# A CONVEXITY-PRESERVING AND PERIMETER-DECREASING <br> PARAMETRIC FINITE ELEMENT METHOD FOR THE AREA-PRESERVING CURVE SHORTENING FLOW 

WEI JIANG*, CHUNMEI SU ${ }^{\dagger}$, AND GANGHUI ZHANG ${ }^{\ddagger}$

#### Abstract

We propose and analyze a semi-discrete parametric finite element scheme for solving the area-preserving curve shortening flow. The scheme is based on Dziuk's approach (SIAM J. Numer. Anal. 36(6): 1808-1830, 1999) for the anisotropic curve shortening flow. We prove that the scheme preserves two fundamental geometric structures of the flow with an initially convex curve: (i) the convexity-preserving property, and (ii) the perimeter-decreasing property. To the best of our knowledge, the convexity-preserving property of numerical schemes which approximate the flow is rigorously proved for the first time. Furthermore, the error estimate of the semi-discrete scheme is established, and numerical results are provided to demonstrate the structure-preserving properties as well as the accuracy of the scheme.

Key words. area-preserving curve shortening flow, parametric finite element method, error estimate, convexity-preserving, perimeter-decreasing

1. Introduction. Consider the volume-preserving mean curvature flow driven by the motion law

$$
\begin{equation*}
v=(H-\langle H\rangle) \mathcal{N}, \quad \text { on } \quad \Gamma_{t}, \tag{1.1}
\end{equation*}
$$

where $\Gamma_{t}$ is a family of smooth hypersurfaces in $\mathbb{R}^{n}, v$ denotes the velocity, $\mathcal{N}$ is the inner normal vector, $H$ represents the scalar mean curvature (with the sign convention that $H$ is positive for balls), and $\langle H\rangle:=\int_{\Gamma_{t}} H d s^{n-1} / \int_{\Gamma_{t}} d s^{n-1}$ is the average mean curvature along $\Gamma_{t}$. It is well-known that the volume-preserving mean-curvature flow can be interpreted as the $L^{2}$-gradient flow of the area functional under configurations with a fixed volume [37]. The volume-preserving mean curvature flow has the following fundamental geometric properties, i.e.,
(i) Volume-preserving blue [2, Lemma 5.25]. It can be immediately verified that the volume enclosed by $\Gamma_{t}$ is indeed preserved by noticing

$$
\frac{\mathrm{d}}{\mathrm{~d} t}\left|\Omega_{t}\right|=-\int_{\Gamma_{t}} v \cdot \mathcal{N} d s^{n-1}=-\int_{\Gamma_{t}}(H-\langle H\rangle) d s^{n-1}=0
$$

where $\Omega_{t}$ is the region enclosed by $\Gamma_{t}$. In dimension two (i.e., $n=2$ ), it becomes the area-preserving property for a planar curve.
(ii) Area-shrinking blue [2, Lemma 5.25]. Actually, one can easily check that

$$
\frac{\mathrm{d}}{\mathrm{~d} t}\left|\Gamma_{t}\right|=-\int_{\Gamma_{t}} H v \cdot \mathcal{N} d s^{n-1}=-\int_{\Gamma_{t}}(H-\langle H\rangle)^{2} d s^{n-1} \leq 0
$$

When $n=2$, it becomes perimeter-decreasing for a planar curve.

[^0](iii) Convexity-preserving. When $n=2$, it was shown by Gage that starting from an initially, smooth and convex closed curve, this flow (1.1) preserves the convexity and evolves the curve into a circle [23]. Furthermore, Huisken extended the result to higher dimensional cases [25]. For more general initial data, interested readers may refer to [1,22].
In this paper, we focus on the planar curve $(n=2)$. In this case, the volumepreserving mean curvature flow is also known as the area-preserving curve shortening flow (AP-CSF), and it can be parametrized by the following equation 23 ]
\[

$$
\begin{cases}\partial_{t} X=\left(H-\frac{2 \pi}{L}\right) \mathcal{N}, & \xi \in \mathbb{S}^{1},  \tag{1.2}\\ X(\xi, 0)=X^{0}(\xi), & \xi \in \mathbb{S}^{1}\end{cases}
$$
\]

where $X(\xi, t): \mathbb{S}^{1} \times[0, T] \rightarrow \Gamma_{t} \subseteq \mathbb{R}^{2}, L:=L(t)$ is the length of $\Gamma_{t}$, by recalling the theorem of turning tangents [17], i.e., $\int_{\Gamma_{t}} H d s^{1}=2 \pi$, for a simple closed curve $\Gamma_{t}$.

Nowadays, the AP-CSF has found important applications in many research areas, such as material science and image processing [27], and it can be viewed as an areapreserving variant of the CSF [35,42] or a limit flow of nonlocal Ginzburg-Landau equation [13]. There have been extensive numerical investigations concerning with the CSF or AP-CSF in the last decades. Among them, parametric finite element methods (PFEMs) have been widely proposed for simulating the CSF and some other related geometric flows [3], e.g., the surface diffusion flow 4], and anisotropic geometric flows 6, 10. Numerical approximations to the CSF by using PFEMs could date back to the pioneering work of Dziuk [18] in 1991. Since then, various techniques have been introduced to make the designed PFEMs more accurate and efficient in practical simulations, including the method of Barrett, Garcke and Nürnberg (the BGN scheme) [6, 7] based on a novel variational formulation, the method of Deckelnick and Dziuk by introducing an artificial tangential velocity [15], and the method proposed by Elliott and Fritz based on special reparametrizations [21. These methods induce appropriate tangential motions that lead to good mesh distribution property, which play a vital role in numerical simulations. Recently, more and more attention has been paid to designing "structure-preserving" (e.g., area-preserving or perimeterdecreasing) PFEMs for solving geometric evolution flows [3, 4, 28.

However, error estimates for these schemes seem difficult and quite challenging. For example, Dziuk first studied the convergence of a semi-discrete linearly implicit PFEM for the CSF [19] and anisotropic CSF [20, respectively, based on a finite difference structure; Li developed a new technique to analyze the convergence of semi-discrete high-order PFEMs for the CSF 33 and mean curvature flow of closed surfaces [34, respectively. For Dziuk's fully discrete linearly implicit scheme [19], until very recently, an optimal error estimate in $H^{1}$ has been established by Ye and Cui 44. As for the error analysis about other numerical methods of the CSF or other related geometric flows, we refer to [5, 15, 21, 26, 30, 31, 39 .

Back to the AP-CSF, there exist various numerical methods in the literature, e.g., the finite difference method [35], the MBO method [29, 40, the crystalline algorithm 43] and PFEMs [11,38. Particularly, structure-preserving properties were investigated in [11, 38, 41, 43. For example, the semi-discrete PFEM in 11 based on an elegant variational formulation was shown to preserve the length shortening property, and the fully discrete crystalline algorithm in [43, the semi-discrete polygonal evolution law in 41 based on the definition of tangent and normal vectors/velocities at each vertex, the fully discrete PFEM in 38 was shown to be area-preserving and perimeter-decreasing. However, error estimates have been barely studied for the above
mentioned methods, except for the crystalline algorithm in 43 where the error estimate was only established for the curvature since the numerical scheme was designed based on the crystalline approximation which merely involves the curvature. To the best of our knowledge, there exists few numerical analysis about numerical methods for solving the AP-CSF, and the convexity-preserving property has never been investigated in the literature. The reason lies in that the nonlocal term in the AP-CSF has brought troubles and considerable challenges in numerical analysis.

In this paper, we propose a semi-discrete PFEM for the AP-CSF based on Dziuk's approach for anisotropic CSF [20], investigate its structure-preserving properties and present its error analysis. Specifically, we prove that our scheme preserves two important geometric structures of the AP-CSF, i.e., convexity-preserving and perimeterdecreasing properties. As far as we know, this is the first job to rigorously prove the convexity-preserving property and to give the error estimate of numerical methods for solving the AP-CSF.

To start, (1.2) can be written more explicitly as

$$
\begin{equation*}
\partial_{t} X=\frac{1}{\left|\partial_{\xi} X\right|} \partial_{\xi}\left(\frac{\partial_{\xi} X}{\left|\partial_{\xi} X\right|}\right)-\frac{2 \pi}{L}\left(\frac{\partial_{\xi} X}{\left|\partial_{\xi} X\right|}\right)^{\perp} \tag{1.3}
\end{equation*}
$$

where $(a, b)^{\perp}:=(-b, a)$. This naturally yields a weak formulation: for any $v \in$ $\left(H^{1}\left(\mathbb{S}^{1}\right)\right)^{2}$, it holds

$$
\begin{equation*}
\int_{\mathbb{S}^{1}}\left|\partial_{\xi} X\right| \partial_{t} X \cdot v \mathrm{~d} \xi+\int_{\mathbb{S}^{1}} \frac{\partial_{\xi} X}{\partial_{\xi} X \mid} \cdot \partial_{\xi} v \mathrm{~d} \xi+\int_{\mathbb{S}^{1}} \frac{2 \pi}{L}\left(\partial_{\xi} X\right)^{\perp} \cdot v \mathrm{~d} \xi=0 \tag{1.4}
\end{equation*}
$$

As mentioned in [19], the derived linearly implicit PFEM from the above formulation for the CSF (with the last term missing) may fail to preserve the length shortening property of the CSF. To overcome this, Dziuk proposed another scheme based on the lumping of masses in [19] for the CSF. Here we utilize the similar approach: find a solution $X_{h}(\xi, t) \in V_{h} \times[0, T]$ satisfying the weak form (2.4) with initial condition $X_{h}(\xi, 0)=I_{h} X^{0}$, where $V_{h}$ is a vector valued Lagrange finite element space consisting of piecewise linear polynomial and $I_{h}$ is the standard Lagrange interpolation. Similar as in [14], the semi-discrete scheme focuses on the motion of the initial polygon, which is determined by the evolution of the vertices. We show that if the initial curve is convex, then the evolved polygon keeps convex all the time. Moreover, the perimeter of the polygon is decreasing. To show the convexity-preserving property, we characterize the convexity of a polygon by the positivity of the oriented area of all adjacent triangles, which will be shown by a contradiction argument. Surprisingly, the perimeter-decreasing property can be reduced to a pure trigonometric inequality when the polygon keeps convex. We note that nondegeneration of vertices is necessary to ensure the evolved polygons are well-behaved. This will be guaranteed by the error estimate of the scheme, which shows that the semi-discrete scheme (2.4) converges in $H^{1}$ at the first order, and the lower bound of the edge lengths of the polygon could keep positive all the time.

The rest of the paper is organized as follows. In Section 2, we start with the spatial discretization which approximates the AP-CSF and summarize our main results. In Section 3, we prove that the numerical scheme rigorously preserves two important geometric structures of the flow, i.e., the convexity-preserving and perimeter-decreasing properties. Then, we present the proof of the error estimate of the scheme in Section 4. Finally, some numerical results produced by the scheme are provided in Section 5 to validate our theoretical results.
2. Spatial discretization and main results. Let $0=\xi_{0}<\xi_{1}<\ldots<\xi_{N}=$ $2 \pi$ be a partition of $\mathbb{S}^{1}=[0,2 \pi]$. We denote $h_{j}=\xi_{j}-\xi_{j-1}$ by the length of the interval $I_{j}:=\left[\xi_{j-1}, \xi_{j}\right]$ and $h=\max _{j} h_{j}$. Throughout the paper, we use a periodic index, i.e., $f_{j}=f_{j \pm N}$ when involved. We assume that the partition and the exact solution are regular in the following senses, respectively:
(Assumption 2.1) There exist constants $C_{p}$ and $C_{P}$ such that

$$
\min _{j} h_{j} \geq C_{p} h, \quad\left|h_{j+1}-h_{j}\right| \leq C_{P} h^{2}, \quad 1 \leq j \leq N
$$

(Assumption 2.2) Suppose that the unique solution of (1.2) with an initial value $X^{0} \in H^{2}\left(\mathbb{S}^{1}\right)$ satisfies $X \in W^{1, \infty}\left([0, T], H^{2}\left(\mathbb{S}^{1}\right)\right)$, i.e.,

$$
K(X):=\|X\|_{W^{1, \infty}\left([0, T], H^{2}\left(\mathbb{S}^{1}\right)\right)}<\infty .
$$

We further assume that there exist constants $0<\kappa_{1}<\kappa_{2}$ such that

$$
\kappa_{1} \leq\left|\partial_{\xi} X(\xi, t)\right| \leq \kappa_{2}, \quad \forall(\xi, t) \in \mathbb{S}^{1} \times[0, T]
$$

We define the following finite element space consisting of piecewise linear functions satisfying periodic boundary conditions:

$$
V_{h}=\left\{v \in C^{0}\left(\mathbb{S}^{1}, \mathbb{R}^{2}\right):\left.v\right|_{I_{j}} \in P_{1}\left(I_{j}\right), \quad 1 \leq j \leq N, \quad v\left(\xi_{0}\right)=v\left(\xi_{N}\right)\right\},
$$

where $P_{1}$ denotes all polynomials with degrees at most 1 . For any continuous function $v \in C^{0}\left(\mathbb{S}^{1}, \mathbb{R}^{2}\right)$, the linear interpolation $I_{h} v \in V_{h}$ is uniquely determined through $I_{h} v\left(\xi_{j}\right)=v\left(\xi_{j}\right)$ for all $1 \leq j \leq N$ and can be explicitly written as $I_{h} v(\xi)=$ $\sum_{j=1}^{N} v\left(\xi_{j}\right) \varphi_{j}(\xi)$, where $\varphi_{j}$ represents the standard Lagrange basis function satisfying $\varphi_{j}\left(\xi_{i}\right)=\delta_{i j}$. We have the following basic estimates from finite element theory.

