# Relation to a property of the angular momentum zero space of states of four fermions in an angular momentum $j=9 / 2$ shell unexpectedly found to be stationary for any rotationally invariant two-body interaction 

K. Neergård<br>Fjordtoften 17, 4700 Ncestved, Denmark

#### Abstract

The existence of states with angular momenta $I=4$ and 6 of four fermions in an angular momentum $j=9 / 2$ shell that are stationary for any rotationally invariant two-body interaction despite the presence of other states with the same angular momentum, the Escuderos-Zamick states, is shown to be equivalent to the invariance to any such interaction of the span of states generated from $I=0$ states by one-body operators. This invariance is verified by exact calculation independently of previous verifications of the equivalent statement. It explains the occurrence of the Escuderos-Zamick states for just $I=4$ and 6 . The action of an arbitrary interaction on the invariant space and its orthogonal complement is analyzed, leading to a relation of the Escuderos-Zamick energy levels to levels with $I=10$ and 12. Aspects of the observed spectra of ${ }^{94} \mathrm{Ru},{ }^{96} \mathrm{Pd}$, and ${ }^{74} \mathrm{Ni}$ are discussed in the light of this relation.

## I. INTRODUCTION

Escuderos and Zamick found in a numeric study of the system of four nucleons in an angular momentum $j=9 / 2$ shell of a semi-magic nucleus that for each angular momentum $I=4$ and 6 , the states in one irreducible module of the angular momentum algebra, briefly a multiplet, are stationary for any rotationally invariant two-body interaction [1], that is, solvable in Talmi's terminology [2], despite the presence of other multiplets with the same $I$. It follows that they have definite seniority $v$ [2], which gives rise, in certain nuclei, to particular patterns of transition rates in E2 decay and single-nucleon transfer (3) 5]. The solvability of the Escuderos-Zamick states was subsequently confirmed in exact calculations by Van Isacker and Heinze [3, 4], and Qi, Xu and Liotta [6]. These calculation are case-by-case examinations of the individual instances of two-body and total angular momentum, which led the authors of [4] to conclude that "a simple, intuitive reason for [the solvability] is still lacking". I show below that the existence of the Escuderos-Zamick states is equivalent to a property of the space of $I=0$ states of the system. The verification of this property again leads to an examination of several cases one by one. The equivalence explains, however, that the solvable multiplets occur for exactly $I=4$ and 6 .

Throughout this paper, $j=9 / 2$. Let $\Phi_{0}$ denote the space of $I=0$ states of the four-fermion system, and let $a_{m}$ be the annihilator of a fermion in the state $|j m\rangle$ in the conventional notation [7]. One can then define a space

$$
\begin{equation*}
\Phi_{4}=\operatorname{span}_{m, m^{\prime}} a_{m}^{\dagger} a_{m^{\prime}} \Phi_{0} \tag{1}
\end{equation*}
$$

The property to be verified below and shown there to be equivalent to the existence of the Escuderos-Zamick states is the following. $\Phi_{4}$ is invariant to any rotationally invariant two-body interaction. To see how this explains the appearance of solvable multiplets for just $I=4$ and 6 , note that the tensor operators $T_{I M_{I}}=\sum_{m m^{\prime}}(-)^{j-m^{\prime}}$ $\left\langle j m j-m^{\prime} \mid I M_{I}\right\rangle a_{m}^{\dagger} a_{m^{\prime}}$, where $\left\langle j_{1} m_{1} j_{2} m_{2} \mid j m\right\rangle$ is the vec-

tor coupling coefficient [7], form a basis for the span of operators $a_{m}^{\dagger} a_{m^{\prime}}$. The subspace of $\Phi_{4}$ carrying quantum numbers $I, M_{I}$ is $T_{I M_{I}} \Phi_{0}$. Now consider Table I, obtained by a straightforward count of $m$-combinations. Since $\Phi_{0}$ is 2-dimensional, $T_{I M_{I}} \Phi_{0}$ has dimension 2 , at most. Angular momenta $I=4$ and 6 are the only ones allowing more than 2 linearly independent multiplets in the four-fermion system, exactly 3 in both cases. It may be verified by direct calculation, and also follows from a general result in Sec III that in each case, $T_{I M_{I}} \Phi_{0}$ is exactly 2 -dimensional. If $\Phi_{4}$ is invariant to a Hermitian and rotationally invariant operator $V$, then so is also $T_{I M_{I}} \Phi_{0}$, and so is then also its 1-dimensional orthogonal complement within the space of states with quantum numbers $I, M_{I}$. This means that the states in the orthogonal complement are eigenstates of $V$.

The proof of equivalence is completed in Sec. [II and the verification of the invariance of $\Phi_{4}$ in Sec. IV] Analyzing the actions of an arbitrary $V$ on $\Phi_{4}$ and its orthogonal complement $\Phi_{4}^{\perp}$ reveals remarkable regularities, one of which leads to a rule for relative level spacings that is accessible to experimental verification and so far lacks fundamental explanation. This analysis is the topic of Secs. V and VI followed by my conclusion in Sec. VII. A detail of my formalism is discussed and one other observed regularity explained in two appendices.

## II. ANALYSIS

Below, $I_{\mathrm{E}}=4$ or 6 . Important for the following is also the space $\Phi_{3}$ of states with $I=j$ of three $j=9 / 2$ fermions, which is spanned by single multiplets $\Phi_{3 v}$ with $v=1$ and 3 . For each $v$, at most one multiplet with a given $I$ can be formed by adding a $j=9 / 2$ fermion to the states in $\Phi_{3 v}$. This multiplet can be written $P_{I} \operatorname{span}_{m} a_{m}^{\dagger} \Phi_{3 v}$, where $P_{I}$ is the projection onto angular momentum $I$. It may be verified by direct calculation, and also follows from the general result in Sec III, that for each $I_{\mathrm{E}}$, these two multiplets are independent. The space $\Phi_{I_{\mathrm{E}} \gamma}=P_{I_{\mathrm{E}}} \operatorname{span}_{m} a_{m}^{\dagger} \Phi_{31}$ necessarily has $v=2$. By Table its orthogonal complement $\Phi_{I_{\mathrm{E}} \beta}$ within $P_{I_{\mathrm{E}}} \operatorname{span}_{m} a_{m}^{\dagger} \Phi_{3}$ then has $v=4$. The Escuderos-Zamick multiplet $\Phi_{I_{\mathrm{E}} \alpha}$ is, by definition, the orthogonal complement of $\Phi_{I_{\mathrm{E}} \beta}$ within the space of states with $I=I_{\mathrm{E}}$ and $v=4$ of the four fermions. It may be characterized also among such states by vanishing parentage by $\Phi_{33}$ [1]. Evidently, it is also the orthogonal complement of $P_{I_{\mathrm{E}}} \operatorname{span}_{m} a_{m}^{\dagger} \Phi_{3}$ within the space of states with $I=I_{\mathrm{E}}$.

