigma(a) \notin A$. It follows that $\sigma(A) \neq A$, which is a contradiction.

Next, we prove the prove the " $\Rightarrow$ " direction by proving its contraposition: if $\operatorname{Sizes}(\mathcal{A} / G)$ has a sub-vector whose elements sum up to $k$, then $\operatorname{Fixed}_{G}\left(\mathcal{M}_{k}\right) \neq \emptyset$. Let $A \subseteq \mathcal{A}$ denote the union of alternatives that correspond to the components of the sub-vector. Notice that for any $a \in \mathcal{A}$ and any $\sigma \in G$, we have $\sigma(a) \in \operatorname{Orbit}_{G}(a)$. Therefore, $\sigma(A)=A$, which means that $G$ has a fixed point in $\mathcal{M}_{k}$.

## C. 4 Proof of Claim 4

Claim 4. $\left(\mathcal{E}=\mathcal{M}_{\ell}\right)$. For any $G \leqslant \mathcal{S}_{\mathcal{A}}$, any $1 \leq \ell \leq m$, and any partition $\vec{m}$ of $m$,
(i) $\operatorname{Fixed}_{G}\left(\mathbb{H}_{m, n}^{\mathcal{M}}\right) \neq \emptyset \Rightarrow n$ is feasible by $\operatorname{Coins}^{\ominus}(\operatorname{Sizes}(\mathcal{A} / G), \ell)$
(ii) $n$ is feasible by $\operatorname{Coins}^{\ominus}(\vec{m}, \ell) \Rightarrow \operatorname{FIXED}_{G_{\vec{m}}}\left(\mathbb{H}_{m, n}^{\mathcal{M}}\right) \neq \emptyset$.

Proof. Proof of part (i) of Claim 4. Suppose $G$ has a fixed point in $\mathbb{H}_{m, n}^{\mathcal{E}}$, denoted by $\vec{h}$. Let $O_{1}^{\mathcal{M}_{\ell}}, \ldots, O_{T}^{\mathcal{M}_{\ell}}$ denote the orbits in $\mathcal{M}_{\ell}$ under $G$ such that each $\ell$-committee in each orbit appears at least once in $\vec{h}$, that is,

$$
\forall 1 \leq t \leq T, \forall R \in O_{t}^{\mathcal{M}_{\ell}},[\vec{h}]_{R}>0
$$

We note that $O_{1}^{\mathcal{M}_{\ell}}, \ldots, O_{T}^{\mathcal{M}_{\ell}}$ may not be a partition of $\mathcal{M}_{\ell}$, because some $\ell$-committees may not appear in $\vec{h}$. Because $\vec{h}$ is a fixed point of $G$ in $\mathbb{H}_{m, n}^{\mathcal{E}}$, the $\ell$-committees in the same obit $O_{t}^{\mathcal{M}_{\ell}}$ appear for the same number of times in $\vec{h}$. For every $1 \leq t \leq T$, fix an arbitrary committee $A_{t} \in O_{t}^{\mathcal{M}_{\ell}}$. We have $\sum_{t=1}^{T}\left|O_{t}^{\mathcal{M}_{\ell}}\right| \times[\vec{h}]_{R_{t}}=n$. Therefore,

$$
n \in \operatorname{Feas}\left(\left|O_{1}^{\mathcal{M}_{\ell}}\right|, \ldots,\left|O_{T}^{\mathcal{M}_{\ell}}\right|\right)
$$

Let $O_{1}^{\mathcal{A}}, O_{2}^{\mathcal{A}}, \ldots, O_{S}^{\mathcal{A}}$ denote the orbits in $\mathcal{A} / G$ in the non-decreasing order w.r.t. their sizes, which means that $\operatorname{Sizes}(\mathcal{A} / G)=\left(\left|O_{1}^{\mathcal{A}}\right|, \ldots,\left|O_{S}^{\mathcal{A}}\right|\right)$. To prove $\operatorname{Sizes}(\mathcal{A} / G) \in \mathcal{E} \mathcal{M}_{\ell}(m, n)$, it suffices to prove that for every $1 \leq t \leq T$, there exists a partition $\vec{\ell}$ of $\ell$ such that $\operatorname{lcm}(\operatorname{Sizes}(\mathcal{A} / G) \oslash \vec{\ell})$ is a divisor of $\left|O_{t}^{\mathcal{M}_{\ell}}\right|$. We explicitly construct $\vec{\ell}$ as follows.

$$
\vec{\ell} \triangleq\left(\left|O_{1}^{\mathcal{A}} \cap A_{t}\right|, \ldots,\left|O_{S}^{\mathcal{A}} \cap A_{t}\right|\right)
$$

It is not hard to verify that $\vec{\ell}$ is a partition of $\ell$. Next, we prove

$$
\begin{equation*}
\forall 1 \leq t \leq T, 1 \leq s \leq S, \frac{\operatorname{lcm}\left([\operatorname{Sizes}(\mathcal{A} / G)]_{s},[\vec{\ell}]_{s}\right)}{[\vec{\ell}]_{s}} \text { is a divisor of }\left|O_{t}^{\mathcal{M}_{\ell}}\right| \tag{10}
\end{equation*}
$$

To prove (10), we first prove the following claim.
Claim 5. For any $G \leq \mathcal{S}_{\mathcal{A}}$, any $1 \leq \ell \leq m$, any $A \in \mathcal{M}_{\ell}$, and any orbit $O \in \mathcal{A} / G$ with $O \cap A \neq \emptyset$,

$$
\frac{\operatorname{lcm}(|O|,|O \cap A|)}{|O \cap A|} \text { is a divisor of }\left|\operatorname{OrBIT}_{G}^{\mathcal{M}}(A)\right|
$$

Proof. To simplify notation, we let $A^{*} \triangleq O \cap A, \ell^{*} \triangleq\left|A^{*}\right|$, and $m^{*} \triangleq|O|$. Claim 10 follows after the following two observations:

$$
\begin{equation*}
\frac{\operatorname{lcm}\left(m^{*}, \ell^{*}\right)}{\ell^{*}} \text { is a divisor of }\left|\operatorname{OrBIT}_{G}^{\mathcal{M}_{\ell^{*}}}\left(A^{*}\right)\right|, \tag{11}
\end{equation*}
$$

and

$$
\begin{equation*}
\left|\operatorname{OrBIT}_{G}^{\mathcal{M}_{\ell^{*}}}\left(A^{*}\right)\right| \text { is a divisor of }\left|\operatorname{OrBiT}_{G}^{\mathcal{M}_{\ell}}(A)\right| \tag{12}
\end{equation*}
$$

Notice that (11) is equivalent to $m^{*}$ being a divisor of $\ell^{*} \times\left|\operatorname{OrBIT}_{G}^{\mathcal{M}_{\ell^{*}}}\left(A^{*}\right)\right|$. Also notice that $\ell^{*} \times\left|\operatorname{OrBit}_{G}^{\mathcal{M}_{\ell^{*}}}\left(A^{*}\right)\right|$ is the size of the multi-set that consists of all alternatives in all $\ell^{*}$-committees in the orbit of $A^{*}$ under $G$. That is,

$$
\hat{M} \triangleq \bigcup \operatorname{OrBiT}_{G}^{\mathcal{M}_{\ell^{*}}}\left(A^{*}\right)
$$

The hat on $\hat{M}$ indicates that it is a multi-set. Therefore, it suffices to prove that every alternative $a \in O$ appears the same number of times in $\hat{M}$. In fact, because $\operatorname{OrBIT}_{G}^{\mathcal{M}}{ }^{\ell^{*}}\left(A^{*}\right)$ is a subgroup of $G, G$ can be partitioned to $\frac{|G|}{\left|\operatorname{Orbit~}_{G}^{\mathcal{M}^{*}}\left(A^{*}\right)\right|}$ left cosets of $\operatorname{Orbit}_{G}^{\mathcal{M}_{\ell^{*}}}\left(A^{*}\right)$, and every $B \in \operatorname{OrBit}_{G}^{\mathcal{\mathcal { L } ^ { * }}}\left(A^{*}\right)$ is the image of a left cosets of $\operatorname{OrBIT}_{G}^{\mathcal{M}}{ }_{\ell^{*}}\left(A^{*}\right)$ on $A^{*}$. Let $\hat{M}^{*} \triangleq \bigcup_{\sigma \in G} \sigma\left(A^{*}\right)$ denote the multi-set that consists of all alternatives in the imagines of $A^{*}$ under $G$, we have

$$
\hat{M}^{*}=\left|\operatorname{STAB}_{G}^{\mathcal{M}_{\ell^{*}}}\left(A^{*}\right)\right| \times \hat{M}
$$

Viewing $\hat{M}^{*}$ as $\bigcup_{a \in A^{*}} G(a)$, we note that for every $a \in A^{*}, G(a)=O$ (because $O \in \mathcal{A} / G$ ). Therefore, $\hat{M}^{*}=\left|A^{*}\right| \times O$, which means that each alternative $a \in O$ appears the same number of times. It follows that each alternative $a \in O$ appears the same number of times in $\hat{M}$ as well, which proves (11).