Lemma 2.1 ( [12]). Under Assumption 2.1, there exists a constant $C$ depending on $C_{p}, C_{P}$ such that the following estimates hold:
(i) (Interpolation estimate). For any $Y \in H^{2}\left(\mathbb{S}^{1}\right)$, we have

$$
\begin{align*}
& \left\|Y-I_{h} Y\right\|_{L^{2}} \leq C h^{k}\|Y\|_{H^{k}}, \quad k=1,2 ; \quad\left\|Y-I_{h} Y\right\|_{L^{\infty}} \leq C h^{1 / 2}\|Y\|_{H^{1}},  \tag{2.1}\\
& \left\|\partial_{\xi}\left(Y-I_{h} Y\right)\right\|_{L^{2}} \leq C h\|Y\|_{H^{2}}, \quad\left\|\partial_{\xi} I_{h} Y\right\|_{L^{2}} \leq C\|Y\|_{H^{1}}
\end{align*}
$$

(ii) (Inverse estimate). For $v_{h} \in V_{h}$, we have

$$
\begin{equation*}
\left\|v_{h}\right\|_{L^{\infty}} \leq C h^{-1 / 2}\left\|v_{h}\right\|_{L^{2}}, \quad\left\|v_{h}\right\|_{H^{1}} \leq C h^{-1}\left\|v_{h}\right\|_{L^{2}} . \tag{2.2}
\end{equation*}
$$

Definition 2.2. We call a function

$$
\begin{equation*}
X_{h}(\xi, t)=\sum_{j=1}^{N} X_{j}(t) \varphi_{j}(\xi): \mathbb{S}^{1} \times[0, T] \rightarrow \mathbb{R}^{2} \tag{2.3}
\end{equation*}
$$

is a semidiscrete solution of (1.3) if it satisfies the following weak formulation

$$
\begin{align*}
& \int_{\mathbb{S}^{1}}\left|\partial_{\xi} X_{h}\right| \partial_{t} X_{h} \cdot v_{h} \mathrm{~d} \xi+\int_{\mathbb{S}^{1}} \frac{\partial_{\xi} X_{h}}{\partial_{\xi} X_{h} \mid} \cdot \partial_{\xi} v_{h} \mathrm{~d} \xi  \tag{2.4}\\
& +\int_{\mathbb{S}^{1}} \frac{\mathbf{h}^{2}\left|\partial_{\xi} X_{h}\right|}{6} \partial_{\xi} \partial_{t} X_{h} \cdot \partial_{\xi} v_{h} \mathrm{~d} \xi+\int_{\mathbb{S}^{1}} \frac{2 \pi}{L_{h}}\left(\partial_{\xi} X_{h}\right)^{\perp} \cdot v_{h} \mathrm{~d} \xi=0, \quad \forall v_{h} \in V_{h},
\end{align*}
$$

with initial condition $X_{h}(\xi, 0)=I_{h} X^{0}$, where $L_{h}$ represents the perimeter of the evolved curve (image of $X_{h}$ ), i.e.,

$$
L_{h}:=\sum_{j=1}^{N} h_{j}\left|\partial_{\xi} X_{h} \|_{I_{j}}=\sum_{j=1}^{N}\right| X_{j}-X_{j-1} \mid=: \sum_{j=1}^{N} q_{j},
$$

and $\mathbf{h}$ is a piecewise constant $\mathbf{h}=h_{j}$ on $I_{j}$.
REMARK 2.1. A similar version of (2.4) was proposed and analyzed in [19, (9) and (15)] and [20, Definition 4.1] for CSF and anisotropic CSF, respectively. The introduction of the third term $\int_{\mathbb{S}^{1}} \frac{\mathbf{h}^{2}\left|\partial_{\xi} X_{h}\right|}{6} \partial_{\xi} \partial_{t} X_{h} \cdot \partial_{\xi} v_{h} \mathrm{~d} \xi$ in (2.4) gives rise to the so-called mass-lumped scheme (similar to (3.1)) that preserves the length shortening property for the CSF, which was missing for the original formulation (e.g., (1.4) ). On the other hand, a more natural explanation was given in [39, (1.6) and (3.12)], where it was shown that (2.4) is equivalent to the following scheme
$\int_{\mathbb{S}^{1}}\left|\partial_{\xi} X_{h}\right| I_{h}\left(\partial_{t} X_{h} \cdot v_{h}\right) \mathrm{d} \xi+\int_{\mathbb{S}^{1}} \frac{\partial_{\xi} X_{h}}{\left|\partial_{\xi} X_{h}\right|} \cdot \partial_{\xi} v_{h} \mathrm{~d} \xi+\int_{\mathbb{S}^{1}} \frac{2 \pi}{L_{h}}\left(\partial_{\xi} X_{h}\right)^{\perp} \cdot v_{h} \mathrm{~d} \xi=0, \forall v_{h} \in V_{h}$,
which looks like the original version (1.4) with the Lagrangian interpolation introduced for the first term.

Next we present the main results of this paper.
THEOREM 2.3. (Convexity-preserving) Suppose the initial curve $X_{h}(\xi, 0)=$ $I_{h} X^{0}$ is a convex $N$-polygon, then it is always a convex $N$-polygon during the evolution by (2.4) if $q_{j}>0$ for all $j$.

THEOREM 2.4. (Perimeter-decreasing) Let $X_{h}$ be the solution of (2.4) with convex initial data, then the perimeter of the closed curve is decreasing, i.e.,

$$
\begin{equation*}
\frac{\mathrm{d}}{\mathrm{~d} t} L_{h} \leq 0 \tag{2.5}
\end{equation*}
$$

Remark 2.2. For the cases of classical CSF or anisotropic CSF and the corresponding solutions based on similar formulations as in (2.4), by direct computations based on a finite difference structure, it was shown in [19, 20] that the length of each element of $X_{h}$ is decreasing, i.e., $q_{j}^{\prime}(t) \leq 0$ for $1 \leq j \leq N$. This directly implies the perimeter-decreasing property. We point out that this property can also be obtained by standard energy estimates for the CSF. However, in our AP-CSF case, both arguments fail to derive the perimeter-decreasing property. We have to carry out a more careful investigation in which the convexity property plays a vital role (Section 3.2).

THEOREM 2.5. (Error estimate) Let $X(\xi, t)$ be a solution of (1.3) satisfying Assumption 2.2. Assume that the partition of $\mathbb{S}^{1}$ satisfies Assumption 2.1. Then there exists $h_{0}>0$ such that for all $0<h \leq h_{0}$, there exists a unique semi-discrete solution $X_{h}$ for (2.4). Furthermore, the solution satisfies

$$
\int_{0}^{T}\left\|\partial_{t} X-\partial_{t} X_{h}\right\|_{L^{2}}^{2} \mathrm{~d} s+\sup _{[0, T]}\left\|X-X_{h}\right\|_{H^{1}}^{2} \leq C h^{2}
$$

where $h_{0}$ and $C$ depend on $C_{p}, C_{P}, \kappa_{1}, \kappa_{2}, T$ and $K(X)$. In particular, we have

$$
\begin{equation*}
\min _{j} q_{j}(t)>0, \quad \forall t \in[0, T] . \tag{2.6}
\end{equation*}
$$

3. Convexity-preserving and perimeter-decreasing properties. Similar as in [16], we rewrite (2.4) into a lumped mass formulation. More precisely, taking

$$
v_{h}=\left(\varphi_{j}, 0\right)=\left(\frac{\xi-\xi_{j-1}}{h_{j}} \chi_{I_{j}}+\frac{\xi_{j+1}-\xi}{h_{j+1}} \chi_{I_{j+1}}, 0\right)
$$

in (2.4), where $\chi$ is the characteristic function, calculations in [20] give

$$
\begin{aligned}
& \int_{\mathbb{S}^{1}}\left|\partial_{\xi} X_{h}\right| \partial_{t} X_{h} \cdot v_{h} \mathrm{~d} \xi+\int_{\mathbb{S}^{1}} \frac{\partial_{\xi} X_{h}}{\left|\partial_{\xi} X_{h}\right|} \cdot \partial_{\xi} v_{h} \mathrm{~d} \xi+\int_{\mathbb{S}^{1}} \frac{\mathbf{h}^{2}\left|\partial_{\xi} X_{h}\right|}{6} \partial_{\xi} \partial_{t} X_{h} \cdot \partial_{\xi} v_{h} \mathrm{~d} \xi \\
= & \frac{q_{j}+q_{j+1}}{2} \dot{X}_{j}^{[1]}-\left(\mathcal{T}_{j+1}^{[1]}-\mathcal{T}_{j}^{[1]}\right),
\end{aligned}
$$

where $a^{[1]}$ denotes the first component of the vector $a \in \mathbb{R}^{2}$, and

$$
\mathcal{T}_{j}:=\frac{X_{j}-X_{j-1}}{\left|X_{j}-X_{j-1}\right|}, \quad \mathcal{N}_{j}=\left(\frac{X_{j}-X_{j-1}}{\left|X_{j}-X_{j-1}\right|}\right)^{\perp}
$$

For the last term involving the perimeter, we similarly compute

$$
\begin{aligned}
& \int_{\mathbb{S}^{1}} \frac{2 \pi}{L_{h}}\left(\partial_{\xi} X_{h}\right)^{\perp} \cdot v_{h} \mathrm{~d} \xi \\
= & \int_{\xi_{j-1}}^{\xi_{j}} \frac{2 \pi}{L_{h}} \frac{q_{j}}{h_{j}} \mathcal{N}_{j} \cdot\left(\frac{\xi-\xi_{j-1}}{h_{j}}, 0\right) \mathrm{d} \xi+\int_{\xi_{j}}^{\xi_{j+1}} \frac{2 \pi}{L_{h}} \frac{q_{j+1}}{h_{j+1}} \mathcal{N}_{j+1} \cdot\left(\frac{\xi_{j+1}-\xi}{h_{j+1}}, 0\right) \mathrm{d} \xi \\
= & \frac{\pi}{L_{h}} q_{j} \mathcal{N}_{j}^{[1]}+\frac{\pi}{L_{h}} q_{j+1} \mathcal{N}_{j+1}^{[1]} .
\end{aligned}
$$

Similarly taking $v_{h}=\left(0, \varphi_{j}\right)$ yields the equation for the second component. Thus the weak formulation (2.4) is equivalent to the following lumped mass formulation (3.1)

$$
\frac{q_{j}+q_{j+1}}{2} \dot{X}_{j}=\mathcal{T}_{j+1}-\mathcal{T}_{j}-\frac{\pi}{L_{h}}\left(q_{j} \mathcal{N}_{j}+q_{j+1} \mathcal{N}_{j+1}\right)=\mathcal{T}_{j+1}-\mathcal{T}_{j}-\frac{\pi}{L_{h}}\left(X_{j+1}-X_{j-1}\right)^{\perp}
$$

Hence it remains to solve the ODE system (3.1) and the image of $X_{h}$ is a polygon with $X_{j}(t)$ as the vertices.

For further studies, we derive some important formulae which will be used frequently. Straightforward calculations as in [16, Proposition 4.1], 20, Lemma 3.1, Lemma 4.2] and [39, Lemma 2.4, Lemma 3.2] lead to

$$
\begin{gather*}
\partial_{t}\left|\partial_{\xi} X\right|=-\left|\partial_{\xi} X\right|\left|\partial_{t} X\right|^{2}+\partial_{t} X \cdot R\left|\partial_{\xi} X\right|  \tag{3.2}\\
\frac{\mathrm{d}}{\mathrm{~d} t} q_{j}=-\frac{1}{q_{j}+q_{j+1}}\left|\mathcal{T}_{j+1}-\mathcal{T}_{j}\right|^{2}-\frac{1}{q_{j}+q_{j-1}}\left|\mathcal{T}_{j-1}-\mathcal{T}_{j}\right|^{2}+\mathcal{T}_{j} \cdot\left(R_{j}-R_{j-1}\right) \\
=-\frac{q_{j}+q_{j+1}}{4}\left|\dot{X}_{j}-R_{j}\right|^{2}-\frac{q_{j}+q_{j-1}}{4}\left|\dot{X}_{j-1}-R_{j-1}\right|^{2}+\mathcal{T}_{j} \cdot\left(R_{j}-R_{j-1}\right) \tag{3.3}
\end{gather*}
$$

where for simplicity we denote

$$
\begin{equation*}
R:=-\frac{2 \pi}{L} \mathcal{N}, \quad R_{j}:=-\frac{2 \pi}{L_{h}} \frac{\mathcal{N}_{j} q_{j}+\mathcal{N}_{j+1} q_{j+1}}{q_{j}+q_{j+1}} \tag{3.5}
\end{equation*}
$$

By using above quantities, the equation (3.1) can also be written as

$$
\begin{equation*}
\dot{X}_{j}-R_{j}=2\left(\mathcal{T}_{j+1}-\mathcal{T}_{j}\right) /\left(q_{j}+q_{j+1}\right) \tag{3.6}
\end{equation*}
$$

In this section, we will prove that this semi-discrete geometric flow preserves the convexity of polygons under the nondegeneration property of vertices, which can be guaranteed by (2.6). Furthermore, the perimeter-decreasing property is also shown for convex initial data.
3.1. Proof of Theorem 2.3. First, we carry out some clarifications concerning with a polygon. We denote $\mathcal{P}=\left(Y_{1}, \ldots, Y_{N}\right)$ as an $N$-polygon with $Y_{j}$ being its vertices and $\overline{Y_{j-1} Y_{j}}$ being the edge connecting $Y_{j-1}$ and $Y_{j}$. We emphasize that $\mathcal{P}=\left(Y_{1}, \ldots, Y_{N}\right)$ has exactly $N$ sides, i.e., none of any three adjacent points are collinear. We say $\mathcal{P}$ is a convex polygon if it is the boundary of a convex set. Without loss of generality, we assume that $Y_{j}$ is arranged in an anticlockwise way. We define the oriented area of three points $Y_{1}, Y_{2}, Y_{3} \in \mathbb{R}^{2}$ as

$$
\operatorname{Area}\left(Y_{1}, Y_{2}, Y_{3}\right):=\frac{1}{2}\left|\begin{array}{lll}
1 & x_{1} & y_{1} \\
1 & x_{2} & y_{2} \\
1 & x_{3} & y_{3}
\end{array}\right|=\frac{1}{2}\left(Y_{3}-Y_{2}\right) \cdot\left(Y_{2}-Y_{1}\right)^{\perp}
$$

where $Y_{i}=\left(x_{i}, y_{i}\right), i=1,2,3$. The following characterizations of convexity are straightforward.