In the remainder of this paper, $V$ denotes any rotationally invariant two-body interaction. Because $V$ acts as a scalar on the irreducible module $\Phi_{I_{\mathrm{E}} \alpha}$, the states in $\Phi_{I_{\mathrm{E}} \alpha}$ being eigenstates of $V$ is equivalent to $\Phi_{I_{\mathrm{E}} \alpha}$ being invariant to $V$. By Hermiticity of $V$ and conservation of angular momentum, this is, in turn, equivalent to $P_{I_{\mathrm{E}}} \operatorname{span}_{m} a_{m}^{\dagger} \Phi_{3}$ being invariant to $V$. The space $\operatorname{span}_{m} a_{m}^{\dagger} \Phi_{3}$ cannot contain states with $I>2 j$. For every $I \leq 2 j$ except $I=4$ and 6 , it may be verified by direct calculation, and also follows from the general result in Sec III, that $P_{I} \operatorname{span}_{m} a_{m}^{\dagger} \Phi_{3}$ exhausts the space of states of the four fermions with angular momentum $I$ and thus is invariant to any rotationally invariant operator. Invariance of both spaces $P_{I_{\mathrm{E}}} \operatorname{span}_{m} a_{m}^{\dagger} \Phi_{3}$ to $V$ is then equivalent to $\Phi_{4}=\operatorname{span}_{m} a_{m}^{\dagger} \Phi_{3}$ being invariant to $V$. In summary, the existence of the Escuderos-Zamick states is equivalent to $\Phi_{4}$ being invariant to any $V$.

To establish the equivalence stated in the introduction, it remains to show that $\Phi_{4}$ can be written in the form (11). To this end, notice $\operatorname{span}_{m} a_{m} \Phi_{0} \subset \Phi_{3}$. It may be verified by direct calculation, and also follows from the general result in Sec III, that the left hand side exhausts $\Phi_{3}$ so that $\operatorname{span}_{m} a_{m} \Phi_{0}=\Phi_{3}$. This evidently leads to the expression (11). The remainder of this paper is dedicated to a proof (independent of the proofs in [3, 4, 6] of the equivalent statement) that $\Phi_{4}$ as given by (11) is actually invariant to any $V$, and analyses of the actions of an arbitrary $V$ on $\Phi_{4}$ and its orthogonal complement.

## III. $\operatorname{SPACES} \Phi_{0}$ AND $\Phi_{4}$

The structure of multi-fermion states in the $j=9 / 2$ shell is conveniently described in terms of creation oper-
ators

$$
\begin{equation*}
\alpha_{m}^{\dagger}=\sqrt{\frac{(j+m)!}{(j-m)!}} a_{m}^{\dagger} \tag{2}
\end{equation*}
$$

corresponding to unnormalized single-fermion states. In terms of the usual complex coordinates $\left(I_{0}, I_{ \pm}\right)$of the total angular momentum $I$ [7], these operators obey

$$
\begin{gather*}
{\left[I_{0}, \alpha_{m}^{\dagger}\right]=m \alpha_{m}^{\dagger}} \\
{\left[I_{+}, \alpha_{m}^{\dagger}\right]= \begin{cases}\alpha_{m+1}^{\dagger}, & m<j, \\
0, & m=j,\end{cases} }  \tag{3}\\
{\left[I_{-}, \alpha_{m}^{\dagger}\right]= \begin{cases}(j+m)(j-m+1) \alpha_{m-1}^{\dagger}, & m>-j, \\
0, & m=-j\end{cases} }
\end{gather*}
$$

A state of four $j=9 / 2$ fermions can be expanded on the states

$$
\begin{equation*}
\left|m_{1} m_{2} m_{3} m_{4}\right\rangle=\left(\prod_{i=1}^{4} \alpha_{m_{i}}^{\dagger}\right)| \rangle \tag{4}
\end{equation*}
$$

with $j \geq m_{1}>m_{2}>m_{3}>m_{4} \geq-j$, where $\rangle$ is the vacuum. The eigenspaces of $I_{0}$ with eigenvalues $M_{I}$ are spanned by the states with $\sum_{i} m_{i}=M_{I}$. The space $\Phi_{0}$ is the subspace of the $M_{I}=0$ space characterized by $J_{+} \Phi_{0}=0$. Since there are 18 states $\left|m_{1} m_{2} m_{3} m_{4}\right\rangle$ with $M_{I}=0$ and 16 with $M_{I}=1$ (in accordance with the total multiplicities for $I \geq 0$ and 1 in Table (I), this constraint can be expressed by a homogeneous system of 16 linear equations in 18 expansion coefficients. The equations turn out independent in accordance with the dimension 2 of $\Phi_{0}$. Two linearly independent solution are

$$
\begin{align*}
\phi_{0} & =\left|\frac{9}{2} \frac{7}{2} \frac{-7}{2} \frac{-9}{2}\right\rangle-\left|\frac{9}{2} \frac{5}{2} \frac{-5}{2} \frac{-9}{2}\right\rangle+\left|\frac{9}{2} \frac{3}{2} \frac{-3}{2} \frac{-9}{2}\right\rangle-\left|\frac{9}{2} \frac{1}{2} \frac{-1}{2} \frac{-9}{2}\right\rangle \\
& +\left|\frac{7}{2} \frac{5}{2} \frac{-5}{2} \frac{-7}{2}\right\rangle-\left|\frac{7}{2} \frac{3}{2} \frac{-3}{2} \frac{-7}{2}\right\rangle+\left|\frac{7}{2} \frac{1}{2} \frac{-1}{2} \frac{-7}{2}\right\rangle+\left|\frac{5}{2} \frac{3}{2} \frac{-3}{2} \frac{-5}{2}\right\rangle \\
& -\left|\frac{5}{2} \frac{1}{2} \frac{-1}{2} \frac{-5}{2}\right\rangle+\left|\frac{3}{2} \frac{1}{2} \frac{-1}{2} \frac{-3}{2}\right\rangle \\
\phi_{1} & =-5\left|\frac{9}{2} \frac{7}{2} \frac{-7}{2} \frac{-9}{2}\right\rangle+5\left|\frac{9}{2} \frac{5}{2} \frac{-5}{2} \frac{-9}{2}\right\rangle+\left|\frac{9}{2} \frac{3}{2} \frac{-3}{2} \frac{-9}{2}\right\rangle \\
& -7\left|\frac{9}{2} \frac{1}{2} \frac{-1}{2} \frac{-9}{2}\right\rangle+9\left|\frac{7}{2} \frac{5}{2} \frac{-5}{2} \frac{-7}{2}\right\rangle-3\left|\frac{7}{2} \frac{3}{2} \frac{-3}{2} \frac{-7}{2}\right\rangle \\
& -9\left|\frac{7}{2} \frac{1}{2} \frac{-1}{2} \frac{-7}{2}\right\rangle-6\left|\frac{5}{2} \frac{3}{2} \frac{-3}{2} \frac{-5}{2}\right\rangle \\
& -14\left|\frac{9}{2} \frac{3}{2} \frac{-5}{2} \frac{-7}{2}\right\rangle-6\left|\frac{7}{2} \frac{5}{2} \frac{-3}{2} \frac{-9}{2}\right\rangle+16\left|\frac{9}{2} \frac{1}{2} \frac{-3}{2} \frac{-7}{2}\right\rangle \\
& +6\left|\frac{7}{2} \frac{3}{2} \frac{-1}{2} \frac{-9}{2}\right\rangle-25\left|\frac{9}{2} \frac{-1}{2} \frac{-3}{2} \frac{-5}{2}\right\rangle-6\left|\frac{5}{2} \frac{3}{2} \frac{1}{2} \frac{-9}{2}\right\rangle \\
& +9\left|\frac{7}{2} \frac{1}{2} \frac{-3}{2} \frac{-5}{2}\right\rangle+6\left|\frac{5}{2} \frac{3}{2} \frac{-1}{2} \frac{-7}{2}\right\rangle . \tag{5}
\end{align*}
$$