Next, we prove (12). Notice that for any $\sigma \in G$, if $\sigma(A)=A$, then we must have $\sigma\left(A^{*}\right)=A^{*}$, because only alternatives in $O$ can be mapped to $O$ by permutations in $G$. Therefore, $\operatorname{STAB}_{G}^{\mathcal{M}_{\ell}}(A)$ is a subgroup of $\operatorname{STAB}_{G}^{\mathcal{M}_{\ell^{*}}}\left(A^{*}\right)$. It follows from Lagrange's theorem that $\left|\operatorname{StaB}_{G}^{\mathcal{M}_{\ell}}(A)\right|$ is a divisor of $\left|\operatorname{StaB}_{G}^{\mathcal{M}_{\ell^{*}}}\left(A^{*}\right)\right|$. Meanwhile, the orbit-stabilizer theorem (applied to $\mathcal{M}_{\ell^{*}}$ and $\mathcal{M}_{\ell}$ ) gives us

$$
|G|=\left|\operatorname{OrBiT}_{G}^{\mathcal{M}_{\ell^{*}}}\left(A^{*}\right)\right| \times\left|\operatorname{StaB}_{G}^{\mathcal{M}_{\ell^{*}}}\left(A^{*}\right)\right|=\left|\operatorname{OrBIT}_{G}^{\mathcal{M}_{\ell}}(A)\right| \times\left|\operatorname{Stab}_{G}^{\mathcal{M}_{\ell}}(A)\right|,
$$

which implies (12) and completes the proof of Claim 5.
(10) then follows after the applications of Claim 5 to $O=O_{s}^{\mathcal{A}}$ and $A=A_{t}$ for all $1 \leq t \leq T, 1 \leq s \leq S$. This completes the proof of part (i) of Claim 4.
Proof of part (ii) of Claim 4. Let $\vec{m}=\left(m_{1}, \ldots, m_{S}\right)$ denote a partition of $m$ such that $n$ is feasible by $\operatorname{Coins}^{\ominus}(\vec{m}, \ell)$. We will explicitly construct a permutation group $G_{\vec{m}}^{*}$ and prove that it satisfies the desired properties.

Suppose $\operatorname{lcm}(\vec{m})=\operatorname{lcm}\left(m_{1}, \ldots, m_{S}\right)=p_{1}^{q_{1}^{\max }} \times p_{2}^{q_{2}^{\max }} \times \cdots p_{T}^{q_{\text {max }}}$, where $p_{1}, \ldots, p_{T}$ are different prime numbers and for every $1 \leq s \leq S, q_{s}^{\max } \in \mathbb{N}$. Let $\vec{p} \triangleq\left(p_{1}, \ldots, p_{S}\right)$ and for every $\vec{q}=\left(q_{1}, \ldots, q_{S}\right) \in \mathbb{Z}_{\geq 0}^{S}$, define

$$
\vec{p}^{\vec{q}} \triangleq p_{1}^{q_{1}} \times p_{2}^{q_{2}} \times \cdots p_{S}^{q_{S}}
$$

Using this notation, we have $\operatorname{lcm}(\vec{m})=\vec{p}^{\vec{q}^{\max }}$, where $\vec{q}^{\max }=\left(q_{1}^{\max }, \ldots, q_{T}^{\max }\right)$. For any $1 \leq s \leq S$, let

$$
m_{s}=\vec{p}^{\vec{q}^{s}} \text { and } \operatorname{gcd}\left(d_{s}, d_{s}^{\prime}\right)=\vec{p}^{\vec{q}^{*}}
$$

where $\vec{q}^{s}=\left(q_{1}^{s}, \ldots, q_{T}^{s}\right) \in \mathbb{Z}_{\geq 0}^{T}$ and $\vec{q}^{* *}=\left(q_{1}^{s *}, \ldots, q_{T}^{s *}\right) \in \mathbb{Z}_{\geq 0}^{T}$. It follows that for all $t \leq T$, $q_{t}^{\max }=\max _{s \leq S}\left\{q_{g}^{s}\right\}$.
Definition $14\left(\mathcal{M}_{\vec{m}}\right)$. Given $\vec{m}$ with $\operatorname{lcm}(\vec{n})=p_{1}^{q_{1}^{\max }} \times p_{2}^{q_{2}^{\max }} \times \cdots p_{T}^{q_{T}^{\max }}$, define $\mathcal{M}_{\vec{m}}=$ $\bigcup_{s=1}^{S} A_{s} \subseteq \mathbb{Z}_{\geq 0}^{q_{1}+\cdots+q_{T}+1}$, where

$$
A_{s} \triangleq\{s\} \times \prod_{t=1}^{T}\left(\left\{0, \ldots, p_{t}-1\right\}^{q_{t}^{s}} \times\{0\}^{q_{t}-q_{t}^{s}}\right)
$$

Example 15. Let $m=14$ and $\vec{m}=(8,6)$. That is, $S=2$. We have $\operatorname{lcm}(\vec{m})=2^{3} \times 3=$ $(2,3)^{(3,1)}$, i.e., $T=2, p_{1}=2, q_{1}^{\max }=3, p_{2}=1, q_{2}^{\max }=1$. Because $m_{1}=8=2^{3} \times 3^{0}$ and $m_{2}=6=2^{1} \times 3^{1}$, we have $\mathcal{M}_{(8,6)}=A_{1} \cup A_{2}$ defined as follows.

Definition $15\left(\boldsymbol{G}_{\overrightarrow{\boldsymbol{m}}}^{*}\right)$. Given $\vec{m}$ with $\operatorname{lcm}(\vec{m})=p_{1}^{q_{1}^{\max }} \times p_{2}^{q_{2}^{\max }} \times \cdots p_{T}^{q_{T}^{\max }}$, define

$$
G_{\vec{m}}^{*} \triangleq\left\{\sigma_{\vec{p}}: \vec{p} \in\{0\} \times \prod_{t=1}^{T}\left\{0, \ldots, p_{t}-1\right\}^{q_{t}^{\max }}\right\}
$$

For any $\sigma_{\vec{\beta}_{1}}, \sigma_{\vec{\beta}_{2}} \in G_{\vec{m}}^{*}$, we define $\sigma_{\vec{\beta}_{1}} \circ \sigma_{\vec{\beta}_{2}} \triangleq \sigma_{\vec{\beta}_{1}+\vec{\beta}_{2}} \bmod \vec{p}^{*}$, where $\vec{p}^{*}=(S+1, \underbrace{p_{1}, \ldots, p_{1}}_{q_{1}^{\max }}, \ldots, \underbrace{p_{T}, \ldots, p_{T}}_{q_{T}^{\max }})$ and $\bmod$ is the coordinate-wise modular arithmetic.

Definition $16\left(\boldsymbol{G}_{\vec{m}}^{*}\right.$ acting on $\left.\mathcal{M}_{\vec{m}}\right)$. For any $\sigma_{\vec{p}} \in G_{\vec{m}}^{*}$ and any $\vec{p}^{\prime} \in \mathcal{M}_{\vec{m}}$, we define $\sigma_{\vec{p}}\left(\vec{p}^{\prime}\right) \triangleq \vec{p}^{\prime}+\vec{p} \bmod \vec{p}^{s *}$, where

$$
\vec{p}^{s *} \triangleq\{S+1\} \times \prod_{t=1}^{T}\left(\left\{p_{t}-1\right\}^{q_{t}^{s}} \times\{0\}^{q_{t}-q_{t}^{s}}\right)
$$

Example 16. Continuing the setting of Example 15, we have $\vec{p}^{*}=(3,2,2,2,3), \vec{p}^{1 *}=$ $(3,2,2,2,1)$, and $\vec{p}^{2 *}=(3,2,1,1,3)$.

$$
\begin{array}{cc}
\sigma_{(0,1,1,1,2)} \circ \sigma_{(0,1,1,1,2)}=\sigma_{(0,2,2,2,4)} & \bmod \vec{p}^{*}=\sigma_{(0,0,0,0,1)} \\
\sigma_{(0,1,1,1,2)}(1,1,0,0,0)=(1,2,1,1,2) & \bmod \vec{p}^{1 *}=(1,0,1,1,0) \\
\sigma_{(0,1,1,1,2)}(2,1,0,0,0)=(2,2,1,1,2) & \bmod \vec{p}^{2 *}=(2,0,0,0,2)
\end{array}
$$

It is not hard to verify that $\left|\mathcal{M}_{\vec{m}} / G_{\vec{m}}^{*}\right|=\operatorname{lcm}(\vec{d})$ and $\mathcal{M}_{\vec{m}} / G_{\vec{m}}^{*}=\left\{O_{1}^{\mathcal{M}_{\vec{m}}}, \ldots, O_{S}^{\mathcal{M}}\right\}$, which means that $\operatorname{Sizes}\left(\mathcal{A} / G_{\vec{m}}^{*}\right)=\vec{m}$.

Let $\mathcal{M}_{\vec{m}, \ell}$ denote the set of all $\ell$-committees of $\mathcal{M}_{\vec{m}}$. We use the following claim to construct a fixed point of $G_{\vec{m}}^{*}$ in $\mathbb{H}_{m, n}^{\mathcal{M}_{\vec{m}}, \ell}$.

Claim 6. Let $\mathcal{M}_{\vec{m}}$ be defined as in Definition 14. For any $\vec{\ell}=\left(\ell_{1}, \ldots, \ell_{S}\right) \in \mathbb{Z}_{\geq 0}^{S}$ that is a partition of $\ell$ such that $\vec{\ell} \leq \vec{m}$, there exists $A \in \mathcal{M}_{\vec{m}, \ell}$ such that for every $1 \leq s \leq S$, $\left|A \cap O_{s}^{\mathcal{M}} \vec{m}\right|=\ell_{s}$ and $\left|\operatorname{ORBIT}_{G}^{\mathcal{M}, \ell}(A)\right|=\operatorname{lcm}(\vec{m} \oslash \vec{\ell})$.