Lemma 3.1. Let $\mathcal{P}=\left(X_{1}, \ldots, X_{N}\right)$ be an $N$-polygon. The following statements are equivalent:
(i) The $N$-polygon $\mathcal{P}=\left(X_{1}, \ldots, X_{N}\right)$ is convex;
(ii) Any internal angle $\angle X_{j-1} X_{j} X_{j+1}<\pi$ for $j=1, \ldots, N$;
(iii) $S_{j}:=\operatorname{Area}\left(X_{j-1}, X_{j}, X_{j+1}\right)>0$ for $j=1, \ldots, N$;
(iv) $S_{j}^{k}:=\operatorname{Area}\left(X_{j-1}, X_{j}, X_{k}\right)>0$ for $j=1, \ldots, N$ and $k \neq j-1, j$.

Here, we set $X_{0}=X_{N}$ and $X_{N+1}=X_{1}$ when involved.
Proof. Clearly we have (i) $\Leftrightarrow$ (ii) $\Leftrightarrow$ (iii) and (iv) $\Rightarrow$ (iii). It suffices to show (i) $\Rightarrow$ (iv). Indeed, by the support property of convex polygons [24, Theorem 4.2], for any $X \in$ $\overline{X_{j-1} X_{j}}$, there exists a support hyperplane $\ell(X)$ such that $\mathcal{P}$ is contained in one of the two closed halfspaces determined by $\ell(X)$. It's obvious that $\overline{X_{j-1} X_{j}} \subseteq \ell(X)$. In particular, for any $k \neq j-1, j, X_{k}$ lies in the same halfspace determined by $\ell(X)$, i.e., there exists a nonzero vector $\mathcal{N} \in \mathbb{R}^{2}$ such that

$$
\begin{equation*}
\mathcal{N} \cdot\left(X_{j}-X_{j-1}\right)=0, \quad \mathcal{N} \cdot\left(X_{k}-X_{j-1}\right)>0(k \neq j-1, j) \tag{3.7}
\end{equation*}
$$

Thus we can write $\mathcal{N}=\varepsilon\left(X_{j}-X_{j-1}\right)^{\perp}$. Noticing

$$
2 S_{j}^{k}=\left(X_{k}-X_{j}\right) \cdot\left(X_{j}-X_{j-1}\right)^{\perp}=\left(X_{k}-X_{j-1}\right) \cdot \mathcal{N} / \varepsilon, \quad k \neq j-1, j
$$

which together with (iii) implies $\varepsilon>0$, this yields (iv) by recalling (3.7) and the proof is completed.

Inspired by (2.3) and (3.1), to prove Theorem 2.3 , it suffices to show that for any $t>0$, the $N$-polygon $\mathcal{P}=\left(X_{1}, \ldots, X_{N}\right)$ is convex. We first compute the evolution formula of the oriented area of the triangles consisting of three adjacent vertices.

Lemma 3.2. Under the flow (3.1), if $q_{j}>0$ for any $j$, then the oriented area $S_{j}(t)$ satisfies

$$
\begin{align*}
\frac{\mathrm{d}}{\mathrm{~d} t} S_{j}(t)= & -a_{j} \cdot S_{j}+b_{j} \cdot S_{j+1}^{j-2}+c_{j} \cdot S_{j}^{j+2}+\frac{1}{q_{j}+q_{j+1}} \frac{\pi}{L_{h}}\left|X_{j+1}-X_{j-1}\right|^{2} \\
& +\frac{1}{q_{j-1}+q_{j}} \frac{\pi}{L_{h}}\left(X_{j}-X_{j+1}\right) \cdot\left(X_{j}-X_{j-2}\right)  \tag{3.8}\\
& +\frac{1}{q_{j+1}+q_{j+2}} \frac{\pi}{L_{h}}\left(X_{j}-X_{j-1}\right) \cdot\left(X_{j}-X_{j+2}\right),
\end{align*}
$$

where $a_{j}, b_{j}, c_{j}$ are positive functions defined by
$a_{j}=\frac{2}{q_{j} q_{j-1}}+\frac{2}{q_{j} q_{j+1}}+\frac{2}{q_{j+1} q_{j+2}}, \quad b_{j}=\frac{2}{q_{j-1}\left(q_{j-1}+q_{j}\right)}, \quad c_{j}=\frac{2}{q_{j+2}\left(q_{j+1}+q_{j+2}\right)}$.
Proof. By definition, it can be observed

$$
S_{j}=\frac{1}{2}\left(X_{j+1}-X_{j}\right) \cdot\left(X_{j}-X_{j-1}\right)^{\perp}=\frac{q_{j} q_{j+1}}{2} \mathcal{T}_{j+1} \cdot \mathcal{N}_{j}
$$

Employing the flow equation (3.1), we derive

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{~d} t} S_{j} & =\frac{1}{2} \frac{\mathrm{~d}}{\mathrm{~d} t}\left(X_{j+1} \cdot X_{j}^{\perp}+X_{j} \cdot X_{j-1}^{\perp}-X_{j+1} \cdot X_{j-1}^{\perp}\right) \\
& =\frac{1}{2} \frac{\mathrm{~d} X_{j+1}}{\mathrm{~d} t} \cdot\left(X_{j}^{\perp}-X_{j-1}^{\perp}\right)-\frac{1}{2} \frac{\mathrm{~d} X_{j}}{\mathrm{~d} t} \cdot\left(X_{j+1}^{\perp}-X_{j-1}^{\perp}\right)+\frac{1}{2} \frac{\mathrm{~d} X_{j-1}}{\mathrm{~d} t} \cdot\left(X_{j+1}^{\perp}-X_{j}^{\perp}\right) \\
& \triangleq: J_{1}+J_{2}+J_{3}
\end{aligned}
$$

where we have used the property $u \cdot v^{\perp}=-v \cdot u^{\perp}$ for any $u, v \in \mathbb{R}^{2}$. Applying (3.1), one can calculate $J_{j}$ as

$$
\begin{aligned}
& \left(q_{j+1}+q_{j+2}\right) J_{1}=\frac{q_{j}}{2}\left(q_{j+1}+q_{j+2}\right) \dot{X}_{j+1} \cdot \mathcal{N}_{j} \\
= & q_{j}\left(\mathcal{T}_{j+2}-\mathcal{T}_{j+1}-\frac{\pi}{L_{h}}\left(X_{j+2}-X_{j}\right)^{\perp}\right) \cdot \mathcal{N}_{j} \\
= & \frac{X_{j+2}-X_{j}}{q_{j+2}} \cdot q_{j} \mathcal{N}_{j}-\left(1+\frac{q_{j+1}}{q_{j+2}}\right) \mathcal{T}_{j+1} \cdot q_{j} \mathcal{N}_{j}-\frac{\pi}{L_{h}}\left(X_{j+2}-X_{j}\right) \cdot q_{j} \mathcal{T}_{j} \\
= & \frac{2}{q_{j+2}} S_{j}^{j+2}-\left(\frac{2}{q_{j+1}}+\frac{2}{q_{j+2}}\right) S_{j}-\frac{\pi}{L_{h}}\left(X_{j}-X_{j-1}\right) \cdot\left(X_{j+2}-X_{j}\right) .
\end{aligned}
$$

Similarly one easily gets

$$
\begin{aligned}
\left(q_{j}+q_{j+1}\right) J_{2} & =-\left(\frac{2}{q_{j}}+\frac{2}{q_{j+1}}\right) S_{j}+\frac{\pi}{L_{h}}\left|X_{j+1}-X_{j-1}\right|^{2} \\
\left(q_{j-1}+q_{j}\right) J_{3} & =-\left(\frac{2}{q_{j-1}}+\frac{2}{q_{j}}\right) S_{j}+\frac{2}{q_{j-1}} S_{j+1}^{j-2}+\frac{\pi}{L_{h}}\left(X_{j}-X_{j+1}\right) \cdot\left(X_{j}-X_{j-2}\right)
\end{aligned}
$$

Combining the above equations together yields (3.8) immediately.
Now we turn to the proof of convexity-preservation.
Proof of Theorem 2.3. Define the function $F(t):=\min \left\{S_{j}(t), 1 \leq j \leq N\right\}$. It follows from the assumption that $F(0)>0$. By the definition of $N$-polygon and Lemma 3.1 (iii), it suffices to show $F(t)>0$, for $t \in(0, T]$.

We argue by contradiction. Suppose the contrary, by continuity there exists the smallest time $0<t_{0} \leq T$ such that $F\left(t_{0}\right)=0$. Then we have
(1) there exists some triangle such that the oriented area achieves zero at $t_{0}$, without loss of generality, we may assume $S_{2}\left(t_{0}\right)=\operatorname{Area}\left(X_{1}, X_{2}, X_{3}\right)\left(t_{0}\right)=0$;
(2) the $N$-polygon $\mathcal{P}(t)=\left(X_{1}(t), \ldots, X_{N}(t)\right)$ is convex for $0 \leq t<t_{0}$, hence by Lemma 3.1 (iv), it holds

$$
S_{j}^{k}(t)>0, \quad \forall 0 \leq t<t_{0}, \quad \forall j=1, \ldots, N, \quad \forall k \neq j-1, j .
$$

Thus by (3.8), one has

$$
\begin{equation*}
0 \geq \frac{\mathrm{d}}{\mathrm{~d} t} S_{2}\left(t_{0}\right)=b_{2} \cdot S_{3}^{0}\left(t_{0}\right)+c_{2} \cdot S_{2}^{4}\left(t_{0}\right)+Q\left(t_{0}\right) \tag{3.9}
\end{equation*}
$$

where

$$
\begin{aligned}
Q\left(t_{0}\right)= & \frac{1}{q_{2}+q_{3}} \frac{\pi}{L_{h}}\left|X_{3}-X_{1}\right|^{2}\left(t_{0}\right)+\frac{1}{q_{1}+q_{2}} \frac{\pi}{L_{h}}\left(X_{2}-X_{3}\right) \cdot\left(X_{2}-X_{0}\right)\left(t_{0}\right) \\
& +\frac{1}{q_{3}+q_{4}} \frac{\pi}{L_{h}}\left(X_{2}-X_{1}\right) \cdot\left(X_{2}-X_{4}\right)\left(t_{0}\right)
\end{aligned}
$$

Noticing that (1) implies that $X_{1}\left(t_{0}\right), X_{2}\left(t_{0}\right), X_{3}\left(t_{0}\right)$ are collinear. There are two possibilities: (i) $\left(X_{2}-X_{1}\right) \cdot\left(X_{3}-X_{2}\right)\left(t_{0}\right)>0$; (ii) $\left(X_{2}-X_{1}\right) \cdot\left(X_{3}-X_{2}\right)\left(t_{0}\right)<0$. Next we discuss it case by case.
Case (i): $\left(X_{2}-X_{1}\right) \cdot\left(X_{3}-X_{2}\right)\left(t_{0}\right)>0$.
Firstly by (2) and continuity, we easily find that $S_{3}^{0}\left(t_{0}\right) \geq 0, S_{2}^{4}\left(t_{0}\right) \geq 0$. We claim that $Q\left(t_{0}\right) \geq 0$. Actually, notice that in this case it holds

$$
\left|X_{3}-X_{1}\right|\left(t_{0}\right)=\left|X_{3}-X_{2}\right|\left(t_{0}\right)+\left|X_{2}-X_{1}\right|\left(t_{0}\right)=q_{2}\left(t_{0}\right)+q_{3}\left(t_{0}\right)
$$

which implies

$$
\frac{\pi}{L_{h}} \frac{\left|X_{3}-X_{1}\right|^{2}}{q_{2}+q_{3}}\left(t_{0}\right)=\frac{\pi}{L_{h}} \frac{\left(q_{2}+q_{3}\right)^{2}}{q_{2}+q_{3}}\left(t_{0}\right)=\frac{\pi}{L_{h}}\left(q_{2}+q_{3}\right)\left(t_{0}\right)
$$

