# Recurrence and transience of Rademacher series 

Satyaki Bhattacharya and Stanislav Volkov*

October 14, 2022

#### Abstract

We introduce the notion of a-walk $S(n)=a_{1} X_{1}+\cdots+a_{n} X_{n}$, based on a sequence of positive numbers $\mathbf{a}=\left(a_{1}, a_{2}, \ldots\right)$ and a Rademacher sequence $X_{1}, X_{2}, \ldots$. We study recurrence/transience (properly defined) of such walks for various sequences of a. In particular, we establish the classification in the cases where $a_{k}=\left\lfloor k^{\beta}\right\rfloor, \beta>0$, as well as in the case $a_{k}=\left\lceil\log _{\gamma} k\right\rceil$ or $a_{k}=\log _{\gamma} k$ for $\gamma>1$.

Keywords: recurrence, transience, Rademacher distribution, non-homogeneous Markov chains. AMS subject classification: 60G50, 60J10.

## 1 Introduction

We will say that a random variable $X$ has a Rademacher distribution and write $X \sim \mathcal{R}$ ademacher, if $\mathbb{P}(X=+1)=\mathbb{P}(X=-1)=\frac{1}{2}$.

Let $X_{i} \sim \mathcal{R}$ ademacher, $i=1,2, \ldots$, be i.i.d., and $\mathcal{F}_{n}=\sigma\left(X_{1}, X_{2}, \ldots, X_{n}\right)$ be the sigma-algebra generated by the first $n$ members of this sequence. Let $\mathbf{a}=\left(a_{1}, a_{2}, \ldots\right)$ be a non-random sequence of positive numbers. Define the a-walk as

$$
S(n)=a_{1} X_{1}+a_{2} X_{2}+\cdots+a_{n} X_{n}=\sum_{k=1}^{n} a_{k} X_{k}
$$

with the convention $S(0)=0$.
Definition 1. Let $C \geq 0$. We call the a-walk $S$ defined above $C$-recurrent, if the event $\{|S(n)| \leq$ $C\}$ occurs for infinitely many $n$. (In case when $C=0$, this is equivalent to the usual recurrence, i.e., $S(n)=0$ for infinitely many $n$, so we will call the walk just recurrent.)

We call the a-walk transient, if it is not $C$-recurrent for any $C \geq 0$.

[^0]Our aim is to determine the probability that the a-walk for given a and $C$ is recurrent; in principle, this probability may be different ${ }^{1}$ from 0 and 1 . A simplest example of an a-walk is when all $a_{i} \equiv a \in \mathbb{R}_{+}$. Such a random walk is obviously a.s. recurrent since it is equivalent to the one-dimensional simple random walk.

The question of recurrence is naturally related to the Littlewood-Offord problem which deals with the maximization of probability $\mathbb{P}(S(n)=v)$ over all $v$, subject to various hypotheses on $\mathbf{a}$. In particular, in [7] the authors develop an inverse Littlewood-Offord theory, using which they show that this probability is large only when the elements of a are contained in a generalized arithmetic progression; see also (4].

The study of a-walk is also somewhat relevant to the conjecture by Boguslaw Tomaszewski (1986), which says that $\mathbb{P}\left(|S(n)| \leq \sqrt{a_{1}^{2}+\cdots+a_{n}^{2}}\right) \geq \frac{1}{2}$ for all sequences a and all $n$. The conjecture was recently proved by Nathan Keller and Ohad Klein in [2].

Let us first start with some general statements. First, we show that the choice of $C>0$ is sometimes unimportant for the definition of $C$-recurrence.

Theorem 1. Suppose that $a_{n} \rightarrow \infty$ and at the same time $\left|a_{n}-a_{n-1}\right| \rightarrow 0$ as $n \rightarrow \infty$. Then if an a-walk is $C$-recurrent with a positive probability for some $C>0$ then it is $\tilde{C}$-recurrent with a positive probability for all $\tilde{C}>0$.

Proof. Since the notion of $C$-recurrence is monotone in $C$, i.e. if an a-walk is $C_{1}$-recurrent for $C_{1}>0$ then it is $C_{2}$-recurrent for all $C_{2} \geq C_{1}$, it suffices to prove that $C$-recurrence implies $\frac{2 C}{3}$-recurrence.

Indeed, suppose the a-walk is $C$-recurrent; formally, if we define the events

$$
\begin{aligned}
E & =\{S(n) \in[-C, C] \text { for infinitely many } n\} \\
\tilde{E} & =\{S(n) \in[-2 C / 3,2 C / 3] \text { for infinitely many } n\}
\end{aligned}
$$

then $\mathbb{P}(E)>0$. We want to show that $\mathbb{P}(\tilde{E})>0$ as well.
Let $n_{1}$ be so large that $\left|a_{i}-a_{i-1}\right|<C / 6$ for all $i \geq n_{1}$. Define the sequence $n_{k}, k \geq 2$, by setting

$$
n_{k}=\min \left\{i \geq n_{k-1}+1: a_{i} \geq a_{n_{k-1}}+C / 6\right\}
$$

(which is well-defined since $a_{i} \rightarrow \infty$ ), then trivially

$$
\begin{equation*}
\frac{C}{6} \leq a_{n_{k+1}}-a_{n_{k}} \leq \frac{C}{3} \quad \text { for each } k=1,2, \ldots \tag{1}
\end{equation*}
$$

[^1]Fix a positive integer $K$ and for $y=\left(y_{1}, y_{2}, \ldots, y_{K}\right) \in \Omega_{K}:=\{-1,+1\}^{K}$ define

$$
\begin{aligned}
\bar{X}_{K} & =\left\{X_{1}, X_{2}, \ldots, X_{K}\right\} \\
s_{y} & =a_{1} y_{1}+a_{2} y_{2}+\ldots a_{k} y_{K} .
\end{aligned}
$$

Let $y \in \Omega_{K}$ be such that $\mathbb{P}\left(\left\{\bar{X}_{K}=y\right\} \cap E\right)>0$. Observe that

$$
\left\{\bar{X}_{K}=y\right\} \cap E=\left\{\bar{X}_{K}=y\right\} \cap B_{K}\left(s_{y}\right)
$$

where

$$
\begin{aligned}
& B_{K}^{+}(u)=\left\{\text { there exist } m_{1}<m_{2}<\ldots \text { such that } u+\sum_{i=K+1}^{m_{j}} a_{i} X_{i} \in[0, C]\right\} ; \\
& B_{K}^{-}(u)=\left\{\text { there exist } m_{1}^{\prime}<m_{2}^{\prime}<\ldots \text { such that } u+\sum_{i=K+1}^{m_{j}^{\prime}} a_{i} X_{i} \in[-C, 0]\right\} ; \\
& B_{K}(u)=B_{K}(u)^{+} \cup B_{K}(u)^{-} .
\end{aligned}
$$

Since $\left\{\bar{X}_{K}=y\right\}$ and $B_{K}(u)$ are independent, we have

$$
\mathbb{P}\left(\left\{\bar{X}_{K}=y\right\} \cap B_{K}\left(s_{y}\right)\right)=\mathbb{P}\left(\bar{X}_{K}=y\right) \mathbb{P}\left(B_{K}\left(s_{y}\right)\right)
$$

Consequently, $\mathbb{P}\left(B_{K}\left(s_{y}\right)\right)>0$, and as a result, $\mathbb{P}\left(B_{K}^{+}\left(s_{y}\right)\right)>0$ or $\mathbb{P}\left(B_{K}^{-}\left(s_{y}\right)\right)>0$ (or both).
Let $\Omega_{K}^{*} \subseteq \Omega_{K}$ contain those $y$ s for which there is an index $k$ such that $n_{k+2} \leq K$ and $y_{n_{k}}=-1$, $y_{n_{k+1}}=+1, y_{n_{k+2}}=-1$; let $k$ be the smallest such index. For $y \in \Omega_{K}^{*}$ define the mappings $\sigma^{+}, \sigma^{-}: \Omega_{K}^{*} \rightarrow \Omega_{K}$ by

$$
\begin{aligned}
& \sigma^{+}(y)= \begin{cases}-y_{i}, & \text { if } i=n_{k} \text { or } i=n_{k+1} ; \\
y_{i}, & \text { otherwise }\end{cases} \\
& \sigma^{-}(y)= \begin{cases}-y_{i}, & \text { if } i=n_{k+1} \text { or } i=n_{k+2} \\
y_{i}, & \text { otherwise }\end{cases}
\end{aligned}
$$

Then for $y \in \Omega_{K}^{*}$

$$
\begin{aligned}
& s_{\sigma^{+}(y)}=s_{y}+2 a_{n_{k}}-2 a_{n_{k}+1} \in\left[s_{y}-2 C / 3, s_{y}-C / 3\right], \\
& s_{\sigma^{-}(y)}=s_{y}-2 a_{n_{k}}+2 a_{n_{k}+1} \in\left[s_{y}+C / 3, s_{y}+2 C / 3\right] .
\end{aligned}
$$

As a result, it is not hard to see that

$$
\begin{aligned}
& \left\{\bar{X}_{K}=\sigma^{+}(y)\right\} \cap B_{K}^{+}\left(s_{y}\right) \subseteq\left\{\sum_{i=1}^{m} a_{i} X_{i} \in[-2 C / 3,2 C / 3] \text { for infinitely many } m s\right\}=\tilde{E}, \\
& \left\{\bar{X}_{K}=\sigma^{-}(y)\right\} \cap B_{K}^{-}\left(s_{y}\right) \subseteq\left\{\sum_{i=1}^{m} a_{i} X_{i} \in[-2 C / 3,2 C / 3] \text { for infinitely many } m s\right\}=\tilde{E}
\end{aligned}
$$

Since at least one of $B_{K}^{+}\left(s_{y}\right)$ and $B_{K}^{-}\left(s_{y}\right)$ has a positive probability, $\mathbb{P}\left(\bar{X}_{K}=\sigma^{ \pm}(y)\right)=2^{-K}$ and the events on the LHS are independent, we conclude that $\mathbb{P}(\tilde{E})>0$.

Now it only remains to show that there exists $y \in \Omega_{K}^{*}$ such that $\mathbb{P}\left(\left\{\bar{X}_{K}=y\right\} \cap E\right)>0$. Let $\kappa:=\kappa(K)=\max \left\{k \in \mathbb{Z}_{+}: n_{k} \leq K\right\}$; obviously, $\kappa(K) \rightarrow \infty$ as $K \rightarrow \infty$. If we choose $y$ from $\Omega_{K}$ uniformly, we can trivially bound the probability that $y \notin \Omega_{K}^{*}$ by $2^{2}$

$$
\left(1-\frac{1}{8}\right)^{\lfloor\kappa / 3\rfloor} \rightarrow 0 \quad \text { as } \kappa \rightarrow \infty
$$

by grouping together triples $\left(X_{n_{1}}, X_{n_{2}}, X_{n_{3}}\right),\left(X_{n_{4}}, X_{n_{5}}, X_{n_{6}}\right)$, etc.; in each such a triple

$$
\mathbb{P}\left(\left(X_{n_{k}}, X_{n_{k+1}}, X_{n_{k+2}}\right)=(-1,+1,-1)\right)=1 / 8
$$

Hence

$$
\begin{equation*}
\mathbb{P}(E)=\sum_{y \in \Omega_{K}} \mathbb{P}\left(\left\{\bar{X}_{K}=y\right\} \cap E\right)=\sum_{y \in \Omega_{K}^{*}} \mathbb{P}\left(\left\{\bar{X}_{K}=y\right\} \cap E\right)+\mathbb{P}\left(\left\{\bar{X}_{K} \in \Omega_{K} \backslash \Omega_{K}^{*}\right\} \cap E\right) . \tag{2}
\end{equation*}
$$

Since $\mathbb{P}\left(\left\{\bar{X}_{K} \in \Omega_{K} \backslash \Omega_{K}^{*}\right\} \cap E\right) \leq \mathbb{P}\left(\bar{X}_{K} \in \Omega_{K} \backslash \Omega_{K}^{*}\right)$, by making $K$ sufficiently large, we can ensure that the second term on the RHS of (2) is less than $\mathbb{P}(E)$, implying that there exist some $y \in \Omega_{K}^{*}$ such that $\mathbb{P}\left(\left\{\bar{X}_{K}=y\right\} \cap E\right)>0$, as required.

