Abstract

The recent precise measurement of the W -mass by the CDF II collaboration is indicative of new physics beyond the Standard Model. On the other hand, a resolution of the longstanding muon $g - 2$ anomaly also calls for additional dynamics. In this work, we accommodate the two aforementioned anomalies in an extension of the minimal Type-II seesaw model. That is, the minimal Type-II model is augmented with an additional doubly charged scalar and vector leptons. While a chirality-flip of the vector leptons can predict the observed value of muon $g - 2$, the value of the recently reported W -mass can also be simultaneously achieved through the oblique parameters of the model. In addition, we further show that the parameter region allowing for the simultaneous resolution of the two anomalies complies with the neutrino mass data, lepton flavour violation and electroweak vacuum stability up to the Planck scale.

I. INTRODUCTION

The discovery of the Higgs boson of mass 125 GeV [1, 2] at the Large Hadron Collider (LHC) completes the particle spectrum of the Standard Model (SM). Moreover, the interactions of the boson with SM fermions and gauge bosons are increasingly in agreement with the corresponding SM values. Despite this success, certain pressing inconsistencies within the SM necessitate additional dynamics beyond-the-SM (BSM). That the SM alone cannot stabilise the electroweak (EW) vacuum up to the Planck scale is one such theoretical shortcoming [3–7]. However, additional bosonic degrees of freedom over and above the SM ones can potentially offset this destabilising effect coming from the t-quark (see the references in [8]). The remedy in this case lies in introducing additional scalar degrees of freedom that can potentially counter the effect from the t-quark and stabilise the vacuum till the Planck scale. On the experimental front, for instance, the SM fails to account for the observed non-zero neutrino masses and their mixings. However, appropriately augmenting the SM by additional fields can lead to a non-zero neutrino mass via the seesaw mechanism. Of these, the popular Type-II seesaw [9–11] employs a complex scalar $SU(2)_L$ triplet and is also known to be attractive from the perspective of baryogenesis and collider signatures. It has also been shown to alleviate the vacuum instability problem [12–14].

In addition, certain fresh experimental results over the past few years have reinforced the claims of additional dynamics beyond the SM. First, the long-standing discrepancy in the muon anomalous magnetic moment reported by Brookhaven E821 [15] has now been confirmed by Fermilab E989 through its "MUON G-2" experiment [16, 17]. The combined result is quoted as

$$\Delta a_\mu = (2.51 \pm 0.59) \times 10^{-9}, \quad (1)$$

which is 4.2σ away from the SM prediction. Secondly, a recent measurement of the W -boson mass by the CDF collaboration sets the value at [18]

$$M_W = 80.4335 \text{ GeV} \pm 6.4 \text{ MeV}(\text{stat}) \pm 6.9 \text{ MeV}(\text{sys}), \quad (2)$$

an apparent 7.2σ disagreement with the SM value, i.e., $M_W = 80.357 \pm 4 \text{ MeV}(\text{stat}) \pm 4 \text{ MeV}(\text{sys})$. If such a discrepancy persists in other experimental data, it must indicate presence of new physics (NP) encoded through the oblique parameters [19, 20]. In fact, the announcement of the W -mass has spurred a series of investigations, each invoking some NP scenario, some of the earliest ones being [21–27]. Further speculations in this direction have included, for instance, supersymmetric models [28–33], non-supersymmetric extended Higgs sectors [34–51], vector-like fermions [52–56], leptoquarks [57–59] and SM effective field theory [60–63].

In this work, we aim to offer an explanation of the two aforementioned anomalies using Type-II seesaw as the basic framework. Pedagogy dictates to look at the minimal Type-II framework first. And it is seen that despite its attractiveness, the Type-II seesaw model predicts a negative muon magnetic moment [64], and hence, cannot account for the observed discrepancy. And this can be

understood from the chirality structure of the Yukawa interactions of the scalar triplet. This calls for extending the minimal Type-II model. And the extension used in this work comprises a doubly charged $SU(2)_L$ singlet scalar and vector-like leptons (VLLs), first introduced in [65]. The VLLs can have novel origins such as Grand Unification [66, 67] and the SM suitably augmented by VLLs can in fact explain the muon $g - 2$ anomaly [68–71]. However, the minimal VLL scenario does not offer solutions to the neutrino mass and vacuum instability problems. Moreover, it gets rather constrained by the measurements of the Higgs to dimuon decay made by ATLAS [72] and CMS [73]. Some other recent studies employing vector leptons and additional scalar multiplets to address the muon anomaly are [74–79].

A doubly charged scalar is an ingredient of certain classes of BSM scenarios, the minimal left-right symmetric model (LRSM) augmented with scalar triplets being an example. That is, the triplets Δ_L ($\mathbf{1}, \mathbf{3}, \mathbf{1}, 2$) and Δ_R ($\mathbf{1}, \mathbf{1}, \mathbf{3}, 2$) are introduced under the LRSM gauge group $SU(3)_c \times SU(2)_L \times SU(2)_R \times U(1)_{B-L}$ [80], over and above the minimal field content. On the other hand, some investigations involving a scalar triplet and VLLs are [81–83]. We thus have two doubly charged scalars in this scenario instead of one as in the case of ordinary Type-II seesaw¹. The VLLs include both doublets and singlets under $SU(2)_L$, the latter carrying one unit of electric charge. We show in this study how a positive contribution of the sought magnitude to the muon $g - 2$ can be obtained in this framework through a non-zero mixing of the two doubly charged bosons. We also demonstrate that tuning the Yukawa interactions and the triplet vacuum expectation value (VEV) correctly can help evade the constraints coming from the non-observation of charged lepton flavour violation (CLFV) [85]. In addition, we compute the one-loop RG equations corresponding to this model and subsequently show that a stable EW vacuum exists within the parameter region that reproduces the observed pattern of neutrino masses and mixings and accommodates the muon and CDF II anomalies.

This paper is organised as follows. We detail in field content and the corresponding interactions in section II. The relevant constraints are listed in section III. We review the chirality-flip in the muon $g - 2$ amplitude in section IV demonstrate how the observed M_W can be simultaneously achieved. Section V presents an analysis combining vacuum stability, muon $g - 2$ and the various relevant constraints. We summarise in section VI. Various important formulae are relegated to the Appendix.

II. THE MODEL

The minimal Type-II seesaw model employs a $SU(2)_L$ complex scalar triplet Δ in addition to the scalar doublet ϕ . We invoke the field content introduced in [65] wherein the minimal Type-II

¹ [84] presents explanations the muon anomaly in models featuring a two doubly charged scalars but no additional fermions over and above the SM ones.

Field	$SU(3)_c \times SU(2)_L \times U(1)_Y$
Δ	$(1, 3, 1)$
k^{++}	$(1, 1, 2)$
$L_{L,R}$	$(1, 2, -1/2)$
$E'_{L,R}$	$(\mathbf{1}, \mathbf{1}, -1)$

TABLE I: Quantum numbers of the relevant fields under the SM gauge group.

model sector is augmented by a doubly charged scalar singlet k^{++} and the following VLL multiplets:

$$L_{L,R} = \begin{pmatrix} N_{L,R} \\ E_{L,R} \end{pmatrix}, \quad E'_{L,R}. \quad (3a)$$

The quantum numbers of the BSM fields are shown in Table I. The scalar doublet and the triplet can be parameterised as under.

$$\phi = \begin{pmatrix} \phi^+ \\ \frac{1}{\sqrt{2}}(v + \phi_0 + i\eta_0) \end{pmatrix}, \quad \Delta = \begin{pmatrix} \frac{\delta^+}{\sqrt{2}} & \delta^{++} \\ \frac{1}{\sqrt{2}}(v_\Delta + \delta_0 + i\chi_0) & -\frac{\delta^+}{\sqrt{2}} \end{pmatrix} \quad (4a)$$

Here, v and v_Δ denote the VEVs acquired by the CP-even neutral components of ϕ and Δ respectively.