On the other hand, by the triangle inequality, one can estimate

$$
\begin{aligned}
& \frac{1}{q_{1}+q_{2}} \frac{\pi}{L_{h}}\left(X_{2}-X_{3}\right) \cdot\left(X_{2}-X_{0}\right) \geq-\frac{1}{q_{1}+q_{2}} \frac{\pi}{L_{h}}\left(q_{3} \cdot\left(q_{1}+q_{2}\right)\right)=-\frac{\pi}{L_{h}} q_{3}, \\
& \frac{1}{q_{3}+q_{4}} \frac{\pi}{L_{h}}\left(X_{2}-X_{1}\right) \cdot\left(X_{2}-X_{4}\right) \geq-\frac{\pi}{L_{h}} q_{2} .
\end{aligned}
$$

Thus

$$
Q\left(t_{0}\right) \geq \frac{\pi}{L_{h}}\left(q_{2}+q_{3}\right)\left(t_{0}\right)-\frac{\pi}{L_{h}} q_{3}\left(t_{0}\right)-\frac{\pi}{L_{h}} q_{2}\left(t_{0}\right)=0
$$

Recalling (3.9), all above inequalities become equalities, i.e., $S_{3}^{0}\left(t_{0}\right)=S_{2}^{4}\left(t_{0}\right)=0$, and

$$
\left|X_{2}-X_{0}\right|\left(t_{0}\right)=q_{1}\left(t_{0}\right)+q_{2}\left(t_{0}\right), \quad\left|X_{2}-X_{4}\right|\left(t_{0}\right)=q_{2}\left(t_{0}\right)+q_{3}\left(t_{0}\right)
$$

This means $X_{0}, X_{1}, X_{2}, X_{3}, X_{4}$ are collinear at $t_{0}$ and are arranged in order, i.e., $\left(X_{j+1}-X_{j}\right)\left(t_{0}\right)=d_{j}\left(X_{1}-X_{0}\right)\left(t_{0}\right)$ with $d_{j}>0, j=1,2,3$. In particular,

$$
S_{3}\left(t_{0}\right)=0, \quad\left(X_{3}-X_{2}\right) \cdot\left(X_{4}-X_{3}\right)\left(t_{0}\right)>0
$$

Repeating the above procedure by another $N-4$ times, we get that at time $t_{0}$, all vertices $\left(X_{0}, X_{1}, \ldots, X_{N}\right)$ are collinear and are arranged in order, i.e.,

$$
X_{j+1}\left(t_{0}\right)-X_{j}\left(t_{0}\right)=d_{j}\left(X_{1}\left(t_{0}\right)-X_{0}\left(t_{0}\right)\right), \quad d_{j}>0, \quad j=1,2, \ldots, N-1
$$

which contradicts with the periodic condition $X_{0}=X_{N}$.
Case (ii): $\left(X_{2}-X_{1}\right) \cdot\left(X_{3}-X_{2}\right)\left(t_{0}\right)<0$.

This means $\left(X_{3}-X_{2}\right)\left(t_{0}\right)=d_{2}\left(X_{2}-X_{1}\right)\left(t_{0}\right)$ with $d_{2}<0$. By (2) and continuity, we have $S_{3}\left(t_{0}\right) \geq 0, S_{2}^{4}\left(t_{0}\right) \geq 0$. On the other hand, by definition, one finds

$$
\begin{aligned}
S_{3}\left(t_{0}\right) & =\frac{1}{2}\left(X_{4}-X_{3}\right) \cdot\left(X_{3}-X_{2}\right)^{\perp}\left(t_{0}\right)=\frac{1}{2}\left(X_{4}-X_{2}\right) \cdot\left(X_{3}-X_{2}\right)^{\perp}\left(t_{0}\right) \\
& =\frac{d_{2}}{2}\left(X_{4}-X_{2}\right) \cdot\left(X_{2}-X_{1}\right)^{\perp}\left(t_{0}\right)=d_{2} S_{2}^{4}\left(t_{0}\right) \leq 0
\end{aligned}
$$

It follows $S_{3}\left(t_{0}\right)=0$ and $X_{1}, X_{2}, X_{3}, X_{4}$ are collinear. We claim that

$$
\left(X_{4}-X_{3}\right) \cdot\left(X_{3}-X_{2}\right)\left(t_{0}\right)<0
$$

Otherwise, Case (i) happens for the collinear points $X_{2}, X_{3}, X_{4}$. Differentiating $S_{3}$ at $t_{0}$ and repeating the arguments as in Case (i) involving $S_{3}$ will lead to the conclusion that $X_{1}, X_{2}, X_{3}, X_{4}, X_{5}$ are collinear and are arranged in order, which contradicts with the premise that $\left(X_{2}-X_{1}\right) \cdot\left(X_{3}-X_{2}\right)\left(t_{0}\right)<0$. Thus it holds

$$
S_{3}\left(t_{0}\right)=0, \quad\left(X_{4}-X_{3}\right) \cdot\left(X_{3}-X_{2}\right)\left(t_{0}\right)<0
$$

Repeating this argument, we can conclude that all vertices $X_{1}, X_{2}, \ldots, X_{N}$ are collinear, furthermore, every three adjacent vertices are interlaced, i.e.,

$$
\left(X_{j+1}-X_{j}\right) \cdot\left(X_{j}-X_{j-1}\right)\left(t_{0}\right)<0, \quad j=1, \ldots, N
$$

In particular, all exterior angles of the polygon $\mathcal{P}\left(t_{0}\right)$ are $\pi$. On the other hand, noticing each exterior angle $\alpha_{j}$ is continuous, by continuity and convexity, we have

$$
N \pi=\sum_{j=1}^{N} \alpha_{j}\left(t_{0}\right)=\lim _{t \rightarrow t_{0}} \sum_{j=1}^{N} \alpha_{j}(t)=2 \pi
$$

which leads to a contradiction since $N \geq 3$.
REmark 3.1. A similar argument holds for Dziuk's semi-discrete scheme [19] for the CSF. More precisely, under nondegeneration of vertices $\left(q_{j}>0\right)$ we can first prove that if the initial polygon is convex, then the evolved polygon under the semi-discrete scheme of the CSF is also convex unless all vertices are collinear at some $t_{0}>0$, in which case the area vanishes, i.e., $\operatorname{Area}\left(\mathcal{P}\left(t_{0}\right)\right)=0$. On the other hand, applying the error estimate of the scheme for the CSF [19, 20], we arrive at

$$
\begin{aligned}
\left|\operatorname{Area}\left(\Gamma_{t_{0}}\right)-\operatorname{Area}\left(\mathcal{P}\left(t_{0}\right)\right)\right| & =\left|\int_{\mathbb{S}^{1}} \partial_{\xi} x \cdot y \mathrm{~d} \xi-\int_{\mathbb{S}^{1}} \partial_{\xi} x_{h} \cdot y_{h} \mathrm{~d} \xi\right| \\
& \leq \int_{\mathbb{S}^{1}}\left|\partial_{\xi} x-\partial_{\xi} x_{h}\right| \cdot|y| \mathrm{d} \xi+\int_{\mathbb{S}^{1}}\left|\partial_{\xi} x_{h}\right| \cdot\left|y-y_{h}\right| \mathrm{d} \xi \\
& \leq C \sup _{[0, T]}\left\|X-X_{h}\right\|_{H^{1}\left(\mathbb{S}^{1}\right)} \leq C h
\end{aligned}
$$

where $\Gamma_{t}$ represents the real curve driven by the AP-CSF. This implies that Area $\left(\mathcal{P}\left(t_{0}\right)\right)$ stays away from zero, if Area $\left(\Gamma_{t}\right)$ has a positive lower bound for $t \in(0, T]$ and $h$ is small enough. This leads to a contradiction!

### 3.2. Proof of Theorem 2.4,

Proof. Applying (3.3), we get the derivative of the perimeter

$$
\frac{\mathrm{d}}{\mathrm{~d} t} L_{h}=\sum_{j=1}^{N} \frac{\mathrm{~d}}{\mathrm{~d} t} q_{j}=\sum_{j=1}^{N}\left(-\frac{1}{q_{j}+q_{j+1}}\left|\mathcal{T}_{j+1}-\mathcal{T}_{j}\right|^{2}-\frac{1}{q_{j}+q_{j-1}}\left|\mathcal{T}_{j-1}-\mathcal{T}_{j}\right|^{2}\right)
$$

$$
\begin{aligned}
& +\frac{2 \pi}{L_{h}} \sum_{j=1}^{N}\left(-\frac{q_{j+1}}{q_{j}+q_{j+1}} \mathcal{T}_{j} \cdot \mathcal{N}_{j+1}+\frac{q_{j-1}}{q_{j}+q_{j-1}} \mathcal{T}_{j} \cdot \mathcal{N}_{j-1}\right) \\
= & -2 \sum_{j=1}^{N} \frac{\left|\mathcal{T}_{j+1}-\mathcal{T}_{j}\right|^{2}}{q_{j}+q_{j+1}}-\frac{2 \pi}{L_{h}} \sum_{j=1}^{N} \mathcal{T}_{j} \cdot \mathcal{N}_{j+1}
\end{aligned}
$$

where we have used the fact that

$$
\begin{aligned}
& \sum_{j=1}^{N}\left(-\frac{q_{j+1}}{q_{j}+q_{j+1}} \mathcal{T}_{j} \cdot \mathcal{N}_{j+1}+\frac{q_{j-1}}{q_{j}+q_{j-1}} \mathcal{T}_{j} \cdot \mathcal{N}_{j-1}\right) \\
= & \sum_{j=1}^{N}\left(-\frac{q_{j+1}}{q_{j}+q_{j+1}} \mathcal{T}_{j} \cdot \mathcal{N}_{j+1}-\frac{q_{j}}{q_{j}+q_{j+1}} \mathcal{N}_{j+1} \cdot \mathcal{T}_{j}\right)=-\sum_{j=1}^{N} \mathcal{T}_{j} \cdot \mathcal{N}_{j+1}
\end{aligned}
$$

We denote $\alpha_{j}$ by the exterior angle of the polygon at $X_{j}$. By Theorem 2.3] $\mathcal{P}(t)$ keeps convex for all $t$, which implies $0<\alpha_{j}<\pi$ for $j=1, \ldots, N$, and $\sum_{j=1}^{N} \alpha_{j}=2 \pi$. Direct computations yield

$$
\left|\mathcal{T}_{j+1}-\mathcal{T}_{j}\right|^{2}=2-2 \cos \alpha_{j}=4 \sin ^{2}\left(\alpha_{j} / 2\right), \quad \text { and } \quad \mathcal{T}_{j} \cdot \mathcal{N}_{j+1}=-\sin \alpha_{j}
$$

By Cauchy-Schwarz inequality, one easily gets

$$
\sum_{j=1}^{N} 2 \sin \left(\frac{\alpha_{j}}{2}\right) \leq\left(\sum_{j=1}^{N} \frac{4 \sin ^{2}\left(\frac{\alpha_{j}}{2}\right)}{q_{j}+q_{j+1}}\right)^{\frac{1}{2}}\left(\sum_{j=1}^{N} q_{j}+q_{j+1}\right)^{\frac{1}{2}}=\left(2 L_{h}\right)^{\frac{1}{2}}\left(\sum_{j=1}^{N} \frac{4 \sin ^{2}\left(\frac{\alpha_{j}}{2}\right)}{q_{j}+q_{j+1}}\right)^{\frac{1}{2}}
$$

Hence we derive

$$
\frac{\mathrm{d} L_{h}}{\mathrm{~d} t}=-2 \sum_{j=1}^{N}\left(\frac{4 \sin ^{2}\left(\frac{\alpha_{j}}{2}\right)}{q_{j}+q_{j+1}}-\frac{\pi}{L_{h}} \sin \alpha_{j}\right) \leq \frac{-2}{L_{h}}\left(2\left(\sum_{j=1}^{N} \sin \left(\frac{\alpha_{j}}{2}\right)\right)^{2}-\pi \sum_{j=1}^{N} \sin \alpha_{j}\right) \leq 0
$$

where in the last inequality we have utilized a trigonometric inequality (cf. Lemma 3.3 below) and the proof is completed.