Our next result shows that if the sequence $\mathbf{a}$ is non-decreasing, then the walk will always "jump" over 0 infinitely many times, even if the walk is not $C$-recurrent.

Theorem 2. Suppose that $a_{i}$ is a non-decreasing positive sequence. Then the event $\{S(n)>0\}$ holds for infinitely many $n$ a.s. The same is true for the event $\{S(n)<0\}$.

The theorem immediately follows from symmetry and the more general
Proposition 1. Suppose that $a_{i}$ is a non-decreasing sequence, $m$ is an integer such that $a_{m+1}>0$, and $S(m)=A>0$. Define

$$
\tau=\inf \{k \geq 0: S(m+k) \leq 0\}
$$

Let $Y_{j} \sim \mathcal{R}$ ademacher be i.i.d., and

$$
\tilde{\tau}=\inf \left\{k \geq 0: Y_{1}+Y_{2}+\cdots+Y_{k} \leq-r\right\}
$$

where $r=\left\lceil A / a_{m+1}\right\rceil$; note that $\tilde{\tau}<\infty$ a.s. and that, in fact, $Y_{1}+\cdots+Y_{\tilde{\tau}}=-r$. Then $\tau$ is stochastically smaller than $\tilde{\tau}$, that is,

$$
\mathbb{P}(\tau>m) \leq \mathbb{P}(\tilde{\tau}>m), \quad m=0,1,2, \ldots
$$

[^2]Proof. We will use coupling. Indeed, we can write

$$
S(m+j)=A+a_{m+1} Y_{1}+a_{m+2} Y_{2}+\cdots+a_{m+j} Y_{j}, \quad j=1,2, \ldots
$$

Suppose that $\tilde{\tau}=k$, that is

$$
\begin{aligned}
Y_{1}>-r, Y_{1}+Y_{2}>-r & \ldots, Y_{1}+Y_{2}+\cdots+Y_{k-1}>-r ; \\
Y_{1}+Y_{2}+\cdots+Y_{k-1}+Y_{k} & =-r .
\end{aligned}
$$

Then, recalling that $a_{i}$ is a non-decreasing sequence,

$$
\begin{aligned}
S(m+k) & =A+a_{m+1} Y_{1}+\cdots+a_{m+k-1} Y_{k-1}+a_{m+k} Y_{k} \\
& \leq A+a_{m+1} Y_{1}+\cdots+a_{m+k-2} Y_{k-2}+a_{m+k-1} Y_{k-1}+a_{m+k-1} Y_{k} \quad\left(\text { since } Y_{k}=-1\right) \\
& =A+a_{m+1} Y_{1}+\cdots+a_{m+k-2} Y_{k-2}+a_{m+k-1}\left[Y_{k-1}+Y_{k}\right] \\
& \leq A+a_{m+1} Y_{1}+\cdots+a_{m+k-2} Y_{k-2}+a_{m+k-2}\left[Y_{k-1}+Y_{k}\right] \\
& =A+a_{m+1} Y_{1}+\cdots+a_{m+k-2}\left[Y_{k-2}+Y_{k-1}+Y_{k}\right] \\
& \leq \cdots \leq A+a_{m+1}\left[Y_{1}+\ldots+Y_{k}\right]=A-r a_{m+1} \leq 0,
\end{aligned}
$$

since $Y_{k}, Y_{k-1}+Y_{k}, Y_{k-2}+Y_{k-1}+Y_{k}, \ldots, Y_{1}+\cdots+Y_{k}$ are all negative. Therefore, $\tau \leq \tilde{\tau}$.
Throughout the paper we will use a version of the Azuma-Hoeffding inequality; compare with the results of [3].

Lemma 1. Suppose that $b_{1}, b_{2}, \ldots, b_{m}$ is a sequence of non-negative numbers and $\mathcal{S}=b_{1} Y_{1}+b_{2} Y_{2}+$ $\cdots+b_{m} Y_{m}$, where $Y_{j} \sim \mathcal{R}$ ademacher are i.i.d. Then

$$
\begin{equation*}
\mathbb{P}(|\mathcal{S}| \geq A) \leq 2 \exp \left(-\frac{A^{2}}{2\left(b_{1}^{2}+\cdots+b_{m}^{2}\right)}\right) \text { for all } A>0 \tag{3}
\end{equation*}
$$

We also state the following fairly standard result.
Lemma 2. Let $T_{i}=Y_{1}+\cdots+Y_{i}$ be a simple random walk. Suppose that $L_{k}$ and $y_{k}, k=1,2, \ldots$, are two sequences such that $L_{k} \rightarrow \infty, y_{k} \rightarrow \infty$ and $y_{k} / \sqrt{L_{k}} \rightarrow r>0$. Then

$$
\lim _{k \rightarrow \infty} \mathbb{P}\left(\max _{1 \leq i \leq L_{k}} T_{i} \geq y_{k}\right)=2 \mathbb{P}(\eta \geq r)=2-2 \Phi(r)
$$

where $\eta \sim \mathcal{N}(0,1)$ and $\Phi(\cdot)$ is its $C D F$.
Proof. Let $\tilde{y}_{k}=\left\lceil y_{k}\right\rceil \in \mathbb{Z}_{+}$. By the reflection principle,

$$
\begin{aligned}
\mathbb{P}\left(\max _{1 \leq i \leq L_{k}} T_{i} \geq y_{k}\right) & =\mathbb{P}\left(\max _{1 \leq i \leq L_{k}} T_{i} \geq \tilde{y}_{k}\right)=2 \mathbb{P}\left(T_{L_{k}} \geq \tilde{y}_{k}\right)-\mathbb{P}\left(T_{L_{k}}=\tilde{y}_{k}\right) \\
& =2 \mathbb{P}\left(\frac{T_{L_{k}}}{\sqrt{L_{k}}} \geq \frac{\tilde{y}_{k}}{\sqrt{L_{k}}}\right)+O\left(\frac{1}{\sqrt{L_{k}}}\right) \rightarrow 2 \mathbb{P}(\eta \geq r)
\end{aligned}
$$

by the Central Limit Theorem, using also the fact that $\tilde{y}_{k} / y_{k} \rightarrow 1$.

## 2 Integer-valued a-walks

Suppose that the sequence a contains only integers.
Proposition 2. Let $z \in \mathbb{Z}$. Suppose that the sequence

$$
\int_{0}^{\pi} \cos (t z) \prod_{k=1}^{n} \cos \left(t a_{k}\right) \mathrm{d} t, \quad n=1,2, \ldots
$$

is summable. Then the events $\{S(n)=z\}$ occur for finitely many $n$ a.s.
Proof. The result follows from standard Fourier analysis. Indeed,

$$
\mathbb{E} e^{i t S(n)}=\sum_{k \in \mathbb{Z}} e^{i t k} \mathbb{P}(S(n)=k)
$$

where the sum above goes, in fact, effectively over a finite number of $k \mathrm{~s}$ (as $\left.|S(n)| \leq a_{1}+\cdots+a_{n}\right)$. At the same time,

$$
\int_{-\pi}^{\pi} e^{i t(k-z)} \mathrm{d} t= \begin{cases}2 \pi, & \text { if } k=z \\ 0, & \text { if } k \in \mathbb{Z} \backslash\{z\} .\end{cases}
$$

By changing the order of summation and integration, we obtain

$$
\frac{1}{2 \pi} \int_{-\pi}^{\pi} \mathbb{E} e^{i t(S(n)-z)} \mathrm{d} t=\frac{1}{2 \pi} \sum_{k \in \mathbb{Z}} \int_{-\pi}^{\pi} e^{i t(k-z)} \mathbb{P}(S(n)=k) \mathrm{d} t=\mathbb{P}(S(n)=z) .
$$

On the other hand,

$$
\frac{1}{2 \pi} \int_{-\pi}^{\pi} \mathbb{E} e^{i t(S(n)-z)} \mathrm{d} t=\frac{1}{2 \pi} \int_{-\pi}^{\pi} e^{-i t z} \prod_{k=1}^{n} \mathbb{E} e^{i t a_{k} X_{k}} \mathrm{~d} t=\frac{1}{\pi} \int_{0}^{\pi} \cos (t z) \prod_{k=1}^{n} \cos \left(t a_{k}\right) \mathrm{d} t
$$

by the symmetry of cos and the fact that the imaginary part must equal zero. Now the result follows from the Borel-Cantelli lemma, since $\sum_{n} \mathbb{P}(S(n)=z)<\infty$.

Corollary 1. Suppose that the sequence

$$
\int_{0}^{\pi}\left|\prod_{k=1}^{n} \cos \left(t a_{k}\right)\right| \mathrm{d} t, \quad n=1,2, \ldots
$$

is summable. Then the $\mathbf{a}$-walk is transient a.s.
Proof. From Proposition 2 we know that for each $z \in \mathbb{Z}$

$$
\pi \mathbb{P}(S(n)=z)=\int_{0}^{\pi} \cos (t z) \prod_{k=1}^{n} \cos \left(t a_{k}\right) \mathrm{d} t \leq \int_{0}^{\pi}\left|\cos (t z) \prod_{k=1}^{n} \cos \left(t a_{k}\right)\right| \mathrm{d} t \leq \int_{0}^{\pi}\left|\prod_{k=1}^{n} \cos \left(t a_{k}\right)\right| \mathrm{d} t
$$

Hence the event $\{S(n)=z\}$ occurs finitely often a.s. for each $z$. Since for each $C>0$ there are only finitely many integers in $[-C, C]$ we conclude that the walk is not $C$-recurrent a.s. for every $C$.

An interesting and quite natural example is when $\mathbf{a}=(1,2,3, \ldots)$, i.e., $a_{i}=i$. It was previously published in the IMS Bulletin [8], in the Student Puzzle Corner no. 37.

Theorem 3. The a-walk with $\mathbf{a}=(1,2,3, \ldots)$ is a.s. transient.
This statement follows from a much stronger Theorem 4. but for the sake of completeness, we present its self-contained proof.