As for how the additional fields interact, we first show the scalar potential below:

$$V = V_2 + V_3 + V_4, \quad (5)$$

where V_2, V_3 and V_4 respectively contain the operators of mass dimension 2,3 and 4. That is,

$$V_2 = \mu_\phi^2 (\phi^\dagger \phi) + M_\Delta^2 \text{Tr}(\Delta^\dagger \Delta) + M_S^2 |k^{++}|^2, \quad (6a)$$

$$V_3 = \mu_1 \phi^T (i\sigma_2) \Delta^\dagger \phi + \mu_2 \text{Tr}(\Delta^\dagger \Delta^\dagger) k^{++} + \text{h.c.} \quad (6b)$$

$$V_4 = \frac{\lambda}{2} (\phi^\dagger \phi)^2 + \frac{\lambda_1}{2} [\text{Tr}(\Delta^\dagger \Delta)]^2 + \frac{\lambda_2}{2} \left([\text{Tr}(\Delta^\dagger \Delta)]^2 - \text{Tr}(\Delta^\dagger \Delta \Delta^\dagger \Delta) \right) + \frac{\lambda_3}{2} |k^{++}|^4 \\ + \lambda_4 \phi^\dagger \phi \text{Tr}(\Delta^\dagger \Delta) + \lambda_5 \phi^\dagger [\Delta, \Delta^\dagger] \phi + \lambda_6 \phi^\dagger \phi |k^{++}|^2 + \lambda_7 \text{Tr}(\Delta^\dagger \Delta) |k^{++}|^2 \\ + \lambda_8 (\tilde{\phi}^\dagger \Delta \phi k^{--} + \text{h.c.}). \quad (6c)$$

All parameters in the scalar potential are chosen real to rule out CP-violation. Electroweak symmetry breaking (EWSB) leads to mixings between the component scalars of Δ and ϕ , as well as between Δ and k^{++} , subject to the conservation of electric charge and CP. The mass eigenstates thus emerging are the CP-even (h, H), the CP-odd A , the singly charged H^\pm , and the doubly charged (H_1^{++}, H_2^{++}). The constraint on the ρ -parameter dictates $v_\Delta \lesssim 4$ GeV in which case mixings involving the neutral and singly charged states can be rendered negligibly small. The

corresponding physical masses in this limit are

$$M_h^2 \simeq \lambda v^2, \quad (7a)$$

$$M_H^2 = M_A^2 \simeq M_\Delta^2 + \frac{1}{2}(\lambda_4 + \lambda_5)v^2, \quad (7b)$$

$$M_{H^+}^2 = M_\Delta^2 + \frac{1}{2}\lambda_4 v^2. \quad (7c)$$

On the other hand, $\lambda_8 \neq 0$ can lead to a sizeable mixing between the doubly charged states despite the stringent upper limit on v_Δ . The mass terms then have the following form for $v_\Delta \ll v$ and $\mu_2 \ll \lambda_8 v$:

$$\mathcal{L}_m^{++} = \begin{pmatrix} \delta^{--} & k^{--} \end{pmatrix} \begin{pmatrix} M_\Delta^2 + \frac{1}{2}\lambda_4 v^2 & \frac{1}{2}\lambda_8 v^2 \\ \frac{1}{2}\lambda_8 v^2 & M_S^2 + \frac{1}{2}\lambda_6 v^2 \end{pmatrix} \begin{pmatrix} \delta^{++} \\ k^{++} \end{pmatrix} \quad (8a)$$

We diagonalise the mass matrix in Eq.(8a) by rotating (δ^{++}, k^{++}) by an angle θ and obtain the mass eigenstates $H_{1,2}^{++}$ having masses $M_{1,2}^{++}$. Thus,

$$\begin{pmatrix} \delta^{++} \\ k^{++} \end{pmatrix} = \begin{pmatrix} \cos\theta & \sin\theta \\ -\sin\theta & \cos\theta \end{pmatrix} \begin{pmatrix} H_1^{++} \\ H_2^{++} \end{pmatrix} \quad (9a)$$

We also give below the expressions for $M_{1,2}^{++}$ and θ in the $v_\Delta \ll v$ limit:

$$(M_{1,2}^{++})^2 = \frac{1}{2}[(A + B) \pm \sqrt{(A - B)^2 + 4C^2}] , \quad (10a)$$

$$\tan 2\theta = \frac{2C}{B - A} , \quad \text{where} \quad (10b)$$

$$A = M_\Delta^2 + \frac{1}{2}\lambda_4 v^2 , \quad (10c)$$

$$B = M_S^2 + \frac{1}{2}\lambda_6 v^2 , \quad (10d)$$

$$C = \frac{1}{2}\lambda_8 v^2 . \quad (10e)$$

We discuss the fermionic interactions next. First, the bare mass terms of the VLLs and their interactions with the Higgs doublet ϕ are

$$\mathcal{L}_{Y,\phi}^{\text{VLL}} = -M\overline{L}_L L_R - M'\overline{E}'_L E'_R - y_4\overline{L}_L \phi E'_R - y'_4\overline{L}_R \phi E'_L + \text{h.c.} \quad (11a)$$

The mixings of the VLLs with the SM leptons are neglected in this work for simplicity². The mass terms of the VLLs then take the form

$$\mathcal{L}_{Y,\phi}^{\text{VLL}} \supset - \begin{pmatrix} \overline{E}_R & \overline{E}'_R \end{pmatrix} \begin{pmatrix} M & \frac{y'_4 v}{\sqrt{2}} \\ \frac{y_4 v}{\sqrt{2}} & M' \end{pmatrix} \begin{pmatrix} E_L \\ E'_L \end{pmatrix} + \text{h.c.} \quad (12a)$$

² The mixings, even if allowed, are rendered small from the non-observation of CLFV. This has been explicitly demonstrated in [86] for VLLs having quantum numbers identical to the present scenario. Therefore, they anyway do not majorly modify the muon $g - 2$ prediction in this model thereby justifying the choice. Other constraints on such mixings, although subleading to CLFV, stem from the measurement of $pp \rightarrow h \rightarrow \mu\mu$ [69] and $pp \rightarrow h \rightarrow 4l$ [87].

The non-hermitian matrix in Eq.(12a) is diagonalisable by the bi-unitary transformation

$$U_R^\dagger M_V U_L = M_V^d, \quad (13)$$

where

$$M_V = \begin{pmatrix} M & \frac{y'_4 v}{\sqrt{2}} \\ \frac{y_4 v}{\sqrt{2}} & M' \end{pmatrix}, \quad M_V^d = \begin{pmatrix} M_1 & 0 \\ 0 & M_2 \end{pmatrix} \quad \text{and} \quad U_{L(R)} = \begin{pmatrix} \cos\alpha_{L(R)} & \sin\alpha_{L(R)} \\ -\sin\alpha_{L(R)} & \cos\alpha_{L(R)} \end{pmatrix}. \quad (14)$$

Therefore, the VLLs in the mass basis, i.e., $E_{L(R)1}$ and $E_{L(R)2}$, are obtained by rotating the flavour basis as

$$\begin{pmatrix} E_{L(R)} \\ E'_{L(R)} \end{pmatrix} = U_{L(R)} \begin{pmatrix} E_{L(R)1} \\ E_{L(R)2} \end{pmatrix}. \quad (15a)$$

Taken up next are the Yukawa interactions involving the triplet Δ . Denoting an SM lepton doublet (singlet) as $L_{\alpha L}$ ($l_{\alpha R}$), one writes

$$\mathcal{L}_{Y,\Delta} = \mathcal{L}_{Y,\Delta}^{\text{SM}} + \mathcal{L}_{Y,\Delta}^{\text{VLL}}, \quad (16a)$$

$$\mathcal{L}_{Y,\Delta}^{\text{SM}} = - \sum_{\alpha,\beta=e,\mu,\tau} y_{\Delta}^{\alpha\beta} \overline{L_{\alpha L}^c} i\sigma_2 \Delta L_{\beta L} + \text{h.c.}, \quad (16b)$$

$$\mathcal{L}_{Y,\Delta}^{\text{VLL}} = -2 \sum_{\alpha=e,\mu,\tau} y_{\Delta}^{\alpha 4} \overline{L_{\alpha L}^c} i\sigma_2 \Delta L_L - y_{\Delta}^{44} \overline{L_L^c} i\sigma_2 \Delta L_L + \text{h.c.} \quad (16c)$$

One notes that $\mathcal{L}_{Y,\Delta}^{\text{VLL}}$ describes how the VLLs interact with Δ and is an addition over the minimal Type-II. Finally, we describe the Yukawa interactions involving k^{++} below.

$$\mathcal{L}_{Y,k^{++}} = \mathcal{L}_{Y,k^{++}}^{\text{SM}} + \mathcal{L}_{Y,k^{++}}^{\text{VLL}}, \quad (17a)$$

$$\mathcal{L}_{Y,k^{++}}^{\text{SM}} = - \sum_{\alpha,\beta=e,\mu,\tau} y_S^{\alpha\beta} \overline{l_{\alpha R}^c} l_{\beta R} k^{++} + \text{h.c.}, \quad (17b)$$

$$\mathcal{L}_{Y,k^{++}}^{\text{VLL}} = -2 \sum_{\alpha=e,\mu,\tau} y_S^{\alpha 4} \overline{l_{\alpha R}^c} E'_R k^{++} - y_S^{44} \overline{E'_R} E'_R k^{++} + \text{h.c.} \quad (17c)$$

It is convenient to describe a framework in terms of masses and mixing angles. The following scalar quartic couplings are solved in terms of physical scalar masses and the mixing angle θ as under.

$$\lambda = \frac{M_h^2}{v^2}, \quad (18a)$$

$$\lambda_4 = \frac{2(M_{H^+}^2 - M_{\Delta}^2)}{v^2}, \quad (18b)$$

$$\lambda_5 = \frac{2(M_H^2 - M_{H^+}^2)}{v^2}, \quad (18c)$$

$$\lambda_6 = \frac{2[(M_1^{++})^2 \sin^2\theta + (M_2^{++})^2 \cos^2\theta - M_S^2]}{v^2}, \quad (18d)$$

$$\lambda_8 = \frac{2\sin\theta\cos\theta[(M_2^{++})^2 - (M_1^{++})^2]}{v^2}. \quad (18e)$$

The independent parameters in the scalar sector are therefore $\{v, v_\Delta, \mu_2, M_h, M_H, M_H^+, M_1^{++}, M_2^{++}, M_\Delta, M_S, \lambda_1, \lambda_2, \lambda_3, \lambda_7\}$. Of these, we fix $M_h = 125$ GeV and $v \simeq 246$ GeV for $v_\Delta \ll v$.