Here, $\phi_{0}$ evidently has $v=0$. The state $\phi_{0}+2 \phi_{1}$ is orthogonal to $\phi_{0}$ and thus has $v=4$. In the expansion of $\phi_{1}$, the coefficients of $\left|\frac{7}{2} \frac{5}{2} \frac{-3}{2} \frac{-9}{2}\right\rangle$ and $\left|\frac{7}{2} \frac{3}{2} \frac{-1}{2} \frac{-9}{2}\right\rangle$ are equal except for opposite signs. This is because in the expansion of $I_{+} \phi_{1}$, the coefficient of $\left|\frac{7}{2} \frac{5}{2} \frac{-1}{2} \frac{-9}{2}\right\rangle$ gets contributions only from these two coefficients. Similar comparisons explain that all the four states $\left|\frac{7}{2} \frac{5}{2} \frac{-3}{2} \frac{-9}{2}\right\rangle$, $\left|\frac{7}{2} \frac{3}{2} \frac{-1}{2} \frac{-9}{2}\right\rangle,\left|\frac{5}{2} \frac{3}{2} \frac{1}{2} \frac{-9}{2}\right\rangle$, and $\left|\frac{5}{2} \frac{3}{2} \frac{-1}{2} \frac{-7}{2}\right\rangle$ have equal coefficients except for a sign. The ratios of coefficients of $\left|m_{1} m_{2} m_{3} m_{4}\right\rangle$ and $\left|-m_{4},-m_{3},-m_{2},-m_{1}\right\rangle$ are
$\prod_{i=1}^{4}\left(j-m_{i}\right)!/\left(j+m_{i}\right)$ ! so that the corresponding ratios in the basis of states $\left(\prod_{i=1}^{4} a_{m_{i}}^{\dagger}\right)\rangle$ equal one, as required by the symmetry under half-turn rotations about axes perpendicular to the quantization axis.

Since $\Phi_{4}$ is rotationally invariant, its invariance to $V$ is equivalent to invariance of its $M_{I}=0$ subspace

$$
\begin{equation*}
\Phi_{40}=\operatorname{span}_{m} n_{m} \Phi_{0} \tag{6}
\end{equation*}
$$

where $n_{m}=a_{m}^{\dagger} a_{m}$. This space is spanned by the 20 states $n_{m} \phi_{i}$ with $m=j, j-1, \ldots,-j$ and $i \in\{0,1\}$. Each of these states is obtained by selecting in the expansion (5) of $\phi_{i}$ the terms where the orbit $|j m\rangle$ is occupied. Not all of them are linearly independent. Thus evidently $n_{m} \phi_{0}=n_{-m} \phi_{0}$. Further, $I_{0} \phi_{1}=0$ is a linear relation among the 10 states $n_{m} \phi_{1}$. There remain 14 states, which turn out linearly independent. This number coincides with the total multiplicity for $I \leq 2 j$, excepting the Escuderos-Zamick multiplets. The $M_{I}=0$ state in every remaining multiplet thus belongs to $\Phi_{40}$. Consequently, every such multiplet is contained in $\Phi_{4}$. This requires, in turn, that the multiplets $P_{I_{\mathrm{E}}} \operatorname{span}_{m} a_{m}^{\dagger} \Phi_{3 v}$ with $v=1$ and 3 be independent, that for $I \leq 2 j$ and $I \neq 4,6$, the space $P_{I} \operatorname{span}_{m} a_{m}^{\dagger} \Phi_{3}$ exhaust the space of states with angular momentum $I$, and that equality hold in the inclusion $\operatorname{span}_{m} a_{m} \Phi_{0} \subset \Phi_{3}$, all of which was used in Secs. प and II.

I choose in $\Phi_{40}$ a basis $\left(\psi_{i} \mid i=1, \ldots, 14\right)$, where $\left(\psi_{i} \mid i=\right.$ $1, \ldots, 5)$ are the states $n_{m} \phi_{0}$ with $m=j, j-1, \ldots, 1 / 2$ in this order, and $\left(\psi_{i} \mid i=6, \ldots, 14\right)$ are the states $n_{m} \phi_{1}$ with $m=j, j-1, \ldots,-j+1$ in this order. By Hermiticity and angular momentum conservation, $\Phi_{40}$ is invariant to $V$ if and only if its orthogonal complement $\Phi_{40}^{\perp}$ within the $M_{I}=0$ space is so. This space is spanned by the states