Proof of Theorem 圆. Let $A_{n}=\{S(n)=0\}=\left\{X_{1}+2 X_{2}+\cdots+n X_{n}=0\right\}$. Then $\mathbb{P}\left(A_{n}\right)=Q_{n} / 2^{n}$, where
$Q_{n}=$ number of ways to put $\pm$ in the sequence $* 1 * 2 * 3 * \cdots * n$ such that the sum equals 0 .
For example, $Q_{1}=Q_{2}=0, Q_{3}=Q_{4}=2, Q_{5}=Q_{6}=0, Q_{7}=8, Q_{8}=14$, etc. It was essentially shown in [6] that

$$
Q_{n} \sim \sqrt{\frac{6}{\pi}} \frac{2^{n}}{n^{3 / 2}} \quad \text { when } n \bmod 4 \in\{0,3\}
$$

(and zero otherwise) as $n \rightarrow \infty$, meaning that the ratio of the RHS and the LHS converges to one. Consequently, $\sum_{n} \mathbb{P}\left(A_{n}\right) \sim \sum_{n} \frac{\text { const }}{n^{3 / 2}}<\infty$ and the events $A_{n}$ occur a.s. finitely often by the Borel-Cantelli lemma. Hence the walk is a.s. not recurrent.

Moreover, since for any $m \in \mathbb{Z}$

$$
\mathbb{P}\left(S(n+2|m|)=S(n)-m \mid \mathcal{F}_{n}\right) \geq \frac{1}{2^{2 m}}
$$

(by making the signs of $X_{n+1}, X_{n+2}, \ldots, X_{n+2|m|}$ alternate), we conclude that if the event $\{S(n)=$ $m\}$ occurs infinitely often, then $A_{n}$ shall also occur infinitely often a.s., leading to contradiction. As a result, $\mathbb{P}(\{S(n)=m\}$ i.o. $)=0$ for all integer $m \mathrm{~s}$, and thus the walk is a.s. not $C$-recurrent for any non-negative $C$.

Remark 1. Though the $(1,2,3, \ldots)$-walk is transient, it still can jump over zero infinitely many times, as it was shown by Theorem 圆.

In fact, Theorem 3 can be generalized greatly, using the result from [5], or even a weaker result of [1], which provide the estimates for the maximum number of solutions of the equation $\sum_{i=1}^{n} \varepsilon_{i} a_{i}=t$ where $\epsilon_{i} \in\{0,1\}$ while $a_{i}$ 's and $t$ are all integers.

Theorem 4. Let a be such that all $a_{i}$ 's are distinct integers. Then a-walk is a.s. transient.
Proof. The main result of [5] implies that for any $\epsilon>0$

$$
\operatorname{card}\left(\left\{\left(x_{1}, x_{2}, \ldots, x_{n}\right): \text { all } x_{i}= \pm 1, a_{1} x_{1}+\cdots+a_{n} x_{n}=m\right\}\right) \leq \frac{(1+\epsilon) 2^{n+3}}{n^{3 / 2} \sqrt{\pi}}
$$

for all $n \geq n_{0}(\epsilon)$ and all $m$. Setting $\epsilon=1$, and fixing $m \in \mathbb{Z}$, we obtain that

$$
\sum_{n=n_{0}(1)}^{\infty} \mathbb{P}(S(n)=m) \leq \sum_{n=n_{0}(1)}^{\infty} \frac{2 \cdot 2^{n+3}}{n^{3 / 2} \sqrt{\pi}} \times \frac{1}{2^{n}}=\frac{16}{\sqrt{\pi}} \sum_{n=n_{0}(1)}^{\infty} \frac{1}{n^{3 / 2}}<\infty .
$$

Therefore, by the Borel-Cantelli lemma, only finitely many events $\{S(n)=m\}$ occur a.s. Since $S(n)$ takes only integer values, this implies that $\{|S(n)| \leq C\}$ happens finitely often a.s. for any $C>0$.

## Remark 2.

(a) It is not difficult to see that under the condition of Theorem母it suffices that all $a_{k}$ 's are distinct only starting from some $k_{0} \geq 1$.
(b) If $a_{k}=\left\lfloor k^{\beta}\right\rfloor$ with $\beta \geq 1$, then we immediately have a.s. transience by Theorem 4 .

## 3 A non-trivial recurrent example

We assume here that $\mathbf{a}=\left(B_{1}, B_{2}, B_{3}, \ldots\right)$ where each $B_{k}$ is a consecutive block of $k$ 's of length precisely $L_{k} \geq 1$. Denote also by $i_{k}=1+L_{1}+L_{2}+\cdots+L_{k-1}$ the index of the first element of the $k$-th block. For example, if $L_{k}=2^{k}$, then $i_{k}=2^{k}-1$ and

$$
\mathbf{a}=(1,1, \underbrace{2,2,2,2}_{L_{2} \text { times }}, \underbrace{3,3,3,3,3,3,3,3}_{L_{3} \text { times }}, \underbrace{4, \ldots, 4}_{L_{4} \text { times }}, \ldots),
$$

one can also notice that $a_{i}=\left\lfloor\log _{2}(i+1)\right\rfloor=\left\lceil\log _{2}(i+2)\right\rceil-1$.
Theorem 5. Suppose that for some $\varepsilon>0, r>0$, and $k_{0}$ we have

$$
\begin{gather*}
\frac{L_{k}}{L_{1}+L_{2}+\cdots+L_{k^{\prime}}} \\
\frac{L_{k}}{L_{k^{\prime}+1}+L_{k^{\prime}+2}+\cdots+L_{k-1}}  \tag{4}\\
L_{k} \geq k^{4}
\end{gather*}
$$

whenever $k-k^{\prime} \geq \frac{k}{\ln k}-2$ and $k, k^{\prime} \geq k_{0}$. Then the $\mathbf{a}$-walk described above is a.s. recurrent.
Remark 3. One can easily check that the conditions of the theorem are satisfied if $a_{k}=\left\lfloor\left(\log _{\gamma} k\right)^{\beta}\right\rfloor$, where $\gamma>1$ and $\beta \in(0,1]$.

Proof of Theorem [5. We will proceed in FIVE steps.

## Step 1: Preliminaries

First, we need the following lemma, which is probably known.

Lemma 3. Let $m \in \mathbb{Z}_{+}$and $T_{m}$ be a simple symmetric random walk on $\mathbb{Z}^{1}$, that is, $T_{m}=Y_{1}+$ $\cdots+Y_{m}$, where $Y_{i} \sim \mathcal{R}$ ademacher are i.i.d. There exists a universal constant $c_{1}>0$ such that for all integers $z$ such that $|z| \leq 2 \sqrt{m}$, assuming that $m$ is sufficiently large and $m+z$ is even,

$$
\mathbb{P}\left(T_{m}=z\right) \geq \frac{c_{1}}{\sqrt{m}}
$$

Proof. W.l.o.g. assume $z \geq 0$. We have

$$
\mathbb{P}\left(T_{m}=z\right)=\mathbb{P}\left(\frac{T_{m}+m}{2}=\frac{z+m}{2}\right)=\mathbb{P}(\tilde{T}=w)
$$

where $\tilde{T} \sim \operatorname{Bin}(m, 1 / 2)$ and $w=\frac{z+m}{2} \in \mathbb{Z}_{+}$. Note that $\tilde{m} \leq w \leq \tilde{m}+\sqrt{m}$ where $\tilde{m}=m / 2$. So

$$
\begin{aligned}
\mathbb{P}(\tilde{T}=w) & =\binom{m}{w} 2^{-m}=\binom{2 \tilde{m}}{\tilde{m}} \frac{1}{2^{2 \tilde{m}}} \frac{\tilde{m}!\tilde{m}!}{w!(m-w)!}=\frac{1+o(1)}{\sqrt{\pi \tilde{m}}} \frac{(2 \tilde{m}-w+1)(2 \tilde{m}-w+2) \ldots \tilde{m}}{(\tilde{m}+1)(\tilde{m}+2) \ldots w} \\
& =\frac{1+o(1)}{\sqrt{\pi \tilde{m}}}\left(1-\frac{w-\tilde{m}}{\tilde{m}+1}\right)\left(1-\frac{w-\tilde{m}}{\tilde{m}+2}\right) \ldots\left(1-\frac{w-\tilde{m}}{w}\right) \\
& \geq \frac{1+o(1)}{\sqrt{\pi \tilde{m}}}\left(1-\frac{\sqrt{m}}{\tilde{m}+1}\right)^{w-\tilde{m}} \geq \frac{1+o(1)}{\sqrt{\pi \tilde{m}}}\left(1-\frac{\sqrt{2}+o(1)}{\sqrt{\tilde{m}}}\right)^{\sqrt{2 \tilde{m}}}=\frac{e^{-2}+o(1)}{\sqrt{\pi m / 2}} \geq \frac{0.1}{\sqrt{m}}
\end{aligned}
$$

for large enough $m$.
Corollary 2. Let $T_{m}, m=0,1,2, \ldots$, be as simple symmetric random walk as in Lemma图. Assume that $m$ and $k$ are positive integers such that $k^{2} \leq m$. Let $u \in \mathbb{Z}$, and either $k$ is odd, or both $k$ and $m-u$ are even. Then for large $k s$

$$
\mathbb{P}\left(T_{m}-u \bmod k=0\right) \geq \frac{c_{1}}{2 k}
$$

where $c_{1}$ is the constant from Lemma 3
Proof of Corollary 圆. First, assume that $m$, and hence $u$, are both even. Since $\left(T_{m}-u\right) \bmod k=$ $0 \Longleftrightarrow T_{m}=\tilde{u} \bmod k$, where $\tilde{u}=(u \bmod k) \in\{0,1,2, \ldots, k-1\}$, it suffices to show the statement for $\tilde{u}$.

Let $M=\lfloor 2 \sqrt{m}\rfloor \in(2 \sqrt{m}-1,2 \sqrt{m}\rfloor$ and define

$$
\begin{gathered}
\mathbb{I}=[-M,-M+1, \ldots,-1,0,1, \ldots, M]=\mathbb{I}_{0} \cup \mathbb{I}_{1} ; \\
\mathbb{I}_{0}=\{z \in \mathbb{I}: z \text { is even }\} ; \quad \mathbb{I}_{1}=\{z \in \mathbb{I}: z \text { is odd }\} .
\end{gathered}
$$

There are at least $M$ elements in each $\mathbb{I}_{0}$ and $\mathbb{I}_{1}$.

If $k$ is odd, then each of these two sets contains at least $\left\lfloor\frac{M}{k}\right\rfloor$ elements $z$ such that $z=\tilde{u} \bmod k$. If $m$ is even (odd, resp.) for all $z$ either in $\mathbb{I}_{0}$ (in $\mathbb{I}_{1}$, resp.) by Lemma 3 for large $k$ s (and hence large $m$ ) we have $\mathbb{P}\left(T_{m}=z\right) \geq c_{1} / \sqrt{m}$. Consequently,

$$
\begin{aligned}
\mathbb{P}\left(T_{m}=\tilde{u} \bmod k\right) & \left.\geq \sum_{z \in \mathbb{I},} \mathbb{z = \tilde { u } \operatorname { m o d } k} \mathbb{P}_{m}=z\right) \geq\left\lfloor\frac{M}{k}\right\rfloor \times \frac{c_{1}}{\sqrt{m}} \geq\left(\frac{M}{k}-1\right) \times \frac{c_{1}}{\sqrt{m}} \\
& \geq\left(\frac{2 \sqrt{m}-1}{k}-1\right) \times \frac{c_{1}}{\sqrt{m}} \geq\left(1-\frac{1}{k}\right) \times \frac{c_{1}}{\sqrt{m}}=\frac{c_{1}}{k}-O\left(k^{-2}\right)
\end{aligned}
$$

since $m \geq k^{2}$.
If $k$ is even, then if $m$ is even (and thus $a$ is also even) then $\mathbb{I}_{0}$ contains at least $\left\lfloor\frac{M}{k}\right\rfloor$ elements $z$ such that $z=\tilde{u} \bmod k$ and at the same time Lemma 3 is applicable for $z \in \mathbb{I}_{0}$. On the other hand, if $m$ (and so $u$ ) is odd then $\mathbb{I}_{1}$ contains at least $\left\lfloor\frac{M}{k}\right\rfloor$ elements $z$ such that $z=\tilde{u} \bmod k$ and Lemma 3 is applicable for $z \in \mathbb{I}_{1}$. The rest of the proof is the same as for the case when $k$ is odd.