Lemma 3.3. Define

$$
f_{N}\left(\beta_{1}, \ldots, \beta_{N}\right):=\left(\sum_{j=1}^{N} \sin \beta_{j}\right)^{2}-\frac{1}{2}\left(\sum_{j=1}^{N} \beta_{j}\right)\left(\sum_{j=1}^{N} \sin \left(2 \beta_{j}\right)\right), \quad 0 \leq \beta_{j} \leq \frac{\pi}{2}
$$

Then it holds $f_{N}\left(\beta_{1}, \ldots, \beta_{N}\right) \geq 0$.
Proof. We prove $f_{N}\left(\beta_{1}, \ldots, \beta_{N}\right) \geq 0$ by induction. For $N=1$, we have

$$
f_{1}\left(\beta_{1}\right)=\sin ^{2} \beta_{1}-\frac{\beta_{1}}{2} \cdot \sin \left(2 \beta_{1}\right)=\sin \beta_{1} \cos \beta_{1}\left(\tan \beta_{1}-\beta_{1}\right) \geq 0
$$

Now suppose $f_{N-1}\left(\beta_{1}, \ldots, \beta_{N-1}\right) \geq 0$, we first compute

$$
\frac{\partial f_{N}\left(\beta_{1}, \ldots, \beta_{N}\right)}{\partial \beta_{N}}=2 \cos \beta_{N} \cdot \sum_{j=1}^{N} \sin \beta_{j}-\frac{1}{2} \sum_{j=1}^{N} \sin \left(2 \beta_{j}\right)-\sum_{j=1}^{N} \beta_{j} \cdot \cos \left(2 \beta_{N}\right)
$$

$$
\begin{aligned}
& \geq 2 \cos ^{2} \beta_{N} \cdot \sum_{j=1}^{N} \sin \beta_{j}-\sum_{j=1}^{N} \sin \beta_{j} \cos \beta_{j}-\sum_{j=1}^{N} \beta_{j} \cdot \cos \left(2 \beta_{N}\right) \\
& =\sum_{j=1}^{N}\left(\sin \beta_{j}-\sin \beta_{j} \cos \beta_{j}-\left(\beta_{j}-\sin \beta_{j}\right) \cdot \cos \left(2 \beta_{N}\right)\right) \\
& \geq \sum_{j=1}^{N}\left(\sin \beta_{j}-\sin \beta_{j} \cos \beta_{j}-\left(\beta_{j}-\sin \beta_{j}\right)\right)=: \sum_{j=1}^{N} B_{j}\left(\beta_{j}\right) .
\end{aligned}
$$

Noticing

$$
\frac{\partial B_{j}}{\partial \beta_{j}}=\cos \beta_{j}-\cos ^{2} \beta_{j}+\sin ^{2} \beta_{j}-\left(1-\cos \beta_{j}\right)=2 \cos \beta_{j}-2 \cos ^{2} \beta_{j} \geq 0
$$

this implies $B_{j}$ is increasing and particularly,

$$
B_{j}\left(\beta_{j}\right) \geq B_{j}(0)=0, \quad \beta_{j} \in[0, \pi / 2], \quad j=1, \ldots, N
$$

Hence one gets $\frac{\partial f_{N}\left(\beta_{1}, \ldots, \beta_{N}\right)}{\partial \beta_{N}} \geq 0$, and by induction,

$$
f_{N}\left(\beta_{1}, \ldots, \beta_{N}\right) \geq f_{N}\left(\beta_{1}, \ldots, \beta_{N-1}, 0\right)=f_{N-1}\left(\beta_{1}, \ldots, \beta_{N-1}\right) \geq 0
$$

which completes the proof. $\square$
4. Proof of Theorem 2.5. In this section we present the error estimate by following the lines of Dziuk's argument [20] and Pozzi-Stinner's computation [39]. We establish the stability estimate and length element difference under the assumption of boundedness of the semi-discrete length element. Then a bound of the semi-discrete length element is given. All above preliminary estimates together with the continuity argument enable us to derive the desired error bound. Throughout this section, we suppose Assumptions 2.1 and 2.2 are always valid and we denote $C>0$ by a general constant and may change from line to line. For simplicity we omit the space whenever the norm is defined on $\mathbb{S}^{1}$.

We first give the stability estimate.
Lemma 4.1. Suppose further the solution of (2.4) satisfies

$$
\begin{equation*}
\inf _{\xi}\left|\partial_{\xi} X_{h}\right| \geq c_{0}>0, \quad \text { and } \quad \sup _{\xi}\left|\partial_{\xi} X_{h}\right| \leq C_{0}, \quad \forall 0 \leq t \leq T^{*} \leq T \tag{4.1}
\end{equation*}
$$

Then for any $t \in\left[0, T^{*}\right]$, we have

$$
\begin{equation*}
\int_{0}^{t} \int_{\mathbb{S}^{1}}\left|\partial_{t} X-\partial_{t} X_{h}\right|^{2} q_{h} \mathrm{~d} \xi \mathrm{~d} s+\sup _{0 \leq s \leq t} \int_{\mathbb{S}^{1}}\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2} q_{h} \mathrm{~d} \xi \leq C \int_{0}^{t}\left\|q-q_{h}\right\|_{L^{2}}^{2} \mathrm{~d} s+C h^{2} \tag{4.2}
\end{equation*}
$$

where $\mathcal{T}=\frac{\partial_{\xi} X}{\left|\partial_{\xi} X\right|}, \mathcal{T}_{h}=\frac{\partial_{\xi} X_{h}}{\left|\partial_{\xi} X_{h}\right|}, q=\left|\partial_{\xi} X\right|, q_{h}=\left|\partial_{\xi} X_{h}\right|$ and $C$ depends on $C_{p}, C_{P}, \kappa_{1}$, $c_{0}, C_{0}$ and $K(X)$.

Proof. We first notice that the boundedness of the length element will imply the boundedness of the perimeter. Indeed, by Assumption 2.2 and (4.1), one easily gets

$$
\begin{equation*}
2 \pi \kappa_{1} \leq L \leq 2 \pi \kappa_{2}, \quad 2 \pi c_{0} \leq L_{h} \leq 2 \pi C_{0}, \quad \forall t \in\left[0, T^{*}\right] \tag{4.3}
\end{equation*}
$$

Recalling $\partial_{\xi} X \neq 0, \partial_{\xi} X_{h} \neq 0,|\mathcal{T}|=\left|\mathcal{T}_{h}\right|=1$, this enables us to write the following

$$
\begin{align*}
\left|\partial_{\xi} X-\partial_{\xi} X_{h}\right|^{2} & =\left|\partial_{\xi} X\right|^{2}+\left|\partial_{\xi} X_{h}\right|^{2}-2 \partial_{\xi} X \cdot \partial_{\xi} X_{h} \\
& =\left(q-q_{h}\right)^{2}+2 q q_{h}-2 q q_{h} \mathcal{T} \cdot \mathcal{T}_{h}  \tag{4.4}\\
& =\left(q-q_{h}\right)^{2}+q q_{h}\left(2-2 \mathcal{T} \cdot \mathcal{T}_{h}\right)=\left(q-q_{h}\right)^{2}+q q_{h}\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2}
\end{align*}
$$

Taking the difference between (1.4) and (2.4), we obtain the error equation

$$
\begin{aligned}
& \int_{\mathbb{S}^{1}}\left(\left|\partial_{\xi} X\right| \partial_{t} X-\left|\partial_{\xi} X_{h}\right| \partial_{t} X_{h}\right) \cdot v_{h} \mathrm{~d} \xi+\int_{\mathbb{S}^{1}}\left(\mathcal{T}-\mathcal{T}_{h}\right) \cdot \partial_{\xi} v_{h} \mathrm{~d} \xi \\
& +\int_{\mathbb{S}^{1}}\left(\frac{2 \pi}{L}\left(\partial_{\xi} X\right)^{\perp}-\frac{2 \pi}{L_{h}}\left(\partial_{\xi} X_{h}\right)^{\perp}\right) \cdot v_{h} \mathrm{~d} \xi=\int_{\mathbb{S}^{1}} \frac{\mathbf{h}^{2}\left|\partial_{\xi} X_{h}\right|}{6} \partial_{\xi} \partial_{t} X_{h} \cdot \partial_{\xi} v_{h} \mathrm{~d} \xi
\end{aligned}
$$

holds for any $v_{h} \in V_{h}$. Taking $v_{h}=I_{h}\left(\partial_{t} X\right)-\partial_{t} X_{h} \in V_{h}$ in the above equation yields

$$
\begin{aligned}
& \int_{\mathbb{S}^{1}}\left|\partial_{t} X-\partial_{t} X_{h}\right|^{2} q_{h} \mathrm{~d} \xi+\int_{\mathbb{S}^{1}}\left(\mathcal{T}-\mathcal{T}_{h}\right)\left(\partial_{\xi} \partial_{t} X-\partial_{\xi} \partial_{t} X_{h}\right) \mathrm{d} \xi \\
= & \int_{\mathbb{S}^{1}} \partial_{t} X \cdot\left(q_{h}-q\right)\left(I_{h} \partial_{t} X-\partial_{t} X_{h}\right) \mathrm{d} \xi+\int_{\mathbb{S}^{1}} \frac{\mathbf{h}^{2} q_{h}}{6} \partial_{\xi} \partial_{t} X_{h} \cdot \partial_{\xi}\left(I_{h} \partial_{t} X-\partial_{t} X_{h}\right) \mathrm{d} \xi \\
& +\int_{\mathbb{S}^{1}} q_{h} \cdot\left(\partial_{t} X-\partial_{t} X_{h}\right)\left(\partial_{t} X-I_{h} \partial_{t} X\right) d \xi+\int_{\mathbb{S}^{1}}\left(\mathcal{T}-\mathcal{T}_{h}\right) \cdot\left(\partial_{\xi} \partial_{t} X-\partial_{\xi} I_{h} \partial_{t} X\right) \mathrm{d} \xi \\
& +\int_{\mathbb{S}^{1}} \frac{2 \pi}{L}\left(\partial_{\xi} X-\partial_{\xi} X_{h}\right)^{\perp} \cdot\left(\partial_{t} X_{h}-I_{h} \partial_{t} X\right) \mathrm{d} \xi \\
& +\int_{\mathbb{S}^{1}}\left(\frac{2 \pi}{L}-\frac{2 \pi}{L_{h}}\right)\left(\partial_{\xi} X_{h}\right)^{\perp} \cdot\left(\partial_{t} X_{h}-I_{h} \partial_{t} X\right) \mathrm{d} \xi \triangleq: J_{1}+J_{2}+J_{3}+J_{4}+J_{5}+J_{6}
\end{aligned}
$$

The estimates of the second term on the left side and $J_{j}$ for $1 \leq j \leq 4$ can be found in [20, Lemma 5.1], which read as

$$
\begin{aligned}
& \int_{\mathbb{S}^{1}}\left(\mathcal{T}-\mathcal{T}_{h}\right) \cdot\left(\partial_{\xi} \partial_{t} X-\partial_{\xi} \partial_{t} X_{h}\right) \mathrm{d} \xi \\
& \geq \frac{\mathrm{d}}{\mathrm{~d} t}\left(\int_{\mathbb{S}^{1}}\left(1-\mathcal{T} \cdot \mathcal{T}_{h}\right) q_{h} \mathrm{~d} \xi\right)-C\left\|\partial_{\xi} \partial_{t} X\right\|_{L^{\infty}}\left(\int_{\mathbb{S}^{1}}\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2} q_{h} d \xi+\left\|q-q_{h}\right\|_{L^{2}}^{2}\right) \\
& J_{1} \leq \varepsilon \int_{\mathbb{S}^{1}}\left|\partial_{t} X-\partial_{t} X_{h}\right|^{2} q_{h} \mathrm{~d} \xi+C(\varepsilon)\left\|\partial_{t} X\right\|_{L^{\infty}}^{2} \int_{\mathbb{S}^{1}} \frac{\left(q-q_{h}\right)^{2}}{q_{h}} \mathrm{~d} \xi+C\left\|q_{h}\right\|_{L^{\infty}}^{2}\left\|\partial_{t} X\right\|_{H^{1}}^{2} h^{2} \\
& \leq \varepsilon \int_{\mathbb{S}^{1}}\left|\partial_{t} X-\partial_{t} X_{h}\right|^{2} q_{h} \mathrm{~d} \xi+C(\varepsilon)\left\|\partial_{t} X\right\|_{L^{\infty}}^{2}\left\|q-q_{h}\right\|_{L^{2}}^{2}+C h^{2}\left\|\partial_{t} X\right\|_{H^{1}}^{2}, \\
& J_{2} \leq \frac{1}{24}\left\|q_{h}\right\|_{L^{\infty}}\left\|\partial_{t} X\right\|_{H^{1}}^{2} h^{2} \leq C h^{2}\left\|\partial_{t} X\right\|_{H^{1}}^{2} \\
& J_{3} \leq \varepsilon \int_{\mathbb{S}^{1}}\left|\partial_{t} X-\partial_{t} X_{h}\right|^{2} q_{h} \mathrm{~d} \xi+C(\varepsilon)\left\|q_{h}\right\|_{L^{\infty}}\left\|\partial_{t} X\right\|_{H^{1}}^{2} h^{2} \\
& \leq \varepsilon \int_{\mathbb{S}^{1}}\left|\partial_{t} X-\partial_{t} X_{h}\right|^{2} q_{h} \mathrm{~d} \xi+C(\varepsilon) h^{2}\left\|\partial_{t} X\right\|_{H^{1}}^{2} \\
& J_{4} \leq C\left\|\partial_{t} X\right\|_{H^{2}}\left\|\mathcal{T}-\mathcal{T}_{h}\right\|_{L^{2}} h \leq C \int_{\mathbb{S}^{1}}\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2} q_{h} \mathrm{~d} \xi+C h^{2}\left\|\partial_{t} X\right\|_{H^{2}}^{2},
\end{aligned}
$$

where $\varepsilon$ is a generic small positive constant which will be chosen later. It remains to estimate $J_{5}$ and $J_{6}$. For $J_{5}$, we decompose it as $J_{5}=J_{51}+J_{52}$ with

$$
J_{51}=\int_{\mathbb{S}^{1}} \frac{2 \pi}{L}\left(\partial_{\xi} X-\partial_{\xi} X_{h}\right)^{\perp} \cdot\left(\partial_{t} X-I_{h} \partial_{t} X\right) \mathrm{d} \xi
$$

$$
J_{52}=\int_{\mathbb{S}^{1}} \frac{2 \pi}{L}\left(\partial_{\xi} X-\partial_{\xi} X_{h}\right)^{\perp} \cdot\left(\partial_{t} X_{h}-\partial_{t} X\right) \mathrm{d} \xi
$$