$$
\begin{align*}
& \chi_{1}=14\left|\frac{9}{2} \frac{3}{2} \frac{-5}{2} \frac{-7}{2}\right\rangle+6\left|\frac{7}{2} \frac{5}{2} \frac{-3}{2} \frac{-9}{2}\right\rangle \\
& +\frac{2}{153}\left(-768\left|\frac{9}{2} \frac{7}{2} \frac{-7}{2} \frac{-9}{2}\right\rangle+231\left|\frac{9}{2} \frac{5}{2} \frac{-5}{2} \frac{-9}{2}\right\rangle\right. \\
& +927\left|\frac{9}{2} \frac{3}{2} \frac{-3}{2} \frac{-9}{2}\right\rangle-72\left|\frac{9}{2} \frac{1}{2} \frac{-1}{2} \frac{-9}{2}\right\rangle \\
& +159\left|\frac{7}{2} \frac{5}{2} \frac{-5}{2} \frac{-7}{2}\right\rangle-553\left|\frac{7}{2} \frac{3}{2} \frac{-3}{2} \frac{-7}{2}\right\rangle \\
& +56\left|\frac{7}{2} \frac{1}{2} \frac{-1}{2} \frac{-7}{2}\right\rangle-640\left|\frac{5}{2} \frac{3}{2} \frac{-3}{2} \frac{-5}{2}\right\rangle \\
& \left.-712\left|\frac{5}{2} \frac{1}{2} \frac{-1}{2} \frac{-5}{2}\right\rangle-840\left|\frac{3}{2} \frac{1}{2} \frac{-1}{2} \frac{-3}{2}\right\rangle\right), \\
& \chi_{2}=16\left|\frac{9}{2} \frac{1}{2} \frac{-3}{2} \frac{-7}{2}\right\rangle+6\left|\frac{7}{2} \frac{3}{2} \frac{-1}{2} \frac{-9}{2}\right\rangle \\
& +\frac{16}{1071}\left(516\left|\frac{9}{2} \frac{7}{2} \frac{-7}{2} \frac{-9}{2}\right\rangle-105\left|\frac{9}{2} \frac{5}{2} \frac{-5}{2} \frac{-9}{2}\right\rangle\right. \\
& -171\left|\frac{9}{2} \frac{3}{2} \frac{-3}{2} \frac{-9}{2}\right\rangle+450\left|\frac{9}{2} \frac{1}{2} \frac{-1}{2} \frac{-9}{2}\right\rangle \\
& +345\left|\frac{7}{2} \frac{5}{2} \frac{-5}{2} \frac{-7}{2}\right\rangle+1225\left|\frac{7}{2} \frac{3}{2} \frac{-3}{2} \frac{-7}{2}\right\rangle \\
& +364\left|\frac{7}{2} \frac{1}{2} \frac{-1}{2} \frac{-7}{2}\right\rangle+430\left|\frac{5}{2} \frac{3}{2} \frac{-3}{2} \frac{-5}{2}\right\rangle \\
& \left.+880\left|\frac{5}{2} \frac{1}{2} \frac{-1}{2} \frac{-5}{2}\right\rangle+966\left|\frac{3}{2} \frac{1}{2} \frac{-1}{2} \frac{-3}{2}\right\rangle\right), \\
& \chi_{3}=25\left|\frac{9}{2} \frac{-1}{2} \frac{-3}{2} \frac{-5}{2}\right\rangle+6\left|\frac{5}{2} \frac{3}{2} \frac{1}{2} \frac{-9}{2}\right\rangle \\
& +\frac{25}{1071}\left(834\left|\frac{9}{2} \frac{7}{2} \frac{-7}{2} \frac{-9}{2}\right\rangle+2184\left|\frac{9}{2} \frac{5}{2} \frac{-5}{2} \frac{-9}{2}\right\rangle\right. \\
& +1629\left|\frac{9}{2} \frac{3}{2} \frac{-3}{2} \frac{-9}{2}\right\rangle+279\left|\frac{9}{2} \frac{1}{2} \frac{-1}{2} \frac{-9}{2}\right\rangle \\
& -750\left|\frac{7}{2} \frac{5}{2} \frac{-5}{2} \frac{-7}{2}\right\rangle-847\left|\frac{7}{2} \frac{3}{2} \frac{-3}{2} \frac{-7}{2}\right\rangle \\
& -931\left|\frac{7}{2} \frac{1}{2} \frac{-1}{2} \frac{-7}{2}\right\rangle-376\left|\frac{5}{2} \frac{3}{2} \frac{-3}{2} \frac{-5}{2}\right\rangle \\
& \left.-3310\left|\frac{5}{2} \frac{1}{2} \frac{-1}{2} \frac{-5}{2}\right\rangle-2100\left|\frac{3}{2} \frac{1}{2} \frac{-1}{2} \frac{-3}{2}\right\rangle\right), \\
& \chi_{4}=9\left|\frac{7}{2} \frac{1}{2} \frac{-3}{2} \frac{-5}{2}\right\rangle+6\left|\frac{5}{2} \frac{3}{2} \frac{-1}{2} \frac{-7}{2}\right\rangle \\
& +\frac{3}{119}\left(-150\left|\frac{9}{2} \frac{7}{2} \frac{-7}{2} \frac{-9}{2}\right\rangle-231\left|\frac{9}{2} \frac{5}{2} \frac{-5}{2} \frac{-9}{2}\right\rangle\right. \\
& -162\left|\frac{9}{2} \frac{3}{2} \frac{-3}{2} \frac{-9}{2}\right\rangle-81\left|\frac{9}{2} \frac{1}{2} \frac{-1}{2} \frac{-9}{2}\right\rangle \\
& +45\left|\frac{7}{2} \frac{5}{2} \frac{-5}{2} \frac{-7}{2}\right\rangle+196\left|\frac{7}{2} \frac{3}{2} \frac{-3}{2} \frac{-7}{2}\right\rangle \\
& +301\left|\frac{7}{2} \frac{1}{2} \frac{-1}{2} \frac{-7}{2}\right\rangle+232\left|\frac{5}{2} \frac{3}{2} \frac{-3}{2} \frac{-5}{2}\right\rangle \\
& \left.+508\left|\frac{5}{2} \frac{1}{2} \frac{-1}{2} \frac{-5}{2}\right\rangle+126\left|\frac{3}{2} \frac{1}{2} \frac{-1}{2} \frac{-3}{2}\right\rangle\right) . \tag{7}
\end{align*}
$$

It is straightforward to check $\psi_{i}^{\dagger} \chi_{k}=0$ for every $i, k$ using $\|\left|m_{1} m_{2} m_{3} m_{4}\right\rangle \|^{2}=\prod_{i=1}^{4}\left(j+m_{i}\right)!/\left(j-m_{i}\right)$ !. For example,

$$
\begin{align*}
\psi_{6}^{\dagger} \chi_{1} & =\phi_{1}^{\dagger} n_{9 / 2} \chi_{1}=(-14) \cdot \frac{3}{7} \cdot 14 \\
& +\frac{2}{153}((-5) \cdot(-786)+5 \cdot 231  \tag{8}\\
& \quad+1 \cdot 927+(-7) \cdot(-72))=0
\end{align*}
$$

## IV. INTERACTION $V$ AND INVARIANCE OF $\Phi_{4}$

Every $V$ is a linear combination of five basic interactions $V_{J}$, where $J=0,2, \ldots, 2 j-1$. They can be chosen in the form

$$
\begin{equation*}
V_{J}=\frac{1}{2} \sum_{M=-J}^{J} P_{J M}^{\dagger} P_{J M} \tag{9}
\end{equation*}
$$

with

$$
\begin{equation*}
P_{J M}=c_{J} \sum_{m_{1}+m_{2}=M}\left\langle j m_{1} j m_{2} \mid J M\right\rangle a_{m_{2}} a_{m_{1}} \tag{10}
\end{equation*}
$$

where $c_{J}$ is a positive constant. I set

$$
\begin{align*}
& c_{J}\left\langle j m_{1} j m_{2} \mid J M\right\rangle \\
& \quad=\binom{2 J}{J+M}^{-1 / 2} \sqrt{\frac{\left(j+m_{1}\right)!\left(j+m_{2}\right)!}{\left(j-m_{1}\right)!\left(j-m_{2}\right)!}} c_{m_{1} m_{2}}^{J} \tag{11}
\end{align*}
$$

so that by (2),

$$
\begin{equation*}
P_{J M}^{\dagger}=\binom{2 J}{J+M}^{-1 / 2} \sum_{m_{1}+m_{2}=M} c_{m_{1} m_{2}}^{J} \alpha_{m_{1}}^{\dagger} \alpha_{m_{2}}^{\dagger} \tag{12}
\end{equation*}
$$

The definition (11) implies $c_{m_{1} m_{2}}^{J}=0$ for $\left|m_{1}+m_{2}\right|>$ $J$. It follows from $\left[I_{+}, P_{J J}^{\dagger}\right]=0$, (12), (3), and (11) that $c_{J}$ can be chosen such that $c_{m_{1} m_{2}}^{J}=$ $(-1)^{j-m_{1}}$ for $m_{1}+m_{2}=J$. From $\left[I_{-}, P_{J M}^{\dagger}\right]=$ $\sqrt{(J+M)(J-M+1)} P_{J, M-1}^{\dagger}$ for $M>-J$, (12), and (3), one gets the recursion relation

$$
\begin{array}{r}
\left(J-m_{1}-m_{2}\right) c_{m_{1} m_{2}}^{J}=\left(j-m_{1}\right)\left(j+m_{1}+1\right) c_{m_{1}+1, m_{2}}^{J} \\
+\left(j-m_{2}\right)\left(j+m_{2}+1\right) c_{m_{1}, m_{2}+1}^{J}, \tag{13}
\end{array}
$$