## Step 2: Splitting $S(n)$

Recall that that $i_{k}$ denotes the first index of block $k$ and note that the sum of all the steps within block $k$ can be represented as

$$
S\left(i_{k+1}-1\right)-S\left(i_{k}-1\right)=k \cdot T_{k}, \quad T_{k}=X_{1}^{(k)}+\cdots+X_{L_{k}}^{(k)}
$$

where $X_{j}^{(k)}$,s are i.i.d. $\mathcal{R}$ ademacher random variables.
For $m=2, \ldots$, let

$$
k_{m}= \begin{cases}\lfloor m \ln m\rfloor & \text { if }\lfloor m \ln m\rfloor \text { is odd }  \tag{5}\\ \lfloor m \ln m\rfloor+1 & \text { if }\lfloor m \ln m\rfloor \text { is even. }\end{cases}
$$

Thus $k_{m}$ is always odd; $k_{m}, m=2,3, \ldots$ equal $1,3,5,7,9,13,15,19,23$, etc. Define also

$$
A_{m}=\left\{S(j)=0 \text { for some } i_{k_{m}} \leq j<i_{k_{m}+1}\right\}
$$

the event that $S(j)$ hits zero for the steps within block $B_{k_{m}}$, and the sequence of sigma-algebras

$$
\mathcal{G}_{m}=\mathcal{F}_{i_{k_{m+1}}-1}=\sigma\left(\bigcup_{\ell=1}^{k_{m}} \sigma\left(X_{1}^{(\ell)}, X_{2}^{(\ell)}, \ldots, X_{L_{\ell}}^{(\ell)}\right)\right)
$$

Intuitively, $\mathcal{G}_{m}$ contains all the information about the walk during its steps corresponding to the first $k_{m}$ blocks.

To simplify notations, let us now write $k=k_{m}$ and $k^{\prime}=k_{m-1}$, and observe that

$$
\begin{equation*}
k-k^{\prime}=k_{m}-k_{m-1} \geq m \ln m-(m-1) \ln (m-1)-2=\ln m-1+O\left(\frac{1}{m}\right) \geq \ln m-2 \tag{6}
\end{equation*}
$$

for large $m$.
Let us split $S(j)$ where $j \in\left[i_{k}, i_{k+1}\right)$, as follows:

$$
\begin{aligned}
S(j) & =S\left(i_{k^{\prime}}\right)+\sum_{n=k^{\prime}+1}^{k-1}\left(X_{1}^{(n)}+\cdots+X_{L_{n}}^{(n)}\right)+k \cdot\left(X_{1}^{(k)}+\cdots+X_{j-i_{k}}^{(k)}\right) \\
& =S\left(i_{k^{\prime}}\right)+\left[\sum_{n=k^{\prime}+1}^{k-2}\left(X_{1}^{(n)}+\cdots+X_{L_{n}}^{(n)}\right)+(k-1) \sum_{\ell=1}^{i_{k}-2 k^{2}-1} X_{\ell}^{(k-1)}\right] \\
& +(k-1) \cdot \Sigma_{3}+k \cdot\left(X_{1}^{(k)}+\cdots+X_{j-i_{k}}^{(k)}\right) \\
& =\Sigma_{1}+\Sigma_{2}+(k-1) \cdot \Sigma_{3}+k \cdot \Sigma_{4}
\end{aligned}
$$

where $\Sigma_{1}=S\left(i_{k^{\prime}}\right)$ and

$$
\begin{aligned}
& \Sigma_{2}=\sum_{n=k^{\prime}+1}^{k-2} n T_{n}+(k-1) T_{k-1}^{\prime}, \quad T_{k-1}^{\prime}=\sum_{\ell=i_{k-1}}^{i_{k}-1-2 k^{2}} X_{\ell}^{(k-1)} ; \\
& \Sigma_{3}=X_{i_{k}-2 k^{2}}^{(k-1)}+X_{i_{k}-2 k^{2}+1}^{(k-1)}+\cdots+X_{i_{k}-2}^{(k-1)}+X_{i_{k}-1}^{(k-1)} ; \\
& \Sigma_{4}=X_{1}^{(k)}+X_{2}^{(k)}+\cdots+X_{j-i_{k}}^{(k)} .
\end{aligned}
$$

Note that $\Sigma_{i}, i=1,2,3,4$ are independent, and $\Sigma_{3}$ has precisely $2 k^{2}$ terms.

## Step 3: Estimating $\Sigma_{1}$

Recall that $k=k_{m}, k^{\prime}=k_{m-1}$ and let

$$
E_{m-1}=\left\{\left|\Sigma_{1}\right|<k \sqrt{L_{k}}\right\} \in \mathcal{G}_{m-1} .
$$

By Lemma 1 and (4), assuming $k$ is large,

$$
\begin{align*}
\mathbb{P}\left(E_{m-1}^{c}\right) & \leq \mathbb{P}\left(\left|S\left(k^{\prime}\right)\right| \geq k^{\prime} \sqrt{L_{k}}\right) \leq 2 \exp \left(-\frac{k^{\prime 2} \cdot L_{k}}{2\left(L_{1}+2^{2} \cdot L_{2}+3^{2} \cdot L_{3}+\cdots+k^{\prime 2} \cdot L_{k^{\prime}}\right)}\right)  \tag{7}\\
& \leq 2 \exp \left(-\frac{L_{k}}{2\left(L_{1}+L_{2}+L_{3}+\cdots+L_{k^{\prime}}\right)}\right) \leq 2 \exp (-(1+\varepsilon / 2) \ln k)=\frac{2}{k^{1+\varepsilon / 2}}=: \varepsilon_{m}
\end{align*}
$$

## Step 4: Estimating $\Sigma_{2}$

Again, by Lemma 1 and (4), assuming that $k$ is sufficiently large,

$$
\left.\begin{array}{rl}
\mathbb{P}\left(\left|\Sigma_{2}\right| \geq k \sqrt{\frac{L_{k}}{r}}\right.
\end{array}\right) \leq 2 \exp \left(-\frac{k^{2} r^{-1} L_{k}}{2\left[\left(k^{\prime}+1\right)^{2} L_{k^{\prime}+1}+\cdots+(k-2)^{2} L_{k-2}+(k-1)^{2}\left(L_{k-1}-2 k^{2}\right)\right]}\right) .
$$

Consequently,

$$
\begin{equation*}
\mathbb{P}\left(\left|\Sigma_{2}\right|<k \sqrt{L_{k} / r}\right) \geq 0.2 \quad \text { for large } k . \tag{8}
\end{equation*}
$$

## Step 5: Finishing the proof

We have a trivial lower bound

$$
\begin{align*}
\mathbb{P}\left(A_{m} \mid E_{m-1}, \mathcal{G}_{m-1}\right) & \geq \mathbb{P}\left(A_{m}| | \Sigma_{2} \left\lvert\,<k \sqrt{\frac{L_{k}}{r}}\right., E_{m-1}, \mathcal{G}_{m-1}\right) \times \mathbb{P}\left(\left.\left|\Sigma_{2}\right|<k \sqrt{\frac{L_{k}}{r}} \right\rvert\, E_{m-1}, \mathcal{G}_{m-1}\right) \\
& =:(*) \times 0.2 \quad \text { for large } k \tag{9}
\end{align*}
$$

by (8) , since the second multiplier equals $\mathbb{P}\left(\left|\Sigma_{2}\right|<k \sqrt{L_{k} / r}\right)$ by independence.
Let

$$
\operatorname{Div}_{k}=\left\{\Sigma_{1}+\Sigma_{2}+(k-1) \Sigma_{3}=0 \bmod k\right\}=\left\{\Sigma_{1}+\Sigma_{2}-\Sigma_{3}=0 \bmod k\right\}
$$

Since only on the event $\operatorname{Div}_{k}$, it is possible that $S(j)=0$ for some $j$ (since the step sizes are $\pm k$ in the block $B_{k}$ ), we conclude that for large $k$

$$
\begin{align*}
(*) & =\mathbb{P}\left(A_{m}\left|\operatorname{Div}_{k},\left|\Sigma_{2}\right|<k \sqrt{\frac{L_{k}}{r}}, E_{m-1}, \mathcal{G}_{m-1}\right) \times \mathbb{P}\left(\operatorname{Div}_{k}| | \Sigma_{2} \left\lvert\,<k \sqrt{\frac{L_{k}}{r}}\right., E_{m-1}, \mathcal{G}_{m-1}\right)\right. \\
& \geq \mathbb{P}\left(A_{m}\left|\operatorname{Div}_{k},\left|\Sigma_{2}\right|<k \sqrt{\frac{L_{k}}{r}}, E_{m-1}, \mathcal{G}_{m-1}\right) \times \frac{c_{1}}{2 k}\right. \tag{10}
\end{align*}
$$

due to the fact that by Corollary $2, \mathbb{P}\left(\operatorname{Div}_{k} \mid \mathcal{F}_{i_{k}-2 k^{2}-1}\right) \geq c_{1} /(2 k)$. On the other hand,

$$
\begin{align*}
\mathbb{P}\left(A_{m}\left|\operatorname{Div}_{k},\left|\Sigma_{2}\right|<k \sqrt{\frac{L_{k}}{r}}, E_{m-1}, \mathcal{G}_{m-1}\right)\right. & \geq \min _{z \in Z_{k}} \mathbb{P}\left(z+T_{m}=0 \text { for some } m \in\left[0, L_{k}\right]\right) \\
& \geq \beta:=1-\Phi\left(r^{-1 / 2}+3\right)>0 \tag{11}
\end{align*}
$$

where $z+T_{m}$ is a simple random walk starting at $z$ (see Lemma 3), and

$$
Z_{k}=\left\{z \in \mathbb{Z}:|z| \leq\left(r^{-1 / 2}+3\right) \sqrt{L_{k}}\right\} .
$$

Indeed, using the last part of (4), and the conditions we imposed, we have

$$
\left|\Sigma_{1}+\Sigma_{2}+(k-1) \Sigma_{3}\right| \leq k \sqrt{L_{k}}+k \sqrt{L_{k} / r}+2(k-1) k^{2}<\left(1+r^{-1 / 2}+2\right) k \sqrt{L_{k}}
$$

for large $k, S(j)=\left[\Sigma_{1}+\Sigma_{2}+(k-1) \Sigma_{3}\right]+k \cdot \Sigma_{4}$, and by Lemma 2

$$
\liminf _{k \rightarrow \infty} \min _{z \in Z_{k}} \mathbb{P}\left(z+T_{m}=0 \text { for some } m \in\left[0, L_{k}\right]\right) \geq 2 \mathbb{P}\left(\eta>r^{-1 / 2}+3\right)=2 \beta
$$

so the minimum in (11) is $\geq \beta$ for all sufficiently large $k$.
Finally, from (9), (10), and (11) we get that

$$
\sum_{m} \mathbb{P}\left(A_{m} \mid E_{m-1}, \mathcal{G}_{m-1}\right) \geq \sum_{m} \frac{0.2 c_{1} \beta}{2 m \log m}=+\infty
$$

and $\mathbb{P}\left(E_{m}^{c}\right)$ is summable by (17), so we can apply Lemma 5 of Appendix 1 to conclude that events $A_{m}$ occur infinitely often and thus our a-walk is recurrent.