A non-zero v_Δ leads to non-zero neutrino-mass elements of the form $m_\nu^{\alpha\beta} = \sqrt{2}y_\Delta^{\alpha\beta}v_\Delta$. This necessitates $y_\Delta^{\alpha\beta}$ to be complex. All other Yukawa couplings are taken real since they do not participate in neutrino mass generation. One can also eliminate y_4, y'_4 in favour of the VLL masses and α_L, α_R as

$$y_4 = \frac{\sqrt{2}}{v}(M_2 \sin\alpha_L \cos\alpha_R - M_1 \cos\alpha_L \sin\alpha_R), \quad (19a)$$

$$y'_4 = \frac{\sqrt{2}}{v}(M_2 \cos\alpha_L \sin\alpha_R - M_1 \sin\alpha_L \cos\alpha_R). \quad (19b)$$

The neutral member of the VLL multiplet, N , then has the mass

$$M_N = M = M_1 \cos\alpha_L \cos\alpha_R + M_2 \sin\alpha_L \sin\alpha_R. \quad (20)$$

The independent parameters in the fermionic sector are therefore $\{m_\nu^{\alpha\beta}, y_\Delta^{\alpha 4}, y_\Delta^{44}, y_S^{\alpha\beta}, y_S^{\alpha 4}, y_S^{44}, M_1, M_2, \alpha_L, \alpha_R\}$ of which $m_\nu^{\alpha\beta}$ are determined by the neutrino-oscillation data.

III. CONSTRAINTS

We discuss here the constraints on the model from theory and experiments.

A. Theoretical constraints

The bounds $|\lambda_i| \leq 4\pi, |y_i| < \sqrt{4\pi}$ ensure that the theory remains perturbative, where λ_i (y_i) denotes a generic quartic (Yukawa) coupling. In addition, the following conditions ensure a bounded-from-below (BFB) scalar potential for large field values of the constituent scalar fields:

$$\lambda > 0, \lambda_1 > 0, 2\lambda_1 + \lambda_2 > 0, \lambda_3 > 0, \quad (21a)$$

$$\lambda_4 \pm \lambda_5 + \sqrt{\lambda\lambda_1} > 0, \sqrt{\lambda(\lambda_1 + \frac{\lambda_2}{2})} > 0, \lambda_4 \pm \lambda_5 + \sqrt{\lambda(\lambda_1 + \frac{\lambda_2}{2})} > 0, \quad (21b)$$

$$\lambda_6 + \sqrt{\lambda\lambda_3} > 0, \lambda_7 + \sqrt{\lambda_1\lambda_3} > 0, \lambda_7 + \sqrt{\lambda_3(\lambda_1 + \frac{\lambda_2}{2})} > 0. \quad (21c)$$

A given condition in the aforementioned set comes from demanding the scalar potential remains BFB in a given direction in the field space. Unitarity leads to additional constraints on the quartic couplings. A tree-level $2 \rightarrow 2$ scattering matrix can be constructed between various two particle states consisting of charged and neutral scalars [88, 89]. Unitarity demands that the absolute value

of each eigenvalue of the aforementioned matrix must be bounded from above at 8π . The conditions for the present scenario are derived in [65] and are given below³

$$|\lambda_1 + \lambda_2| \leq 8\pi, \quad |\lambda_4 - 2\lambda_5| \leq 8\pi, \quad |\lambda_4 \pm \lambda_5| \leq 8\pi, \quad |2\lambda_1 + 3\lambda_2| \leq 16\pi, \quad (22a)$$

$$\left(\lambda + \lambda_1 - \lambda_2 \pm \sqrt{(\lambda - \lambda_1 + \lambda_2)^2 + 16\lambda_5^2} \right) \leq 16\pi, \quad (22b)$$

$$\left(\lambda + \lambda_7 \pm \sqrt{(\lambda - \lambda_7)^2 + 8\lambda_8^2} \right) \leq 16\pi, \quad (22c)$$

$$\left(\lambda_4 + 2\lambda_5 + \lambda_6 \pm \sqrt{(\lambda_4 - 2\lambda_5 - \lambda_6)^2 + 24\lambda_8^2} \right) \leq 16\pi. \quad (22d)$$

Finally, these bounds obtained from demanding perturbativity and a BFB as well as unitary scalar potential are imposed at each energy scale in the analysis using RGEs.

B. Neutrino mass

The U_{PMNS} matrix diagonalizes the neutrino mass matrix m_ν , *i.e.*,

$$m_\nu = U_{\text{PMNS}}^* m_\nu^{\text{diag}} U_{\text{PMNS}}^T, \quad (23a)$$

$$\text{with } U_{\text{PMNS}} = V_{\text{PMNS}} \times \text{diag}(1, e^{i\alpha_{21}/2}, e^{i\alpha_{31}/2}) \text{ and} \quad (23b)$$

$$V_{\text{PMNS}} = \begin{pmatrix} c_{12}c_{13} & s_{12}c_{13} & s_{13}e^{-i\delta_{CP}} \\ -s_{12}c_{23} - c_{12}s_{23}s_{13}e^{i\delta_{CP}} & c_{12}c_{23} - s_{12}s_{23}s_{13}e^{i\delta_{CP}} & s_{23}c_{13} \\ s_{12}s_{23} - c_{12}c_{23}s_{13}e^{i\delta_{CP}} & -c_{12}s_{23} - s_{12}c_{23}s_{13}e^{i\delta_{CP}} & c_{23}c_{13} \end{pmatrix}, \quad (23c)$$

where $s_{ij} = \sin \theta_{ij}$, $c_{ij} = \cos \theta_{ij}$, δ_{CP} is the Dirac phase, and α_{21} and α_{31} are the Majorana phases. The neutrino oscillation parameters are fixed to their central values [91] as

$$\begin{aligned} \sin^2 \theta_{12} &= 0.307, \quad \sin^2 \theta_{23} = 0.510, \quad \sin^2 \theta_{13} = 0.021, \\ \Delta m_{21}^2 &= 7.45 \times 10^{-5} \text{ GeV}^2, \quad \Delta m_{32}^2 = 2.53 \times 10^{-3} \text{ GeV}^2, \\ \delta_{CP} &= 1.41\pi, \quad \alpha_{21} = \alpha_{31} = 0. \end{aligned} \quad (24)$$

The mass of the lightest neutrino and Majorana phases are additionally taken zero in the present analysis.

C. Collider constraints

Limits on the VLL masses are weak for negligible mixing of the VLLs with the SM leptons, which is the case here. A limit from colliders for a heavy charged lepton quotes $M, M' > 102.6 \text{ GeV}$ [92]. A weak limit $\sim \mathcal{O}(\text{MeV})$ on masses neutral leptons comes from Big Bang Nucleosynthesis (BBN) [92]. We therefore take $M_N, M_1, M_2 > 110 \text{ GeV}$ in the present analysis. Next we discuss

³ The results have been checked with [90] in the appropriate limit.

possible exclusion bounds on the doubly charged scalar masses. We find that stringent limits such as $M_{1,2}^{++} \gtrsim 1$ TeV apply for doubly charged scalars dominantly decaying to an l^+l^+ pair [93, 94]. The bounds are much weaker when the W^+W^+ mode dominates and this occurs for $v_\Delta > 10^{-4}$ GeV in the minimal Type-II model [95].

The NP sector in this study is further constrained by the Higgs signal strength data from the LHC. And the most stringent constraint for negligible $\phi_0 - \delta_0$ mixing comes from the measurement of the $h \rightarrow \gamma\gamma$ signal strength. The presence of additional charged scalars and leptons implies that additional one-loop contributions to the $h\gamma\gamma$ amplitude shall arise thereby modifying the corresponding decay width *w.r.t.* the SM. The amplitude stemming from the charged scalars $H^+, H_{1,2}^{++}$ and the VLLs $E_{1,2}^\pm$ is given by [96–98]

$$\mathcal{M}_{h \rightarrow \gamma\gamma}^{\text{NP}} = \sum_{S=H^+, H_1^{++}, H_2^{++}} q_S^2 \frac{\lambda_{hSS^*v}}{2M_S^2} A_0\left(\frac{M_h^2}{4M_S^2}\right) + \sum_{i=1,2} y_{hE_i E_i} A_{1/2}\left(\frac{M_h^2}{4M_i^2}\right) \quad (25a)$$

Where, in addition to $q_{H^+} = 1$, $q_{H_{1,2}^{++}} = 2$,

$$\lambda_{hH^+H^-} = \lambda_4 v, \quad (26a)$$

$$\lambda_{hH_1^{++}H_1^{--}} = v\{(\lambda_4 - \lambda_5)c_\theta^2 + \lambda_6 s_\theta^2 - 2\lambda_8 s_\theta c_\theta\}, \quad (26b)$$

$$\lambda_{hH_1^{++}H_2^{--}} = v\{(\lambda_4 - \lambda_5)s_\theta^2 + \lambda_6 c_\theta^2 + 2\lambda_8 s_\theta c_\theta\}, \quad (26c)$$

$$y_{hE_1 E_1} = \frac{1}{2v} \left[M_1 \left(-1 + \cos(2\alpha_L)\cos(2\alpha_R) \right) + M_2 \left(\sin(2\alpha_L)\sin(2\alpha_R) \right) \right], \quad (26d)$$

$$y_{hE_2 E_2} = \frac{1}{2v} \left[M_2 \left(-1 + \cos(2\alpha_L)\cos(2\alpha_R) \right) + M_1 \left(\sin(2\alpha_L)\sin(2\alpha_R) \right) \right]. \quad (26e)$$