which then determines $c_{m_{1} m_{2}}^{J}$ for $-J \leq m_{1}+m_{2}<J$. (Continuation of the recursion in fact results in $c_{m_{1} m_{2}}^{J}=$ 0 for $m_{1}+m_{2}<-J$. Terms in (13) with $m_{1}$ or $m_{2}$ equal to $j$, which involve undefined values of $c_{m_{1}^{\prime} m_{2}^{\prime}}^{J}$, are just omitted.) All $c_{m_{1} m_{2}}^{J}$ turn out integral, which is explained in Appendix A. From the definition (11) and symmetries of the vector coupling coefficients [7], one gets

$$
\begin{gather*}
c_{m_{1} m_{2}}^{J}=-c_{m_{2} m_{1}}^{J}, \\
c_{m_{1} m_{2}}^{J}=\frac{\left(j-m_{1}\right)!\left(j-m_{2}\right)!}{\left(j+m_{1}\right)!\left(j+m_{2}\right)!} c_{-m_{2},-m_{1}}^{J}, \tag{14}
\end{gather*}
$$

whence by (12) and (2) follows

$$
\begin{align*}
P_{J M}= & \binom{2 J}{J+M}^{-1 / 2} \\
& \sum_{m_{1}+m_{2}=M} c_{m_{1} m_{2}}^{J} \frac{\left(j+m_{1}\right)!\left(j+m_{2}\right)!}{\left(j-m_{1}\right)!\left(j-m_{2}\right)!} \alpha_{m_{2}} \alpha_{m_{1}} \\
= & \binom{2 J}{J+M}^{-1 / 2} \sum_{m_{1}+m_{2}=M} c_{-m_{2},-m_{1}}^{J} \alpha_{m_{2}} \alpha_{m_{1}} \tag{15}
\end{align*}
$$

in terms of annihilation operators

$$
\begin{equation*}
\alpha_{m}=\sqrt{\frac{(j-m)!}{(j+m)!}} a_{m} \tag{16}
\end{equation*}
$$

obeying

$$
\begin{equation*}
\left\{\alpha_{m}, \alpha_{m^{\prime}}^{\dagger}\right\}=\delta_{m, m^{\prime}} \tag{17}
\end{equation*}
$$

It follows that the action of $V_{J}$ on a basic state $\left|m_{1} m_{2} m_{3} m_{4}\right\rangle$ can be described by the following operation $u_{J m}^{p q}$. If $m_{p}+m_{q}-m$ is outside the range of $m$ 's, then $u_{J m}^{p q}\left|m_{1} m_{2} m_{3} m_{4}\right\rangle=0$. Otherwise replace $m_{p}$ and $m_{q}$ by $m$ and $m_{p}+m_{q}-m$. If this results in two $m$ 's being equal, $u_{J m}^{p q}\left|m_{1} m_{2} m_{3} m_{4}\right\rangle=0$. Otherwise reorder, if necessary, the $m$ 's to decreasing order and multiply the state by the sign of the permutation. Finally multiply the state by $\binom{2 J}{J+m_{p}+m_{q}}^{-1} c_{m, m_{p}+m_{q}-m}^{J} c_{-m_{q},-m_{p}}^{J}$. Then

$$
\begin{equation*}
V_{J}\left|m_{1} m_{2} m_{3} m_{4}\right\rangle=\sum_{1 \leq p<q \leq 4, m} u_{J m}^{p q}\left|m_{1} m_{2} m_{3} m_{4}\right\rangle \tag{18}
\end{equation*}
$$

The state $V_{J} \chi_{i}$ is obtained by applying this formula to each term in the expansion (7) of $\chi_{i}$. I did this calculation for every $J, i$ and found that in every case, $V_{J} \chi_{i}$ is a linear combination of $\left\{\chi_{i} \mid i=1, \ldots, 4\right\}$. This proves that $\Phi_{40}^{\perp}$, and in turn, $\Phi_{40}, \Phi_{4}$, and the orthogonal complement $\Phi_{4}^{\perp}$ of the latter, are invariant to every $V$. For completeness, I also verified directly that every $V_{J} \psi_{i}$ is a linear combination of $\left\{\psi_{i} \mid i=1, \ldots, 14\right\}$.

## V. ACTION OF $V$ ON $\Phi_{40}^{\perp}$

The expansion of $V_{J} \chi_{i}$ on states $\chi_{k}$ may be expressed by a matrix $V^{\perp J}=\left(v_{i k}^{\perp J} \mid i, k=1, \ldots, 4\right)$ defined by

$$
\begin{equation*}
V_{J} \chi_{i}=\sum_{k=1}^{4} v_{k i}^{\perp J} \chi_{k} \tag{19}
\end{equation*}
$$

These matrices are given by

$$
\begin{align*}
& V^{\perp 0}=\left(\begin{array}{cccc}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{array}\right), \\
& \bar{V}^{\perp 2}=-\frac{1071}{16} V^{\perp 2} \\
& =\left(\begin{array}{cccc}
-318150 & 170280 & 249300 & -18468 \\
90027 & -161100 & 94950 & 59778 \\
0 & 51408 & -420903 & 28917 \\
-207088 & 422480 & -1012475 & -50895
\end{array}\right), \\
& \bar{V}^{\perp 4}=-\frac{51}{64} V^{\perp 4} \\
& =\left(\begin{array}{cccc}
-800100 & 170280 & 249300 & -18468 \\
90027 & -643350 & 99450 & 59778 \\
0 & 51408 & -902853 & 28917 \\
-207088 & 422480 & -1012475 & -532845
\end{array}\right),  \tag{20}\\
& \bar{V}^{\perp 6}=\frac{187}{102400} V^{\perp 6} \\
& =\left(\begin{array}{cccc}
578277 & 170280 & 249300 & -18468 \\
90027 & 733327 & 94950 & 59778 \\
0 & 51408 & 47524 & 2897 \\
-207088 & 422480 & -1012475 & 845532
\end{array}\right), \\
& \bar{V}^{\perp 8}=\frac{2431}{278691840} V^{\perp 8} \\
& =\left(\begin{array}{cccc}
647892 & 170280 & 249300 & -18468 \\
90027 & 804942 & 94950 & 59778 \\
0 & 51408 & 545139 & 28917 \\
-207088 & 422480 & -1012475 & 915147
\end{array}\right),
\end{align*}
$$

where the fractions are determined by the condition that the entries in each $\bar{V}^{J}$ be coprime integers. That the pairing force $V_{0}$ kills the $v=4$ space $\Phi_{40}^{\perp}$ is no surprise. The matrices $\bar{V}^{\perp J}$ exhibit the remarkable similarity

$$
\begin{equation*}
\bar{V}^{\perp 2}=\bar{V}^{\perp 4}+481950=\bar{V}^{\perp 6}-896427=\bar{V}^{\perp 8}-966042 \tag{21}
\end{equation*}
$$

with multiplication of the scalars by the unit matrix understood. Like the invariance of the entire $\Phi_{40}^{\perp}$, this regularity lacks fundamental explanation. It follows that the interactions $\bar{V}_{J}$ represented on $\Phi_{40}^{\perp}$ by these matrices also act identically on $\Phi \frac{\perp}{40}$ except for these scalar terms. Any linear combination of these interactions, that is, an arbitrary $V$, then acts on $\Phi_{40}^{\perp}$ as a linear combination of any one of them and a scalar. This applies, in particular, to the two-body interaction $\boldsymbol{I}^{2}-j(j+1) N$, where $N=\sum_{m} n_{m}$. Because $N$ acts on the four-body space as the scalar 4, conversely then every $V_{J}$ acts on $\Phi_{40}^{\perp}$ as a linear combination of $\boldsymbol{I}^{2}$ and a scalar. This explains, in particular, the zeros in the third row and first column of every $V^{\perp J}$. For no $\left|m_{1} m_{2} m_{3} m_{4}\right\rangle$ in the expansion (77) of $\chi_{1}$, the expansion of $\boldsymbol{I}^{2}\left|m_{1} m_{2} m_{3} m_{4}\right\rangle$ on states $\left|m_{1} m_{2} m_{3} m_{4}\right\rangle$ indeed contains $\left|\frac{9}{2} \frac{-1}{2} \frac{-3}{2} \frac{-5}{2}\right\rangle$. Therefore $\chi_{3}$ cannot appear in the expansion of $\boldsymbol{I}^{2} \chi_{1}$ on states $\chi_{i}$.