## 4 Continuous example

The example of a-walk described in Theorem [5 roughly corresponds to the case $a_{k}=\left\lceil\log _{\gamma} k\right\rceil$, $k=1,2, \ldots$. But what if $a_{k}$ 's take non-integer values, but, for example, equal

$$
a_{k}=\log _{\gamma} k \equiv c \ln k, \quad k=1,2, \ldots,
$$

where $\gamma=e^{1 / c}>1$ ? In this Section we will study this example. It is unreasonable to assume that such a-walk is recurrent, because of the irrationality of the step sizes, however, we might want to investigate if this walk is $C$-recurrent for some $C>0$. Our main result is the following

Theorem 6. Let $c>0$ and $a_{k}=c \ln k$. Then the $\mathbf{a}$-walk is a.s. $C$-recurrent for every $C>0$.
To prove this theorem, it is sufficient to show that whatever the value $c>0$ is, $\{|S(n)| \leq 3\}$ happens i.o. almost surely. Indeed, take any $C>0$. Then the statement that $\mathbf{a}^{\prime}$-walk with $a_{k}^{\prime}=$ $\frac{3 c}{C} \ln k, k=1,2, \ldots$, is 3 -recurrent is equivalent to the statement that a-walk with $a_{k}=c \ln k$ is $C$-recurrent.

The proof will proceed similarly to that of Theorem 5. Let us define $k_{m}$ slightly differently from (5); namely, let

$$
k_{m}= \begin{cases}\lfloor m \ln m\rfloor & \text { if }\lfloor m \ln m\rfloor \text { is even; } \\ \lfloor m \ln m\rfloor-1 & \text { if }\lfloor m \ln m\rfloor \text { is odd }\end{cases}
$$

Thus now $k_{m}$ are always even. As before, set $k=k_{m}$, and $k^{\prime}=k_{m-1}$, and define

$$
i_{k}=\left\lceil\gamma^{k}\right\rceil=\max \left\{i \geq 1: a_{i}<k\right\}+1=\min \left\{i \geq 1: a_{i} \geq k\right\} \in\left[\gamma^{k}, \gamma^{k}+1\right)
$$

i.e., the first index when $a_{i}$ starts exceeding $k$. For $i \in J_{k}:=\left[i_{k}, i_{k+1}\right)$ write

$$
\begin{array}{cccc}
S(i)=S\left(i_{k^{\prime}}-1\right)+\left[S\left(i_{k}-1\right)-S\left(i_{k^{\prime}}-1\right)-\Sigma_{3}\right] & +\Sigma_{3} & +\left[S(i)-S\left(i_{k}-1\right)\right] \\
=\Sigma_{1} & +\Sigma_{2} & +\Sigma_{3} & +\Sigma_{4}(i) \tag{12}
\end{array}
$$

where

$$
\Sigma_{3}=\left[S\left(i_{k-1}+k^{2}-1\right)-S\left(i_{k-1}-1\right)\right]+\left[S\left(i_{k}\right)-S\left(i_{k}-k^{2}\right)\right] .
$$

Note that $\Sigma_{i}, i=1,2,3,4$ are independent, and $\Sigma_{3}$ has $2 \cdot k^{2}$ terms, and contains the first $k^{2}$ and the last $k^{2}$ steps of the walk, when the step sizes lie in $[k, k+1)$.

Let

$$
\begin{equation*}
E_{m-1}=\left\{\left|\Sigma_{1}\right|<k \sqrt{i_{k}}\right\}=\left\{S\left(i_{k_{m-1}}\right)<k_{m} \sqrt{i_{k_{m}}}\right\} \tag{13}
\end{equation*}
$$

By Lemma 1, since $a_{i}<k^{\prime}<k$ for $i<i_{k^{\prime}}$,

$$
\begin{align*}
\mathbb{P}\left(E_{m-1}^{c}\right) & =\mathbb{P}\left(\left|\Sigma_{1}\right| \geq k \sqrt{i_{k}}\right) \leq 2 \exp \left(-\frac{i_{k} k^{2}}{2 \sum_{j=1}^{i_{k^{\prime}}} a_{j}^{2}}\right) \leq 2 \exp \left(-\frac{i_{k}}{2 i_{k^{\prime}}}\right) \leq 2 \exp \left(-\frac{\gamma^{k}-1}{2 \gamma^{k^{\prime}}}\right) \\
& =2 \exp \left(-\frac{\gamma^{k-k^{\prime}}(1+o(1))}{2}\right)=2 \exp \left(-\frac{\gamma^{\ln m-2}}{2+o(1)}\right)=2 \exp \left(-\frac{m^{\ln \gamma}}{2 \gamma^{2}+o(1)}\right)=: \varepsilon_{m-1} \tag{14}
\end{align*}
$$

using (6) for $k$ sufficiently $\operatorname{larg} 3^{3}$. Observe that $\varepsilon_{m}$ is summable.

Similarly, by Lemma 1

$$
\mathbb{P}\left(\left|\Sigma_{2}\right| \geq 2 k \sqrt{i_{k}}\right) \leq 2 \exp \left(-\frac{4 k^{2} i_{k}}{2 k^{2}\left(i_{k}-i_{k^{\prime}}-2 k^{2}\right)}\right)<2 e^{-2}=0.27 \ldots
$$

Hence,

$$
\begin{equation*}
\mathbb{P}\left(F_{m}\right) \geq 0.72 \text { where } F_{m}=\left\{\left|\Sigma_{2}\right|<2 k \sqrt{i_{k}}\right\} . \tag{15}
\end{equation*}
$$

Lemma 4. Let $n=k^{2}$ where $k$ is an even positive integer, and assume also that $k$ is sufficiently large. Suppose that $X_{i}, Y_{i}, i=1,2, \ldots, n$, are i.i.d. Rademacher. Let

$$
\begin{equation*}
T=(k-1)\left(X_{1}+X_{2}+\cdots+X_{n}\right)+k\left(Y_{1}+Y_{2}+\cdots+Y_{n}\right) . \tag{16}
\end{equation*}
$$

Then

$$
\mathbb{P}(T=j) \geq \frac{c_{1}^{2}}{4 n} \quad \text { for each } j=0, \pm 2, \pm 4, \ldots, \pm n
$$

where $c_{1}$ is the constant from Lemma 3.

[^3]Proof. It follows from Corollary 2 that

$$
\mathbb{P}\left(X_{1}+\cdots+X_{n}=\ell\right) \geq \frac{c_{1}}{2 k}, \quad \mathbb{P}\left(Y_{1}+\cdots+Y_{n}=\ell\right) \geq \frac{c_{1}}{2 k} \quad \text { for all even } \ell \text { such that }|\ell| \leq 2 k
$$

Let $j=2 \tilde{j} \in\{0,2,4, \ldots, n-2, n\}$. Consider the sequence of $k-1$ numbers

$$
\tilde{j}, \tilde{j}-k, \tilde{j}-2 k, \tilde{j}-3 k, \ldots, \tilde{j}-(k-2) k
$$

they all give different remainders when divided by $k-1$. Hence there must be an $m \in\{0,1, \ldots, k-2\}$ such that $\tilde{j}-m k=b(k-1)$ and $b$ is an integer; moreover, since $0 \leq \tilde{j} \leq n / 2$, we have $b \in$ $\left[-\frac{k(k-2)}{k-1}, \frac{n}{2(k-1)}\right]$. For such $m$ and $b$ we have $j=2 \tilde{j}=(2 m) k+(2 b)(k-1)$, and, since both $|2 m|$ and $|2 b| \leq 2 k$,

$$
\mathbb{P}(T=j) \geq \mathbb{P}\left(X_{1}+\cdots+X_{n}=2 b\right) \cdot \mathbb{P}\left(Y_{1}+\cdots+Y_{n}=2 m\right) \geq\left(\frac{c_{1}}{2 k}\right)^{2}=\frac{c_{1}^{2}}{4 n}
$$

by (17). The result for negative $j$ follows by symmetry.
Corollary 3. Let $\varepsilon=\frac{2 c k^{4}}{\gamma^{k-1}}$. Then for large even $k$

$$
\mathbb{P}\left(\Sigma_{3} \in[j-\varepsilon, j+\varepsilon]\right) \geq \frac{c_{1}^{2}}{4 k^{2}} \quad \text { for each } j=0, \pm 2, \pm 4, \ldots, \pm k^{2}
$$

Proof. $\Sigma_{3}$ has the same distribution as

$$
\sum_{\ell=1}^{k^{2}} c \ln \left(i_{k-1}-1+\ell\right) X_{\ell}+\sum_{\ell=1}^{k^{2}} c \ln \left(i_{k}-\ell\right) Y_{\ell}
$$

for some i.i.d. $X_{\ell}, Y_{\ell} \sim \mathcal{R}$ ademacher. At the same time, for $\ell \geq 1$,

$$
\begin{aligned}
\left|c \ln \left(i_{k-1}-1+\ell\right)-(k-1)\right| & =\left|c \ln \left(\left\lceil\gamma^{k-1}\right\rceil+\ell-1\right)-(k-1)\right| \\
& \leq\left|c \ln \left(\gamma^{k-1}+\ell\right)-(k-1)\right|=c \ln \left(1+\frac{\ell}{\gamma^{k-1}}\right) \leq \frac{c \ell}{\gamma^{k-1}}
\end{aligned}
$$

Similarly,

$$
k-c \ln \left(i_{k}-\ell\right)=k-c \ln \left(\left\lceil\gamma^{k}\right\rceil-\ell\right)=k-c \ln \left(\gamma^{k}-\ell^{\prime}\right)=-c \ln \left(1-\frac{\ell^{\prime}}{\gamma^{k}}\right) \in\left[0, \frac{c \ell}{\gamma^{k-1}}\right]
$$

for some $\ell^{\prime} \in[\ell-1, \ell]$, assuming $\ell=o\left(\gamma^{k}\right)$. As a result, for $T$ defined by (16),

$$
\left|\Sigma_{3}-T\right| \leq \sum_{\ell=1}^{k^{2}} \frac{2 c \ell}{\gamma^{k-1}}=\frac{c k^{2}\left(k^{2}+1\right)}{\gamma^{k-1}} \leq \frac{2 c k^{4}}{\gamma^{k-1}} .
$$

Now the result follows from Lemma 4 .