Proof. For every $1 \leq s \leq S$ such that $d_{s}^{\prime}>0$, let

$$
\operatorname{gcd}\left(d_{s}, d_{s}^{\prime}\right)=p_{1}^{q_{1}^{s *}} \times p_{2}^{q_{2}^{s *}} \times \cdots \times p_{T}^{q_{T}^{s *}}
$$

where $\left(q_{1}^{s *}, \ldots, q_{T}^{s *}\right) \in \mathbb{Z}_{\geq 0}^{T}$. Define

$$
\vec{\Delta}^{s} \triangleq\left(\Delta_{1}^{s}, \ldots, \Delta_{T}^{s}\right)=\vec{q}^{s}-\vec{q}^{s *} \text { and } \vec{\Delta}^{\max } \triangleq\left(\max _{s \leq S}\left\{\Delta_{1}^{s}\right\}, \ldots, \max _{s \leq S}\left\{\Delta_{T}^{s}\right\}\right)
$$

Then, we have

$$
\frac{\operatorname{lcm}\left(m_{s}, \ell_{s}\right)}{\ell_{s}}=\frac{m_{s}}{\operatorname{gcd}\left(m_{s}, \ell_{s}\right)}=\vec{p}^{\vec{\Delta}^{s}},
$$

which means that

$$
\begin{equation*}
\operatorname{lcm}(\vec{m} \oslash \vec{\ell})=\operatorname{lcm}\left(\left\{\frac{m_{s}}{\operatorname{gcd}\left(m_{s}, \ell_{s}\right)}: s \leq S\right\}\right)=\vec{p}^{\vec{\Delta}^{\max }} \tag{13}
\end{equation*}
$$

For every $1 \leq t \leq T$, define $A_{s}^{t} \triangleq\left\{0, \ldots, p_{t}-1\right\}^{\Delta_{t}^{s}}$ to be the first $\Delta_{t}^{s}$ "free" coordinates for $p_{t}$ and define $B_{s}^{t}$ denote the remaining coordinates for $p_{t}$. That is, we can represent $A_{s}$ as follows.

$$
A_{s}=\{s\} \times \prod_{t=1}^{T}(\underbrace{\left\{0, \ldots, p_{t}-1\right\}^{\Delta_{t}^{s}}}_{A_{s}^{t}} \times \underbrace{\left\{0, \ldots, p_{t}-1\right\}^{q_{t}^{s *}} \times\{0\}^{q_{t}-q_{t}^{s}}}_{B_{s}^{t}})
$$

Fix $A_{s}^{\prime} \subseteq \prod_{t=1}^{T} A_{s}^{t}$ to be an arbitrary set with $\left|A_{s}^{\prime}\right|=\frac{\ell_{s}}{\operatorname{gcd}\left(m_{s}, \ell_{s}\right)}$. We define $A_{s}^{*} \subseteq A_{s}$ to be the extension of $A_{s}^{\prime}$ such that the coordinates not appear in $A_{s}^{\prime}$ take all combinations of values. Formally,

$$
A_{s}^{*} \triangleq\left\{\{s\} \times \prod_{t=1}^{T}\left(\left.\vec{a}\right|_{A_{s}^{t}}, \vec{b}\right): \vec{a} \in A_{s}^{\prime}, \vec{b} \in B_{s}^{t}\right\},
$$

where $\left.\vec{a}\right|_{A_{s}^{t}}$ is the $A_{s}^{t}$ components of $\vec{a}$. Then we define $A \triangleq \bigcup_{s=1}^{S} A_{s}^{*}$ and define the following set of permutations in $G_{\vec{m}}^{*}$.

$$
G \triangleq\left\{\sigma_{\vec{p}}: \vec{p} \in\{0\} \times \prod_{t=1}^{T}\left(\{0\}^{\Delta_{t}^{\max }} \times\left\{0, \ldots, p_{t}-1\right\}^{q_{t}-\Delta_{t}^{\max }}\right)\right\}
$$

Example 17. Continuing the setting of Example 16, we let $\vec{d}^{\prime}=(6,4)$, which means that $\operatorname{gcd}\left(d_{1}, d_{1}^{\prime}\right)=2=2^{1} \times 3^{0}$ and $\operatorname{gcd}\left(d_{2}, d_{2}^{\prime}\right)=2=2^{1} \times 3^{0}$. Therefore,

$$
\begin{aligned}
& \vec{\Delta}^{1}=(3,0)-(1,0)=(2,0), \vec{\Delta}^{2}=(1,1)-(1,0)=(0,1), \text { and } \vec{\Delta}^{\max }=(2,1) \\
& A_{1}=\{1\} \times \underbrace{\{0,1\} \times\{0,1\}}_{A_{1}^{1}} \times \underbrace{\{0,1\}}_{B_{1}^{1}} \times \underbrace{\{0\}}_{B_{1}^{2}} \\
& A_{2}=\{2\} \times \underbrace{\{0,1\} \times\{0\} \times\{0\}}_{B_{1}^{1}} \times \underbrace{\{0,1,2\}}_{A_{1}^{2}}
\end{aligned}
$$

Let $A_{1}^{\prime}=\{(0,0),(0,1),(1,0)\}$ and $A_{2}^{\prime}=\{0,1\}$. We have

$$
\begin{aligned}
A_{1}^{*} & =\{1\} \times\{(0,0),(0,1),(1,0)\} \times\{0,1\} \times\{0\} \\
A_{2}^{*} & =\{2\} \times\{0,1\} \times\{0\} \times\{0\} \times\{0,1\} \\
G & =\left\{\sigma_{\vec{p}}: \vec{p} \in\{0\} \times\{0\} \times\{0\} \times\{0,1\} \times\{0\}\right\}
\end{aligned}
$$

It follows that for every $\sigma \in G$ and every $s \leq S$, we have $\sigma\left(A_{s}^{*}\right)=A_{s}^{*}$. Therefore, $\sigma$ is a stabilizer of $A$ in $G_{\vec{m}}^{*}$, which means that

$$
\left|\operatorname{STAB}_{G_{m}^{*}}^{\mathcal{M}_{\vec{m}}, \ell}(A)\right| \geq|G|=\prod_{t=1}^{T} p_{t}^{q_{t}-\Delta_{t}^{\max }}=\frac{\vec{p}^{\vec{q}^{\max }}}{\vec{p}^{\vec{\Delta}^{\max }}}=\frac{\left|G_{\vec{m}}^{*}\right|}{\operatorname{lcm}\left(\left\{\frac{\operatorname{lcm}\left(m_{s}, \ell_{s}\right)}{\ell_{s}}: s \leq S\right\}\right)}
$$

The last equation follows after (13). Therefore, following the orbit-stabilizer theorem, we have

$$
\begin{equation*}
\left|\operatorname{OrBIT}_{G_{\vec{m}}^{*}}^{\mathcal{M}_{\vec{m}, \ell}}(A)\right|=\frac{\left|G_{\overrightarrow{\vec{m}}}^{*}\right|}{\left|\operatorname{STAB}_{G_{\vec{m}}^{*}, \ell}^{\mathcal{M}_{\vec{m}}}(A)\right|} \leq \operatorname{lcm}(\vec{m} \oslash \vec{\ell}) \tag{14}
\end{equation*}
$$

Claim 6 follows after (14) and Claim 5.
Back to the proof for the second part of Claim 4, suppose $n=\sum_{w=1}^{W} n_{w} \times \operatorname{lcm}\left(\vec{m} \oslash \vec{\ell}^{w}\right)$. Let $A^{1}, \ldots, A^{W} \in \mathcal{M}_{\vec{m}, \ell}$ denote the $\ell$-committees guaranteed by Claim 6 applied to $\mathcal{M}_{\vec{m}}$ (Definition 14), $G_{\vec{m}}^{*}$ (Definition 15), and $\vec{\ell}^{1}, \ldots, \vec{\ell}^{W}$, respectively. Let

$$
P_{\vec{d}} \triangleq \bigcup_{w=1}^{W} n_{w} \times \operatorname{ORBIT}_{G_{\vec{m}}^{*}}^{\mathcal{M}_{\vec{m}, \ell}}\left(A^{w}\right)
$$

Because for every $w \leq W$ and every $\sigma \in G_{\vec{m}}^{*}, \sigma\left(\operatorname{OrBIT}_{G_{\vec{m}}}^{\mathcal{M}_{\vec{m}}, \ell}\right)=\operatorname{ORBIT}_{G_{\vec{m}}^{*}}^{\mathcal{M}_{\vec{m}}^{*}, \ell}$, we have $\operatorname{Hist}\left(\sigma\left(P_{\vec{d}}\right)\right)=\operatorname{Hist}\left(P_{\vec{d}}\right)$, which means that $\operatorname{Hist}\left(\sigma\left(P_{\vec{d}}\right)\right) \in \mathbb{H}_{m, n}^{\mathcal{M}}$, which proves part (ii) of Claim 4.

## C. 5 Corollary 1 and Theorem 5

We first prove a useful corollary of Theorem 1 about the special case of $(\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{1}, \mathcal{M}_{1}\right)$.
Corrollary $1\left((\mathcal{E}, \mathcal{D})=\left(\mathcal{L}_{1}, \mathcal{M}_{\mathbf{1}}\right)\right)$. For $\left(\mathcal{L}_{1}, \mathcal{M}_{1}\right)$ rules, the strong ANR impossibility never holds; at-large ANR impossibility holds if and only if $m=5$ or $m \geq 7$.

Proof. Suppose for the sake of contradiction that the strong ANR impossibility holds for some $m \geq 2$. By Theorem 1 , there exists a partition $\vec{m}$ of $m$ that does not contain 1 and same-length partition $\vec{\ell}$ of 1 such that $\vec{m} \circledast \vec{\ell}=1$. This means that the $\vec{m}$ component that corresponds to the 1 component in $\vec{\ell}$ is 1 , which is a contradiction.

Due to basic number theory, a set of denominations $\mathcal{C}$ can make any sufficiently large $n$ if and only if $\operatorname{lcm}(\mathcal{C})=1$. Therefore, to prove the "if" part of at-large ANR impossibility, it suffices to construct $\vec{m}$ such that $\operatorname{Coins}^{\circledast}(\vec{m}, 1)$ contains co-prime numbers as follows.

- When $m=5$, let $\vec{m}=(3,2)$ and consider $\vec{\ell} \in\{(1,0),(0,1)\}$. Then, $\{2,3\} \subseteq \operatorname{Coins}^{\circledast}(\vec{m}, 1)$.
- When $m \geq 7$, let $\vec{m}$ to be defined as in define (2). It is not hard to verify that $m_{1}$ and $m_{2}$ are co-primes. Consider $\vec{\ell} \in\{(1,0),(0,1)\}$. Then, $\left\{m_{1}, m_{2}\right\} \subseteq \operatorname{Coins}^{\circledast}(\vec{m}, 1)$.