Applying Assumption 2.2, (4.3), (4.4) and the interpolation estimate (2.1), we derive

$$
\begin{aligned}
J_{51} & \leq C \int_{\mathbb{S}^{1}}\left|\partial_{\xi} X-\partial_{\xi} X_{h}\right|^{2} \mathrm{~d} \xi+C \int_{\mathbb{S}^{1}}\left|\partial_{t} X-I_{h} \partial_{t} X\right|^{2} \mathrm{~d} \xi \\
& =C\left(\int_{\mathbb{S}^{1}} q q_{h}\left(\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2}+\left(q-q_{h}\right)^{2}\right) \mathrm{d} \xi+\left\|\partial_{t} X-I_{h} \partial_{t} X\right\|_{L^{2}}^{2}\right) \\
& \leq C\left\|\partial_{\xi} X\right\|_{L^{\infty}} \int_{\mathbb{S}^{1}}\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2} q_{h} \mathrm{~d} \xi+C \int_{\mathbb{S}^{1}}\left(q-q_{h}\right)^{2} \mathrm{~d} \xi+C h^{2}\left\|\partial_{t} X\right\|_{H^{1}}^{2} \\
J_{52} & \leq C(\varepsilon) \int_{\mathbb{S}^{1}}\left|\partial_{\xi} X-\partial_{\xi} X_{h}\right|^{2} \mathrm{~d} \xi+\varepsilon \int_{\mathbb{S}^{1}}\left|\partial_{t} X_{h}-\partial_{t} X\right|^{2} q_{h} \mathrm{~d} \xi \\
& =C(\varepsilon) \int_{\mathbb{S}^{1}} q q_{h}\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2}+\left(q-q_{h}\right)^{2} \mathrm{~d} \xi+\varepsilon \int_{\mathbb{S}^{1}}\left|\partial_{t} X_{h}-\partial_{t} X\right|^{2} q_{h} \mathrm{~d} \xi \\
& \leq C(\varepsilon)\left\|\partial_{\xi} X\right\|_{L^{\infty}} \int_{\mathbb{S}^{1}}\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2} q_{h} \mathrm{~d} \xi+C(\varepsilon)\left\|q-q_{h}\right\|_{L^{2}}^{2}+\varepsilon \int_{\mathbb{S}^{1}}\left|\partial_{t} X_{h}-\partial_{t} X\right|^{2} q_{h} \mathrm{~d} \xi
\end{aligned}
$$

Similarly we decompose $J_{6}=J_{61}+J_{62}$ with

$$
\begin{aligned}
& J_{61}=\int_{\mathbb{S}^{1}}\left(\frac{2 \pi}{L}-\frac{2 \pi}{L_{h}}\right)\left(\partial_{\xi} X_{h}\right)^{\perp} \cdot\left(\partial_{t} X-I_{h} \partial_{t} X\right) \mathrm{d} \xi \\
& J_{62}=\int_{\mathbb{S}^{1}}\left(\frac{2 \pi}{L}-\frac{2 \pi}{L_{h}}\right)\left(\partial_{\xi} X_{h}\right)^{\perp} \cdot\left(\partial_{t} X_{h}-\partial_{t} X\right) \mathrm{d} \xi
\end{aligned}
$$

Noticing

$$
\begin{equation*}
\left|L-L_{h}\right| \leq\left\|q-q_{h}\right\|_{L^{1}} \leq C\left\|q-q_{h}\right\|_{L^{2}} \tag{4.5}
\end{equation*}
$$

this together with (4.3), (4.1) and (2.1) lead to

$$
\begin{aligned}
J_{61} & \leq C\left|L-L_{h}\right|^{2}+C\left\|\partial_{t} X-I_{h} \partial_{t} X\right\|_{L^{2}}^{2} \leq C\left\|q-q_{h}\right\|_{L^{2}}^{2}+C h^{2}\left\|\partial_{t} X\right\|_{H^{1}}^{2} \\
J_{62} & \leq C \int_{\mathbb{S}^{1}}\left|L_{h}-L\right| q_{h}^{\frac{1}{2}}\left|\partial_{t} X_{h}-\partial_{t} X\right| \mathrm{d} \xi \leq C(\varepsilon)\left|L_{h}-L\right|^{2}+\varepsilon \int_{\mathbb{S}^{1}} q_{h}\left|\partial_{t} X_{h}-\partial_{t} X\right|^{2} \mathrm{~d} \xi \\
& \leq C(\varepsilon)\left\|q-q_{h}\right\|_{L^{2}}^{2}+\varepsilon \int_{\mathbb{S}^{1}} q_{h}\left|\partial_{t} X_{h}-\partial_{t} X\right|^{2} \mathrm{~d} \xi
\end{aligned}
$$

Combining the above inequalities, we obtain

$$
\begin{aligned}
\int_{\mathbb{S}^{1}}\left|\partial_{t} X-\partial_{t} X_{h}\right|^{2} q_{h} \mathrm{~d} \xi+\frac{\mathrm{d}}{\mathrm{~d} t} \int_{\mathbb{S}^{1}}\left(1-\mathcal{T} \cdot \mathcal{T}_{h}\right) q_{h} \mathrm{~d} \xi & \leq 4 \varepsilon \int_{\mathbb{S}^{1}}\left|\partial_{t} X-\partial_{t} X_{h}\right|^{2} q_{h} \mathrm{~d} \xi \\
& +C(\varepsilon) h^{2}\left\|\partial_{t} X\right\|_{H^{2}}^{2}+C(\varepsilon, K(X))\left\|q-q_{h}\right\|_{L^{2}}^{2}+C(\varepsilon, K(X)) \int_{\mathbb{S}^{1}}\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2} q_{h} \mathrm{~d} \xi
\end{aligned}
$$

Choosing $\varepsilon$ small enough, integrating both sides with respect to time from 0 to $t$, noticing that

$$
\begin{aligned}
& \int_{\mathbb{S}^{1}}\left(1-\mathcal{T} \cdot \mathcal{T}_{h}\right)(0) q_{h}(0) \mathrm{d} \xi
\end{aligned}=\frac{1}{2} \int_{\mathbb{S}^{1}}\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2}(0) q_{h}(0) \mathrm{d} \xi \overline{\mathbb{S}^{1}}, \partial_{\xi} X-\left.\partial_{\xi} X_{h}\right|^{2}(0) \mathrm{d} \xi \leq C\left\|\partial_{\xi}\left(X-I_{h} X\right)(0)\right\|_{L^{2}}^{2} \leq C h^{2}\left\|X^{0}\right\|_{H^{2}}^{2},
$$

we are led to the estimate (4.2) with appropriate constant $C$ by applying Gronwall's inequality and Sobolev embedding $H^{1}\left(\mathbb{S}^{1}\right) \hookrightarrow L^{\infty}\left(\mathbb{S}^{1}\right)$.

Lemma 4.2. Suppose

$$
\int_{\mathbb{S}^{1}}\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2} q_{h} \mathrm{~d} \xi+\left\|q-q_{h}\right\|_{L^{2}}^{2} \leq C_{1} h^{2}, \quad \forall t \in\left[0, T^{*}\right]
$$

then there exists a constant $h_{0}$ such that for any $0<h \leq h_{0}$, we have

$$
\inf _{\xi} q_{h} \geq 3 \kappa_{1} / 4, \quad \text { and } \quad \sup _{\xi} q_{h} \leq 3 \kappa_{2} / 2, \quad \forall t \in\left[0, T^{*}\right]
$$

where the constant $h_{0}$ depends on $C_{1}, C_{p}, C_{P}, \kappa_{1}, \kappa_{2}$ and $K(X)$.
Proof. Applying the triangle inequality, the interpolation error estimate (2.1), and the inverse estimate (2.2), we can derive

$$
\begin{aligned}
\left\|\partial_{\xi} X-\partial_{\xi} X_{h}\right\|_{L^{\infty}} & \leq\left\|\partial_{\xi} X-I_{h} \partial_{\xi} X\right\|_{L^{\infty}}+\left\|\partial_{\xi} X_{h}-I_{h} \partial_{\xi} X\right\|_{L^{\infty}} \\
& \leq C h^{1 / 2}\left\|\partial_{\xi} X\right\|_{H^{1}}+C h^{-1 / 2}\left\|\partial_{\xi} X_{h}-I_{h} \partial_{\xi} X\right\|_{L^{2}} \\
& \leq C h^{1 / 2}\|X\|_{H^{2}}+C h^{-1 / 2}\left\|\partial_{\xi} X_{h}-\partial_{\xi} X\right\|_{L^{2}}
\end{aligned}
$$

The assumption and equality (4.4) imply

$$
\left\|\partial_{\xi} X-\partial_{\xi} X_{h}\right\|_{L^{2}} \leq\left(\int_{\mathbb{S}^{1}} q q_{h}\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2} \mathrm{~d} \xi\right)^{1 / 2}+\left\|q-q_{h}\right\|_{L^{2}} \leq \sqrt{C_{1}}\left(1+\left\|\partial_{\xi} X\right\|_{L^{\infty}}^{1 / 2}\right) h
$$

Then it follows that

$$
\left\|\partial_{\xi} X-\partial_{\xi} X_{h}\right\|_{L^{\infty}} \leq C\left(K(X), C_{1}\right) h^{1 / 2}
$$

and the conclusion follows by recalling Assumption 2.2.
In order to estimate the length element difference, we first give the following preliminary lemma by following the lines of [39, Lemma 3.2, Lemma 4.1].

Lemma 4.3. Given the assumptions of Lemma 4.1, then there exists a constant $C$ depending on $\kappa_{1}, C_{p}, C_{P}, c_{0}, C_{0}, T$ such that the following estimates hold for $t \in\left[0, T^{*}\right]$ :

$$
\begin{align*}
& \quad\left|R-R_{j}\right| \leq C\left(\left|L-L_{h}\right|+\left|\mathcal{T}-\mathcal{T}_{j}\right|+\left|\mathcal{T}-\mathcal{T}_{j+1}\right|\right), \quad j=1, \ldots, N  \tag{4.6}\\
& \int_{0}^{t}\left(q_{j}+q_{j+1}\right)\left|\dot{X}_{j}-R_{j}\right|^{2} \mathrm{~d} s \leq C h, \quad j=1, \ldots, N \tag{4.7}
\end{align*}
$$

where $R$ and $R_{j}$ are defined as (3.5). Moreover, we have the estimates on $I_{j}$ :

$$
\begin{align*}
& \sum_{k=j-1}^{j+1}\left\|\mathcal{T}-\mathcal{T}_{k}\right\|_{L^{2}\left(I_{j}\right)}^{2} \leq C h^{2}\|X\|_{H^{2}\left(S_{j}\right)}^{2}+C\left\|\mathcal{T}-\mathcal{T}_{h}\right\|_{L^{2}\left(S_{j}\right)}^{2} \\
& \sum_{k=j-1}^{j}\left\|\partial_{t} X-\dot{X}_{k}\right\|_{L^{2}\left(I_{j}\right)}^{2} \leq C h^{2}\left\|\partial_{t} X\right\|_{H^{1}\left(I_{j}\right)}^{2}+C\left\|\partial_{t} X-\partial_{t} X_{h}\right\|_{L^{2}\left(I_{j}\right)}^{2},  \tag{4.8}\\
& \sum_{k=j-1}^{j+1}\left\|q h_{j}-q_{k}\right\|_{L^{2}\left(I_{j}\right)}^{2} \leq C h^{4}\|X\|_{H^{2}\left(S_{j}\right)}^{2}+C h^{2}\left\|q-q_{h}\right\|_{L^{2}\left(S_{j}\right)}^{2}
\end{align*}
$$

with $S_{j}=I_{j} \cup I_{j+1} \cup I_{j-1}$.

