In this study, we demonstrate a new anisotropic solution to the Einstein field equations in Finch-Skea spacetime. The physical features of stellar configuration are studied in previous investigations. We create a model that meets all physical plausibility conditions for a variety of stars and plot graphs for **4U 1820-30**.

1 Introduction

In astrophysics, compact stars are usually the end-point of stellar evolution. These compact objects have incredibly high densities compared to other atomic matter. In astronomy, researchers attracted much attention by studying white dwarfs, neutron stars, and black holes, commonly referred to as compact stars because they have similar structures and characteristics. In compact stars, the matter could be anisotropic. The nature of anisotropy can change the evolution and subsequently, the physical properties of stellar objects. Understanding the non-negligible effects of anisotropy on the stellar object parameters such as mass, pressure, composition, etc., are essential for a viable physical model of a compact star.

In a stellar configuration, anisotropy can happen for a variety of reasons, including the presence of a solid core, type P superfluid, phase transition, mixing of two fluids, the presence of an external field, etc. [1], [2] and [3] have looked at models of a compact star, uncharged spheres with isotropic pressures. Neutral anisotropic matter was examined by [4], [5] and [6], [7]. Among the authors who highlight charged isotropic compact models are [8], [9], [10], [11] and [12]. The general model with charge and anisotropy was analyzed by [13], [14] and [15]. [16] did pioneering

work on compact objects. They discovered hydrostatic equilibrium after studying static spherically anisotropic symmetry configurations. They conclude that anisotropy may not have been disregarded when calculating the mass and surface redshift of compact stars. [17] argued that matter might be anisotropic when it comes to objects with densities that are significantly higher than nuclear density. According to [18], superfluid development inside the star may also cause anisotropy in pressure to increase. [19] proposed a number of models with spherically anisotropic distribution at constant densities. The identical task was carried out by [20], but with variable densities. [21] explored how anisotropy in pressure affected the mass, structure, and physical characteristics of compact objects and obtained an equation of state relating radial pressure and tangential pressure in various versions of the precise solution. For spherically symmetric static anisotropic stellar configuration, [22], [23], [24] all provide a class of accurate solutions to the Einstein field equation. Anisotropy was suggested to be a crucial prerequisite for the dense matter density regime by [25], [26]. [27] purposefully introduced local anisotropy in the self-gravitating system. In modern research, As proposed by [28] relativistic compact objects, pressure anisotropy cannot be ignored. The investigations by [29] and [30] highlighted a number of intriguing characteristics of exact solutions to the Einstein-Maxwell system for charged anisotropic quark stars. The existence of charge and anisotropy

in the star interior has been the subject of numerous recent studies by [31]. Generalized isothermal models were discovered by [32] and superdense models were examined by [33]. The study of [34] contains further new precise solutions for charged anisotropic stars. [35] discovered exact models for charged anisotropic materials with a quadratic equation of state. [36] and [37], using charged stellar models with Van der Waals and modified Van der Waals equations of state, respectively.

In this study, we will produce solutions to Einstein's field equations for anisotropic fluid distributions that are static and spherically symmetric. Because we assume that the matter inside the fluid sphere is uncharged, anisotropy plays a significant role in our concept. We use the compact object 4U 1820-30 to compare our model to observational data.

The work is organized as follows: section 2 contains Einstein field equations and their solutions. The constants of integration are obtained in section 3. Section 4 contains physical analysis and we conclude the work in section 5.

2 EINSTEIN'S FIELD EQUATIONS AND ITS SOLUTIONS

Consider a static spherically symmetric spacetime metric as

$$ds^2 = e^{v(r)} dt^2 - e^{\lambda(r)} dr^2 - r^2(d\theta^2 + \sin^2 \theta d\phi^2), \quad (1)$$

where λ and ν are unknown functions dependent on radial coordinate r . The stress-energy-momentum tensor for anisotropy matter distribution is of the form

$$T_{ij} = (\rho + p)u_i u_j - p g_{ij} + \pi_{ij}, \quad (2)$$

where ρ and p are energy density and isotropic pressure, respectively, and u^i is the radial 4-velocity vector, π_{ij} is anisotropic stress tensor given by

$$\pi_{ij} = \sqrt{3}S \left[C_i C_j - \frac{1}{3}(u_i u_j - g_{ij}) \right], \quad (3)$$

the non-vanishing components of energy-momentum tensor are

$$\begin{aligned} T_0^0 &= \rho, & T_1^1 &= -\left(p + \frac{2S}{\sqrt{3}}\right), \\ T_2^2 &= T_3^3 = \left(p - \frac{S}{\sqrt{3}}\right). \end{aligned} \quad (4)$$