The "only if" part of at-large ANR impossibility is proved in the following cases.

- When $m=2, \mathcal{D M}_{1}(m)=\{(2)\}$. We have Coins ${ }^{\circledast}((2), 1)=\{2\}$, which means that the ANR impossibility does not hold for all odd $n$ 's.
- When $m=3, \mathcal{D M}_{1}(m)=\{(3)\}$. We have $\operatorname{Coins}^{\circledast}((3), 1)=\{3\}$, which means that the ANR impossibility does not hold for all $n$ 's that are not divisible by 3 .
- When $m=4, \mathcal{D M}_{1}(m)=\{(4),(2,2)\}$. We have Coins ${ }^{\circledast}((4), 1)=\{4\}$ and Coins $^{\circledast}((2,2), 1)=$ $\{2\}$, which means that the ANR impossibility does not hold for all odd $n$ 's.
- When $m=6, \mathcal{D M}_{1}(m)=\left\{(6),(4,2),(3,3),(2,2,2\}\right.$. We have $\operatorname{Coins}^{\circledast}((6), 1)=\{6\}$, Coins ${ }^{\circledast}((4,2), 1)=\{4,2\}$, Coins $^{\circledast}((3,3), 1)=\{3\}$, and $\operatorname{Coins}^{\circledast}((2,2,2), 1)=\{2\}$, which means that the ANR impossibility does not hold for all $n$ 's that are divisible by neither 2 or 3 .

Theorem 5. Under the Common Settings, at-large ANR impossibility holds if

| $\mathcal{E}$ | $\mathcal{L}_{k}$ | $\mathcal{M}_{k}$ |
| :---: | :---: | :---: |
| $\mathcal{L}_{\ell}$ | $m \geq 8, \ell \leq \frac{m}{2}-2$, and $k \leq m$ | $m \geq 12, \ell \leq \frac{m}{4}-2$, and $k \leq m-1$ |
| $\mathcal{M}_{\ell}$ | $m \geq 4, \ell \leq m-2$, and $k \leq m$ | $m \geq 2, k \leq m-1$, and |

Moreover, under the conditions in the table, the ANR impossibility holds for every $n \geq$ $m^{2} / 2$.

Proof. According to basic number theory, a set of denominations $\mathcal{C}$ can make any sufficiently large $n$ if and only if $\operatorname{gcd}(\mathcal{C})=1$. To provide sufficient conditions for at-large ANR
impossibility, we will define $\vec{m}$ such that Coins ${ }^{\circledast}(\vec{m}, \ell)$ contains co-prime numbers. Defined

$$
\vec{m}=\left(m_{1}, m_{2}\right) \triangleq \begin{cases}\left(\frac{m+1}{2}, \frac{m-1}{2}\right) & 2 \nmid m  \tag{2}\\ \left(\frac{m}{2}+1, \frac{m}{2}-1\right) & 4 \mid m \\ \left(\frac{m}{2}+2, \frac{m}{2}-2\right) & 4 \nmid m \text { and } 2 \mid m\end{cases}
$$

It is not hard to verify that $m_{1}$ and $m_{2}$ are co-primes and for every $n \geq m^{2} / 2, n$ is feasible by $\left\{m_{1}, m_{2}\right\}$.
Proof for $\left(\mathcal{L}_{\ell}, \mathcal{L}_{k}\right)$. When $m \geq 8, \vec{m} \geq(2,2)$, which means that it satisfies the sub-vector constraint for $\mathcal{D}=\mathcal{L}_{k}$. Consider $\vec{\ell} \in\{(\ell, 0),(0, \ell)\}$. When $\ell \leq \frac{m}{2}-2, \vec{\ell} \leq \vec{m}$. It follows that for every $n \geq m^{2} / 2, n$ is feasible by $\left\{m_{1}, m_{2}\right\} \subseteq \operatorname{Coins}^{\circledast}(\vec{d}, \ell)$. The ANR impossibility holds due to the ( $\mathcal{L}_{\ell}, \mathcal{M}_{k}$ ) case of Theorem 1.
Proof for $\left(\mathcal{L}_{\ell}, \boldsymbol{\mathcal { M }}_{\boldsymbol{k}}\right)$. Consider $\vec{m}=\left(m_{1}, m_{2}\right)$ defined in (2). When $k \notin\left\{m_{1}, m_{2}\right\}$, then we have $\left\{m_{1}, m_{2}\right\} \subseteq \operatorname{Coins}^{\circledast}(\vec{d}, \ell)$, via $\vec{\ell}=(\ell, 0)$ and $(0, \ell)$, respectively. When $k \in\left\{m_{1}, m_{2}\right\}$, then we consider $\vec{m}=(m-2 \ell-1, \ell+1, \ell)$ and $\vec{\ell} \in\{(0, \ell, 0),(0,0, \ell)\}$. It follows that $\{\ell+1, \ell\} \subseteq \operatorname{Coins}^{\ominus}(\vec{d}, \ell)$. The ANR impossibility holds due to the $\left(\mathcal{L}_{\ell}, \mathcal{M}_{k}\right)$ case of Theorem 1 .

Proof for $\left(\mathcal{M}_{\ell}, \mathcal{L}_{k}\right)$. Let $\vec{m}=(\ell, m-\ell)$ and $\vec{\ell}=(\ell, 0)$. Then $1 \in \operatorname{Coins}^{\ominus}(\vec{d}, \ell)$. The ANR impossibility holds due to the $\left(\mathcal{M}_{\ell}, \mathcal{L}_{k}\right)$ case of Theorem 1.
Proof for $\left(\mathcal{M}_{\ell}, \mathcal{M}_{\boldsymbol{k}}\right)$. When $\ell \notin\{k, m-k\}$, then we let $\vec{m}=(\ell, m-\ell)$ and $\vec{\ell}=(\ell, 0)$, which means that $1 \in \operatorname{Coins}^{\otimes}(\vec{d}, \ell)$. Therefore, any $n$ is feasible. Because $\ell \notin\{k, m-k\}$, the sub-vector constraint is satisfied. When $\ell \in\{k, m-k\}$ and $\ell \leq m / 2-3$, define $\vec{m}$ as in (2). The ANR impossibility holds due to the $\left(\mathcal{M}_{\ell}, \mathcal{M}_{k}\right)$ case of Theorem 1.

Lemma 3. For any $m, n, 1 \leq \ell^{*} \leq \ell \leq m$, and $1 \leq k^{*} \leq k \leq m$, we have the following relationship between the ANR impossibilities for different combinations of $(\mathcal{E}, \mathcal{D})$, where an edge $(\mathcal{E}, \mathcal{D}) \rightarrow\left(\mathcal{E}^{\prime}, \mathcal{D}^{\prime}\right)$ mean that if the $A N R$ impossibility holds for the source setting $(\mathcal{E}, \mathcal{D})$, then it holds for the sink setting $\left(\mathcal{E}^{\prime}, \mathcal{D}^{\prime}\right)$ as well.

Proof. $\left(\mathcal{L}_{\ell}, \mathcal{M}_{k}\right) \rightarrow\left(\mathcal{M}_{\ell}, \mathcal{M}_{k}\right)$ and $\left(\mathcal{L}_{\ell}, \mathcal{L}_{k}\right) \rightarrow\left(\mathcal{M}_{\ell}, \mathcal{L}_{k}\right)$ : For any $\vec{d}$ and $\vec{d}^{\prime}$, we have $1 \mathrm{~cm}(\vec{d} \varnothing$ $\left.\vec{d}^{\prime}\right) \mid \operatorname{lcm}\left(\vec{d} \circledast \vec{d}^{\prime}\right)$. Therefore, $\mathcal{E} \mathcal{L}_{\ell}(m, n) \subseteq \mathcal{E} \mathcal{M}_{\ell}(m, n)$.
$\left(\mathcal{L}_{\ell}, \mathcal{M}_{k}\right) \rightarrow\left(\mathcal{L}_{\ell}, \mathcal{L}_{k}\right)$ and $\left(\mathcal{M}_{\ell}, \mathcal{M}_{k}\right) \rightarrow\left(\mathcal{M}_{\ell}, \mathcal{L}_{k}\right)$ : This follows after $\mathcal{D} \mathcal{L}_{k}(m) \subseteq \mathcal{D M}_{k}(m)$.
$\left(\mathcal{L}_{\ell}, \mathcal{M}_{k}\right) \rightarrow\left(\mathcal{L}_{\ell^{\prime}}, \mathcal{M}_{k}\right),\left(\mathcal{L}_{\ell}, \mathcal{L}_{k}\right) \rightarrow\left(\mathcal{L}_{\ell^{\prime}}, \mathcal{L}_{k^{\prime}}\right)$, and $\left(\mathcal{M}_{\ell}, \mathcal{L}_{k}\right) \rightarrow\left(\mathcal{M}_{\ell}, \mathcal{L}_{k^{\prime}}\right)$ : This follows after (1) $\mathcal{D} \mathcal{L}_{k}(m) \subseteq \mathcal{D} \mathcal{L}_{k^{\prime}}(m)$, because any $\vec{d}$ with no more than $k$ ones has no more than
$k^{\prime} \geq k$ ones; and (ii) $\mathcal{E} \mathcal{L}_{\ell}(m, n) \subseteq \mathcal{E} \mathcal{L}_{\ell^{\prime}}(m, n)$, because for any $\overrightarrow{d^{\prime}} \in \mathcal{S}_{\ell}^{0}$, there exists $\overrightarrow{d^{\prime \prime}} \in \mathcal{S}_{\ell}^{0}$ with $\vec{d}^{\prime \prime} \leq \vec{d}^{\prime}$.