Proof. Firstly (4.6) can be easily derived by employing Assumption 2.1 and (4.1):

$$
\begin{aligned}
\left|R-R_{j}\right| & =\left|-\frac{2 \pi}{L} \mathcal{N}+\frac{2 \pi}{L_{h}} \frac{\mathcal{N}_{j} q_{j}+\mathcal{N}_{j+1} q_{j+1}}{q_{j}+q_{j+1}}\right| \\
& \leq\left|-\frac{2 \pi}{L} \mathcal{N}+\frac{2 \pi}{L_{h}} \mathcal{N}\right|+\left|\frac{2 \pi}{L_{h}} \frac{q_{j}\left(\mathcal{N}-\mathcal{N}_{j}\right)}{q_{j}+q_{j+1}}\right|+\left|\frac{2 \pi}{L_{h}} \frac{q_{j+1}\left(\mathcal{N}-\mathcal{N}_{j+1}\right)}{q_{j}+q_{j+1}}\right| \\
& \leq C\left(\left|L-L_{h}\right|+\left|\mathcal{T}-\mathcal{T}_{j}\right|+\left|\mathcal{T}-\mathcal{T}_{j+1}\right|\right)
\end{aligned}
$$

For (4.7), equation (3.4) implies

$$
\begin{aligned}
& \int_{0}^{t}\left(q_{j}+q_{j+1}\right)\left|\dot{X}_{j}-R_{j}\right|^{2}+\left(q_{j}+q_{j-1}\right)\left|\dot{X}_{j-1}-R_{j-1}\right|^{2} \mathrm{~d} s \\
& =4 \int_{0}^{t} \mathcal{T}_{j} \cdot\left(R_{j}-R_{j-1}\right)-\frac{\mathrm{d}}{\mathrm{~d} t} q_{j} \mathrm{~d} s \\
& \leq 4 \int_{0}^{t} \mathcal{T}_{j} \cdot \frac{2 \pi}{L_{h}}\left(-\frac{\mathcal{N}_{j} q_{j}+\mathcal{N}_{j+1} q_{j+1}}{q_{j}+q_{j+1}}+\frac{\mathcal{N}_{j} q_{j}+\mathcal{N}_{j-1} q_{j-1}}{q_{j}+q_{j-1}}\right) \mathrm{d} s+4 q_{j}(0) \\
& \leq C \int_{0}^{t}\left|\mathcal{T}_{j} \cdot \frac{\mathcal{N}_{j+1} q_{j+1}}{q_{j}+q_{j+1}}\right|+\left|\mathcal{T}_{j} \cdot \frac{\mathcal{N}_{j-1} q_{j-1}}{q_{j}+q_{j-1}}\right| \mathrm{d} s+C h \\
& \leq \varepsilon \int_{0}^{t} \frac{\left|\mathcal{T}_{j+1}-\mathcal{T}_{j}\right|^{2}}{q_{j}+q_{j+1}}+\frac{\left|\mathcal{T}_{j-1}-\mathcal{T}_{j}\right|^{2}}{q_{j}+q_{j-1}} \mathrm{~d} s+C(\varepsilon) \int_{0}^{t} \frac{q_{j+1}^{2}}{q_{j}+q_{j+1}}+\frac{q_{j-1}^{2}}{q_{j}+q_{j-1}} \mathrm{~d} s+C h \\
& \leq \varepsilon \int_{0}^{t} \frac{\left|\mathcal{T}_{j+1}-\mathcal{T}_{j}\right|^{2}}{q_{j}+q_{j+1}}+\frac{\left|\mathcal{T}_{j-1}-\mathcal{T}_{j}\right|^{2}}{q_{j}+q_{j-1}} \mathrm{~d} s+C(\varepsilon) h \\
& =\frac{\varepsilon}{4} \int_{0}^{t}\left(q_{j}+q_{j+1}\right)\left|\dot{X}_{j}-R_{j}\right|^{2}+\left(q_{j}+q_{j-1}\right)\left|\dot{X}_{j-1}-R_{j-1}\right|^{2} \mathrm{~d} s+C(\varepsilon) h
\end{aligned}
$$

where for the second inequality we used (4.3) and (2.1) to get that

$$
\frac{2 \pi}{L_{h}} \leq C, \quad q_{j}(0)=h_{j}\left|\partial_{\xi} X_{h}^{0}\right|=h_{j}\left|\partial_{\xi} I_{h} X^{0}\right| \leq C(X) h
$$

for the third inequality we employed Young's inequality and the fact $\mathcal{T}_{j} \cdot \mathcal{N}_{j}=0$ to derive

$$
\begin{aligned}
\left|\mathcal{T}_{j} \cdot \frac{\mathcal{N}_{j+1} q_{j+1}}{q_{j}+q_{j+1}}\right| & =\left|\left(\mathcal{T}_{j}-\mathcal{T}_{j+1}\right) \cdot \frac{\mathcal{N}_{j+1} q_{j+1}}{q_{j}+q_{j+1}}\right| \\
& \leq\left|\mathcal{T}_{j}-\mathcal{T}_{j+1}\right| \frac{q_{j+1}}{q_{j}+q_{j+1}} \leq \varepsilon \frac{\left|\mathcal{T}_{j}-\mathcal{T}_{j+1}\right|^{2}}{q_{j}+q_{j+1}}+C(\varepsilon) \frac{q_{j+1}^{2}}{q_{j}+q_{j+1}}
\end{aligned}
$$

and for the last equality we used (3.6). Obviously (4.7) follows by taking $\varepsilon=1$. The estimates in (4.8) can be established by using similar arguments as in [39, Lemma 4.1] and are deleted here for brevity.

Next we present the key length difference estimate with the aid of Lemma 4.3
Lemma 4.4. Given the assumptions of Lemma 4.1, then we have

$$
\left\|q-q_{h}\right\|_{L^{2}}^{2} \leq C \int_{0}^{t} \int_{\mathbb{S}^{1}}\left|\partial_{t} X-\partial_{t} X_{h}\right|^{2} q_{h} \mathrm{~d} \xi \mathrm{~d} s+C \int_{0}^{t} \int_{\mathbb{S}^{1}}\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2} q_{h} \mathrm{~d} \xi \mathrm{~d} s+C h^{2}
$$

where $C$ is a constant depending on $C_{p}, C_{P}, \kappa_{1}, c_{0}, C_{0}, T^{*}$ and $K(X)$.

Proof. By definition, one has

$$
\int_{\mathbb{S}^{1}}\left(q(\xi, t)-q_{h}(\xi, t)\right)^{2} \mathrm{~d} \xi=\sum_{j=1}^{N} \int_{I_{j}}\left(q(\xi, t)-q_{j}(t) / h_{j}\right)^{2} d \xi
$$

By integration for $\frac{\mathrm{d}}{\mathrm{d} t}\left(h_{j} q-q_{j}\right)$, we can write

$$
\left(h_{j} q-q_{j}\right)(t)=\left(h_{j} q-q_{j}\right)(0)+\int_{0}^{t}\left(h_{j} \partial_{t} q-\dot{q}_{j}\right) \mathrm{d} s=: P+\int_{0}^{t} A \mathrm{~d} s
$$

where by the interpolation error estimate (2.1) and inverse estimate (2.2), $P$ satisfies

$$
|P|=h_{j}| | \partial_{\xi} X^{0}|-| \partial_{\xi} I_{h} X^{0}\left\|_{I_{j}} \leq C h\right\| \partial_{\xi}\left(X^{0}-I_{h} X^{0}\right)\left\|_{L^{\infty}\left(I_{j}\right)} \leq C h^{3 / 2}\right\| X^{0} \|_{H^{2}\left(I_{j}\right)}
$$

Applying (3.2) and (3.4), on each grid element $I_{j}=\left[\xi_{j-1}, \xi_{j}\right]$, we can write $A$ as

$$
\begin{aligned}
A=\frac{\mathrm{d}}{\mathrm{~d} t}\left(h_{j} q-q_{j}\right)= & -\left(\frac{h_{j} q}{2}\left|\partial_{t} X-R\right|^{2}-\frac{q_{j}+q_{j+1}}{4}\left|\dot{X}_{j}-R_{j}\right|^{2}\right) \\
& -\left(\frac{h_{j} q}{2}\left|\partial_{t} X-R\right|^{2}-\frac{q_{j}+q_{j-1}}{4}\left|\dot{X}_{j-1}-R_{j-1}\right|^{2}\right) \\
& -\left(h_{j} q\left(\partial_{t} X-R\right) \cdot R+\mathcal{T}_{j} \cdot\left(R_{j}-R_{j-1}\right)\right) \triangleq:-A^{+}-A^{-}-\hat{A}
\end{aligned}
$$

The terms $\int_{0}^{t}\left|A^{+}\right| \mathrm{d} s$ and $\int_{0}^{t}\left|A^{-}\right| \mathrm{d} s$ are estimated in [39, Lemma 4.4], which read as

$$
\begin{aligned}
& \int_{0}^{t}\left(\left|A^{+}\right|+\left|A^{-}\right|\right) \mathrm{d} s \leq C Q_{j}+C h\left(\int_{0}^{t} \sum_{k=j-1}^{j}\left|\partial_{t} X-R-\left(\dot{X}_{k}-R_{k}\right)\right|^{2} \mathrm{~d} s\right)^{1 / 2} \\
& Q_{j}:=\left(\int_{0}^{t}\left(\left|h_{j} q-q_{j}\right|^{2}+\left|h_{j} q-q_{j+1}\right|^{2}+\left|h_{j} q-q_{j-1}\right|^{2}\right) \mathrm{d} s\right)^{1 / 2}
\end{aligned}
$$

where (4.7) has been used. Applying (4.6), we immediately get

$$
\begin{aligned}
& \int_{0}^{t}\left(\left|A^{+}\right|+\left|A^{-}\right|\right) \mathrm{d} s \leq C Q_{j}+C h T_{j}+C h Y_{j}+C h\left(\int_{0}^{t}\left|L-L_{h}\right|^{2} \mathrm{~d} s\right)^{1 / 2} \\
& T_{j}:=\left(\int_{0}^{t} \sum_{k=j-1}^{j+1}\left|\mathcal{T}-\mathcal{T}_{k}\right|^{2} \mathrm{~d} s\right)^{1 / 2}, \quad Y_{j}:=\left(\int_{0}^{t}\left|\partial_{t} X-\dot{X}_{j}\right|^{2}+\left|\partial_{t} X-\dot{X}_{j-1}\right|^{2} \mathrm{~d} s\right)^{1 / 2}
\end{aligned}
$$

It remains to estimate $\int_{0}^{t}|\hat{A}| \mathrm{d} s$. By definition, one has

$$
\begin{aligned}
\hat{A}= & \frac{h_{j} q}{2}\left(\partial_{t} X-R\right) \cdot\left(-\frac{2 \pi}{L} \mathcal{N}\right)-\frac{2 \pi}{L_{h}} \frac{q_{j+1}}{q_{j}+q_{j+1}} \mathcal{T}_{j} \cdot \mathcal{N}_{j+1} \\
& +\frac{h_{j} q}{2}\left(\partial_{t} X-R\right) \cdot\left(-\frac{2 \pi}{L} \mathcal{N}\right)+\frac{2 \pi}{L_{h}} \frac{q_{j-1}}{q_{j}+q_{j-1}} \mathcal{T}_{j} \cdot \mathcal{N}_{j-1} \triangleq: \hat{A}_{1}+\hat{A}_{2}
\end{aligned}
$$

Recalling (3.6), we observe

$$
\mathcal{T}_{j} \cdot \mathcal{N}_{j+1}=\mathcal{T}_{j} \cdot\left(\mathcal{T}_{j+1}-\mathcal{T}_{j}\right)^{\perp}=-\mathcal{N}_{j} \cdot\left(\mathcal{T}_{j+1}-\mathcal{T}_{j}\right)=-\frac{q_{j}+q_{j+1}}{2} \mathcal{N}_{j} \cdot\left(\dot{X}_{j}-R_{j}\right)
$$

which implies

$$
\hat{A}_{1}=h_{j} q\left(\partial_{t} X-R\right) \cdot\left(-\frac{\pi}{L} \mathcal{N}+\frac{\pi}{L_{h}} \mathcal{N}_{j}\right)
$$

$$
+\left(q_{j+1}-h_{j} q\right)\left(\partial_{t} X-R\right) \cdot \frac{\pi}{L_{h}} \mathcal{N}_{j}+\left(\left(\dot{X}_{j}-R_{j}\right)-\left(\partial_{t} X-R\right)\right) \cdot \frac{\pi}{L_{h}} q_{j+1} \mathcal{N}_{j} .
$$

Therefore, by the assumptions and (4.6), we can estimate

$$
\begin{aligned}
& \int_{0}^{t}\left|\hat{A}_{1}\right| \mathrm{d} s \leq C h \int_{0}^{t}\left|\frac{\pi \mathcal{N}}{L}-\frac{\pi \mathcal{N}_{j}}{L_{h}}\right|+\left|\dot{X}_{j}-R_{j}-\partial_{t} X+R\right| \mathrm{d} s+C \int_{0}^{t}\left|q_{j+1}-h_{j} q\right| \mathrm{d} s \\
& \leq C h \int_{0}^{t}\left|L-L_{h}\right|+\sum_{k=j}^{j+1}\left|\mathcal{T}-\mathcal{T}_{k}\right| \mathrm{d} s+C \int_{0}^{t}\left|q_{j+1}-h_{j} q\right| \mathrm{d} s+C h \int_{0}^{t}\left|\dot{X}_{j}-\partial_{t} X\right| \mathrm{d} s \\
& \leq C h\left(\int_{0}^{t}\left|L-L_{h}\right|^{2} \mathrm{~d} s\right)^{1 / 2}+C Q_{j}+C h T_{j}+C h Y_{j},
\end{aligned}
$$

and similar estimates can be established for $\int_{0}^{t}\left|\hat{A}_{2}\right| \mathrm{d} s$.
To summarize, we obtain the following estimate on $I_{j}$

$$
\left|h_{j} q-q_{j}\right| \leq C h^{3 / 2}\left\|X^{0}\right\|_{H^{2}\left(I_{j}\right)}+C h\left(\int_{0}^{t}\left\|q-q_{h}\right\|_{L^{2}}^{2} \mathrm{~d} s\right)^{1 / 2}+C Q_{j}+C h T_{j}+C h Y_{j}
$$

where we have used (4.5). Applying (4.8), we get

$$
\begin{aligned}
& \left\|h_{j} q(t)-q_{j}(t)\right\|_{L^{2}\left(I_{j}\right)}^{2} \leq C h^{4}\left(\left\|X^{0}\right\|_{H^{2}\left(I_{j}\right)}^{2}+\int_{0}^{t}\left\|\partial_{t} X\right\|_{H^{1}\left(I_{j}\right)}^{2}+\|X\|_{H^{2}\left(S_{j}\right)}^{2} \mathrm{~d} s\right) \\
& +C h^{2} \int_{0}^{t} h\left\|q-q_{h}\right\|_{L^{2}}^{2}+\left\|q-q_{h}\right\|_{L^{2}\left(S_{j}\right)}^{2}+\left\|\mathcal{T}-\mathcal{T}_{h}\right\|_{L^{2}\left(S_{j}\right)}^{2}+\left\|\partial_{t} X-\partial_{t} X_{h}\right\|_{L^{2}\left(S_{j}\right)}^{2} \mathrm{~d} s
\end{aligned}
$$

