(Dated: August 9, 2022)

We present the constraints on the axial-vector and pseudo-scalar mediated WIMP-nucleus interactions from the PandaX-4T experiment, using the data set corresponding to a total exposure of 0.63 tonne-year. No significant signal excess is observed, and the most stringent upper limits to date on the spin-dependent WIMP-neutron scattering cross section are set at 90% confidence level with the minimum WIMP-neutron scattering cross section of  $5.8 \times 10^{-42} \text{ cm}^2$  for WIMP mass of 40 GeV/ $c^2$ . Exclusion limits on the axial-vector and pseudo-scalar simplified models are also derived.

There are plenty of evidences indicating that a large amount of dark matter exists in our universe. However its nature is still elusive [1]. Weakly interacting massive particle (WIMP) is a plausible dark matter candidate which arises from super-symmetry model naturally. Various methods are utilized to hunt for WIMPs, including direct search, indirect search and the collider search. Based on the dual-phase xenon time projection chamber (TPC), the sensitivity of WIMP-nucleus interaction has been improved significantly over the past decades [2–7].

The PandaX-4T experiment, located at the China Jinping Underground Laboratory (CJPL) [8, 9], is one of the largest xenon TPC experiments with 3.7-tonne of liquid xenon in the sensitive volume. The cylindrical TPC is covered by 24 polytetrafluoroethylene (PTFE) panels on the side and 368 Hamamatsu R11410-23 3-inch photomultiplier tubes (PMTs) on the top and bottom, with four electrodes placed inside to construct the drift and extraction electric field. Once an incoming energetic particle scatters off xenon nuclei or electron, prompt scintillation light (S1) and ionized electrons are generated, the latter then drift upward to the liquid xenon surface and produce the electroluminescence light (S2) in the gaseous xenon region under the electric fields. Both S1 and S2are detected by the PMTs, from which the scattering position and deposited energy can be reconstructed. The ratio of S2 to S1 provides a powerful signal-background discrimination. More detailed description of PandaX-4T experiment can be found in Refs. [5, 10, 11].

The PandaX-4T experiment has set stringent constraints on the spin-independent (SI) WIMP-nucleon cross section upper limits, excluding  $3.8 \times 10^{-47} \text{cm}^2$ at 40 GeV/ $c^2$  WIMP mass and 90% confidence level (C.L.) [5]. The SI WIMP-nucleus interaction can be introduced by vector or scalar mediators with couplings to WIMPs and quarks in the simplified models. For axial-vector and pseudo-scalar mediators, the tree-level processes yield spin-dependent (SD) WIMP-nucleus interactions instead [12, 13]. Xenon-based experiments are also sensitive to the SD interactions thanks to the significant abundance of odd-A xenon isotopes with non-zero spin (26.4% spin-1/2 <sup>129</sup>Xe and 21.2% spin-3/2 <sup>131</sup>Xe in natural xenon) [14, 15]. The XENON1T experiment has pushed down the SD neutron-only cross-section limits to  $6.3\times10^{-42}{\rm cm}^2$  at 30 GeV/ $c^2$  WIMP mass and 90% C.L. In this letter, we present the search results of SD WIMPnucleus interactions and constraints on the corresponding mediators, based on the PandaX-4T commissioning run data. For pseudo-scalar mediator, due to the momentum suppression on the tree-level SD process, constraints are derived from the loop-level SI process instead.

As for axial-vector couplings to quarks and WIMPs, the WIMP-nucleus SD cross section can be evaluated from chiral effective field theory (EFT) [16–18], which is related to the total spin expectation values of the protons and neutrons in the nucleus in the limit of zero momentum transfer. Therefore, a common practice is to consider two special cases where the WIMPs couple only to protons or to neutrons. The corresponding scattering cross section is expressed as below,

$$\sigma_A = \frac{4\pi}{3(2J+1)} \left(\frac{\mu_A}{\mu_N}\right)^2 S_N(q^2)\sigma_N,\tag{1}$$

where N denotes the proton (p) or neutron (n),  $\mu_N$  is the

reduced mass for WIMP scattering off the nucleon, $\mu_A$ is the reduced mass of WIMP and the target nucleus,  $S_N(q^2)$  is the structure factor for "proton-only" or "neutron-only" cases [16]. Due to the cancellation between spins of nucleon pairs, the SD cross section with nucleus is dominated by the unpaired nucleon, which is neutron for <sup>129</sup>Xe and <sup>131</sup>Xe. It should be noticed that the cross section of "proton-only" case is significantly enhanced due to chiral two-body currents involving the exchange of a pion.