One arrives at a prediction that might be tested experimentally. To the extend of validity of the $j=9 / 2$ shell model, the spacings of the energy levels with angular momenta $I$ and $I^{\prime}$ must have the ratio of $I(I+1)-I^{\prime}\left(I^{\prime}+1\right)$. The nucleus ${ }^{94} \mathrm{Ru}$ has a closed neutron major shell and 4 protons in the $1 g_{9 / 2}$ subshell. The yrast $I=4,6,10$, and 12 levels (with tentative assignments $I=10$ and 12) have excitation energies $2186.6,2498.0,3991.2$, and 4716.6 MeV [8]. The states with $I=10$ and 12 are expected to have fairly pure $1 g_{9 / 2}$ configurations while, according to Das et al. [9], both multiplets with $I=4$ and 6 could be mixtures of those labeled $\gamma$ and $\alpha$ in Sec. III due to perturbation by configurations outside the proton $1 g_{9 / 2}$ shell. The pure Escuderos-Zamick energy levels should then be close to the observed yrast levels. Extrapolation by the spacing rule from $I=10$ and 12
gives excitation energies 2571.9 and 2918.9 MeV , somewhat above the yrast levels. A similar analysis for ${ }^{96} \mathrm{Pd}$, with 4 holes in the $1 g_{9 / 2}$ shell (and tentative assignments of the angular momenta concerned), predicts EscuderosZamick levels at 2237.9 and 2616.8 MeV , closer to the yrast levels at 2099.01 and 2424.19 MeV . Interpreting the second observed $I=4$ and 6 levels in ${ }^{74} \mathrm{Ni}$ [10], with a closed proton major shell and 4 holes in the neutron $1 g_{9 / 2}$ subshell, as Escuderos-Zamick levels leads to the prediction of the $I=10$ and 12 levels at 4287 and 5577 MeV .

Since the operator $\boldsymbol{I}^{2}$ acts on the $M_{I}=0$ space as $I_{-} I_{+}$, the matrix $C$ representing its action on $\Phi_{40}^{\perp}$ is easily calculated by (7), (4), and (3). By comparison with (20), one finds in the notation of (21) that

$$
\begin{align*}
& \frac{1}{3213} \bar{V}^{\perp 2}+156=\frac{1}{3213} \bar{V}^{\perp 4}+306 \\
& \quad=\frac{1}{3213} \bar{V}^{\perp 6}-123=\frac{1}{3213} \bar{V}^{\perp 8}-\frac{434}{3}=C . \tag{22}
\end{align*}
$$

No simple expression in terms of $J$ seems to reproduce these displacements. For $I=4$ and 6 , Van Isacker and Heinze calculated the ratios $r_{I}^{J}=\mu_{I}^{J} / \nu_{J}$, where $\mu_{I}^{J}$ and $\nu_{J}$ are the eigenvalues of $V_{J}$ in the four-fermion system and a two-fermion state with $I=J[3,4]$. From (9)-(11), one gets

$$
\begin{equation*}
\nu_{J}=c_{J}^{2}=\binom{2 J}{J}^{-1} \sum_{m=-j}^{j}\left(c_{m,-m}^{J}\right)^{2} \tag{23}
\end{equation*}
$$

My calculations confirm the values $r_{4}^{J}=\frac{68}{33}, 1, \frac{13}{15}, \frac{114}{55}$ and $r_{6}^{J}=\frac{19}{11}, \frac{12}{13}, 1, \frac{336}{143}$ for $J=2-8$ reported in [3, 4], and further provide $r_{10}^{J}=\frac{23}{33}, \frac{98}{143}, \frac{233}{165}, \frac{2292}{715}$ and $r_{12}^{J}=$ $0, \frac{75}{143}, \frac{93}{55}, \frac{246}{65}$.

## VI. ACTION OF $V$ ON $\Phi_{40}$

Like in (19), the action of $V_{J}$ on the states $\psi_{i}$ may be expressed by matrices $V^{J}$. They are

$$
\begin{align*}
& V^{0}=2\left(\begin{array}{clllllllllllll}
4 & 1 & 1 & 1 & 1 & -2 & -5 & -5 & 1 & 7 & 7 & 1 & -5 & -5 \\
1 & 4 & 1 & 1 & 1 & -5 & -2 & 9 & 3 & -9 & -9 & 3 & 9 & -2 \\
1 & 1 & 4 & 1 & 1 & -5 & 9 & -2 & -6 & 0 & 0 & -6 & -2 & 9 \\
1 & 1 & 1 & 4 & 1 & 1 & 3 & -6 & -2 & 0 & 0 & -2 & -6 & 3 \\
1 & 1 & 1 & 1 & 4 & 7 & -9 & 0 & 0 & -2 & -2 & 0 & 0 & -9 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{array}\right), \\
& V^{2}=\frac{16}{3}\left(\begin{array}{cccccccccccccccc}
630 & 108 & -54 & -162 & -216 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 189 & 189 \\

\end{array}\right), \tag{24}
\end{align*}
$$

to this end that the last eight terms in the expansion of $\phi_{1}$ do not contribute to $V_{0} \phi_{1}$.

For a general $J$, one notices in the upper right $5 \times 8$ submatrix of $V^{J}$ equal contributions to $V_{J} n_{ \pm m} \phi_{1}$ from any $n_{m^{\prime}} \phi_{0}$. This is an immediate consequence of $n_{m^{\prime}} \phi_{0}=$ $n_{-m^{\prime}} \phi_{0}$ and the symmetry under half-turn rotations about an axis perpendicular to the quantization axis. The same pattern is seen in the parts of the sixth rows just below, which display contributions to $V_{J} n_{m} \phi_{1}$ from $n_{j} \phi_{1}$ for $m \neq \pm j$, and again the reason is the symmetry under half-turn rotations about an axis perpendicular to the quantization axis. Such a rotation thus leads to both the replacement of $m$ by $-m$ and the omission of $n_{j} \phi_{1}$ instead of $n_{-j} \phi_{1}$ in the selection of the states $\psi_{i}$.

