In this note we give two proofs of Brooks' Theorem. The first is obtained by modifying an earlier proof and the second by combining two earlier proofs. We believe these proofs are easier to teach in Computer Science courses.

## 1 Introduction

Brooks' Theorem states that every graph in which the maximum degree of a vertex is $\Delta$ can be coloured with $\Delta$ colours, unless it is either a complete graph or an odd cycle.

There are several proofs of Brooks' theorem (see e.g. [5].). The most popular proofs are due to Lovasz [6] and based on the Kempe Chain argument [7].

The proof of Melnikov and Vizing [7] and Wislon [9] uses contradiction. In this note we modify this proof. The modified proof is constructive and implies a linear time algorithm. This is described in Section 2. Some of these techniques are also described in [8].

The proof of Lovasz [6] assumes properties of block-cutpoint trees, and implies a linear time algorithm. Bondy [2, 3] used a result of Chartrand and Kronk [4] in the second step of the proof of Lovasz. Chartrand and Kronk [4] show that every connected non-separable graph has a DFS tree, in which some node has at least two children, unless the graph is a complete graph, or a complete bipartite graph or a circuit. Bondy's proof is again non-constructive. Zajac [10] gave a new proof, which implies a linear time algorithm. In this note we

[^0]combine the proofs of Zajac and Bondy to get a proof that is almost as simple as Bondy's and also results in a linear time algorithm. This proof is described in Section 3.

In the rest of this paper, we assume that $\Delta \geq 3$ (thus, avoiding the case of cycle graphs). We now sketch the greedy method for colouring [3]. If the graph has a vertex $v$ which is of degree less than $\Delta$, then carry out DFS starting at $v$, which becomes the root of the resultant DFS-tree. Pick the nodes of the DFStree in post-order (children before parent) [1], and colour each node with the minimum colour missing amongst its neighbours in the graph. As the parent is coloured after the node, at each node (except the root) at least one neighbour is not coloured, and hence at most $\Delta-1$ colours are present in its neighbourhood; thus each node, except the root can be coloured. The root can also be coloured as it has at most $\Delta-1$ neighbours (and hence at most $\Delta-1$ colours in its neighbourhood). Thus, we need to consider only the case where each vertex is of degree exactly $\Delta$.

## 2 The First Proof

In this section we modify the proof of Melnikov and Vizing [7] and Wilson [9]. Some of these techniques are also described in [8].

Delete any vertex $v$. As the graph is no longer $\Delta$-regular, it can be coloured with $\Delta$ colours in linear time. In the original graph, all vertices except vertex $v$ are coloured. If a colour is absent at $v$, then we can easily colour $v$.

Thus, consider the case where $v$ has $\Delta$ neighbours (say) $v_{1}, v_{2}, v_{3}, \ldots, v_{\Delta}$, of colours $1,2,3, \ldots, \Delta$ respectively. If a colour $\mu$ is absent at some $v_{j}$, then $v_{j}$ can be re-coloured with colour $\mu$, and then $v$ can be given colour $j$. Thus, we will, in the rest of the proof, assume that each $v_{i}$ has exactly one neighbour of each colour (other than colour $i$ ).

As the given graph $G$ does not contain a clique of $\Delta+1$ vertices, $v$ has two neighbours (say, without loss of generality, $v_{1}$ and $v_{3}$ ) that are not adjacent. Note that $v_{1}, v_{2}$ and $v_{3}$ are of colours 1,2 and 3 respectively.

If $v_{1}$ and $v_{3}$ are in different $1-3$ components, by interchanging colours 1 and 3 in one of those components, $v$ can be made to have two neighbours of the same colour, and hence $v$ can be given colour 1 or 3 . Thus, we need to consider only the case when $v_{1}$ and $v_{3}$ are in the same $1-3$ component. If the $1-3$ component containing $v_{1}$ and $v_{3}$ is not a simple path, then let $y$ be the first vertex (from $v_{1}$ ) that is of degree greater than two in the $1-3$ component. Then, as at least three neighbours of $y$ are coloured the same ( 1 or 3 ), at least one colour, say $\mu$, is absent at $y$. Give colour $\mu$ to $y$ and interchange colours 1 and 3 in the $1-3$ path from $v_{1}$ to (but excluding) $y$. As $v_{1}$ is now coloured $3, v$ can be given colour 1 . Thus, we can assume that the $1-3$ component containing $v_{1}$ and $v_{3}$ is a path.

Similarly, we may assume that $v_{2}$ and $v_{3}$ are in same $2-3$ component, $v_{1}$ and $v_{2}$ are in the same $1-2$ component, and these components are simple paths.

We next show how $v$ can be given a valid colour from only colours 1,2 and
3. Let $P_{13}$ be the $1-3$ path between $v_{1}$ and $v_{3}$. If not every vertex on this path has a neighbour coloured 2 , then let $x$ be the first vertex (from $v_{1}$ ) that does not have any neighbour of colour 2 . We recolour $x$ with colour 2 , and interchange colours 1 and 3 in the $v_{1}-x$ subpath of $P_{13}$. Thus, colour 1 becomes free at $v$ and can be used at $v$. Similarly process $P_{12}$, the $1-2$ path between $v_{1}$ and $v_{2}$, and $P_{23}$, the $2-3$ path between $v_{2}$ and $v_{3}$. Hence, we may assume that each vertex of any of paths $P_{12}, P_{13}, P_{23}$ has neighbour(s) of the third colour.