The differential event rate for the WIMP SD interaction can be then written as [19, 20]

$$\frac{dR}{dE} = \frac{\rho_{\chi}\sigma_A}{2m_{\chi}\mu_A^2}\eta(E),\tag{2}$$

where  $m_{\chi}$  and  $\rho_{\chi}$  are the WIMP mass and local density respectively,  $\sigma_A$  is the WIMP-nucleus cross section,  $\eta$  is the mean inverse speed of WIMP velocity distribution. It is recommended that  $\rho_{\chi} = 0.3 \text{ GeV}/(\text{c}^2 \cdot \text{cm}^3)$  and the WIMP motion obeys the standard halo model [21]. Explicitly, the most probable velocity of WIMP in Maxwellian distribution  $v_0 = 238 \text{ km/s}$ , the galactic escape velocity  $v_{\text{esc}} = 544 \text{ km/s}$  and the Earth velocity  $v_{\text{E}} = 254 \text{ km/s}$  are adopted in this analysis. The typical event rate as a function for nuclear recoil energy is shown in Fig. 1. Both the SD "proton-only" and "neutron-only" recoil energy spectra are plotted in addition to the SI case for the WIMP mass of 40 GeV/c<sup>2</sup> and 400 GeV/c<sup>2</sup>, with the detection efficiency [5] overlaid.

FIG. 1. Nuclear recoil energy spectra for the scattering of WIMP on PandaX-4T detector. The SI, SD proton-only, SD neutron-only are illustrated in blue, green and red curves with  $\sigma = 10^{-41} \text{cm}^2$  respectively. The dashed and solid curves represent the 40 GeV/c<sup>2</sup> and 400 GeV/c<sup>2</sup> WIMPs respectively. The detection efficiency of PandaX-4T experiment is plotted in dotted curve with the corresponding axis on the right.

We use the same data set and selections as the WIMP SI analysis [5]. In brief, the S1 signal region of interest requires the S1 in the range of 2 to 135 photoelectron(PE)

in the fiducial volume, and the S2 signal collected in the bottom PMT array  $(S2_b)$  is adopted to avoid bias from PMT saturation. The data is divided into five subsets, according to the detector status. The background models also inherit from Ref. [5] and the detailed values can be find in the Table II of Ref. [5]. The total live time is 86.0 days and the resulting exposure is 0.63 tonne-year.

The 90% confidence level (C.L.) upper limit of SD WIMP-nucleon cross section as a function of WIMP mass is calculated, utilizing the same statistical inference (profile likelihood ratio) in Ref. [5, 21]. The results are shown in Fig. 2 and Fig. 3, for "neutron-only" and "proton-only" interaction respectively. Selected experiment results are also plotted for comparison. In the WIMP mass above 6 GeV/c<sup>2</sup> region, the most stringent upper limit for "neutron-only" interaction in direct detection experiment is obtained, with a minimal cross section (90% C.L.) of  $5.8 \times 10^{-42}$  cm<sup>2</sup> at 40 GeV/c<sup>2</sup> and C.L. is obtained. For the "proton-only" interaction, the xenon detector technique is not competitive to PICO-60 [22] and the minimal cross section of  $1.7 \times 10^{-40}$  cm<sup>2</sup> for 40 GeV/c<sup>2</sup> WIMP is obtained.

FIG. 2. PandaX-4T 90% C.L. upper limit for the SD WIMPneutron cross section, overlaid with that from XENON1T 2019 [15] and PandaX-II 2018 [14]. The green band and dashed red curve represent the  $\pm 1\sigma$  sensitivity band and the median, respectively.

Constraints on the WIMP parameter space can be also provided by collider experiments such as the AT-LAS under various model assumptions. The benchmark models with mediators at the LHC are summarized in Refs. [23–25]. We consider two simplified models with an axial-vector mediator and a pseudo-scalar mediator respectively in this letter.