But by $\sum_{m} m n_{m} \phi_{1}=J_{0} \phi_{1}=0$, the state $n_{-j} \phi_{1}$ equals $n_{j} \phi_{1}$ plus a linear combination of states that are common to both the original and the new basis. Therefore in the original basis, the contribution of $n_{j} \phi_{1}$ to $V_{J} n_{-m} \phi_{1}$ equals its contribution to $V_{J} n_{m} \phi_{1}$. It follows further that when the lower right $9 \times 9$ submatrix of $V^{J}$ is written $\left(v_{m m^{\prime}}^{1 J} \mid m, m^{\prime}>-j\right)$ with indices referring to the basic states $n_{m} \phi_{1}$, then for $m, m^{\prime}<j$, one should have

$$
\begin{equation*}
v_{-m^{\prime},-m}^{1 J}=v_{m^{\prime} m}^{1 J}-\frac{m^{\prime}}{j} v_{j m}^{1 J} \tag{25}
\end{equation*}
$$

This is verified by inspection. Similar patterns occur when a state $n_{m} \phi_{1}$ other than $n_{-j} \phi_{1}$ is omitted in the selection of the states $\psi_{i}$.

It is trivial by $n_{m} \phi_{0}=n_{-m} \phi_{0}$ that the state $n_{m^{\prime}} \phi_{0}$ contributes equally to $V_{J} n_{ \pm m} \phi_{0}$. Therefore when $v_{m m^{\prime}}^{00 J}$ denotes the entries in the upper left $5 \times 5$ submatrix of $V^{J}$ with indices referring to the basic states $n_{m} \phi_{0}$, and $v_{m m^{\prime}}^{01 J}$, those of its neighboring $5 \times 5$ submatrix to the right with indices referring to the basic states $n_{m} \phi_{0}$ and $n_{m^{\prime}} \phi_{1}$, then for both $i=0$ and 1 one has

$$
\begin{align*}
& \frac{1}{2} V_{J} \bar{n}_{m} \phi_{i}=\sum_{m^{\prime}>0} v_{m^{\prime} m}^{0 i J} \bar{n}_{m^{\prime}} \phi_{0} \\
&  \tag{26}\\
& \quad+\text { linear combination of } n_{m^{\prime}} \phi_{1}
\end{align*}
$$

with $\bar{n}_{m}=n_{m}+n_{-m}$. The operators $\bar{n}_{m}$ can be expressed by the tensor operators $T_{I 0}$ defined in the introduction,

$$
\begin{equation*}
\bar{n}_{m}=(-)^{j-m} 2 \sum_{\text {even } I}\langle j m j-m \mid I 0\rangle T_{I 0} \tag{27}
\end{equation*}
$$

Since the states $T_{I 0} \phi_{i}$ span the subspace of $\Phi_{40}$ with angular momentum $I$, which is invariant to $V^{J}$, one can write

$$
\begin{equation*}
V_{J} T_{I 0} \phi_{i}=\sum_{i^{\prime}} w_{i^{\prime} i}^{I J} T_{I 0} \phi_{i^{\prime}} . \tag{28}
\end{equation*}
$$

By combining the equations (26)-(28) and the definition of $T_{I 0}$ in the introduction one obtains

$$
\begin{align*}
v_{m m^{\prime}}^{0 i J}=(-)^{m-m^{\prime}} & \sum_{\text {even } I} \\
& \langle j m j-m \mid I 0\rangle\left\langle j m^{\prime} j-m^{\prime} \mid I 0\right\rangle w_{0 i}^{I J}, \tag{29}
\end{align*}
$$

which is symmetric in $m$ and $m^{\prime}$. This explains that the said submatrices of every $V^{J}$ are symmetric.

A spectacular pattern emerges in the lower left $9 \times 5$ submatrix of every $V^{J}$. For $j>m \geq 1 / 2$ the only contribution to $V_{J} n_{m} \phi_{0}$ from states $n_{m^{\prime}} \phi_{1}$ is a term $\gamma_{J} \bar{n}_{m} \phi_{1}$, where $\gamma_{J}$ is constant. Upon closer inspection taking into account again $\sum_{m} m n_{m} \phi_{1}=0$, this also hold for $m=j$. For every $m$ one thus has

$$
\begin{equation*}
\frac{1}{2} V_{J} \bar{n}_{m} \phi_{0}=\sum_{m^{\prime}>0} v_{m^{\prime} m}^{00 J} \bar{n}_{m^{\prime}} \phi_{0}+\gamma_{J} \bar{n}_{m} \phi_{1} \tag{30}
\end{equation*}
$$

(The states $\bar{n}_{m} \phi_{0}$ span the $v \leq 2$ subspace of $\Phi_{40}$.) This is not dependent on the choice of $\phi_{1}$. Replacing $\phi_{1}$ by any linear combination $\phi_{1}+\epsilon \phi_{0}$ gives a relation of the same structure with the same $\gamma_{J}$. In particular, $\phi_{1}$ could have $v=4$. The origin of this pattern is explained in Appendix B

## VII. CONCLUSION

The existence of the Escuderos-Zamick states was shown to be equivalent to the invariance to any rotationally invariant two-body interaction of the span $\Phi_{4}$ of states generated from angular momentum zero states by one-body operators. This equivalence explains the occurrence of the Escuderos-Zamick states for exactly the angular momenta 4 and 6 . The said property of the angular momentum zero state space was verified by exact calculation. This verification was facilitated by the observation that it is required only for the subspace $\Phi_{40}$ of $\Phi_{4}$ characterized by magnetic quantum number $M_{I}=0$ or its orthogonal complement $\Phi_{40}^{\perp}$ within the $M_{I}=0$ space. The actions of five basic rotationally invariant two-body interactions on 4 basic states in $\Phi_{40}^{\perp}$ and 14 basic states in $\Phi_{40}$ were displayed in matrix form, and remarkable regularities in these matrices disclosed. One of them leads to a rule that relates the Escuderos-Zamick energy levels to levels with $I=10$ and 12 . This rule was applied in a discussion of certain aspects of the spectra of ${ }^{94} \mathrm{Ru},{ }^{96} \mathrm{Pd}$, and ${ }^{74} \mathrm{Ni}$. The said regularity so far lacks fundamental explanation. Understanding it could possibly provide a clue towards a more intuitive understanding of the invariance of $\Phi_{4}$.

## Appendix A: Proof that $c_{m_{1} m_{2}}^{J}$ are integral

First notice that the algorithm for $c_{m_{1} m_{2}}^{J}$ described in Sec. IV ensures the proportionality (11) so that $P_{J M}^{\dagger}$ given by (10) is a tensor operator. Besides (13), $\left[I_{+}, P_{J M}^{\dagger}\right]=\sqrt{(J-M)(J+M+1)} P_{J, M+1}^{\dagger}$, (12), and (3) give

$$
\begin{equation*}
\left(J+m_{1}+m_{2}\right) c_{m_{1} m_{2}}^{J}=c_{m_{1}-1, m_{2}}^{J}+c_{m_{1}, m_{2}-1}^{J} . \tag{A1}
\end{equation*}
$$

With

$$
\begin{equation*}
d_{m_{1} m_{2}}^{J}=\left(J-m_{1}-m_{2}\right)!c_{m_{1} m_{2}}^{J} \tag{A2}
\end{equation*}
$$

the recursion relations (13) and (A1) take the forms

$$
\begin{array}{r}
d_{m_{1} m_{2}}^{J}=\left(j-m_{1}\right)\left(j+m_{1}+1\right) d_{m_{1}+1, m_{2}}^{J} \\
+\left(j-m_{2}\right)\left(j+m_{2}+1\right) d_{m_{1}, m_{2}+1}^{J} \\
\left(J+m_{1}+m_{2}\right)\left(J-m_{1}-m_{2}+1\right) d_{m_{1} m_{2}}^{J}  \tag{A4}\\
=d_{m_{1}-1, m_{2}}^{J}+d_{m_{1}, m_{2}-1}^{J}
\end{array}
$$