The total amplitude and the decay width then become

$$\mathcal{M}_{h \rightarrow \gamma\gamma} = \mathcal{M}_{h \rightarrow \gamma\gamma}^{\text{SM}} + \mathcal{M}_{h \rightarrow \gamma\gamma}^{\text{NP}}, \quad (27)$$

$$\Gamma_{h \rightarrow \gamma\gamma} = \frac{G_F \alpha_{em}^2 M_h^3}{128 \sqrt{2} \pi^3} |\mathcal{M}_{h \rightarrow \gamma\gamma}|^2. \quad (28)$$

where G_F and α_{em} denote respectively the Fermi constant and the QED fine-structure constant. The various loop functions are expressed below [97].

$$A_{1/2}(x) = \frac{2}{x^2} ((x + (x-1)f(x))), \quad (29a)$$

$$A_0(x) = -\frac{1}{x^2} (x - f(x)), \quad (29b)$$

$$\begin{aligned} \text{with } f(x) &= \arcsin^2(\sqrt{x}); \quad x \leq 1 \\ &= -\frac{1}{4} \left[\log \frac{1 + \sqrt{1-x^{-1}}}{1 - \sqrt{1-x^{-1}}} - i\pi \right]^2; \quad x > 1. \end{aligned} \quad (29c)$$

where $A_0(x)$ and $A_{1/2}(x)$ are the amplitudes for the spin-0 and spin- $\frac{1}{2}$ particles in the loop respectively. The signal strength for the $\gamma\gamma$ channel is defined as

$$\mu_{\gamma\gamma} = \frac{\sigma(pp \rightarrow h) \text{BR}(h \rightarrow \gamma\gamma)}{\left[\sigma(pp \rightarrow h) \text{BR}(h \rightarrow \gamma\gamma) \right]_{\text{SM}}} \quad (30)$$

LFV channel	Experimental bound
$\mu \rightarrow e\gamma$	$< 4.2 \times 10^{-13}$ [101]
$\tau \rightarrow e\gamma$	$< 1.5 \times 10^{-8}$ [102]
$\tau \rightarrow \mu\gamma$	$< 1.5 \times 10^{-8}$ [102]
$\mu \rightarrow \bar{e}ee$	$< 1 \times 10^{-12}$ [103]
$\tau \rightarrow \bar{e}ee$	$< 1.4 \times 10^{-8}$ [104]
$\tau \rightarrow \bar{\mu}ee$	$< 8.4 \times 10^{-9}$ [104]
$\tau \rightarrow \bar{\mu}e\mu$	$< 1.6 \times 10^{-8}$ [104]
$\tau \rightarrow \bar{e}\mu\mu$	$< 9.8 \times 10^{-9}$ [104]
$\tau \rightarrow \bar{e}\mu e$	$< 1.1 \times 10^{-8}$ [104]
$\tau \rightarrow \bar{\mu}\mu\mu$	$< 1.2 \times 10^{-8}$ [104]

TABLE II: Latest upper limits on LFV branching ratios.

Given the new scalars and VLLs do not modify the $pp \rightarrow h$ production rate,

$$\mu_{\gamma\gamma} = \frac{\text{BR}(h \rightarrow \gamma\gamma)}{\left[\text{BR}(h \rightarrow \gamma\gamma)\right]_{\text{SM}}}, \quad (31)$$

$$\simeq \frac{\Gamma_{h \rightarrow \gamma\gamma}^{\text{SM}}}{\Gamma_{h \rightarrow \gamma\gamma}}. \quad (32)$$

The latest 13 TeV results on the diphoton signal strength from the LHC read $\mu_{\gamma\gamma} = 0.99^{+0.14}_{-0.14}$ (ATLAS [99]) and $\mu_{\gamma\gamma} = 1.18^{+0.17}_{-0.14}$ (CMS [100]). Upon using the standard combination of signal strengths and uncertainties, we obtain $\mu_{\gamma\gamma} = 1.06 \pm 0.1$ and impose this constraint at 2σ .

D. Charged lepton flavour violation

The presence of both singly and doubly charged scalars in this framework implies that charged lepton flavour violating (CLFV) processes of the form $l_\alpha \rightarrow l_\beta \bar{l}_\gamma l_\delta$ and $l_\alpha \rightarrow l_\beta \gamma$ are triggered at the tree- and one-loop level respectively. However, non observation of CLFV in various experiments has led to stringent upper bounds on the corresponding branching ratios. In this work, we abide by such bounds the latest of which are summarised in Table II below.

IV. THE W -MASS, MUON $g - 2$ AMPLITUDE AND CHARGED LEPTON FLAVOUR VIOLATION

The W -mass predicted by this model can be expressed in terms of the NP contributions to the oblique parameters ΔS , ΔT and ΔU as [?]]

$$M_W^2 = M_{W,\text{SM}}^2 \left[1 + \frac{\alpha_{em}}{c_W^2 - s_W^2} \left(-\frac{\Delta S}{2} + c_W^2 \Delta T + \frac{c_W^2 - s_W^2}{4s_W^2} \Delta U \right) \right] \quad (33)$$

where c_W and α_{em} respectively denote the cosine of the Weinberg angle and the fine-structure constant. A given oblique parameter X in this framework receives NP contributions from scalars Δ and k^{++} sector as well as the VLLs. That is, $\Delta X = \Delta X_{\Delta, k^{++}} + \Delta X_{VLL}$. One expresses below ΔS_{VLL} and ΔT_{VLL} following [105–108]:

$$\Delta S_{VLL} = \frac{1}{2\pi} \left[\sum_i \left((|A_{Ni}^L|^2 + |A_{Ni}^R|^2) \Psi_+(x_N, x_i) + 2A_{Ni}^L A_{Nj}^R \Psi_-(x_N, x_i) \right) + \sum_{ij} \left(-\frac{1}{2} (|X_{ij}^L|^2 + |X_{ij}^R|^2) \chi_+(x_i, x_j) + X_{ij}^L X_{ij}^R \chi_-(x_i, x_j) \right) \right], \quad (34a)$$

$$\Delta T_{VLL} = \frac{1}{16\pi s_W^2 c_W^2} \left[\sum_i \left((|A_{Ni}^L|^2 + |A_{Ni}^R|^2) \theta_+(x_N, x_i) + 2A_{Ni}^L A_{Nj}^R \theta_-(x_N, x_i) \right) + \sum_{ij} \left(-\frac{1}{2} (|X_{ij}^L|^2 + |X_{ij}^R|^2) \theta_+(x_i, x_j) + X_{ij}^L X_{ij}^R \theta_-(x_i, x_j) \right) \right] \quad (34b)$$

where $x_N = \frac{M_N^2}{M_Z^2}$ and $x_{1,2} = \frac{M_{1,2}^2}{M_Z^2}$. The forms of the various functions are given in the Appendix. One further derives for the present scenario:

$$A_{N1}^{L(R)} = c_{L(R)}, \quad A_{N2}^{L(R)} = s_{L(R)}, \quad (35a)$$

$$X_{11}^{L(R)} = -c_{L(R)}^2, \quad X_{12}^{L(R)} = X_{21}^{L(R)} = -c_{L(R)} s_{L(R)}, \quad X_{22}^{L(R)} = -s_{L(R)}^2. \quad (35b)$$

Next, we come to discussing the oblique corrections coming from the scalar sector. We remind that a $(t_3, Y)^4$ scalar couples with Z and γ with the coefficients $e(t_3 c_W^2 - Y s_W^2)/(c_W s_W)$ and $e(t_3 + Y)$ respectively [109]. The two doubly charged scalars δ^{++} and k^{++} respectively carry $(t_3^{(1)} = 1, Y^{(1)} = 1)$ and $(t_3^{(2)} = 0, Y^{(2)} = 2)$. The interactions connecting $H_{1,2}^{++}$ to Z and γ can be parameterised as

$$\begin{aligned} \mathcal{L}_{\text{gauge}}^{\text{doubly charged}} = & ie \left((\partial_\mu H_i^{++}) H_j^{--} - (\partial_\mu H_i^{--}) H_j^{++} \right) (z_{ij} Z^\mu + a_{ij} A^\mu) \\ & + e^2 H_i^{++} H_j^{--} (m_{ij} Z_\mu Z^\mu + n_{ij} Z_\mu A^\mu + p_{ij} A_\mu A^\mu). \end{aligned} \quad (36)$$

We find $p_{ij} = 2a_{ij} = 4\delta_{ij}$. The other coefficients are expressed as 2×2 matrices below.

$$[z] = \begin{pmatrix} (-1 + 2c_{2W} + c_{2\theta})/(s_{2W}) & s_{2\theta}/s_{2W} \\ s_{2\theta}/s_{2W} & (1 + 2c_{2W} - c_{2\theta})/(s_{2W}) \end{pmatrix}, \quad (37)$$

$$[m] = \begin{pmatrix} (c_{2W}^2/s_W^4 c_\theta^2 + 4s_\theta^2) t_W^2 & c_\theta s_\theta (1/s_W^2 - 3/c_W^2) \\ c_\theta s_\theta (1/s_W^2 - 3/c_W^2) & (c_{2W}^2/s_W^4 s_\theta^2 + 4c_\theta^2) t_W^2 \end{pmatrix}, \quad (38)$$

$$[n] = \begin{pmatrix} 2(-1 + 2c_{2W} + c_{2\theta})/(s_W c_W) & 2s_{2\theta}/(s_W c_W) \\ 2s_{2\theta}/(s_W c_W) & -2(1 - 2c_{2W} + c_{2\theta})/(c_W s_W) \end{pmatrix}. \quad (39)$$

⁴ We use the $Q = t_3 + Y$ convention.