The relation between radial pressure, tangential pressure, and anisotropic is given by

$$p_r = p + \frac{2S}{\sqrt{3}}, \quad (5)$$

$$p_t = p - \frac{S}{\sqrt{3}}, \quad (6)$$

$$p_r - p_t = \sqrt{3}S. \quad (7)$$

The Einstein's field equations corresponding to the spacetime metric (1) and the energy-momentum tensor (2) are obtained as ($G=c=1$)

$$8\pi\rho = \frac{1}{r^2} - e^{-\lambda} \left(\frac{1}{r^2} - \frac{\lambda'}{r} \right), \quad (8)$$

$$8\pi p_r = e^{-\lambda} \left(\frac{1}{r^2} + \frac{v'}{r} \right) - \frac{1}{r^2}, \quad (9)$$

$$8\pi p_t = \frac{e^{-\lambda}}{4} \left[2v'' + (v' - \lambda') \left(v' + \frac{2}{r} \right) \right], \quad (10)$$

$$8\pi\sqrt{3}S = (8\pi p_r - 8\pi p_t). \quad (11)$$

We assume metric potential e^λ as,

$$e^\lambda = 1 + \frac{r^2}{R^2}, \quad (12)$$

and

$$e^\nu = F^2, \quad (13)$$

then equation (11) is written as

$$\begin{aligned} F'' - \left(\frac{1 + \frac{2r^2}{R^2}}{r(1 + \frac{r^2}{R^2})} \right) F' - \left(\frac{1 + \frac{2r^2}{R^2}}{r^2(1 + \frac{r^2}{R^2})} + \right. \\ \left. (8\pi\sqrt{3}S + \frac{1}{r^2})(1 + \frac{r^2}{R^2}) \right) F = 0 \end{aligned}, \quad (14)$$

we assume $8\pi\sqrt{3}S$ as

$$8\pi\sqrt{3}S = \frac{(\frac{r^2}{R^2} - \frac{4r^4}{R^4})}{4R^2(1 + \frac{r^2}{R^2})^3}, \quad (15)$$

this choice of $8\pi\sqrt{3}S$ is physically viable as $8\pi\sqrt{3}S = 0$ at $r = 0$.

The solution of equation (14) is given by

$$F = C(1 + \frac{r^2}{R^2})^{5/2} + D(1 + \frac{r^2}{R^2})^{1/2}, \quad (16)$$

where C and D are constants of integration, this leads

$$e^\nu = \left[C \left(1 + \frac{r^2}{R^2} \right)^{5/4} + D \left(1 + \frac{r^2}{R^2} \right)^{1/4} \right]^2, \quad (17)$$

the density, radial pressure and tangential pressure then takes the form,

$$8\pi\rho = \frac{(r^2 + 3R^2)}{(r^2 + R^2)^2}, \quad (18)$$

$$8\pi p_r = \frac{-Dr^2R^2 + C(-r^4 + 3r^2R^2 + 4R^4)}{(r^2 + R^2)^2(DR^2 + C(r^2 + R^2))}, \quad (19)$$

$$8\pi p_t = \frac{-5Dr^2R^4 + C(11r^4R^2 + 27r^2R^4 + 16R^6)}{4(r^3 + R^2)^3(DR^2 + C(r^2 + R^2))}. \quad (20)$$

The spacetime metric (1) will take in the following form as

$$ds^2 = \left[C \left(1 + \frac{r^2}{R^2} \right)^{5/4} + D \left(1 + \frac{r^2}{R^2} \right)^{1/4} \right]^2 dt^2 - \left(1 + \frac{r^2}{R^2} \right) dr^2 - r^2(d\theta^2 + \sin^2\theta d\phi^2) \quad (21)$$

The constants of integration, we calculate in the next section.

3 DETERMINE CONSTANTS

The Spacetime metric (21) should continuously match with Schwarzschild exterior spacetime metric

$$ds^2 = \left(1 - \frac{2M}{r} \right) dt^2 - \left(1 - \frac{2M}{r} \right)^{-1} dr^2 - r^2(d\theta^2 + \sin^2\theta d\phi^2), \quad (22)$$

at the boundary of star $r = a$, and $(p_r)_{(r=a)} = 0$. These two conditions gives

$$M = \frac{a^3}{2(R^2 + a^2)}, \quad (23)$$

Figure 1: Variation of density (ρ) against the radial parameter ($1\text{MeV fm}^{-3} = 1.78 \times 10^{12}\text{gcm}^{-3}$)