Summing up over all grid elements $I_{j}$ yields

$$
C h^{2}\left\|q-q_{h}\right\|_{L^{2}}^{2} \leq C h^{4}+C h^{2} \int_{0}^{t}\left\|q-q_{h}\right\|_{L^{2}}^{2}+\left\|\mathcal{T}-\mathcal{T}_{h}\right\|_{L^{2}}^{2}+\left\|\partial_{t} X-\partial_{t} X_{h}\right\|_{L^{2}}^{2} \mathrm{~d} s
$$

where we have used the inequality

$$
\left\|h_{j} q(t)-q_{j}(t)\right\|_{L^{2}\left(I_{j}\right)}^{2}=h_{j}^{2}\left\|q-q_{h}\right\|_{L^{2}\left(I_{j}\right)}^{2} \geq C h^{2}\left\|q-q_{h}\right\|_{L^{2}\left(I_{j}\right)}^{2} .
$$

Finally, the desired estimate is concluded by a Gronwall's argument.
We are now in a position to prove Theorem 2.5
Proof of Theorem 2.5. Since the nonlinear terms in (3.1) are locally Lipschitz with respect to $X_{j}$, the local existence and uniqueness is guaranteed by standard ODE theory. Let $T^{*} \in(0, T)$ be the maximal time such that the semi-discrete solution $X_{h}$ exists and the following estimates hold

$$
\begin{equation*}
\inf \left|\partial_{\xi} X_{h}\right| \geq \kappa_{1} / 2, \quad \text { and } \quad \sup \left|\partial_{\xi} X_{h}\right| \leq 2 \kappa_{2}, \quad \forall t \in\left[0, T^{*}\right] . \tag{4.9}
\end{equation*}
$$

Combining Lemma 4.1 Lemma 4.4 and employing Gronwall's argument, we can yield that for any $t \in\left[0, T^{*}\right]$, it holds

$$
\begin{equation*}
\int_{0}^{t} \int_{\mathbb{S}^{1}}\left|\partial_{t} X-\partial_{t} X_{h}\right|^{2} q_{h} \mathrm{~d} \xi \mathrm{~d} s+\sup _{0 \leq s \leq t} \int_{\mathbb{S}^{1}}\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2} q_{h} \mathrm{~d} \xi \leq C h^{2} . \tag{4.10}
\end{equation*}
$$

Plugging this back into Lemma 4.4 we obtain for any $t \in\left[0, T^{*}\right]$,

$$
\begin{equation*}
\left\|q-q_{h}\right\|_{L^{2}}^{2} \leq C h^{2} . \tag{4.11}
\end{equation*}
$$

By Lemma 4.2, there exists $h_{0}>0$ depending on $C_{p}, C_{P}, \kappa_{1}, \kappa_{2}, T$ and $K(X)$ such that for any $0<h \leq h_{0}$, we have

$$
\inf \left|\partial_{\xi} X_{h}\right| \geq 3 \kappa_{1} / 4, \quad \text { and } \quad \sup \left|\partial_{\xi} X_{h}\right| \leq 3 \kappa_{2} / 2, \quad \text { at } t=T^{*}
$$

By standard ODE theory, we can uniquely extend the above semi-discrete solution in a neighborhood of $T^{*}$. And by continuity, we obtain

$$
\inf \left|\partial_{\xi} X_{h}\right| \geq \kappa_{1} / 2, \quad \text { and } \quad \sup \left|\partial_{\xi} X_{h}\right| \leq 2 \kappa_{2}, \quad \text { in a neighborhood of } T^{*}
$$

This contradicts to the maximality of $T^{*}$, and thus $T^{*}=T$. Thus (4.9)-(4.11) hold for $t \in[0, T]$ and the nondegeneration property (2.6) follows by (4.9) and Assumption 2.1 by noticing $q_{j}=h_{j} q_{h}$. We derive the error estimate by integration and (4.4):

$$
\begin{aligned}
& \left\|X(\cdot, t)-X_{h}(\cdot, t)\right\|_{H^{1}}^{2}=\int_{\mathbb{S}^{1}}\left|X-X_{h}\right|^{2} \mathrm{~d} \xi+\int_{\mathbb{S}^{1}}\left|\partial_{\xi} X-\partial_{\xi} X_{h}\right|^{2} \mathrm{~d} \xi \\
\leq & 2 \int_{\mathbb{S}^{1}}\left(\int_{0}^{t} \partial_{t} X-\partial_{t} X_{h} \mathrm{~d} s\right)^{2} \mathrm{~d} \xi+2\left\|X^{0}-I_{h} X^{0}\right\|_{L^{2}}^{2}+\left\|q-q_{h}\right\|_{L^{2}}^{2}+\int_{\mathbb{S}^{1}}\left|\mathcal{T}-\mathcal{T}_{h}\right|^{2} q q_{h} \mathrm{~d} \xi \\
\leq & 2 \int_{\mathbb{S}^{1}} T \int_{0}^{t}\left|\partial_{t} X-\partial_{t} X_{h}\right|^{2} \mathrm{~d} s \mathrm{~d} \xi+C h^{2} \leq C h^{2}
\end{aligned}
$$

and the proof is completed.
5. Numerical results. In this section we present a fully discrete version of (2.4) to simulate the AP-CSF. Choose an integer $m$, set the time step $\tau=T / m$ and $t_{k}=k \tau$, $k=0, \ldots, m$. For simplicity we choose a uniform mesh, i.e., $\xi_{j}=j h$ for $j=0, \ldots, N$ and $h=2 \pi / N$. We take $X_{h}^{0}=I_{h} X^{0}$. For $k \geq 1$, find $X_{h}^{k}=\sum_{j=1}^{N} X_{j}^{k} \varphi_{j} \in V_{h}$ by
$\int_{\mathbb{S}^{1}}\left|\partial_{\xi} X_{h}^{k-1}\right| \delta_{\tau} X_{h}^{k} \cdot v_{h} \mathrm{~d} \xi+\int_{\mathbb{S}^{1}} \partial_{\xi} X_{h}^{k} \cdot \partial_{\xi} v_{h} /\left|\partial_{\xi} X_{h}^{k-1}\right| \mathrm{d} \xi$ $+\int_{\mathbb{S}^{1}} h^{2}\left|\partial_{\xi} X_{h}^{k-1}\right| \partial_{\xi} \delta_{\tau} X_{h}^{k} \cdot \partial_{\xi} v_{h} / 6 \mathrm{~d} \xi+\int_{\mathbb{S}^{1}} 2 \pi\left(\partial_{\xi} X_{h}^{k}\right)^{\perp} \cdot v_{h} / L_{h}^{k-1} \mathrm{~d} \xi=0, \quad \forall v_{h} \in V_{h}$, where $\delta_{\tau}$ is the backward finite difference $\delta_{\tau} X_{h}^{m}=\left(X_{h}^{m}-X_{h}^{m-1}\right) / \tau$, and $L_{h}^{k-1}$ is the length of the image of $X_{h}^{k-1}$. Or it can be written equivalently as a discretization for the ODE system (3.1):

$$
\frac{q_{j}^{k-1}+q_{j+1}^{k-1}}{2 \tau}\left(X_{j}^{k}-X_{j}^{k-1}\right)-\frac{X_{j+1}^{k}-X_{j}^{k}}{q_{j+1}^{k-1}}+\frac{X_{j}^{k}-X_{j-1}^{k}}{q_{j}^{k-1}}+\frac{\pi}{L_{h}^{k-1}}\left(X_{j+1}^{k}-X_{j-1}^{k}\right)^{\perp}=0
$$

First, we test the convergence rates in the $L^{2}$ norm, $H^{1}$ seminorm and the error of velocity, respectively. Since the exact solution of the AP-CSF (1.2) is unknown, we consider the following numerical errors

$$
\begin{aligned}
& \left(\mathcal{E}_{1}\right)_{h, \tau}(T):=\max _{1 \leq k \leq T / \tau}\left\|X_{h, \tau}^{k}-X_{h / 2, \tau / 4}^{4 k}\right\|_{L^{2}\left(\mathbb{S}^{1}\right)} \\
& \left(\mathcal{E}_{2}\right)_{h, \tau}(T):=\max _{1 \leq k \leq T / \tau}\left\|\partial_{\xi} X_{h, \tau}^{k}-\partial_{\xi} X_{h / 2, \tau / 4}^{4 k}\right\|_{L^{2}\left(\mathbb{S}^{1}\right)} \\
& \left(\mathcal{E}_{3}\right)_{h, \tau}(T):=\left(\sum_{k=0}^{T / \tau-1} \tau \| \frac{X_{h, \tau}^{k+1}-X_{h, \tau}^{k}}{\tau}-\frac{\left.X_{h / 2, \tau / 4}^{4 k+1}-X_{h / 2, \tau / 4}^{4 k} \|_{L^{2}\left(\mathbb{S}^{1}\right)}^{2}\right)^{1 / 2}}{\tau / 4}\right.
\end{aligned}
$$

where $X_{h, \tau}^{k}$ represents the solution obtained by the above fully discrete scheme with mesh size $h$ and time step $\tau$. The corresponding convergence order is defined as:

$$
\operatorname{Order}_{i}=\log \left(\frac{\left(\mathcal{E}_{i}\right)_{h, \tau}(T)}{\left(\mathcal{E}_{i}\right)_{h / 2, \tau / 4}(T)}\right) / \log 2, \quad i=1,2,3
$$

The errors and convergence orders are displayed in Table 5.1 where we choose $h=2 \pi / N$ and $\tau=0.5 h^{2}$ and the initial value is given by $X^{0}(\xi)=(2 \cos \xi, \sin \xi)$. The results indicate that the numerical solution converges linearly in space in the $H^{1}$ seminorm, which agrees with the theoretical analysis in Theorem 2.5. We can also observe that the solution and the velocity converge quadratically in $L_{t}^{\infty} L_{x}^{2}$ and $L_{t}^{2} L_{x}^{2}$, respectively, which is superior than the result in Theorem 2.5

Table 5.1: Numerical errors up to $T=1 / 4$.

| $N$ | $\left(\mathcal{E}_{1}\right)_{h, \tau}(1 / 4)$ Order $_{1}$ | $\left(\mathcal{E}_{2}\right)_{h, \tau}(1 / 4)$ Order $_{2}$ | $\left(\mathcal{E}_{3}\right)_{h, \tau}(1 / 4)$ Order $_{3}$ |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 16 | $2.08 \mathrm{E}-2$ | - | $1.15 \mathrm{E}-0$ | - | $3.09 \mathrm{E}-2$ | - |
| 32 | $5.42 \mathrm{E}-3$ | 1.94 | $6.01 \mathrm{E}-1$ | 1.94 | $1.01 \mathrm{E}-2$ | 1.61 |
| 64 | $1.37 \mathrm{E}-3$ | 1.99 | $3.03 \mathrm{E}-1$ | 0.99 | $2.76 \mathrm{E}-3$ | 1.87 |
| 128 | $3.42 \mathrm{E}-4$ | 2.00 | $1.52 \mathrm{E}-1$ | 1.00 | $7.09 \mathrm{E}-4$ | 1.96 |

Fig. 5.1: Numerical results for an initial ellipse curve (i.e., $\frac{x^{2}}{4}+y^{2}=1$ ): (a) evolution of the perimeter and area; (b) the asymptotic area loss at $T=1 / 4$.

Finally, we check the structure-preserving properties of our algorithm. As is shown in Fig. 5.1(a), the length of the curve is decreasing during the evolution, which confirms the theoretical analysis in Theorem 2.4. Furthermore, Fig. 5.1(a) shows the area is almost preserving and more specifically, Fig. 5.1(b) indicates that the area enclosed by the curve has an error at $O\left(h^{2}\right)$. The evolution of the polygon with the number of grid points $N=15$, which approximates the evolution of the ellipse determined by $x^{2} / 4+y^{2}=1$, is shown in Fig. 5.2, from which we clearly see that the polygon keeps convex during the evolution, which verifies the convexity-preserving property in Theorem 2.3.