We express below the gauge-boson self-energies coming from scalar loops in terms of the Passarino-Veltman (P-V) functions [110].

$$\begin{aligned}\Pi_{ZZ}^{\Delta,k^{++}}(p^2) &= -4e^2 \sum_{i,j=1,2} z_{ij}^2 B_{00}(p^2, (M_i^{++})^2, (M_j^{++})^2) - 4e^2 \frac{s_W^2}{c_W^2} B_{00}(p^2, M_{H^+}^2, M_{H^+}^2) \\ &\quad - 4e^2 \frac{1}{s_W^2 c_W^2} B_{00}(p^2, M_H^2, M_H^2) + 2e^2 \sum_{i=1,2} m_{ii} A_0((M_i^{++})^2) \\ &\quad + 2e^2 \frac{s_W^2}{c_W^2} A_0(M_{H^+}^2) + 2e^2 \frac{1}{c_W^2 s_W^2} A_0(M_H^2),\end{aligned}\quad (40a)$$

$$\begin{aligned}\Pi_{\gamma\gamma}^{\Delta,k^{++}}(p^2) &= -4e^2 \sum_{i,j=1,2} a_{ij}^2 B_{00}(p^2, (M_i^{++})^2, (M_j^{++})^2) - 4e^2 B_{00}(p^2, M_{H^+}^2, M_{H^+}^2) \\ &\quad + 2e^2 \sum_{i=1,2} p_{ii} A_0((M_i^{++})^2) + 2e^2 A_0(M_{H^+}^2),\end{aligned}\quad (40b)$$

$$\begin{aligned}\Pi_{\gamma Z}^{\Delta,k^{++}}(p^2) &= -4e^2 \sum_{i,j=1,2} a_{ij} z_{ij} B_{00}(p^2, (M_i^{++})^2, (M_j^{++})^2) + 4e^2 \frac{s_W}{c_W} B_{00}(p^2, M_{H^+}^2, M_{H^+}^2) \\ &\quad + e^2 \sum_{i=1,2} n_{ii} A_0((M_i^{++})^2) - 2e^2 \frac{s_W}{c_W} A_0(M_{H^+}^2).\end{aligned}\quad (40c)$$

The P-V functions are evaluated using the publicly available library `LoopTools` [111]. The scalar sector contribution to the S -parameter reads

$$\frac{\alpha_{em}}{4c_W^2 s_W^2} \Delta S_{\Delta,k^{++}} = \frac{\Pi_{ZZ}^{\Delta,k^{++}}(M_Z^2) - \Pi_{ZZ}^{\Delta,k^{++}}(0)}{M_Z^2} - \left. \frac{\partial \Pi_{\gamma\gamma}^{\Delta,k^{++}}(p^2)}{\partial p^2} \right|_{p^2=0} + \frac{c_W^2 - s_W^2}{c_W s_W} \left. \frac{\partial \Pi_{\gamma Z}^{\Delta,k^{++}}(p^2)}{\partial p^2} \right|_{p^2=0} \quad (41)$$

Now $\Delta T_{\Delta,k^{++}}$ has a counterterm at quantum level induced by the counter term of v_Δ , say δv_Δ . And δv_Δ is not unique and depends on the choice of the renormalisation scheme instead. For example, δv_Δ can always be adjusted to cancel potentially large contributions from the scalar loops. Therefore, we set $\Delta T_{\Delta,k^{++}} = 0$ in this work.

For $\Delta U = 0$, global fit studies of the EW parameters [25, 34] in light of the CDF II anomaly reveal the following allowed ranges and correlation for ΔS and ΔT :

$$\Delta S = 0.15 \pm 0.08, \quad \Delta T = 0.27 \pm 0.06, \quad \rho_{ST} = 0.93. \quad (42)$$

Next, we discuss the muon anomalous magnetic moment for this setup. It is reminded that while δ^{++} and k^{++} respectively couple to only left chiral and right chiral leptons, the mass eigenstates H_1^{++} and H_2^{++} couple to both chiralities. That is, the interactions of muons with the VLLs and $H_{1,2}^{++}$ can be expressed as

$$\mathcal{L} = 2 \sum_{i=1,2} \sum_{j=1,2} \bar{\mu}^c (y_L^{ij} P_L + y_R^{ij} P_R) E_i H_j^{++} + \text{h.c.}, \quad (43)$$

where

$$\begin{aligned}y_L^{11} &= y_\Delta^{\mu 4} \cos \alpha_L \cos \theta, \quad y_R^{11} = -y_S^{\mu 4} \sin \alpha_R \sin \theta, \quad y_L^{12} = y_\Delta^{\mu 4} \cos \alpha_L \sin \theta, \quad y_R^{12} = y_S^{\mu 4} \sin \alpha_R \cos \theta, \\ y_L^{21} &= y_\Delta^{\mu 4} \sin \alpha_L \cos \theta, \quad y_R^{21} = y_S^{\mu 4} \cos \alpha_R \sin \theta, \quad y_L^{22} = y_\Delta^{\mu 4} \sin \alpha_L \sin \theta, \quad y_R^{22} = -y_S^{\mu 4} \cos \alpha_R \cos \theta.\end{aligned}\quad (44)$$

We assume $y_\Delta^{e4}, y_\Delta^{\tau4}, y_\Delta^{44}, y_S^{\alpha\beta}, y_S^{e4}, y_S^{\tau4}, y_S^{44}$ to be vanishingly small⁵. The one-loop muon $g-2$ Δa_μ has the following three distinct components in this limit:

$$\Delta a_\mu = (\Delta a_\mu^+)_l + (\Delta a_\mu^{++})_l + (\Delta a_\mu^{++})_{\text{VLL}}. \quad (45)$$

In Eq.(45), $(\Delta a_\mu^+)_l$ ($(\Delta a_\mu^{++})_l$) denotes the contribution from the one-loop amplitude involving SM leptons + singly (doubly) charged scalars. The expression for $(\Delta a_\mu^+)_l$ is given by [64]

$$\begin{aligned} (\Delta a_\mu^+)_l &= -\frac{m_\mu^2}{8\pi^2} \frac{v^2}{v^2 + 2v_\Delta^2} \sum_{\alpha=e,\mu,\tau} (y_\Delta^\dagger U_{\text{PMNS}}^*)_{\mu\alpha} (U_{\text{PMNS}}^T y_\Delta)_{\alpha\mu} \\ &\quad \int_0^1 dx \frac{x^2(1-x)}{m_\mu^2 x^2 + (M_{H^+}^2 - m_\mu^2 - m_\alpha^2)x + m_\alpha^2}, \end{aligned} \quad (46a)$$

$$\simeq -\frac{(m_\nu^2)_{\mu\mu}}{96\pi^2} \frac{m_\mu^2}{v_\Delta^2 M_{H^+}^2}. \quad (46b)$$

The contribution from H^+ is thus negative and identical to the minimal Type-II seesaw. Also,

$$\begin{aligned} (\Delta a_\mu^{++})_l &= -\frac{m_\mu^2}{8\pi^2} \sum_i \sum_\alpha b_i (y_\Delta^\dagger)_{\mu\alpha} (y_\Delta)_{\alpha\mu} \\ &\quad \int_0^1 dx \left[\frac{4x^2(1-x)}{m_\mu^2 x^2 + ((M_i^{++})^2 - m_\mu^2 - m_\alpha^2)x + m_\alpha^2} \right. \\ &\quad \left. + \frac{2x^2(1-x)}{m_\mu^2 x^2 + (m_\alpha^2 - m_\mu^2 - (M_i^{++})^2)x + (M_i^{++})^2} \right], \end{aligned} \quad (47a)$$

where $b_1 = c_\theta^2$, $b_2 = s_\theta^2$

$$\simeq -\frac{(m_\nu^2)_{\mu\mu}}{12\pi^2} \frac{m_\mu^2}{v_\Delta^2} \left(\frac{c_\theta^2}{(M_1^{++})^2} + \frac{s_\theta^2}{(M_2^{++})^2} \right). \quad (47b)$$

The contribution involving the SM leptons and the doubly charged scalars is also found negative. The completely left-chiral couplings between the charged scalars and the SM leptons entails no chirality-flip must occur thereby predicting a negative contribution to the $g-2$ amplitude.