Next consider the case where edge $\left(v_{1}, v_{3}\right)$ is absent but edges $\left(v_{2}, v_{3}\right)$ and $\left(v_{1}, v_{2}\right)$ are both present. As each $v_{i}$ has exactly one neighbour of each of the $\Delta-1$ colours different from $i, v_{1}$ and $v_{3}$ are the neighbours of $v_{2}$ that are coloured 1 and 3 respectively, and $v_{2}$ is the only neighbour of $v_{1}$ and $v_{3}$ coloured 2. Thus we simultaneously recolour vertices $v_{1}$ and $v_{3}$ with colour 2 and vertex $v_{2}$ with colour 3 . As the result, colour 1 becomes free at $v$. So we can give colour 1 to $v$.

We are left with the case where edge $\left(v_{1}, v_{3}\right)$ is absent and at least one of edges $\left(v_{2}, v_{3}\right)$ or $\left(v_{1}, v_{2}\right)$ is absent. Without loss of generality, assume that edge $\left(v_{2}, v_{3}\right)$ is absent along with edge $\left(v_{1}, v_{3}\right)$. (Edge $\left(v_{1}, v_{2}\right)$ may or may not be present). Then paths $P_{13}$ and $P_{23}$ are nontrivial (in that they have intermediate vertices).

If any vertex on $P_{23}$ has two neighbours of colour 1 , then some colour $\mu$ is absent at it. Recolouring that vertex with $\mu$ ensures that $v_{2}$ and $v_{3}$ are not in the same $2-3$ component. Interchanging colours 2 and 3 in one of them solves the problem, as we have seen before.

So, assume that every vertex on $P_{23}$ has exactly one neighbour of colour 1.
Now interchange colours 1 and 3 in $P_{13}$. As a result, $v_{1}$ gets coloured 3 and $v_{3}$ gets coloured 1 and they are still in the same 1-3 component. The condition that each of $v_{1}$ and $v_{3}$ has all the colours in its neighbourhood continues to be valid. Also, note that the neighbourhood of every vertex on $P_{23}$ remains intact.

Let $w$ be the neighbour of $v_{3}$ of colour 2 , and $P_{23}^{\prime}$ be the part of $P_{23}$ from $w$ to $v_{2}$. Let us interchange colours 2 and 3 in $P_{23}^{\prime}$. As a result, $v_{2}$ will get coloured 3 (and $w$ gets coloured 2).

If edge $\left(v_{1}, v_{2}\right)$ is not present, then the new colouring is valid. As both $v_{1}$ and $v_{2}$ are now coloured 3 , colour 2 becomes free and can be used at $v$.

If edge $\left(v_{1}, v_{2}\right)$ is present, then the above colouring is not valid. Give colour 2 to $v_{1}$. In the previous colouring $v_{1}$ was the only neighbour of colour 1 of $v_{2}$. So, $v_{2}$ now has no neighbour of colour 1, and thus can be given colour 1. Colour 3 remains free and can be used at $v$.

Since, each edge on these three paths is examined at most twice, we can colour $v$ in linear time.

## 3 The Second Proof

We combine elements from the proofs of Zajac [10] and Bondy [2, 3] to obtain a simpler proof.

Pick any vertex $v$ of $G$; as $G$ is not $K_{\Delta}, v$ has a pair of non-adjacent neighbours $x$ and $y$. Run DFS starting at $x$, first choosing edge $(x, v)$ and then edge $(v, y)$.

Either the DFS tree is a simple path (Hamiltonian path) or the DFS tree has a node with two children.
Case 1: (The DFS tree is a Hamiltonian path.) As $\Delta \geq 3, v$ must have a neighbour $z$ other than $x$ and $y$. Give colour 1 to both $x$ and $y$. Colour the vertices on the path starting from the child of $y$ to the vertex just before $z$ (leaving $z$ uncoloured for now) in that order. Next colour the vertices on the path starting from the last vertex (the only leaf) back to $z$ in that order. Vertex $v$ can now be coloured.
Case 2: (The DFS tree has a node with two children.) Assume that $p$ is the first vertex that has two children (say, $s$ and $t$ ).

Case 2a: (At least either of $s$ and $t$, w.l.g., say $s$, is a separation point [2, 6. .) If there is no edge from any proper ancestor of $s$ to any proper descendent of $s$, then $s$ is a separation vertex [1].

Remove $s$, and the remnant graph has two components $C_{1}$ and $C_{2}$. Colour each component separately. Now consider the subgraphs $C_{1}+s$ and $C_{2}+s$. As $s$ has fewer than $\Delta$ neighbours in each subgraph, $s$ can be coloured in each using one of the $\Delta$ colours. Interchange a pair of colours in one of the subgraphs so that $s$ gets a common colour.

Case 2b: (Neither $s$ nor $t$ is a separation point.) As we are working with a DFS tree, $(s, t)$ can not be a cross edge 11. Remove vertices $s$ and $t$. As there are edges from the subtree rooted at $s$ and $t$ to ancestors of $p$, removal of these vertices will not disconnect the graph.

Give colour 1 to both the vertices $s$ and $t$. Now run DFS starting at vertex $p$ in $G-\{s, t\}$. Colour the vertices of the DFS tree in post order. As $p$ has two neighbours of colour 1, one colour is available at $p$, when the colouring reaches there.