(Again, terms with undefined values of $d_{m_{1}^{\prime} m_{2}^{\prime}}^{J}$ are omitted.) Setting $m_{1}=j$ so that only the second term occurs on the right in (A3), and using also $d_{j, J-j}^{J}=1$,
one gets for $J-j \geq m_{2} \geq-j$, by repeated application of (A3), an expression for $\bar{d}_{j m_{2}}^{J}$ as a product of two products of $J-j-m_{2}$ consecutive integers. Hence $d_{j m_{2}}^{J}$ is divisible by $\left(J-j-m_{2}\right)!^{2}$, and, all the more, by $\left(J-j-m_{2}\right)$ !. It then follows by induction by means of (A4) that $\left(J-m_{1}-m_{2}\right)$ ! divides $d_{m_{1} m_{2}}^{J}$ for every $m_{1}, m_{2}$ with $m_{1}+m_{2} \geq 0$. Then by (A2), $c_{m_{1} m_{2}}^{J}$ is integral for $m_{1}+m_{2} \geq 0$. For $m_{1}+m_{2}<0$ one can now apply the second equation in (14). In this case, $j+m_{1}<j-m_{2}$ and $j+m_{2}<j-m_{1}$, so the first factor on the right, and hence $c_{m_{1} m_{2}}^{J}$, are integral.

## Appendix B: Explanation of (30)

The first equation in (5) can be written

$$
\begin{equation*}
\phi_{0}=-\frac{1}{2} P^{\dagger^{2}}| \rangle \tag{B1}
\end{equation*}
$$

with

$$
\begin{equation*}
P^{\dagger}=\sum_{m>0}(-)^{j-m} a_{m}^{\dagger} a_{-m}^{\dagger} \tag{B2}
\end{equation*}
$$

Hence

$$
\begin{align*}
& n_{m} \phi_{0}=a_{m}^{\dagger} a_{m} \phi_{0} \\
& \quad=-a_{m}^{\dagger} P^{\dagger}\left[a_{m}, P^{\dagger}\right]| \rangle=-(-)^{j-m} P^{\dagger} a_{m}^{\dagger} a_{-m}^{\dagger}| \rangle \tag{B3}
\end{align*}
$$

and

$$
\begin{align*}
& V_{J} n_{m} \phi_{0}=\frac{1}{2} \sum_{M} P_{J M}^{\dagger} P_{J M} n_{m} \phi_{0} \\
= & -(-)^{j-m} \frac{1}{2} \sum_{M} P_{J M}^{\dagger}\left(P^{\dagger} P_{J M}+\left[P_{J M}, P^{\dagger}\right]\right) a_{m}^{\dagger} a_{-m}^{\dagger}| \rangle . \tag{B4}
\end{align*}
$$

Since $P_{J M} a_{m}^{\dagger} a_{-m}^{\dagger}| \rangle \propto| \rangle$, the first term in the parentheses contributes to $V_{J} n_{m} \phi_{0}$ a term proportional to $P_{J M}^{\dagger} P^{\dagger}| \rangle$, which has $v \leq 2$. I proceed by calculating the commutator $\left[P_{J M}, P^{\dagger}\right]$.

For convenience, I omit for now the factor $c_{J}$ in (10). It is reentered at the end of this appendix. I then have

$$
\begin{align*}
& {\left[P_{J M}, P^{\dagger}\right]=\frac{1}{2} \sum_{m_{1} m_{2} m}(-)^{j-m}} \\
& \quad\left\langle j m_{1} j m_{2} \mid J M\right\rangle\left[a_{m_{2}} a_{m_{1}}, a_{m}^{\dagger} a_{-m}^{\dagger}\right] \\
& =\sum_{m_{1} m_{2}}\left\langle j m_{1} j m_{2} \mid J M\right\rangle \\
& \quad\left((-)^{j-m_{1}} a_{m_{2}} a_{-m_{1}}^{\dagger}+(-)^{j-m_{2}} a_{-m_{2}}^{\dagger} a_{m_{1}}\right) \\
& =\sum_{m_{1} m_{2}}(-)^{j-m_{2}}\left\langle j m_{1} j m_{2} \mid J M\right\rangle\left[a_{-m_{2}}^{\dagger}, a_{m_{1}}\right] \\
& =2 \sum_{m_{1} m_{2}}(-)^{j-m_{2}}\left\langle j m_{1} j m_{2} \mid J M\right\rangle a_{-m_{2}}^{\dagger} a_{m_{1}} \\
& \quad-\sum_{m}(-)^{j+m}\langle j m j-m \mid J M\rangle \\
& =2 \sum_{m_{1} m_{2}}(-)^{j-m_{2}}\left\langle j m_{1} j m_{2} \mid J M\right\rangle a_{-m_{2}}^{\dagger} a_{m_{1}} \\
& \quad+\delta_{J 0} \sqrt{2 j+1} . \tag{B5}
\end{align*}
$$

Since $P_{J 0}^{\dagger} \propto P^{\dagger}$, the last term in this expression is seen by comparison with ( (B2) to contribute in (B4) a term proportional to $n_{m} \phi_{0}$.

Further,

$$
\begin{equation*}
a_{-m_{2}}^{\dagger} a_{m_{1}} a_{m}^{\dagger} a_{-m}^{\dagger}| \rangle=\left(\delta_{m_{1} m}-\delta_{m_{1}-m}\right) a_{-m_{2}}^{\dagger} a_{-m_{1}}^{\dagger}| \rangle, \tag{B6}
\end{equation*}
$$

so the first term in the expression (B5) contributes to the sum in (B4) terms

$$
\begin{equation*}
2 a_{m}^{\dagger} \sum_{M m_{2}}(-)^{j-m_{2}}\left\langle j-m j m_{2} \mid J M\right\rangle P_{J M}^{\dagger} a_{-m_{2}}^{\dagger}| \rangle \tag{B7}
\end{equation*}
$$

- same with $-m$ instead of $m$.

Here [7],

$$
\begin{align*}
& \xi=\sum_{M m_{2}}(-)^{j-m_{2}}\left\langle j-m j m_{2} \mid J M\right\rangle P_{J M}^{\dagger} a_{-m_{2}}^{\dagger}| \rangle \\
& =-\sqrt{\frac{2 J+1}{2 j+1}} \sum_{m_{2} M}\left\langle j-m_{2} J M \mid j-m\right\rangle a_{-m_{2}}^{\dagger} P_{J M}^{\dagger}| \rangle \tag{B8}
\end{align*}
$$

is a member with $M_{I}=-m$ of the space $\Phi_{3}$ defined in Sec. II. With standard relative phases within its multiplet, one therefore has

$$
\begin{equation*}
\xi=(-)^{j+m} a_{m}\left(\zeta \phi_{0}+\eta \phi_{1}\right), \tag{B9}
\end{equation*}
$$

where $\zeta$ and $\eta$ do not depend on $m$. Totally, one arrives at

$$
\begin{equation*}
V_{J} n_{m} \phi_{0}=\eta\left(n_{m}+n_{-m}\right) \phi_{1}+v \leq 2 \text { state }, \tag{B10}
\end{equation*}
$$

which is equivalent to (30) with $\gamma_{J}=\eta c_{J}^{2}$.