The contribution from the VLLs is⁶

$$\begin{aligned} (\Delta a_\mu^{++})_{\text{VLL}} &= \sum_{i=1,2} \sum_{j=1,2} \left[-\frac{m_\mu^2}{4\pi^2} \left(\{(y_L^{ij})^2 + (y_R^{ij})^2\} I_1(M_i, M_j^{++}) + \frac{2M_i}{m_\mu} y_L^{ij} y_R^{ij} I_2(M_i, M_j^{++}) \right) \right. \\ &\quad \left. - \frac{m_\mu^2}{2\pi^2} \left(\{(y_L^{ij})^2 + (y_R^{ij})^2\} I_3(M_i, M_j^{++}) + \frac{2M_i}{m_\mu} y_L^{ij} y_R^{ij} I_4(M_i, M_j^{++}) \right) \right]. \end{aligned} \quad (48)$$

⁵ Demanding Δ, k^{++} and the VLLs to be odd under some \mathbb{Z}_2 symmetry while keeping the SM fields even under the same necessitates $y_\Delta^{44}, y_S^{\alpha\beta}, y_S^{44} = 0$. We refer to the last paragraph of section II for a discussion.

⁶ An excellent review containing analytical formulae for Δa_μ for generic classes of models is [112]

The integrals $I_a(m_1, m_2)$, $a = 1, 2, 3, 4$ for $m_\mu \ll M_{1,2}$, $M_{1,2}^{++}$ are

$$I_1(m_1, m_2) = \int_0^1 dx \frac{x^2(1-x)}{m_1^2 x + m_2^2(1-x)}, \quad (49a)$$

$$I_2(m_1, m_2) = \int_0^1 dx \frac{x^2}{m_1^2 x + m_2^2(1-x)}, \quad (49b)$$

$$I_3(m_1, m_2) = \int_0^1 dx \frac{x^2(1-x)}{m_1^2(1-x) + m_2^2 x}, \quad (49c)$$

$$I_4(m_1, m_2) = \int_0^1 dx \frac{x(1-x)}{m_1^2(1-x) + m_2^2 x}. \quad (49d)$$

Given the integrals $I_a(m_1, m_2)$, $a = 1, 2, 3, 4$ are all positive, the contribution to $(\Delta a_\mu^{++})_{\text{VLL}}$ from the first and third terms in Eq.(48) are negative. On the other hand, a chirality flip is identified in the second and fourth terms. In fact, the chirality-flipping component of $(\Delta a_\mu^{++})_{\text{VLL}}$ can be extracted upon defining $\Delta M \equiv M_2 - M_1 \ll M_1$ and $\Delta M^{++} \equiv M_2^{++} - M_1^{++} \ll M_1^{++}$. We additionally take $\alpha_L = \alpha_R$ for simplicity. The chirality-flipping component in its lowest order of ΔM and ΔM^{++} then becomes

$$(\Delta a_\mu^{++})_{\text{VLL}}^{\text{cf}} \simeq \frac{m_\mu}{4\pi^2} y_\Delta^{\mu 4} y_S^{\mu 4} \sin(2\alpha_R) \sin(2\theta) \frac{\Delta M \Delta M^{++}}{(M_1^{++})^3} f\left(\frac{M_1^2}{(M_1^{++})^2}\right), \quad (50a)$$

$$f(r) = \frac{(-35r^3 + 15r^2 + 27r - 7) + (12r^3 + 40r^2 - 2r - 1)\log(r)}{2(r-1)^5}. \quad (50b)$$

Two important observations that emerge are that (i) the chirality flipping component is enhanced *w.r.t.* the chirality preserving part of $(\Delta a_\mu^{++})_{\text{VLL}}$ and the Type-II like terms by an $\mathcal{O}\left(\frac{M_i}{m_\mu}\right)$ factor, and (ii) the chirality flip can be of either sign. It is therefore possible to generate a positive contribution to Δa_μ of the observed magnitude by choosing the relevant parameters appropriately. We also inspect that the magnitude of $(\Delta a_\mu^{++})_{\text{VLL}}^{\text{cf}}$ is maximised for $\theta = \frac{\pi}{4}$ and $\alpha_L = \frac{\pi}{4}$ when $\alpha_L = \alpha_R$. We shall adhere to these values in this section while quantifying M_W and Δa_μ . While showing the variation of Δa_μ and M_W *w.r.t.* M_2 in Fig.1, we additionally fix $M_1^{++} = 500$ GeV, $\Delta M^{++} = 50$ GeV, $(y_\Delta^{\mu 4}, y_S^{\mu 4}) = (0.5, 0.5)$ and $v_\Delta = 10^{-3}$ GeV. We mention here that the choice of v_Δ and the particle masses is consistent with the LHC excusion bounds and signal strength constraints. The following are the takeaways from FIG.1. Increasing M_2 while holding M_1 and the other parameters fixed accordingly increases Δa_μ and potentially puts it in the sought range. For $M_1 = 800$ GeV, it is seen that Δa_μ is in the 2σ range for $850 \text{ GeV} \lesssim M_2 \lesssim 940 \text{ GeV}$. On the other hand, the larger the mass splitting between the VLLs E_1 and E_2 , the larger the corresponding T -parameter ΔT_{VLL} and hence, the larger is the predicted value of M_W . This explains the monotonically increasing curve on the right panel. In fact, M_W lies in the 2σ corresponding to the CDF II observation for $920 \text{ GeV} \lesssim M_2 \lesssim 955 \text{ GeV}$. For the said choice of the other parameters, one thus identifies $920 \text{ GeV} \lesssim M_2 \lesssim 940 \text{ GeV}$ as the band that simultaneously resolves both the muon $g-2$ and CDF II anomalies in this model. It is important to remind here that while M_W is not sensitive to $y_\Delta^{\mu 4}$ and $y_S^{\mu 4}$, $(\Delta a_\mu^{++})_{\text{VLL}}^{\text{cf}}$ simply scales with the product of two Yukawas. We chose here

FIG. 1: The variation of Δa_μ and M_W with M_2 for $M_1^{++} = 500$ GeV and $\Delta M^{++} = 50$ GeV. The values for the other parameters are given in the panels.

$(y_\Delta^4, y_S^4) = (0.5, 0.5)$ as a reference and the behaviour for other values can be predicted easily. We show in FIG. 2 the parameter regions in the $M_1 - M_2$ plane compatible with the two anomalies for specific choices for the other relevant parameters (as given in the plots). One reads from eqn.(50a) that y_Δ^4 and y_S^4 , $(\Delta a_\mu^{++})_{\text{VLL}}^{\text{cf}} \propto \Delta M \Delta M^{++}$. Increasing ΔM from 50 GeV to 100 GeV keeping the $y_\Delta^4, y_S^4, M_1^{++}$ fixed would accordingly demand a larger ΔM so as to maintain $(\Delta a_\mu^{++})_{\text{VLL}}^{\text{cf}}$ at the same value. This is why the band compatible with the observed Δa_μ in the $M_1 - M_2$ plane gets thinner while moving from the top left to the top right panel of FIG. 2. On the other hand, while M_1^{++} is increased from 500 GeV to 800 GeV with ΔM^{++} fixed at 100 GeV, the chirality-flip contribution tends to decrease thereby entailing an increase in ΔM so as to predict the same Δa_μ as before.

The assumption that $y_\Delta^4, y_\Delta^{\tau 4}, y_S^{\beta 4}$ are suppressed⁷ forbids a similar $\mathcal{O}(M_i/m_\mu)$ chirality-flipped enhancement in $l_\alpha \rightarrow l_\beta \gamma$. Analogously to $(\Delta a_\mu^+)_l$ and $(\Delta a_\mu^{++})_l$, a non-zero $l_\alpha \rightarrow l_\beta \gamma$ amplitude is therefore induced only by the triplet Δ . And since Δ only couples to the left-chiral leptons, the corresponding amplitude is qualitatively similar to as in the minimal Type-II model. The only difference comes from the fact that here we have two doubly charged scalars as opposed to the one in Type-II. One then finds the corresponding branching ratio in the present model to be

$$\text{BR}(l_\alpha \rightarrow l_\beta \gamma) = \frac{\alpha_{em} |m_\nu^2|_{\alpha\beta}^2}{12\pi G_F^2 v_\Delta^4} \left(\frac{1}{8M_{H^+}^2} + \frac{c_\theta^2}{(M_1^{++})^2} + \frac{s_\theta^2}{(M_2^{++})^2} \right)^2 \text{BR}(l_\alpha \rightarrow l_\beta \nu_\alpha \bar{\nu}_\beta). \quad (51)$$

⁷ Even if no such approximation is a priori made, an estimation of the LFV chirality-flipping amplitude using [112] leads to $|y_\Delta^4|, |y_S^4| \sim \mathcal{O}(10^{-4})$ for $\alpha = e, \tau$ here.

FIG. 2: Parameter regions in the $M_1 - M_2$ compliant with all the constraints as well as the 2σ ranges of muon $g - 2$ (magenta) and M_W (blue). The values taken by the other parameters are shown in the plots.