## C. 6 Proof of Theorem 2

Theorem 2 (At-large ANR impossibility: up-to- $L$ preferences). For any $(\mathcal{E}, \mathcal{D}) \in$ $\left\{\mathcal{L}_{\leq L}, \mathcal{M}_{\leq L}: 1 \leq L \leq m\right\} \times\left\{\mathcal{L}_{k}, \mathcal{M}_{k}: 1 \leq k \leq m\right\}$, at-large ANR impossibility holds if and only if

| $\mathcal{E}^{\mathcal{D}}$ | $\mathcal{L}_{k}$ | $\mathcal{M}_{k}$ |
| :---: | :---: | :---: |
| $\mathcal{L}_{\leq L}$ | (i) $m=5$, or <br> (ii) $m \geq 7$, or <br> (iii) $k \geq 2$ | (i) $m=5$ and $k \leq m-1$, or <br> (ii) $m \geq 7$ and $k \leq m-1$, or <br> (iii) $2 \leq k \leq m-2$ |
| $\mathcal{M}_{\leq L}$ | (i) $m=5$, or <br> (ii) $m \geq 7$, or <br> (iii) $\max (L, k) \geq 2$, <br> except $(m, L, k) \in\{(2,1,2),(3,2,1)\}$ | (i) $m=5$ and $k \leq m-1$, or <br> (ii) $m \geq 7$ and $k \leq m-1$, or <br> (iii) $[L] \nsubseteq\{k, m-k\}$ and $k \leq m-1$ |

Moreover, under the conditions in the table, the ANR impossibility holds for every $n \geq$ $m^{2} / 2$.

Proof. The proof is done by applications of Theorem 1 to all cases. Following a similar idea in the proof of Theorem 5 , to prove that at-large ANR impossibility holds, we specify a partition $\vec{m}$ of $m$ (that satisfies the sub-vector constraint) and two $\vec{\ell}$ 's so that the two coins created by them are co-primes.
Proof for $\left(\mathcal{L}_{\leq L}, \mathcal{L}_{k}\right)$. We first prove that when $\mathcal{E}=\mathcal{L}_{\leq L}$, it suffices to focus on $L=1$ case.

Claim 7. For any $m, n, k$ and $L$, the $A N R$ impossibility holds for $\left(\mathcal{L}_{\leq L}, \mathcal{L}_{k}\right)$ (respectively, $\left(\mathcal{L}_{\leq L}, \mathcal{M}_{k}\right)$ ) if and only if it holds for $\left(\mathcal{L}_{1}, \mathcal{L}_{k}\right)$ (respectively, $\left(\mathcal{L}_{1}, \mathcal{M}_{k}\right)$ ).

Proof. Due to Lemma 6, it suffices to prove that for any permutation group $G$, the coins created by $\mathcal{L}_{1}$, i.e., $\operatorname{Sizes}\left(G / \mathcal{L}_{1}\right)$, are finer than the coins created by any $\mathcal{L}_{1}$, i.e., $\operatorname{Sizes}\left(\mathcal{L}_{j} / G\right)$. To see this, let $a$ denote the top-ranked alternative in $R$ and consider the applications of the orbit-stabilizer theorem to $G$ on $\mathcal{L}_{j}$ and on $\mathcal{L}_{1}$, respectively:

$$
\begin{aligned}
& G \text { on } \mathcal{L}_{j}:|G|=|G(R)| \times\left|\operatorname{StaB}_{G}(R)\right| \\
& G \text { on } \mathcal{L}_{1}:|G|=|G(a)| \times\left|\operatorname{StaB}_{G}(a)\right|
\end{aligned}
$$

Therefore,

$$
|G(R)| \times\left|\operatorname{StaB}_{G}(R)\right|=|G(a)| \times\left|\operatorname{Stab}_{G}(a)\right|
$$

Notice that any stabilizer $g \in \operatorname{StaB}_{G}(R)$, which means that $g(R)=R$, preserves the topranked alternative in $R$, which means that $g$ is also a stabilizer of $a$. Therefore, $\operatorname{STAB}_{G}(a)$ is a subgroup of $\operatorname{StaB}_{G}(R)$. It follows from Lagrange's theorem that $\left|\operatorname{Stab}_{G}(R)\right|$ divides $\left|\operatorname{SiAB}_{G}(a)\right|$. Therefore, $|G(a)|$ divides $|G(R)|$, which means that $|G(a)|$ is a finer coin in $\operatorname{Sizes}\left(G / \mathcal{L}_{1}\right)$. This proves the claim.

By Claim 7, it suffices to characterize the ANR impossibility for $\left(\mathcal{L}_{1}, \mathcal{L}_{k}\right)$. The "if" direction is proved in the following cases. When $k \geq 2$, let $\vec{m}=(m-1,1)$, and $\ell=(0,1)$. Then $1 \in \operatorname{Coins}^{\circledast}(\vec{m}, 1)$. By Theorem 1, the ANR impossibility holds for all $n \geq 1$. When $m=5$ and $k=1$, let $\vec{m}=(3,2), \vec{\ell} \in\{(0,1),(1,0)\}$. Then $\{2,3\} \subseteq \operatorname{Coins}^{\circledast}(\vec{m}, 1)$. When $m \geq 7$ and $k=1$, let $\vec{m}$ be defined as in (2) and let $\ell \in\{(0,1),(1,0)\}$. Then $\operatorname{Coins}^{\circledast}(\vec{m}, 1)$ contains two co-prime numbers.

The "only if" direction if proved by enumerating all $\vec{m}$ that satisfies the sub-vector constraint (for $k=1$ ) and all $n$ 's for which the ANR impossibility does not hold as summarized in the following table.

| $m$ | partitions satisfying the sub-vector constraint | ANR Imp does not hold for |
| ---: | :---: | :---: |
| 6 | $\{(6),(4,2),(3,3),(2,2,2)\}$ | $2 \nmid n$ and $3 \nmid n$ |
| 4 | $\{(4),(2,2)\}$ | $2 \nmid n$ |
| 3 | $\{(3)\}$ | $3 \nmid n$ |
| 2 | $\{(2)\}$ | $2 \nmid n$ |

Proof for $\left(\mathcal{L}_{\leq L}, \mathcal{M}_{\boldsymbol{k}}\right)$. Due to Claim 7, the rest of the proof focuses on characterizing ANR impossibility for $\left(\mathcal{L}_{1}, \mathcal{M}_{k}\right)$.

The "if" direction.

- When $m=5$ and $k \in\{1, m-1\}$, let $\vec{m}=(m-1,1), \vec{\ell}=(0,1)$. Then $\{2,3\} \subseteq$ Coins ${ }^{\circledast}(\vec{m}, 1)$.
- When $m \geq 7$ and $k \in\{1, m-1\}$, let $\vec{m}$ be defined as in (2) and let $\vec{\ell} \in\{(0,1),(1,0)\}$. Then Coins ${ }^{\circledast}(\vec{m}, 1)$ contains two co-prime numbers.
- When $2 \leq k \leq m-2$, let $\vec{m}=(m-1,1), \vec{\ell}=(0,1)$. Then $1 \in \operatorname{Coins}^{\circledast}(\vec{m}, 1)$. This means that the ANR impossibility holds for all $n \geq 1$.

The "only if" direction.

- When $k=m$, any partition $\vec{m}$ of $m$ sum up to $k=m$, which means that the ANR impossibility does not hold as $\mathcal{D M}_{k}(m)=\emptyset$. Recall that $\mathcal{D M}_{k}(m)$ is the set of all partitions of $m$ that satisfies the sub-vector constraint for $\mathcal{D}=\mathcal{M}_{k}$ in Theorem 1 as defined in Definition 11.
- When $m=6$ and $k \in\{1, m-1\}$, we have $\mathcal{D M}_{k}(m)=\{(6),(4,2),(3,3),(2,2,2)\}$. It follows that for every $n$ such that $2 \nmid n$ and $3 \nmid n$, the ANR impossibility does not hold.
- When $m=4$ and $k \in\{1, m-1\}$, we have $\mathcal{D M}_{k}(m)=\{(4),(2,2)\}$. Therefore, the ANR impossibility does not hold for every $n$ with $2 \nmid n$.
- When $m=3$ and $k \in\{1, m-1\}$, we have $\mathcal{D M}_{k}(m)=\{(3)\}$. Therefore, the ANR impossibility does not hold for every $n$ with $3 \nmid n$.
- When $m=2$ and $k \in\{1, m-1\}$, we have $\mathcal{D M}_{k}(m)=\{(2)\}$. Therefore, the ANR impossibility does not hold for every $n$ with $2 \nmid n$.

Proof for $\left(\mathcal{M}_{\leq L}, \mathcal{L}_{k}\right)$. The "if" direction.

- When $\max (L, k) \geq 2$ and $m \geq 4$, there are two sub-cases. If $L \geq 2$, then consider the partition $\vec{m}=(m-2,2)$, which does not contain 1 . Therefore, $\vec{m} \in \mathcal{D} \mathcal{L}_{k}(m)$. In light of Lemma 6 , it suffices to show that at-large ANR impossibility holds for $\ell=2 \leq L$. Let $\vec{\ell}=(0,2)$. We have $\operatorname{lcm}(\vec{m} \oslash \vec{\ell})=1$, which means at-large ANR impossibility holds. If $k \geq 2$, then consider $\vec{m}=(m-1,1), \ell=1$, and $\vec{\ell}=(0,1)$, which means that $\operatorname{lcm}(\vec{m} \oslash \vec{\ell})=1$ and therefore at-large ANR impossibility holds.
- When $\max (L, k) \geq 2, m=3$, and $(L, k) \neq(2,1)$, we prove the theorem by explicitly constructing $\vec{m}$ and $\vec{\ell}$ in the following two sub-cases. If $k \geq 2$, then we let $\vec{m}=(2,1)$, $\ell=1$, and $\vec{\ell}=(0,1)$. Otherwise $k=1$ and $L \geq 3$, which means that $L=3=m$. In this case we let $\vec{m}=(3)$ and $\vec{\ell}=(3)$.
- When $\max (L, k) \geq 2, m=2$, and $(\ell, k) \neq(1,2)$, we have $\ell=2$. The theorem is proved by letting $\vec{m}=(2)$ and $\vec{\ell}=(2)$.
- When $\max (L, k)=1$ and either $m=5$ or $m \geq 7$, at-large ANR impossibility holds according to Corollary 1.