Proof of Theorem 6. Recall that $J_{k}=\left[i_{k}, i_{k+1}\right)$ and define

$$
A_{m}=\left\{S(i)=0 \text { for some } i \in J_{k_{m}}\right\}
$$

Then

$$
\begin{equation*}
\mathbb{P}\left(A_{m} \mid E_{m-1}, \mathcal{G}_{m-1}\right) \geq 0.72 \times \mathbb{P}\left(A_{m} \mid F_{m}, E_{m-1}, \mathcal{G}_{m-1}\right) \tag{18}
\end{equation*}
$$

(please see the definition of $F_{m}$ in (15)). Recall formula (12) and write

$$
\tilde{S}(i)=S(i)-\Sigma_{3}=\Sigma_{1}+\Sigma_{2}+\Sigma_{4}(i)
$$

From now on assume that $\left|\Sigma_{1}\right|<k \sqrt{i_{k}}$ and $\left|\Sigma_{2}\right|<2 k \sqrt{i_{k}}$, that is, $E_{m-1}$ and $F_{m}$ occur. Also assume w.l.o.g. that $\Sigma_{1}+\Sigma_{2} \geq 0$. Let

$$
L_{k}=i_{k+1}-i_{k}-k^{2}=(\gamma-1) \gamma^{k}+o\left(\gamma^{k}\right) .
$$

Consider a simple random walk with steps $Y_{i} \sim \mathcal{R}$ ademacher during its first $L_{k}$ steps. The probability that its minimum will be equal to or below the level $-3 \sqrt{i_{k}}=-\frac{3+o(1)}{\sqrt{\gamma-1}} \sqrt{L_{k}}$ converges by Lemma 2 to

$$
2 \mathbb{P}\left(\eta>\frac{3}{\sqrt{\gamma-1}}\right)=2-2 \Phi\left(\frac{3}{\sqrt{\gamma-1}}\right)=: 2 c_{2} \in(0,1)
$$

as $k \rightarrow \infty$ (recall that $\eta \sim \mathcal{N}(0,1)$ ). As a result, by Proposition 1 the probability that for some $j_{0} \in\left\{i_{k}, i_{k}+1, i_{k}+2, \ldots, i_{k}+L_{k}-1\right\}$ we have the downcrossing, that is,

$$
\tilde{S}\left(j_{0}-1\right) \geq 0>\tilde{S}\left(j_{0}\right)
$$

is bounded below by $c_{2}$ for $k$ sufficiently large. Formally, let

$$
\begin{aligned}
j_{0} & =\inf \left\{j>i_{k}: \tilde{S}(j)<0\right\} \\
\mathcal{C}_{0} & =\left\{i_{k} \leq j_{0} \leq i_{k}+L_{k}-1\right\}
\end{aligned}
$$

so we have showed that on $E_{m-1} \cap F_{m} \cap\left\{\Sigma_{1}+\Sigma_{2}>0\right\}$ we have $\mathbb{P}\left(\mathcal{C}_{0}\right)>c_{2}$ for large $k$.
Now assume that event $\mathcal{C}_{0}$ occurred and define additionally

$$
\begin{aligned}
b_{0} & =\tilde{S}\left(j_{0}\right) \in(-k-1,0] \\
\mathcal{C} & =\left\{\max _{0 \leq h \leq k^{2}} \sum_{g=1}^{h} X_{j_{0}+g} \geq k\right\} .
\end{aligned}
$$

Again, from Lemma 2,

$$
\mathbb{P}(\mathcal{C})=2 \mathbb{P}\left(X_{j_{0}+1}+X_{j_{0}+2}+\cdots+X_{j_{0}+k^{2}} \geq k\right) \rightarrow 2(1-\Phi(1))=0.3173 \ldots \quad \text { as } k \rightarrow \infty
$$

From now on assume that $k$ is so large that $\mathbb{P}(\mathcal{C})>0.2$. On the event $\mathcal{C}$ there exists an increasing sequence $j_{1}, j_{2}, \ldots, j_{k}$ such that

$$
j_{0}<j_{1}<j_{2}<\cdots<j_{k} \leq j_{0}+k^{2}<i_{k+1}
$$

such that $X_{j_{0}+1}+X_{j_{0}+2}+\cdots+X_{j_{\ell}}=\ell$ for each $\ell=1,2, \ldots, k$, since the random walk must pass through each integer in $\{1,2, \ldots, k\}$ in order to reach level $k$.

For $\ell=1,2, \ldots, k$, define

$$
\begin{aligned}
b_{\ell}:=\tilde{S}\left(j_{\ell}\right) & =b_{0}+\sum_{h=j_{0}+1}^{j_{\ell}} a_{h} X_{h}=b_{0}+a_{j_{0}}\left[\sum_{h=j_{0}+1}^{j_{\ell}} X_{h}\right]+\sum_{h=j_{0}+1}^{j_{\ell}}\left(a_{h}-a_{j_{0}}\right) X_{h} \\
& =b_{0}+a_{j_{0}} \ell+O\left(\frac{k^{4}}{\gamma^{k}}\right)
\end{aligned}
$$

since for $h \in\left[j_{0}, j_{0}+k^{2}\right] \subseteq\left[i_{k}, i_{k+1}\right)$ we have

$$
\left|a_{h}-a_{j_{0}}\right|=c\left|\ln \frac{a_{h}}{a_{j_{0}}}\right| \leq c\left|\ln \frac{i_{k}+k^{2}}{j_{k}}\right|=O\left(\frac{k^{2}}{\gamma^{k}}\right) .
$$

As a result,

$$
-(k+1)<b_{0}<b_{1}<b_{2}<\cdots<b_{k-1}<(k-1)(k+1)<k^{2}
$$

and moreover the distance between consecutive $b_{g}$ 's is at least two (provided $k$ is large). For $\ell=0,1, \ldots, k-1$ define

$$
\tilde{b}_{\ell}=\sup \left\{x \in 2 \mathbb{Z}: x+b_{\ell} \in\left[\frac{1}{2}, 3-\frac{1}{2}\right)\right\} \equiv-2\left\lfloor\frac{b_{\ell}}{2}-\frac{1}{4}\right\rfloor .
$$

Then $\tilde{b}_{\ell}$ 's are all distinct even integers satisfying $\left|\tilde{b}_{\ell}\right| \leq k^{2}$.
As a result,

$$
\begin{aligned}
\mathbb{P}\left(A_{m} \mid\right. & \left.F_{m}, E_{m-1}, \mathcal{G}_{m-1}\right) \geq c_{2} \times 0.2 \times \mathbb{P}\left(S(i) \in[0,3] \text { for some } i \in J_{k} \mid \mathcal{C}, \mathcal{C}_{0}\right) \\
& \geq c_{2} \times 0.2 \times \mathbb{P}\left(\tilde{S}^{\prime}\left(i_{\ell}\right)+\Sigma_{3} \in[0,3] \text { for some } \ell=0,1, \ldots, k-1 \mid \mathcal{C}, \mathcal{C}_{0}\right) \\
& =c_{2} \times 0.2 \times \mathbb{P}\left(b_{\ell}+\Sigma_{3} \in[0,3] \text { for some } \ell=0,1, \ldots, k-1 \mid \mathcal{C}, \mathcal{C}_{0}\right) \\
& \geq c_{2} \times 0.2 \times \mathbb{P}\left(\tilde{\Sigma}_{3} \in\left[\tilde{b}_{\ell}-\varepsilon, \tilde{b}_{\ell}+\varepsilon\right] \text { for some } \ell=0,1, \ldots, k-1 \mid \mathcal{C}, \mathcal{C}_{0}\right) \\
& =c_{2} \times 0.2 \times \sum_{\ell=0}^{k-1} \mathbb{P}\left(\Sigma_{3} \in\left[\tilde{b}_{\ell}-\varepsilon, \tilde{b}_{\ell}+\varepsilon\right] \mid \mathcal{C}, \mathcal{C}_{0}\right) \geq c_{2} \times 0.2 \times k \times \frac{c_{1}^{2}}{4 k^{2}}=\frac{c_{1}^{2} c_{2}}{20 k}
\end{aligned}
$$

assuming that $\varepsilon$ in Corollary 3 is sufficiently small. Finally,

$$
\mathbb{P}\left(A_{m} \mid E_{m-1}, \mathcal{G}_{m-1}\right) \geq 0.72 \times \mathbb{P}\left(A_{m} \mid F_{m}, E_{m-1}, \mathcal{G}_{m-1}\right) \geq \frac{0.72 c_{1}^{2} c_{2}}{20 k_{m}} \geq \frac{0.036 c_{1}^{2} c_{2}}{m \ln m}
$$

the sum of which diverges. Hence, recalling (14), we can again apply Lemma 5 ,

## 5 Sublinear growth of step sizes

Throughout this Section we assume

$$
a_{k}=\left\lfloor k^{\beta}\right\rfloor, \quad 0<\beta<1 .
$$

Proposition 3. Let $S(n)=a_{1} X_{1}+\cdots+a_{n} X_{n}$ where $a_{k}=\left\lfloor k^{\beta}\right\rfloor, 0<\beta<1$. Then

$$
\mathbb{P}(|S(n)|=z) \leq \frac{\nu}{n^{1 / 2+\beta}} \quad \text { for all large } n
$$

for some $\nu>0$.
Proof. Let $F_{n}(t)=\prod_{k=1}^{n}\left|\cos \left(t a_{k}\right)\right|$. For all $z \in \mathbb{Z}$ we have

$$
\mathbb{P}(S(n)=z)=\frac{1}{2 \pi} \int_{-\pi}^{\pi} e^{-i t z} \mathbb{E} e^{i t S(n)} \mathrm{d} t \leq \frac{1}{2 \pi} \int_{-\pi}^{\pi}\left|\mathbb{E} e^{i t S(n)}\right| \mathrm{d} t=\frac{1}{2 \pi} \int_{-\pi}^{\pi} F_{n}(t) \mathrm{d} t \leq \frac{\nu}{n^{1 / 2+\beta}}
$$

by Lemma 6 for some $\nu>0$, for all large $n$.
Theorem 7. Suppose that $a_{k}=\left\lfloor k^{\beta}\right\rfloor, 0<\beta<1$. Then the $\mathbf{a}$-walk is a.s. transient.
Proof. In the case $\beta>1 / 2$ the a.s. transience follows immediately from Borel-Cantelli lemma and Proposition 3, as $\sum_{n} \mathbb{P}(|S(n)| \leq C)<\infty$ for each $C \geq 1$.

Assume from now on that $0<\beta \leq 1 / 2$. Define $k_{m}, \Delta_{m}, m_{n}$ as in Case 3 of the proof of Lemma 6. Fix a positive integer $M$ and consider now only those $n$ for which $m_{n}=M$. Let $I_{M}=\left\{k_{M}, k_{M}+1, \ldots, k_{M+1}-1\right\}$. Note that the elements of $I_{M}$ are precisely those $n$ for which $a_{n}=M$, and that the caridnality of $I_{M}$ is of order $M^{1 / \beta-1}$. Next, fix some $z \in \mathbb{Z}$ and define

$$
\left.E_{M}=E_{M}(z)=\left\{S(n)=z \text { for some } n \in I_{M}\right\}\right\} .
$$

For each $z$ we will show that $\sum_{M} \mathbb{P}\left(E_{M}\right)<\infty$, and so by the Borel-Cantelli lemma a.s. only finitely many events $E_{M}$ occur. Since $S(n)$ takes only integer values, this will imply that the walk is not $C$-recurrent for any $C \geq 0$.