Also, the branching ratios of the 3-body CLFV decays are given by ⁸

$$\text{BR}(\mu \rightarrow \bar{e}ee) = \frac{|m_\nu^{e\mu}|^2 |m_\nu^{ee}|^2}{16G_F^2 v_\Delta^4} \left(\frac{c_\theta^2}{(M_1^{++})^2} + \frac{s_\theta^2}{(M_2^{++})^2} \right)^2 \text{BR}(\mu \rightarrow e\bar{\nu}_e\nu_\mu), \quad (52a)$$

$$\text{BR}(\tau \rightarrow \bar{l}_\alpha l_\beta l_\gamma) = S \frac{|m_\nu^{\tau\alpha}|^2 |m_\nu^{\beta\gamma}|^2}{16G_F^2 v_\Delta^4} \left(\frac{c_\theta^2}{(M_1^{++})^2} + \frac{s_\theta^2}{(M_2^{++})^2} \right)^2 \text{BR}(\tau \rightarrow \mu\bar{\nu}_\mu\nu_\tau). \quad (52b)$$

In the above, $S = 1(2)$ for $\beta = \gamma$ ($\beta \neq \gamma$), $\text{BR}(\mu \rightarrow e\bar{\nu}_e\nu_\mu) = 100\%$ and $\text{BR}(\tau \rightarrow \mu\bar{\nu}_\mu\nu_\tau) = 17\%$. We reckon that the branching ratios for all $\alpha, \beta = e, \mu, \tau$ is controlled by v_Δ for fixed scalar masses.

⁸ The corresponding formula for the Higgs triplet model is seen in [113, 114]

It is easy to check that the choice $v_\Delta = 10^{-3}$ GeV predicts branching ratios that are well below the CLFV bounds.

V. ELECTROWEAK VACUUM STABILITY

We search here for a stable EW vacuum till the Planck scale that is compliant with observed Δa_μ and M_W . The scalar potential along the direction of the scalar doublet is approximated as $V(\phi) = \frac{1}{4}\lambda(\phi)\phi^4$ for $\phi \gg v$. All running couplings are to be evaluated at a scale $\mu = \phi$. The condition $\lambda(\mu) > 0$ ensures a stable EW vacuum. We choose $M_t = 172.76$ GeV as the input scale from which the couplings start evolving and demand vacuum stability up to the Planck scale. A complete set of the one-loop beta functions is given in the Appendix. One notes that $y_\Delta^{e4} = y_\Delta^{\tau4} = y_\Delta^{44} = y_S^{\alpha\beta} = y_S^{e4} = y_S^{\tau4} = y_S^{44} = 0$ is a fixed point of this model. It is therefore justified to neglect the effect of these parameters in the RGE since assigning tiny values to these at the EW scale ensures that they remain tiny at all scales. We now come to choosing the input scale values for the relevant couplings. First, for a given set of masses and mixing angles, the EW scale values for $\lambda, \lambda_4, \lambda_5, \lambda_6, \lambda_8$ and y_4, y'_4 get fixed from Eqs.(18a)-(18e) and Eqs.(19a)-(19b) respectively. For the rest, we take $\lambda_1 = \lambda_2 = \lambda_7 = 0.01, \lambda_3 = 0.3$. We further fix $y_\Delta^{\mu4} = y_S^{\mu4} = 0.5$ at the input scale, in compliance with the previous section. We interate here that we intend to be demonstrative of a stable vacuum in simultaneity with the observed Δa_μ and M_W , and therefore, refrain from performing an exhaustive scan of the model parameter space. For example, the EW scale value of 0.5 ensures that $y_\Delta^{\mu4} = y_S^{\mu4}$ gently increase with μ and remain well below the perturbative limit at the Planck scale. And this behaviour is not sensitive to the choice of the input scale quartic couplings since $\beta_{y_\Delta^{\mu4}}$ and $\beta_{y_S^{\mu4}}$ at one-loop are independent of the same. We equate $M_\Delta = M_S = M_H^+$ to M_1^{++} , the latter being a common mass scale here. As for the SM t -Yukawa and gauge couplings, we use $M_W = 80.384$ and $\alpha_s(M_Z) = 0.1184$ in which case the t -Yukawa and the gauge couplings at $\mu = M_t$ become $y_t = 0.93690$, $g_1(\mu = M_t) = 0.3583$, $g_2 = 0.6478$, $g_3 = 1.1666$ [4]. The requirements of a perturbative theory and a stable EW vacuum till the Planck scale are henceforth dubbed as 'high-scale validity'. Similar to the previous section, we take $v_\Delta = 10^{-3}$ GeV and run the following scan

$$200 \text{ GeV} < M_1, M_2 < 2 \text{ TeV}, \quad (53a)$$

$$200 \text{ GeV} < M_1^{++}, M_2^{++} < 2 \text{ TeV}, \quad (53b)$$

$$0 < \theta < \frac{\pi}{2}, \quad 0 < \alpha_L = \alpha_R < \frac{\pi}{2}. \quad (53c)$$

The lower limit of $M_{1,2}^{++} > 200$ GeV is consistent with the LHC exclusion bounds for the v_Δ taken. We look for parameter points that now predict a stable vacuum till $M_{\text{Pl}} = 1.22 \times 10^{19}$ GeV, in addition to accounting for Δa_μ and M_W in their respective 2σ bands. We remind that criteria of BFB-ness and unitarity defined by Eqs.(21a)-(21c) and Eqs.(22a)-(22d) respectively are also to be met at each intermediate scale in course of the RG evolution. In Fig.3, we present the parameter

FIG. 3: Parameter points allowed by the various criteria in the $M_1 - M_2$ (top left), $M_1^{++} - M_2^{++}$ (top right) and $\theta - \alpha_L$ (bottom) planes. The colour-coding is explained in the legends.

regions by the aforementioned criteria. We discover that a subset of parameter points predicting the sought values of Δa_μ and M_W is also consistent of a stable vacuum till the Planck scale. We discuss the salient features thereby identified in the following.

- Seeking an explanation of the muon $g - 2$ anomaly does not majorly constrain the $M_1 - M_2$ plane. Only a narrow strip around the $M_1 = M_2$ line is excluded on grounds of requiring $\Delta M \neq 0$ which is necessary to obtain a Δa_μ in the required ballpark, as explained before. However, demanding an M_W in the sought range widens the disallowed band around the $M_1 = M_2$ line. This can be traced back to the oblique parameter values of the VLL sector.

The most stringent constraint is derived from demanding a perturbative theory and a stable vacuum up to M_{Pl} . This can be understood as follows. Since the Yukawa couplings y_4, y'_4 enter the β -functions of the theory, their EW scale values get tightly constrained. For instance, the magnitudes of these Yukawas get bounded from above from the $\lambda > 0$ condition since large Yukawas tend to destabilise the vacuum. Such bounds on y_4, y'_4 translate to the observed constraint in the $M_1 - M_2$ plane. In fact, the $0.35 \lesssim \alpha_L \lesssim 1.2$ bound also has the same origin.

- The muon and CDF anomalies do not put bounds on the scalar masses themselves and instead constrain the mass-splitting at most. However, high-scale validity restricts $M_1^{++}, M_2^{++} \lesssim 320$ GeV. These bounds can be traced back to the bounds on the boundary scale values of the quartic couplings λ_6 and λ_8 that get tightly restricted from high-scale validity. We note that there is no separate restriction on θ coming from high-scale validity.

VI. CONCLUSIONS

The recently reported discrepancy in the measured value of M_W has garnered significant attention in the particle physics community. In addition, the longstanding muon $g - 2$ anomaly that was first reported by BNL, has also aroused a fresh interest in NP constructs after being corroborated by FNAL. In this work, we have proposed an explanation to both these anomalies in a common framework by extending the minimal Type-II seesaw model by a doubly charged scalar singlet, an $SU(2)_L$ doublet of vector-like leptons and a charged $SU(2)_L$ singlet vector-like lepton. We have demonstrated that an appropriate mass splitting between the charged VLLs can predict the observed muon anomalous magnetic moment through a chirality-flip. Simultaneously, by virtue of the S - and T -parameters, the framework also leads to an M_W consistent with the recent observation. In addition, we have also shown that the parameter region accommodating the two anomalies is consistent with the correct pattern of neutrino masses and mixings, lepton flavour violation and a stable EW vacuum up to the Planck scale.