The "only if" direction.

- When $(m, L, k) \in\{(2,1,2),(3,2,1)\}$, we have $\mathcal{D M}_{k}(m)=\{(m)\}$, which means that at-large ANR impossibility does not hold.
- When $\max (L, k)=1$ and $m \in\{2,3,4,6\}$, at-large ANR impossibility does not hold according to Corollary 1.

Proof for $\left(\mathcal{M}_{\leq L}, \mathcal{M}_{\boldsymbol{k}}\right)$. When $[L] \nsubseteq\{k, m-k\}$, there exists $\ell \leq L$ such that $\ell \notin$ $\{k, m-k\}$. Then, at-large ANR impossibility holds by letting $\vec{m}=(m-\ell, \ell)$ and $\vec{\ell}=(0, \ell)$ in Theorem 1. When $[L] \subseteq\{k, m-k\}$. There are two cases:

- Case 1: $L=1$ and $k=1$ or $m-1$. The theorem follows after Corollary 1: at-large ANR impossibility holds if and only if $m=5$ or $m \geq 7$.
- Case 2: $L=2, m=3$, and $k=1$ or 2 . In this case $\mathcal{D M}_{k}(3)=\{(3)\}$, which means that Coins ${ }^{\circledast}(3,2)=\{3\}$. Or equivalently, at-large ANR impossibility does not hold.

## D Materials for Section 5

## D. 1 Proof of Theorem 3

Theorem 3. For any polynomially computable $f$ and any $\left(\mathcal{L}_{m}, \mathcal{D}\right)$ in the Common Settings, Algorithm 1 computes $M F P_{f}$ in polynomial time.

Proof. We first prove that the choice of $\sigma$ in the definition of MFP does not matter. More precisely, we prove that for any profile $P$, any $\sigma_{1}, \sigma_{2} \in \operatorname{MFP}(P)$, and any fixed point $d \in \operatorname{Fixed}_{\operatorname{Stab}(\operatorname{Hist}(P))}(\mathcal{D})$, we have $\sigma_{1}(d)=\sigma_{2}(d)$. Suppose for the sake of contradiction that $\sigma_{1}(d) \neq \sigma_{2}(d)$. Notice that $\operatorname{Hist}\left(\sigma_{1}(P)\right)=\operatorname{Hist}\left(\sigma_{2}(P)\right)$. Therefore, $\operatorname{Hist}\left(\sigma_{2}^{-1} \circ \sigma_{1}(P)\right)=$ $\operatorname{Hist}\left(\sigma_{2}^{-1} \circ \sigma_{2}(P)\right)=\operatorname{Hist}(P)$, which means that $\sigma_{2}^{-1} \circ \sigma_{1} \in \operatorname{StaB}(\operatorname{Hist}(P))$. Because $\sigma_{2}^{-1} \circ$ $\sigma_{1}(d) \neq d, d$ is not a fixed point of $\operatorname{StaB}(\operatorname{Hist}(P))$, which is a contradiction.

We prove that $\left(\operatorname{MFP}_{f} * \bar{r}\right)$ is a most equitable refinement of $\bar{r}$ by proving that for every $P \notin \mathcal{P}_{\bar{r}}, \operatorname{ANR}\left(\operatorname{MFP}_{f} * \bar{r}, P\right)=1$. Intuitively, this is true because any MFP does not depend on the identity of agents or the decisions. Formally, we have the following proof.
$\operatorname{MFP}_{f} * \bar{r}$ satisfies anonymity at $\boldsymbol{P}$. It suffices to prove that for any profile $P^{\prime}$ with $\operatorname{Hist}\left(P^{\prime}\right)=\operatorname{Hist}(P), \operatorname{MFP}(P)=\operatorname{MFP}\left(P^{\prime}\right)$. This follows after noticing that for any permutation $\sigma \in \mathcal{S}_{\mathcal{A}}$,

$$
\operatorname{Hist}(\sigma(P))=\sigma(\operatorname{Hist}(P))=\sigma\left(\operatorname{Hist}\left(P^{\prime}\right)\right)=\operatorname{Hist}\left(\sigma\left(P^{\prime}\right)\right)
$$

More precisely, any $\sigma \in \mathcal{S}_{\mathcal{A}}$ that maximizes $\operatorname{Hist}(\sigma(P))$ according to $\triangleright$ would also maximize $\operatorname{Hist}\left(\sigma\left(P^{\prime}\right)\right)$.
$\operatorname{MFP}_{f} * \overline{\boldsymbol{r}}$ satisfies neutrality at $\boldsymbol{P}$. Suppose for the sake of contradiction that $\mathrm{MFP}_{f} *$ $\bar{r}(P)=\{a\}$ and there exists a permutation $\sigma \in \mathcal{S}_{\mathcal{A}}$ such that $\mathrm{MFP}_{f} * \bar{r}(\sigma(P))=\{b\}$, where $b \neq \sigma(a)$. Let $\sigma_{a} \in \operatorname{MFP}(P)$ and $\sigma_{b} \in \operatorname{MFP}(\sigma(P))$ denote any pair of permutations. We show that $P$ and $\sigma(P)$ are "similar" by proving the following two properties.
(i) $\operatorname{Hist}\left(\sigma_{a}(P)\right)=\operatorname{Hist}\left(\sigma_{b}(\sigma(P))\right)$. Suppose for the sake of contradiction that this does not hold and w.l.o.g. $\operatorname{Hist}\left(\sigma_{a}(P)\right) \triangleright \operatorname{Hist}\left(\sigma_{b}(\sigma(P))\right)$. Then, notice that $\operatorname{Hist}\left(\sigma_{a}(P)\right)=$ $\operatorname{Hist}\left(\sigma_{a} \circ \sigma^{-1}(\sigma(P))\right)$, which means that $\sigma_{a} \circ \sigma^{-1}$ maps $\operatorname{Hist}(\sigma(P))$ to a profile that is ranked higher than $\sigma_{b}(\operatorname{Hist}(\sigma(P)))$. This contradicts the optimality of $\sigma_{b}$, i.e., $\sigma_{b} \in$ $\operatorname{MFP}(P)$.
(ii) $\sigma(a) \in \operatorname{FPD}(\sigma(P), \sigma(\bar{r}(P)))$. Suppose for the sake of contradiction that $\sigma(a) \notin \operatorname{FPD}(\sigma(P), \sigma(\bar{r}(P)))$.

Because $\sigma(a) \in \sigma(\bar{r}(P))$, we must have that $\sigma(a)$ is a fixed point under $\operatorname{Stab}(\operatorname{Hist}(\sigma(P))$, which means that there exists $\sigma^{\prime} \in \operatorname{StaB}(\operatorname{Hist}(\sigma(P)))$ such that $\operatorname{Hist}\left(\sigma^{\prime}(\sigma(P))\right)=$ $\operatorname{Hist}(\sigma(P))$ and $\sigma^{\prime}(\sigma(a)) \neq \sigma(a)$. Let $\sigma^{*}=\sigma^{-1} \circ \sigma^{\prime} \circ \sigma$, we have $\operatorname{Hist}\left(\sigma^{*}(P)\right)=\operatorname{Hist}(P)$ and $\sigma^{*}(a) \neq a$, which means that $a$ is not a fixed point under $\operatorname{Stab}(\operatorname{Hist}(P))$, which is a contradiction.

It follows from (i) that $\sigma_{b} \circ \sigma(P)$ is the most-preferred histogram (which is the same as Hist $\left(\sigma_{a}(P)\right.$ ) among permuted histograms according to $\triangleright$ defined in Defininition 6. Therefore, $\sigma_{b} \circ \sigma \in \operatorname{MFP}(P)$. Notice that because $b \in \operatorname{FPD}(\sigma(P), \sigma(\bar{r}(P)))$, we have $\sigma^{-1}(b) \in \operatorname{FPD}(P) \cap \bar{r}(P)$ according to (ii), where we switch the roles of $a$ and $b$. Also recall that $b \neq \sigma(a)$. Therefore, $\sigma^{-1}(b) \neq a$. Because of the optimality of $a$ and Proposition ??, $a$ has higher priority than $\sigma^{-1}(b)$ for any permutation in $\operatorname{MFP}(P)$, especially $\sigma_{b} \circ \sigma$. Therefore,

$$
\sigma_{b}(\sigma(a))=\sigma_{b} \circ \sigma(a) \triangleright \sigma_{b} \circ \sigma\left(\sigma^{-1}(b)\right)=\sigma_{b}(b),
$$

which contradicts the optimality of $b$, as $\sigma(a) \in \operatorname{FPD}(\sigma(P), \sigma(\bar{r}(P)))$ according to (ii).
$\operatorname{MFP}_{f} * \overline{\boldsymbol{r}}$ is resolute at $\boldsymbol{P}$. This part follows after the definition of $\mathrm{MFP}_{f} * \bar{r}$.

## D. 2 Proof of Theorem 4

Theorem 4. For any polynomially computable $f$ and under the Common Settings where $\mathcal{E}=\mathcal{L}_{m}$, Algorithm 1 runs in polynomial time and computes $M F P_{f}$.