So, fix $z$ from now on, write $S(n)=S\left(k_{M}\right)+R(n)$ where

$$
R(n)=\sum_{i=k_{M}}^{n} a_{i} X_{i}=M \sum_{i=k_{M}}^{n} X_{i},
$$

Observe also that $S\left(k_{M}\right)$ and $R(n)$ are independent. In order $S(n)=z$ for some $n \in I_{M}$, we need that $S\left(k_{M}\right)=z \bmod M$. Let $Q=M^{\frac{1}{2 \beta}+1-\varepsilon}$ for an $\varepsilon \in(0,1 / 2)$. Assuming $M$ is so large that $Q \geq 2|z|$,

$$
\begin{aligned}
\mathbb{P}(|R(n)| \geq Q-|z|) & \leq 2 \exp \left(-\frac{(Q / 2)^{2}}{2 M^{2} \cdot\left(k_{M+1}-k_{M}\right)}\right)=2 \exp \left(-\frac{\beta Q^{2}}{(8+o(1)) M^{2} \cdot M^{\frac{1}{\beta}-1}}\right) \\
& =2 \exp \left(-\frac{\beta M^{1-2 \varepsilon}}{8+o(1)}\right) \quad \text { for all } n \in I_{M}
\end{aligned}
$$

by Lemma hence

$$
\mathbb{P}\left(\max _{n \in I_{M}}|R(n)| \geq Q-|z|\right) \leq\left|I_{M}\right| \times 2 \exp \left(-\frac{\beta M^{1-2 \varepsilon}}{8+o(1)}\right)=: \alpha_{M}=O\left(M^{\frac{1}{\beta}-1} e^{-\frac{\beta M^{1-2 \varepsilon}}{8+o(1)}}\right)
$$

which is summable in $M$. So,

$$
\begin{aligned}
\mathbb{P}\left(E_{M}\right) & \leq \mathbb{P}\left(E_{M}, \max _{n \in I_{M}}|R(n)|<Q-|z|\right)+\mathbb{P}\left(\max _{n \in I_{M}}|R(n)| \geq Q-|z|\right) \\
& =\mathbb{P}\left(E_{M}, S\left(k_{M}\right)=z \bmod M, \max _{n \in I_{M}}|R(n)|<Q-|z|\right)+\alpha_{M}=(*)+\alpha_{M}
\end{aligned}
$$

where the term $\alpha_{M}$ is summable since $1-2 \varepsilon>0$. Since $E_{M}$ implies implies $-S\left(k_{M}\right)=R(n)-z$ for some $n \in I_{M}$,

$$
\begin{aligned}
(*) & \leq \mathbb{P}\left(\left|S\left(k_{M}\right)\right|<Q, S\left(k_{M}\right)=z \bmod M\right)=\sum_{j:|j|<Q, j=z \bmod M} \mathbb{P}\left(\left|S\left(k_{M}\right)\right|=j\right) \\
& \leq \frac{\nu}{k_{M}^{1 / 2+\beta}} \times|\{j:|j|<Q, j=z \bmod M\}| \leq \frac{\nu+o(1)}{M^{1+\frac{1}{2 \beta}}} \times\left[\frac{2 Q+1}{M}+1\right]=\frac{(\nu+o(1))}{\pi M^{1+\varepsilon}}
\end{aligned}
$$

by Proposition 3. The RHS is summable in $M$, which concludes the proof.
Remark 4. By setting $\varepsilon=1 / 2-\delta / 2$, where $\delta>0$ is very close to zero, we can ensure that

$$
\begin{aligned}
\mathbb{P}\left(|S(n)|<M^{1 / 2-\delta} \text { for some } n \in I_{M}\right) & \leq \sum_{z:|z|<M^{1 / 2-\delta}} \mathbb{P}\left(E_{M}(z)\right) \leq\left[\frac{\text { const }}{M^{1+\varepsilon}}+\alpha_{M}\right] \times 2 M^{1 / 2-\delta} \\
& =\frac{2 \text { const }}{M^{1+\delta / 2}}+2 M^{1 / 2-\delta} \alpha_{M}
\end{aligned}
$$

is summable. Hence, a.s. eventually $|S(n)|$ will be larger that $n^{\beta / 2-\delta}$ for any $\delta>0$.

## Appendix 1: Modified conditional Borel-Cantelli lemma

Lemma 5. Suppose that we have an increasing sequence of sigma-algebras $\mathcal{G}_{m}$ and a sequence of $\mathcal{G}_{m}$-measurable events $A_{m}$ and $E_{m}$ such that

$$
\mathbb{P}\left(A_{m} \mid E_{m-1}, \mathcal{G}_{m-1}\right) \geq \alpha_{m}, \quad \mathbb{P}\left(E_{m}^{c}\right) \leq \varepsilon_{m} \quad \text { a.s. }
$$

where the non-negative $\alpha_{n}$ and $\varepsilon_{n}$ satisfy

$$
\begin{equation*}
\sum_{m} \alpha_{m}=\infty, \quad \sum_{m} \varepsilon_{m}<\infty . \tag{19}
\end{equation*}
$$

Then $\mathbb{P}\left(A_{m}\right.$ i.o. $)=1$.

Proof. Let $m>\ell \geq 1$ and $B_{\ell, m}=\bigcap_{i=\ell}^{m} A_{i}^{c}$. We need to show that for any $\ell \geq 1$

$$
\begin{equation*}
\mathbb{P}\left(B_{\ell, \infty}\right)=\mathbb{P}\left(A_{\ell}^{c} \cap A_{\ell+1}^{c} \cap A_{\ell+2}^{c} \cap \ldots\right)=0 \tag{20}
\end{equation*}
$$

We have for $m \geq \ell+1$

$$
\begin{align*}
\mathbb{P}\left(B_{\ell, m}\right) & =\mathbb{P}\left(A_{m}^{c} \cap B_{\ell, m-1}\right) \leq \mathbb{P}\left(A_{m}^{c} \cap B_{\ell, m-1} \cap E_{m-1}\right)+\mathbb{P}\left(E_{m-1}^{c}\right) \\
& =\mathbb{P}\left(A_{m}^{c} \mid B_{\ell, m-1} \cap E_{m-1}\right) \mathbb{P}\left(B_{\ell, n-1} \cap E_{m-1}\right)+\mathbb{P}\left(E_{m-1}^{c}\right)  \tag{21}\\
& \leq \mathbb{P}\left(A_{m}^{c} \mid B_{\ell, m-1} \cap E_{m-1}\right) \mathbb{P}\left(B_{\ell, m-1}\right)+\varepsilon_{m-1} \leq\left(1-\alpha_{m}\right) \mathbb{P}\left(B_{\ell, m-1}\right)+\varepsilon_{m-1} .
\end{align*}
$$

By induction over $m, m-1, m-2, \ldots, \ell+1$ in (21), we get that

$$
\begin{aligned}
\mathbb{P}\left(B_{\ell, m}\right) & \leq \varepsilon_{m-1}+\left(1-\alpha_{m}\right)\left[\left(1-\alpha_{m-1}\right) \mathbb{P}\left(B_{\ell, m-2} \mid \mathcal{G}_{m}\right)+\varepsilon_{m-2}\right] \leq \ldots \\
& \leq \varepsilon_{m-1}+\left(1-\alpha_{m}\right) \varepsilon_{m-2}+\left(1-\alpha_{m}\right)\left(1-\alpha_{m-1}\right) \varepsilon_{m-3}+\ldots \\
& +\left(1-\alpha_{m}\right)\left(1-\alpha_{m-1}\right) \ldots\left(1-\alpha_{\ell+2}\right) \varepsilon_{\ell}+\left(1-\alpha_{m}\right)\left(1-\alpha_{m-1}\right) \ldots\left(1-\alpha_{\ell+1}\right) .
\end{aligned}
$$

Hence, for any integer $M \in(\ell, m)$

$$
\begin{aligned}
\mathbb{P}\left(B_{\ell, m}\right) & \leq \varepsilon_{m-1}+\varepsilon_{m-2}+\cdots+\varepsilon_{M} \\
& +\left(1-\alpha_{m}\right)\left(1-\alpha_{m-1}\right) \cdots\left(1-\alpha_{M+1}\right) \varepsilon_{M-1}+\cdots+\left(1-a_{m}\right)\left(1-\alpha_{m-1}\right) \cdots\left(1-\alpha_{\ell+2}\right) \varepsilon_{\ell} \\
& +\left(1-\alpha_{m}\right)\left(1-\alpha_{m-1}\right) \cdots\left(1-\alpha_{\ell+1}\right) \\
& \leq\left[\varepsilon_{m-1}+\varepsilon_{m-2}+\cdots+\varepsilon_{M}\right] \\
& +\left(1-\alpha_{m}\right)\left(1-\alpha_{m-1}\right) \cdots\left(1-\alpha_{M+1}\right)\left[\varepsilon_{M-1}+\varepsilon_{M-2}+\cdots+\varepsilon_{\ell}+1\right]
\end{aligned}
$$

Fix any $\delta>0$. By (19) we can find an $M$ be so large that $\sum_{i=M}^{\infty} \varepsilon_{i}<\delta / 2$. Then, again by (19), there exists an $m_{0}>M$ such that $\prod_{i=M+1}^{m_{0}}\left(1-\alpha_{i}\right)<\frac{\delta}{2\left(1+\sum_{i=\ell}^{M-1} \varepsilon_{i}\right)}$. Hence, for all $m \geq m_{0}$ we have $\mathbb{P}\left(B_{\ell, m}\right) \leq \delta / 2+\delta / 2=\delta$. Since $\delta>0$ is arbitrary, and $B_{\ell, m}$ is a decreasing sequence of events in $m$, we conclude that $\mathbb{P}\left(B_{\ell, \infty}\right)=0$, as required.

## Appendix 2: Generalization of Blair Sullivan's results

Let $a_{k}=\left\lfloor k^{\beta}\right\rfloor$, where $0<\beta<1$.
Lemma 6. Let $F_{n}(t)=\prod_{k=1}^{n}\left|\cos \left(t a_{k}\right)\right|$. Then

$$
\int_{-\pi}^{\pi} F_{n}(t) \mathrm{d} t=\frac{\sqrt{8 \pi(1+2 \beta)}+o(1)}{n^{\beta+1 / 2}} \quad \text { as } n \rightarrow \infty .
$$

Remark 5. Note that for $\beta=1$ we would have obtained the same result as in [6].
Proof. We will proceed in the spirit of [6]. Note that by symmetry

$$
\int_{-\pi}^{\pi} F_{n}(t) \mathrm{d} t=2 \int_{0}^{\pi} F_{n}(t) \mathrm{d} t=2 \int_{0}^{\pi / 2} F_{n}(t) \mathrm{d} t+2 \int_{0}^{\pi / 2} F_{n}(\pi-t) \mathrm{d} t=4 \int_{0}^{\pi / 2} F_{n}(t) \mathrm{d} t
$$

since $\left|\cos \left((\pi-t) a_{k}\right)\right|=\left|\cos \left(\pi a_{k}-t a_{k}\right)\right|=\left|\cos \left(t a_{k}\right)\right|$ as $a_{k}$ is an integer. Let $\varepsilon>0$ be very small and define

$$
I_{0}=\left[0, \frac{1}{n^{\beta+1 / 2-\varepsilon}}\right], \quad I_{1}=\left[\frac{1}{n^{\beta+1 / 2-\varepsilon}}, \frac{1}{n^{\beta}}\right], \quad I_{2}=\left[\frac{1}{n^{\beta}}, \frac{c_{1}}{n^{\beta}}\right], \quad I_{3}=\left[\frac{c_{1}}{n^{\beta}}, \frac{\pi}{2}\right] .
$$

for some $c_{1}>1$ to be determined later. Then

$$
\int_{0}^{\pi / 2} F_{n}(t) \mathrm{d} t=\int_{I_{0}} F_{n}(t) \mathrm{d} t+\int_{I_{1}} F_{n}(t) \mathrm{d} t+\int_{I_{2}} F_{n}(t) \mathrm{d} t+\int_{I_{3}} F_{n}(t) \mathrm{d} t
$$

We will show that the contribution of all the integrals, except the first one, is negligible, and estimate the value of the first one.