VII. APPENDIX

A. Oblique parameter functions

$$\psi_+(x, y) = \frac{1}{3} - \frac{1}{9} \log\left(\frac{x}{y}\right), \quad (54a)$$

$$\psi_-(x, y) = -\frac{x+y}{6\sqrt{xy}}, \quad (54b)$$

$$\chi_+(x, y) = \frac{5(x^2 + y^2) - 22xy}{9(x-y)^2} + \frac{3xy(x+y) - x^3 - y^3}{3(x-y)^3} \log\left(\frac{x}{y}\right), \quad (54c)$$

$$\chi_-(x, y) = -\sqrt{xy} \left[\frac{x+y}{6xy} - \frac{x+y}{(x-y)^2} + \frac{2xy}{(x-y)^2} \log\left(\frac{x}{y}\right) \right], \quad (54d)$$

$$\theta_+(x, y) = x + y - \frac{2xy}{x+y} \log\left(\frac{x}{y}\right) \quad (54e)$$

$$\theta_-(x, y) = 2\sqrt{xy} \left[\frac{x+y}{x-y} \log\left(\frac{x}{y}\right) - 2 \right]. \quad (54f)$$

B. One-loop beta functions

The one-loop beta function for a quartic coupling λ_i is split into scalar, gauge and fermionic terms as $\beta_{\lambda_i} = \beta_{\lambda_i}^S + \beta_{\lambda_i}^g + \beta_{\lambda_i}^F$. Thus,

$$16\pi^2 \beta_{\lambda}^S = 12\lambda^2 + 6\lambda_4^2 + 4\lambda_5^2 + 2\lambda_6^2 + 4\lambda_8^2, \quad (55a)$$

$$16\pi^2 \beta_{\lambda_1}^S = 14\lambda_1^2 + 4\lambda_1\lambda_2 + 2\lambda_2^2 + 4\lambda_4^2 + 4\lambda_5^2 + 2\lambda_7^2, \quad (55b)$$

$$16\pi^2 \beta_{\lambda_2}^S = 12\lambda_1\lambda_2 + 3\lambda_2^2 - 8\lambda_5^2, \quad (55c)$$

$$16\pi^2 \beta_{\lambda_3}^S = 10\lambda_3^2 + 4\lambda_6^2 + 6\lambda_7^2, \quad (55d)$$

$$16\pi^2 \beta_{\lambda_4}^S = 6\lambda\lambda_4 + 8\lambda_1\lambda_4 + 2\lambda_2\lambda_4 + 4\lambda_4^2 + 8\lambda_5^2 + 2\lambda_6\lambda_7 + 4\lambda_8^2, \quad (55e)$$

$$16\pi^2 \beta_{\lambda_5}^S = 2\lambda\lambda_5 + 2\lambda_1\lambda_5 - 2\lambda_2\lambda_5 + 8\lambda_4\lambda_5 - 4\lambda_8^2, \quad (55f)$$

$$16\pi^2 \beta_{\lambda_6}^S = 6\lambda\lambda_6 + 4\lambda_3\lambda_6 + 4\lambda_6^2 + 6\lambda_4\lambda_7 + 12\lambda_8^2, \quad (55g)$$

$$16\pi^2 \beta_{\lambda_7}^S = 4\lambda_4\lambda_6 + 8\lambda_1\lambda_7 + 2\lambda_2\lambda_7 + 4\lambda_3\lambda_7 + 4\lambda_7^2 + 4\lambda_8^2, \quad (55h)$$

$$16\pi^2 \beta_{\lambda_8}^S = 2\lambda\lambda_8 + 4\lambda_4\lambda_8 - 8\lambda_5\lambda_8 + 4\lambda_6\lambda_8 + 2\lambda_7\lambda_8. \quad (55i)$$

$$16\pi^2\beta_{\lambda}^g = -3\lambda(g_1^2 + 3g_2^2) + \frac{3}{4}g_1^4 + \frac{3}{4}g_1^2g_2^2 + \frac{9}{4}g_2^4, \quad (56a)$$

$$16\pi^2\beta_{\lambda_1}^g = -12\lambda_1(g_1^2 + 2g_2^2) + 12g_1^4 + 24g_1^2g_2^2 + 18g_2^4, \quad (56b)$$

$$16\pi^2\beta_{\lambda_2}^g = -12\lambda_2(g_1^2 + 2g_2^2) - 48g_1^2g_2^2 + 12g_2^4, \quad (56c)$$

$$16\pi^2\beta_{\lambda_3}^g = -48\lambda_3g_1^2 + 192g_1^4, \quad (56d)$$

$$16\pi^2\beta_{\lambda_4}^g = -\lambda_4\left(\frac{15}{2}g_1^2 + \frac{33}{2}g_2^2\right) + 3g_1^4 + 6g_2^4, \quad (56e)$$

$$16\pi^2\beta_{\lambda_5}^g = -\lambda_5\left(\frac{15}{2}g_1^2 + \frac{33}{2}g_2^2\right) - 6g_1^2g_2^2, \quad (56f)$$

$$16\pi^2\beta_{\lambda_6}^g = -\lambda_6\left(\frac{51}{2}g_1^2 + 9g_2^2\right) + 12g_1^4, \quad (56g)$$

$$16\pi^2\beta_{\lambda_7}^g = -\lambda_7(20g_1^2 + 8g_2^2) + 48g_1^4, \quad (56h)$$

$$16\pi^2\beta_{\lambda_7}^g = -\lambda_8(11g_1^2 + 7g_2^2) + 48g_1^4. \quad (56i)$$

$$16\pi^2\beta_{\lambda}^F = 4\lambda(3y_t^2 + 3y_b^2 + y_{\tau}^2 + y_4^2 + (y_4')^2) - 4(3y_t^4 + 3y_b^4 + y_{\tau}^4 + y_4^4 + (y_4')^4), \quad (57a)$$

$$16\pi^2\beta_{\lambda_1}^F = 16\lambda_1(y_{\Delta}^{\mu 4})^2 - 64(y_{\Delta}^{\mu 4})^4, \quad (57b)$$

$$16\pi^2\beta_{\lambda_2}^F = 16\lambda_2(y_{\Delta}^{\mu 4})^2 + 64(y_{\Delta}^{\mu 4})^4, \quad (57c)$$

$$16\pi^2\beta_{\lambda_3}^F = 16\lambda_3(y_S^{\mu 4})^2 - 64(y_S^{\mu 4})^4, \quad (57d)$$

$$16\pi^2\beta_{\lambda_4}^F = \lambda_4\left[\left(8y_{\Delta}^{\mu 4}\right)^2 + 6y_t^2 + 6y_b^2 + 2y_{\tau}^2 + 2y_4^2 + 2(y_4')^2\right], \quad (57e)$$

$$16\pi^2\beta_{\lambda_5}^F = \lambda_5\left[\left(8y_{\Delta}^{\mu 4}\right)^2 + 6y_t^2 + 6y_b^2 + 2y_{\tau}^2 + 2y_4^2 + 2(y_4')^2\right], \quad (57f)$$

$$16\pi^2\beta_{\lambda_6}^F = \lambda_6\left[\left(8y_{\Delta}^{\mu 4}\right)^2 + 6y_t^2 + 6y_b^2 + 2y_{\tau}^2 + 2y_4^2 + 2(y_4')^2\right], \quad (57g)$$

$$16\pi^2\beta_{\lambda_7}^F = \lambda_7\left[\left(8y_{\Delta}^{\mu 4}\right)^2 + \left(8y_S^{\mu 4}\right)^2 + 16y_4^2(y_{\Delta}^{\mu 4})^2\right], \quad (57h)$$

$$16\pi^2\beta_{\lambda_8}^F = \lambda_8\left[\left(4y_{\Delta}^{\mu 4}\right)^2 + \left(4y_S^{\mu 4}\right)^2 + 6y_t^2 + 6y_b^2 + 2y_{\tau}^2 + 2y_4^2 + (y_4')^2\right]. \quad (57i)$$

We next list the β -functions for the relevant Yukawa couplings below.

$$16\pi^2\beta_{y_t} = \frac{9}{2}y_t^3 + y_t(3y_b^2 + y_\tau^2 + y_4^2 + (y'_4)^2 - \frac{17}{12}g_1^2 - \frac{9}{4}g_2^2 - 8g_3^2), \quad (58a)$$

$$16\pi^2\beta_{y_b} = \frac{9}{2}y_b^3 + y_b(3y_t^2 + y_\tau^2 + y_4^2 + (y'_4)^2 - \frac{5}{12}g_1^2 - \frac{9}{4}g_2^2 - 8g_3^2), \quad (58b)$$

$$16\pi^2\beta_{y_\tau} = \frac{5}{2}y_\tau^3 + y_\tau(3y_t^2 + 3y_b^2 + y_4^2 + (y'_4)^2 - \frac{15}{4}g_1^2 - \frac{9}{4}g_2^2), \quad (58c)$$

$$16\pi^2\beta_{y_4} = \frac{5}{2}y_4^3 + y_4(3y_t^2 + 3y_b^2 + (y'_4)^2 - \frac{15}{4}g_1^2 - \frac{9}{4}g_2^2), \quad (58d)$$

$$16\pi^2\beta_{y'_4} = \frac{5}{2}(y'_4)^3 + y'_4(3y_t^2 + 3y_b^2 + y_4^2 - \frac{15}{4}g_1^2 - \frac{9}{4}g_2^2), \quad (58e)$$

$$16\pi^2\beta_{y_\Delta^{\mu 4}} = 8(y_\Delta^{\mu 4})^3 + y_\Delta^{\mu 4}(\frac{y_4^2}{2} - \frac{3}{2}g_1^2 - \frac{9}{2}g_2^2), \quad (58f)$$

$$16\pi^2\beta_{y_S^{\mu 4}} = 8(y_S^{\mu 4})^3 + y_S^{\mu 4}(y_4^2 - 6g_1^2). \quad (58g)$$

Finally, the β -functions for the gauge couplings read

$$16\pi^2\beta_{g_1} = \frac{67}{6}g_1^3, \quad (59a)$$

$$16\pi^2\beta_{g_2} = -\frac{13}{6}g_2^3, \quad (59b)$$

$$16\pi^2\beta_{g_3} = -7g_3^3. \quad (59c)$$