Figure 2: Variation of radial pressure (p_r) against the radial parameter r

$$C = \frac{a^2}{(1 + \frac{a^2}{R^2})^{3/4} [a^2(1 + \frac{a^2}{R^2}) + R^2(\frac{-a^4}{R^4} + \frac{3a^2}{R^2} + 4)]}, \quad (24)$$

Figure 3: Variation of tangential pressure (p_t) against the radial parameter r

Table 1: The estimated and observed values of compact stars

S.No.	Star	M_{\odot}	R (Chossen)	$\rho_o(\text{Mev}/Fm^3)$	$\rho_R(\text{Mev}/Fm^3)$
01	4U 1820-30	1.58	6.5	2138.24	403.491
02	Her-X 1	0.85	5.785	2698.79	509.268
03	SMC X-1	1.29	6.307	2270.49	428.447
04	4U 1538-52	0.87	5.618	2861.75	540.019
05	PSR J1903+327	1.667	6.735	1991.21	375.745
06	Vela X-1	1.77	6.828	1937.42	365.595
07	LMC X-4	1.04	5.929	2569.68	484.904
08	PSR J1614-2230	1.97	6.921	1885.78	355.852

Figure 4: Variation of $(\rho + p_r + 2p_t)$ against the radial parameter r Figure 5: Variation of $(\rho - p_r - 2p_t)$ against the radial parameter r

$$D = \frac{4R^2 - a^2}{4R^2(1 + \frac{a^2}{R^2})^{3/4}}. \quad (25)$$

Substituting the value of C and D in eq. (18), (19) and (20), we get

$$8\pi\rho = \frac{(r^2 + 3R^2)}{(r^2 + R^2)^2}, \quad (26)$$

Figure 6: Variation of $\frac{dp_r}{d\rho}$ against the radial parameter r Figure 7: Variation of $\frac{dp_t}{d\rho}$ against the radial parameter r

$$8\pi p_r = \frac{a^4 r^2 - 4r^2 R^4 - a^2(r^4 - 4R^4)}{(r^2 + R^2)^2(-a^4 + 4R^4 + a^2(r^2 + 4R^2))}, \quad (27)$$

$$8\pi p_t = \frac{R^2(5a^4 r^2 - 20r^2 R^4 + a^2(11r^4 + 12r^2 R^2 + 16R^4))}{(r^2 + R^2)^3(-a^4 + 4R^4 + a^2(r^2 + 4R^2))}. \quad (28)$$

4 Physical analysis

The physically plausible model should satisfy the following conditions

- (i) $\rho(r), p_r(r), p_t(r) \geq 0$, for $0 \leq r \leq R$
- (ii) $\frac{d\rho}{dr}, \frac{dp_r}{dr}, \frac{dp_t}{dr} < 0$, for $0 \leq r \leq R$
- (iii) $\rho + p_r > 0$, for $0 \leq r \leq R$
- (iv) $\rho + p_r + 2p_t \geq 0$, for $0 \leq r \leq R$
- (v) $\rho - p_r - 2p_t \geq 0$, for $0 \leq r \leq R$
- (vi) $0 < \frac{dp_r}{d\rho} < 1$; $0 < \frac{dp_t}{d\rho} < 1$, for $0 \leq r \leq R$

For a physically acceptable model, all the physical plausibility conditions are satisfied for stars in table 1. We have demonstrated graphs for a star 4U1820 – 30. The radial pressure, the tangential pressure, and the density should be positive throughout the mass distribution. Fig(s). 1, 2 and

3 shows that these conditions are satisfied throughout the distribution and decrease with mass distribution. $\rho \geq 0$ is called the null energy condition, which is also satisfied. The third condition is the weak energy condition, which is $\rho + p_r > 0$ fulfills the requirement. Further, the strong energy condition, $\rho + p_r + 2p_t \geq 0$ and the trace energy condition $\rho - p_r - 2p_t \geq 0$ are also satisfied throughout the distribution, as shown in Fig(s). 4 and 5. The fifth condition is called the causality condition, followed by star 4U 1820-30 shown in Fig(s) 6 and 7.

It is clear from figure 8 that adiabatic index $\Gamma > \frac{4}{3}$. The variation of anisotropy is shown in Figure 9, and the computed value of central density and surface density for a particular choice of R are shown in table 1.

5 Conclusion

In this work, we have obtained the exact non-singular solution of Einstein's field equations. The salient features of the model are that all the physical plausibility conditions are satisfied for stars are shown in table 1, and we have plotted graphs for star 4U 1820-30. According to [38], adiabatic index $\Gamma > \frac{4}{3}$, the model is potentially stable. The data demonstrate that the model satisfies all criteria for physical requirements for 4U 1820-30.