Proof. We first verify that Algorithm 1 correctly computes an MFP breaking. (5) holds because $\sigma \in \operatorname{Stab}(\operatorname{Hist}(P))$ if and only if for every ranking $R$, $[\operatorname{Hist}(P)]_{R}=[\operatorname{Hist}(P)]_{\sigma(R)}$. Let $R^{*}=\arg \max _{R \in \operatorname{MPR}(P)}^{\triangleright} \operatorname{Hist}\left(\sigma_{R}(P)\right)$. To verify that $\sigma_{R^{*}}$ is indeed a highest-priority permutation, for the sake of contradiction suppose there exists $\sigma \in \mathcal{S}_{\mathcal{A}}$ such that $\operatorname{Hist}(\sigma(P)) \triangleright$ $\operatorname{Hist}\left(\sigma_{R^{*}}(P)\right)$. This means that $[\operatorname{Hist}(\sigma(P))]_{\triangleright} \geq\left[\operatorname{Hist}\left(\sigma_{R^{*}}(P)\right)\right]_{\triangleright}>0$, where $[\operatorname{Hist}(\sigma(P))]_{\triangleright}$ is the $\triangleright$ coordinate of $\operatorname{Hist}(\sigma(P))$, or in other words, the multiplicity of ranking $\triangleright=[1 \succ$ $\cdots \succ m]$ in $\sigma(P)$. Therefore, $\sigma^{-1}(\triangleright)$ must be a most popular ranking in $P$. This contradicts the maximality of $R^{*}$.

Next, we verify that Algorithm 1 runs in polynomial time in $m, n$, and $|D|$. (5) takes $O\left(m n^{3}\right)$ time. Step 2 takes $\operatorname{poly}(m n)|D|$ time, because it only need to verify whether every $d \in D$ is a fixed point of $\operatorname{Stab}(\operatorname{Hist}(P))$. In step 4, computing $\operatorname{Hist}\left(\sigma_{R}(P)\right)$ (in the list form) for each $R$ takes $O(m n+m \log n)$ time, and each comparison when computing the $\arg \max _{R \in \mathrm{MPR}}^{\triangleright}$ takes poly $(n m)$ time, which means that the overall time for step 4 is poly $(n m)$. Step 5 takes poly $(m|D|)$ time.

## E General Settings

## E. 1 Definitions of Anonymity And Neutrality For General Settings

Intuition. The anonymity for voting rule $\bar{r}: \mathcal{E}^{n} \rightarrow \mathcal{D}$ in the general setting is straightforward. To define neutrality, we need a sensible and consistent way to capture the following idea behind the neutrality:
when agent permutes their preferences in a certain way, the winner is permuted in the same way

This is achieved by leveraging any permutation $\sigma$ over $\mathcal{A}$ to a permutation over $\mathcal{E}$ and a permutation over $\mathcal{D}$. Specifically, for any pair of permutations over $\mathcal{A}, \sigma_{1}$ and $\sigma_{2}$, first applying the counterpart of $\sigma_{1}$ to $\mathcal{E}$ and then applying the counterpart of $\sigma_{2}$ should be the same as directly applying the counterpart of $\sigma_{2} \circ \sigma_{1}$ (which is a permutation over $\mathcal{A}$ ). Such consistency should be enforced for $\mathcal{D}$ as well.

This idea is captured in a well-studied notion in group theory called group actions. Basic definitions and notation about group theory can be found in Appendix A.

Definition 17 (Group actions). A group $G$ acts on a set $X$, if every $g \in G$ can be viewed as a permutation on $X$, such that (1) for all $g_{1}, g_{2} \in G$ and all $x \in X$, we have $g_{1}\left(g_{2}(x)\right)=g_{1} \circ g_{2}(x)$, where $\circ$ is the operation in $G$, and (2) let $I d \in G$ denote the identity, then for all $x \in X$, we have $\operatorname{Id}(x)=x$.

The permutations defined on $k$-committees, $k$-lists, profiles, and histograms in Section 2 are examples of $\mathcal{S}_{\mathcal{A}}$ acting on $k$-committees, $k$-lists, profiles, and histograms, respectively. Notice that the set $X$ that $G$ acts on is not required to be a group.

In this paper, we require that $\mathcal{S}_{\mathcal{A}}$ acts on the setting $(\mathcal{E}, \mathcal{D})$, i.e., $\mathcal{S}_{\mathcal{A}}$ acts on both $\mathcal{E}$ and $\mathcal{D}$ ). For such settings, anonymity, neutrality, and resolvability are defined naturally as follows.

Definition 18 (Anonymity, neutrality, and resolvability for general preferences and decisions). Given the preference space $\mathcal{E}$ and the decision space $\mathcal{D}$, both of which $\mathcal{S}_{\mathcal{A}}$ acts on, for any irresolute rule $\bar{r}$ and any profile $P$, we define
$-\operatorname{ANo}(\bar{r}, P) \triangleq 1$ if for any profile $P^{\prime}$ with $\operatorname{Hist}\left(P^{\prime}\right)=\operatorname{Hist}(P)$, we have $\bar{r}\left(P^{\prime}\right)=\bar{r}(P)$; otherwise $\operatorname{ANO}(\bar{r}, P) \triangleq 0$.
$-\mathrm{NEU}(\bar{r}, P) \triangleq 1$ if for every permutation $\sigma$ over $\mathcal{A}$, we have $r(\sigma(P))=\sigma(r(P))$; otherwise $\operatorname{Nev}(\bar{r}, P) \triangleq 0$.
$-\operatorname{Res}(\bar{r}, P) \triangleq 1$ if $|\bar{r}(P)|=1$; otherwise $\operatorname{RES}(\bar{r}, P) \triangleq 0$.
If $\operatorname{Ano}(\bar{r}, P)=1$ (respectively, $\operatorname{Neu}(\bar{r}, P)=1$ or $\operatorname{Res}(\bar{r}, P)=1$ ), then we say that $\bar{r}$ satisfies anonymity (respectively, neutrality or resolvability) at $P$. We further define $\operatorname{ANR}(\bar{r}, P) \triangleq \operatorname{ANO}(\bar{r}, P) \times \operatorname{NEU}(\bar{r}, P) \times \operatorname{Res}(\bar{r}, P)$. Given $n$, we say that $\bar{r}$ satisfies anonymity (respectively, neutrality, resolvability, or ANR) if and only if for all n-profiles $P$, we have $\operatorname{Ano}(\bar{r}, P)=1($ respectively, $\operatorname{Neu}(\bar{r}, P)=1, \operatorname{Res}(\bar{r}, P)=1$, or $\operatorname{ANR}(\bar{r}, P)=1)$.

## E. 2 Most Equitable Refinements For General Settings

The notions of stabilizer, orbit, and fixed point in Definition 20 can be naturally extended to the general setting $(\mathcal{E}, \mathcal{D})$ that $\mathcal{S}_{\mathcal{A}}$ acts on. For completeness, we recall the general group theoretic definitions of them below.

Definition 19 (Stabilizer, orbit, and fixed point). For any group $G$ that acts on $X$, any $x \in X$, and any subset $X^{\prime} \subseteq X$, define

$$
\text { Stabilizers of } Y \text { under } G: \operatorname{StaB}_{G}\left(X^{\prime}\right) \triangleq\left\{g \in G: \forall x \in X^{\prime}, g(x)=x\right\}
$$

Orbit of $x$ under $G: \operatorname{Orbit}_{G}(x) \triangleq\{g(x): g \in G\}$
Fixed points of $G$ in $X: \operatorname{Fixed}_{G}(X) \triangleq\{x \in X: \forall g \in G, g(x)=x\}$
The subscript $G$ is omitted when $G=\mathcal{S}_{\mathcal{A}}$.
The fixed point decisions can also be defined similarly as follows.
Definition 20 (Fixed-point decisions for general settings). Given any ( $\mathcal{E}, \mathcal{D}$ ) that $\mathcal{S}_{\mathcal{A}}$ acts on, for any n-profile $P \in \mathcal{E}^{n}$ and any set of decisions $D \subseteq \mathcal{D}$, define

Fixed-point decisions: $\operatorname{FPD}(P) \triangleq \operatorname{FIXED}_{\operatorname{Stab}(H i s t(P))}(\mathcal{D})$
Using these definitions, Lemma 1 (existence of most equitable refinements) can be extended to all $(\mathcal{E}, \mathcal{D})$ that $\mathcal{S}_{\mathcal{A}}$ acts on, formally stated in the following lemma, whose proof is similar to the proof of Lemma 1.

Lemma 4 (Existence of most equitable refinements, general settings). For any $(\mathcal{E}, \mathcal{D})$ that $\mathcal{S}_{\mathcal{A}}$ acts on and any anonymous and neutral rule $\bar{r}$, most-equitable refinements of $\bar{r}$ exist. Moreover,

$$
\mathcal{P}_{\bar{r}}=\left\{P \in \mathcal{D}^{n}: \operatorname{FPD}(P) \cap \bar{r}(P)=\emptyset\right\},
$$

and for every most equitable refinement $r^{*}$ and every $P \notin \mathcal{P}_{\bar{r}}, r^{*}(P) \subseteq \operatorname{FPD}(P) \cap \bar{r}(P)$.

## E. 3 ANR Impossibility For General Settings

Following a similar proof as the proof of Lemma 2, we have the following characterization of the ANR impossibility using the two constraints in Definition 4 for general settings.

Theorem 6 (ANR impossibility for general settings). For any $m \geq 2, n \geq 1$, and any $(\mathcal{E}, \mathcal{D})$ that $\mathcal{S}_{\mathcal{A}}$ acts on, the $A N R$ impossibility holds if and only if there exists a permutation group $G \leqslant \mathcal{S}_{\mathcal{A}}$ such that

- The $\mathcal{D}$ constraint: $\operatorname{Fixed}_{G}(\mathcal{D})=\emptyset$.
- The change-making constraint: $n$ is feasible by $\operatorname{Sizes}(\mathcal{E} / G)$.