First, observe that when $0 \leq t a_{k} \leq \pi / 2$ for all $k \leq n$, by the elementary inequality $|\cos u| \leq$ $e^{-u^{2} / 2}$ valid for $|u| \leq \pi / 2$, we have

$$
\begin{equation*}
F_{n}(t) \leq \prod_{k=1}^{n} \exp \left(-\frac{t^{2} a_{k}^{2}}{2}\right)=\exp \left(-\frac{t^{2}}{2} \sum_{k=1}^{n} a_{k}^{2}\right)=\exp \left(-\frac{t^{2} n^{2 \beta+1}(1+o(1))}{2(1+2 \beta)}\right) \tag{22}
\end{equation*}
$$

since $a_{k}^{2}=k^{2 \beta}(1+o(1))$.
$\underline{\text { Case 0: }} t \in I_{0}$
Here $t a_{k} \leq \frac{1}{n^{1 / 2-\varepsilon}} \ll 1$, hence for $n$ large enough

$$
\frac{\left(t a_{k}\right)^{2}}{2} \leq-\ln \cos \left(t a_{k}\right)=\frac{\left(t a_{k}\right)^{2}}{2}+O\left(\left(t a_{k}\right)^{4}\right) \leq(1+o(1)) \frac{\left(t a_{k}\right)^{2}}{2}
$$

yielding $F_{n}(t)=\exp \left(-\frac{t^{2} n^{2 \beta+1} \rho_{n, t}}{2(1+2 \beta)}\right)$ where $\rho_{n, t}=1+o(1)$ for large $n$ (compare with (222)). Since for any $r>0$ we have

$$
\begin{aligned}
\int_{0}^{n^{-\beta-1 / 2+\varepsilon}} \exp \left(-\frac{t^{2} n^{2 \beta+1} r}{2(1+2 \beta)}\right) \mathrm{d} t & =\frac{1}{n^{1 / 2+\beta}} \int_{0}^{n^{\varepsilon}} \exp \left(-\frac{s^{2} r}{2(1+2 \beta)}\right) \mathrm{d} s \\
& =\frac{1}{n^{1 / 2+\beta}}\left[\sqrt{\frac{\pi(1+2 \beta)}{2 r}}+o(1)\right]
\end{aligned}
$$

where the main term is monotone in $r$, by substituting $r=\rho_{n, t}=1+o(1)$ we conclude that

$$
\int_{I_{0}} F_{n}(t) \mathrm{d} t=\frac{1}{n^{1 / 2+\beta}}[\sqrt{\pi(1 / 2+\beta)}+o(1)]
$$

Case 1: $t \in I_{1}$
Since $t a_{k} \leq 1<\pi / 2$, by (22) for some $C_{2}>0$ we have $F_{n}(t) \leq \exp \left(-\frac{n^{2 \varepsilon}(1+o(1))}{2(1+2 \beta)}\right) \leq e^{-C_{2} n^{2 \varepsilon}}$, so $\int_{I_{1}} F_{n}(t) \mathrm{d} t \leq e^{-C_{2} n^{2 \varepsilon}}$, which decays faster than polynomially.
$\underline{\text { Case 2: }} t \in I_{2}$
As in Case 2 in [6], we will use monotonicity of $F_{n}(t)$ in $n$. Let $r=c_{1}^{-1 / \beta} \in(0,1)$ then $\lfloor r n\rfloor^{\beta} \leq(r n)^{\beta}=\frac{n^{\beta}}{c_{1}}$, consequently by (22), since $t \leq \frac{c_{1}}{n^{\beta}}$,

$$
F_{\lfloor r n\rfloor}(t) \leq \exp \left(-\frac{t^{2}(r n)^{2 \beta+1}(1+o(1))}{2(1+2 \beta)}\right)
$$

and since $F_{n}(t) \leq F_{\lfloor r n\rfloor}(t)$, we get a similar bound as in Case 1 .

Case 3: $t \in I_{3}$
Let

$$
\begin{aligned}
& k_{m}=\inf \left\{k \in \mathbb{Z}_{+}: k^{\beta} \geq m\right\}=\left\lceil m^{1 / \beta}\right\rceil, \quad m=1,2, \ldots ; \\
& \Delta_{m}=k_{m+1}-k_{m}=\beta^{-1} m^{\gamma}+O\left(m^{1 / \beta-2}\right)+\rho_{0}, \quad \gamma:=\frac{1-\beta}{\beta},
\end{aligned}
$$

where $\left|\rho_{0}\right| \leq 1$. Then

$$
a_{k}=m \quad \text { if and only if } k \in\left\{k_{m}, k_{m}+1, \ldots, k_{m}+\Delta_{m}-1\left(\equiv k_{m+1}-1\right)\right\} .
$$

For $n \in \mathbb{Z}_{+}$let

$$
m_{n}=\max \left\{m: k_{m} \leq n\right\}=n^{\beta}(1+o(1)), \quad n \in\left[k_{m_{n}}, k_{m_{n}}+\Delta_{m_{n}}-1\right] .
$$

By the inequality between the mean geometric and the mean arithmetic,

$$
\begin{aligned}
F_{n}(t) & =\sqrt{\prod_{k=1}^{n} \cos ^{2}\left(t a_{k}\right)}=\left(\sqrt[n]{\prod_{k=1}^{n} \cos ^{2}\left(t a_{k}\right)}\right)^{n / 2} \leq\left(\frac{\sum_{k=1}^{n} \cos ^{2}\left(t a_{k}\right)}{n}\right)^{n / 2} \\
& =\left(\frac{1}{2}+\frac{U_{n}(t)}{2 n}\right)^{n / 2} \quad \text { where } U_{n}(t)=\sum_{k=1}^{n} \cos \left(2 t a_{k}\right)
\end{aligned}
$$

We will show that if $t$ is not too small, then for some $0 \leq c<1$ we have $U_{n}(t) \leq c n$ and hence $F_{n}(t) \leq\left(\frac{1+c}{2}\right)^{n / 2}$. In order to do that, first note that

$$
U_{n}(t) \leq \sum_{k=1}^{k_{m_{n}}} \cos \left(2 t a_{k}\right)+\left(n-k_{m_{n}}\right)=\sum_{m=1}^{m_{n}} \Delta_{m} \cos (2 t m)+\left(n-k_{m_{n}}\right) .
$$

Let $r \in(0,1)$ and assume w.l.o.g. that $r m_{n}$ is an integer. For $m \in\left[r m_{n}+1, m_{n}\right]$ we have

$$
A \leq \Delta_{m} \leq \bar{A} \text { where } A=\beta^{-1}\left(r m_{n}\right)^{\gamma}+O(1), \quad \bar{A}=\beta^{-1} m_{n}^{\gamma}+O(1)
$$

Consequently,

$$
\begin{aligned}
& \sum_{m=r m_{n}+1}^{m_{n}} \Delta_{m} \cos (2 t m) \leq \sum_{m=r m_{n}+1}^{m_{n}}\left[\bar{A} \cdot \mathbf{1}_{\cos (2 t m) \geq 0}+A \cdot \mathbf{1}_{\cos (2 t m)<0}\right] \cos (2 t m) \\
& =\sum_{m=r m_{n}+1}^{m_{n}}[\bar{A}-A] \cos (2 t m) \mathbf{1}_{\cos (2 t m) \geq 0}+\sum_{m=r m_{n}+1}^{m_{n}} A \cos (2 t m) \\
& \leq(1-r) m_{n}(\bar{A}-A)+A \sum_{m=r m_{n}+1}^{m_{n}} \cos (2 t m)=(1-r) m_{n}(\bar{A}-A) \\
& +A\left(\cos ^{2}\left(r t m_{n}+t\right)-\cos ^{2}\left(t m_{n}+t\right)+\frac{\cos t}{2 \sin t}\left[\sin \left(2 t\left(m_{n}+1\right)\right)-\sin \left(2 t\left(r m_{n}+1\right)\right)\right]\right) \\
& \leq \frac{m_{n}^{1 / \beta}}{\beta}(1-r)\left[1-r^{\gamma}+O\left(m_{n}^{-\gamma}\right)\right]+m_{n}^{\gamma}\left(\frac{r^{\gamma}}{\beta}+O\left(m_{n}^{-\gamma}\right)\right)\left(1+\frac{1}{|\sin t|}\right)
\end{aligned}
$$

Hence, since $m_{n}^{1 / \beta}=n+o(n)$,

$$
\begin{aligned}
U_{n}(t) & \leq \sum_{m=1}^{r m_{n}} \Delta_{m}+\sum_{m=r m_{n}+1}^{m_{n}} \Delta_{m} \cos (2 t m)+\left(n-k_{m_{n}}\right)=k_{r m_{n}+1}+\sum_{m=r m_{n}+1}^{m_{n}} \Delta_{m} \cos (2 t m)+O\left(\Delta_{m_{n}}\right) \\
& \leq r^{1 / \beta} n+\frac{m_{n}^{1 / \beta}}{\beta}(1-r)\left[1-r^{\gamma}+O\left(m_{n}^{-\gamma}\right)\right]+m_{n}^{\gamma}\left(\frac{r^{\gamma}}{\beta}+O\left(m_{n}^{-\gamma}\right)\right)\left(1+\frac{1}{|\sin t|}\right)+O\left(m_{n}^{\gamma \beta}\right) \\
& \leq n\left(r^{1 / \beta}+\frac{(1-r)\left(1-r^{\gamma}\right)}{\beta}\right)+\frac{4 n^{1-\beta} \beta^{-1} r^{\gamma}}{|\sin t|}+o(n)
\end{aligned}
$$

Consider now the the function

$$
h(r, \beta):=r^{1 / \beta}+\frac{(1-r)\left(1-r^{\gamma}\right)}{\beta}=r^{1 / \beta}+\frac{(1-r)\left(1-r^{1 / \beta-1}\right)}{\beta}
$$

and note that

$$
h(1-\beta, \beta)=(1-\beta)^{1 / \beta}+1-(1-\beta)^{1 / \beta-1}=1-\beta(1-\beta)^{1 / \beta-1} \leq 1-e^{-1} \beta<1-\beta / 3
$$

since $\sup _{\beta \in(0,1)}(1-\beta)^{1 / \beta-1}=e^{-1}$ by elementary calculus. So if we set $r=1-\beta \in(0,1)$, by noting $t \leq 2 \sin t$ for $t \in[0, \pi / 2]$, we conclude that $U_{n}(t) \leq\left(1-\frac{\beta}{4}\right) n$ provided that $t \geq \frac{c_{1}}{n^{\beta}}$ for some $c_{1}>0$. Consequently, $\int_{I_{3}} F_{n}(t) \mathrm{d} t \leq\left(1-\frac{\beta}{8}\right)^{n / 2}$ for large $n$, which converges to zero exponentially fast.

## Acknowledgment

We thank Edward Crane and Andrew Wade for providing us with useful references. The research is partially supported by Swedish Science Foundation grants VR 2019-04173 and Crafoord foundation grant no. 20190667.