Proof. Following a similar reasoning as that in the proof of Theorem 1, we have that the ANR impossibility holds if and only exists a permutation group $G \leqslant \mathcal{S}_{\mathcal{A}}$ that satisfies the $\mathcal{D}$-constraint and

The $\mathcal{E}$-histogram constraint: $\operatorname{FIXED}_{G}\left(\mathbb{H}_{m, n}^{\mathcal{E}}\right) \neq \emptyset$
The theorem follows after the following lemma, which proves the equivalence between the $\mathcal{E}$-histotgram constraint and the change-making constraint.

Lemma 5. For any $(\mathcal{E}, \mathcal{D})$ that $\mathcal{S}_{\mathcal{A}}$ acts on, any $G \leqslant \mathcal{S}_{\mathcal{A}}$, and any $n \geq 1$,

$$
\operatorname{FixED}_{G}\left(\mathbb{H}_{m, n}^{\mathcal{E}}\right) \neq \emptyset \Longleftrightarrow n \text { is feasible by } \operatorname{Sizes}(\mathcal{E} / G)
$$

Proof. The " $\Rightarrow$ " direction. Let $P$ denote any $n$-profile such that $\operatorname{Hist}(P)$ is a fixed point under $G$. Then, for any $R \in \mathcal{E}$ and any $g \in G$, we have $[\operatorname{Hist}(P)]_{R}=[\operatorname{Hist}(P)]_{g(R)}$. In other words, preferences in the same orbits appear the same number of times in $P$. Let $O_{1}, \ldots, O_{T}$ denote the orbits in $\mathcal{L}_{\ell}$ under $G$ and for every $1 \leq t \leq T$, fix an arbitrary $\ell$-list $R_{t}^{*} \in O_{t}$. We have $\sum_{t=1}^{T}\left|O_{t}\right| \times[\operatorname{Hist}(P)]_{R_{t}^{*}}=n$. Therefore, $n$ is feasible by $\left\{\left|O_{1}\right|, \ldots,\left|O_{T}\right|\right\}$.

The " $\Leftarrow$ " direction. Let $O_{1}, \ldots, O_{T}$ denote the orbits in $\mathcal{L}_{\ell}$ under $G$. Suppose $n=$ $\sum_{t=1}^{T} \alpha_{t} \times\left|O_{t}\right|$, where $\alpha_{1}, \ldots, \alpha_{T}$ are non-negative integers. Let

$$
P \triangleq \bigcup_{t=1}^{T} \alpha_{t} \times O_{t}
$$

It follows that $\operatorname{Hist}(P)$ is a fixed point under $G$, which proves that $\operatorname{Fixed}_{G}\left(\mathbb{H}_{m, n}^{\mathcal{E}}\right) \neq \emptyset$.

As an example, we consider the setting where the preference (respectively, decision) space is the union of finitely many non-overlapping spaces, each of which $\mathcal{S}_{\mathcal{A}}$ acts on. That is,

$$
\mathcal{E}=\bigcup_{j=1}^{n^{*}} \mathcal{E}_{j} \text { and } \mathcal{D}=\bigcup_{i=1}^{m^{*}} \mathcal{D}_{i}
$$

$\mathcal{S}_{\mathcal{A}}$ naturally acts on $\mathcal{E}$ and $\mathcal{D}$ by extending its action on $\mathcal{E}_{j}$ 's and $\mathcal{D}_{i}$ 's.
Example 18. $\mathcal{L}_{\leq L}=\bigcup_{\ell=1}^{L} \mathcal{L}_{\ell}$.

Lemma 6. Let $\mathcal{E}=\bigcup_{j=1}^{n^{*}} \mathcal{E}_{j}$ and $\mathcal{D}=\bigcup_{i=1}^{m^{*}} \mathcal{D}_{i}$ be unions of disjoint sets that $\mathcal{S}_{\mathcal{A}}$ acts on. The $A N R$ impossibility holds if and only if there exists a permutation group $G \leqslant \mathcal{S}_{\mathcal{A}}$ such that (i) for every $i \leq m^{*}$, $G$ has no fixed point in $\mathcal{D}_{i}$ and (ii) $n \in \operatorname{Feas}\left(\bigcup_{j=1}^{n^{*}} \operatorname{Sizes}\left(\mathcal{E}_{j} / G\right)\right)$.

Proof. The lemma follows after a straightforward application of Theorem 6 by noticing that (1) $G$ has no fixed point in $\mathcal{D}$ if and only if for all $i \leq m^{*}, G$ has no fixed point in $\mathcal{D}_{i}$, and (2) $\operatorname{Feas}(\operatorname{Sizes}(\mathcal{E} / G))=\operatorname{Feas}\left(\bigcup_{j=1}^{n^{*}} \operatorname{Sizes}\left(\mathcal{E}_{j} / G\right)\right)$.

That is, the ANR impossibility holds for $(\mathcal{E}, \mathcal{D})$ rules if and only if there exists $G$ that satisfies all constraints of the $\mathcal{D}_{i}$ 's such that $n$ is feasible by using all coins made by $\mathcal{E}_{j}$ 's. Therefore, it is easier for the ANR impossibility to hold for larger $\mathcal{E}$ and smaller $\mathcal{D}$.

## E. 4 Most-Favorable-Permutation Tie-Breakings for General Settings

In this subsection, we show that MFP tie-breaking can be naturally extended to general settings to obtain most equal refinements as well. Like Definition 6, we will extend a priority order $\triangleright \mathcal{L}_{m}$, w.l.o.g. $\triangleright=[1 \succ 2 \succ \cdots \succ m]$, to any set $X$ that $\mathcal{S}_{\mathcal{A}}$ acts on, especially $X \in\{\mathcal{E}, \mathcal{D}\})$.

First, we partition $X$ into orbits $X=O_{1} \cup \ldots \cup O_{S}$ under $\mathcal{S}_{\mathcal{A}}$, define an arbitrary order over orbits, e.g., $O_{1} \triangleright \cdots \triangleright O_{S}$, and for each orbit $s \leq S$ define a "best" element $x_{s}^{*}$. Then, when comparing $x, x^{\prime} \in X$, the element in the orbit with higher priority is more preferred; and if both are in the same orbit $O_{s}$, compare them w.r.t. the distance to $x_{s}^{*}$, which is defined to be the highest-priority permutation in $\mathcal{S}_{\mathcal{A}}$ that maps $x$ (respectively, $x^{\prime}$ ) to $x_{s}^{*}$. Formally, when $x$ and $x^{\prime}$ are in the same orbit $O_{s}, x \triangleright x^{\prime}$ if and only if

$$
\arg \max _{\sigma \in \mathcal{S}_{\mathcal{A}}}\left(\sigma(x)=x_{s}^{*}\right) \triangleright \arg \max _{\sigma \in \mathcal{S}_{\mathcal{A}}}^{\triangleright}\left(\sigma\left(x^{\prime}\right)=x_{s}^{*}\right)
$$

The order over $\mathcal{E}$ can be naturally extended to histograms as done in Section 5. This extends MFP to $(\mathcal{E}, \mathcal{D})$ that $\mathcal{S}_{\mathcal{A}}$ acts on.

Example 19. Let $m=4, X=\mathcal{L}_{\leq 2}=\mathcal{L}_{1} \cup \mathcal{L}_{2} . \mathcal{L}_{1}$ and $\mathcal{L}_{2}$ are the two orbits under $\mathcal{S}_{\mathcal{A}}$. Suppose the priority over the two orbits are $\mathcal{L}_{1} \triangleright \mathcal{L}_{2}$. Then,

$$
\{1\} \triangleright\{2\} \triangleright\{3\} \triangleright\{4\} \triangleright\{1,2\} \triangleright\{1,3\} \triangleright\{1,4\} \triangleright\{2,3\} \triangleright\{2,4\} \triangleright\{3,4\}
$$

Let $P=2 \times\{2\}+\{3\}+2 \times\{1,3\}+\{2,4\}$ and let $\bar{r}$ denote the approval rule. Then, $\bar{r}(P)=\{2,3\}$. It is not hard to verify that a MFP is $(3,2,1,4)$, which means that $M F P_{f} *$ $\bar{r}(P)=\{2\}$.

Like Theorem 3, MFP tie-breaking computes a most equitable refinement under general settings, as stated in the following theorem.

Theorem 7. For any $(\mathcal{E}, \mathcal{D})$ that $\mathcal{S}_{\mathcal{A}}$ acts on and any anonymous and neutral rule $\bar{r}$, $M F P_{f}$ is well-defined and $\left(M F P_{f} * \bar{r}\right)$ is a most equitable refinement.

The following brute-force algorithm computes MFP tie-breaking for general $(\mathcal{E}, \mathcal{D})$. The runtime of Algorithm 2 is guaranteed in the following theorem.

```
ALGORITHM 2: MFP tie-breaking for general \((\mathcal{E}, \mathcal{D})\).
    for every \(\sigma \in \mathcal{S}_{\mathcal{A}}\) do
        Compute \(\sigma(\operatorname{Hist}(P))\).
        if \(\sigma(\operatorname{Hist}(P)) \triangleright \vec{h}_{\text {max }}\) then
            Let \(\vec{h}_{\max }=\sigma(\operatorname{Hist}(P))\) and let \(\sigma_{\max }=\sigma\).
        end if
    end for
    Compute \(\operatorname{FPD}(P) \cap \bar{r}(P)\)
    return \(\arg \max _{d \in \operatorname{FPD}(P) \cap \bar{r}(P)}^{\triangleright} \sigma_{\text {max }}(d)\)
```

Theorem 8. For any polynomially computable $f$ and any $(\mathcal{E}, \mathcal{D})$ that $\mathcal{S}_{\mathcal{A}}$ acts on, such that computing the outcome of permutation and comparing the priority of two elements for both $\mathcal{E}$ and $\mathcal{D}$ take polynomial time, Algorithm 2 computes $M F P_{f}$ in $m!\cdot p o l y(m, n)$ time.

Proof. The for loop of Algorithm 2 contribute to the $m$ ! factor in the runtime, and the rest operations takes polynomial time.