When the mediator is axial-vector, the mediator couples to all quark flavors equally with one unique coupling constant  $g_q$ , and thus it yields isoscalar couplings to neutrons and protons. In this model, there are four free parameters: WIMP mass  $m_{\chi}$ , mediator mass  $m_V$ , the

FIG. 3. PandaX-4T 90% C.L. upper limit for the SD WIMPproton cross section, overlaid with that from XENON1T 2019 [15], PandaX-II 2018 [14] and PICO-60 2019 [22]. The green band and dashed red curve represent the  $\pm 1\sigma$  sensitivity band and the median, respectively.

coupling of the mediator to WIMP  $g_{\chi}$  and the coupling of the mediator to quark  $g_q$ . Following the Ref. [26], both the tree-level amplitudes and the loop-level amplitudes are calculated, and the latter is negligible. The cross section is given in Ref. [24, 26] with the form

$$\sigma_{\chi N}^{\rm SD} = \frac{0.31 g_q^2 g_\chi^2 \mu_N^2}{\pi m_V^4},\tag{3}$$

where couplings  $g_q = 0.25$  and  $g_{\chi} = 1$  are adopted as a benchmark scenario. Based on this model, the signal energy spectra are generated and the same analysis method is applied. The 95% C.L. exclusion limit on mediator mass is obtained as shown in Fig. 4, with comparisons to collider experiments [27, 28], and other direct detection experiments [15, 29]. In addition, the renormalization group evolution (RGE) effect is considered to account for the corrections from mediator mass scale to the nuclear scale in direct detection [30]. The limit on the mediator mass with RGE effect is also shown in Fig. 4.

In the scenario of pseudo-scalar mediator model, which contains the SD tree-level contribution. However, the amplitudes are momentum-suppressed [31, 32]. The only non-suppressed amplitudes are from the SI interactions induced by loop diagrams. A distinct model, referred as 2HDM+a model, is recommended by the ATLAS/CMS DM Forum [23]. It is one of the simplest gauge-invariant and renormalizable extension of the simplified pseudoscalar model. It contains Higgs doublets (h/H) and a pseudo-scalar mediator (a). Following Ref. [12, 32, 33], the loop-level amplitudes are calculated from the effective Lagrangian. The loop level diagrams are shown as Fig. 5. The cross section is given by

$$\sigma_{\chi N}^{\rm SI} = \frac{\mu_N^2 |C_N^{\rm loop}|^2}{\pi},\tag{4}$$

FIG. 4. PandaX-4T 95% C.L. exclusion limit on the mediator mass for a simplified isoscalar model with an axialvector mediator and a Dirac WIMP, where the coupling constants  $g_q$  and  $g_{\chi}$  are 0.25 and 1, respectively. RGE effect is considered in the limit shown as dashed red line. The results from other direct detection experiments, XENON1T [15] and PICO-60 [29], and collider experiments, ATLAS [27] and CMS [28], are shown for comparison.

where the coefficient  $C_N^{\text{loop}}$  includes 11 free parameters, as described in Ref. [23]. In this letter, the following conventional values are adopted:

$$\tan(\beta) = 10, \alpha = \beta + \frac{\pi}{2}, m_h = 125 \text{ GeV},$$
  
$$m_H = m_{H^{\pm}} = m_A = 600 \text{ GeV}, m_a = 250 \text{ GeV}, \qquad (5)$$
  
$$\theta = 0.1, c1 = 0, c2 = 1, g_{\chi} = 1,$$

where  $\alpha$ ,  $\beta$  and  $\theta$  are the rotation angles.  $c_1$  and  $c_2$ are the coefficients of the quartic term in the interaction.  $g_{\chi}$  is the coupling constant between WIMP and mediator a.  $m_A$  is the mass eigenvalue of the mediator A.  $m_h, m_H, m_{H^+}$  and  $m_{H^-}$  are the mass eigenvalues of the higgs sectors  $h, H, H^+$  and  $H^-$ , respectively. Under this assumption, the normalized exclusion limit dependence (95% C.L.) on the WIMP mass is calculated and shown in Fig. 6. The normalized limit is expressed in terms of the ratio of the excluded cross section ( $\sigma$ ) to the nominal cross section of the model ( $\sigma_{\text{theory}}$ ). The nominal cross section is determined under the assumption that the couplings satisfy  $g_q = g_{\chi} = 1$ , as the Ref. [34] shows. Compared to the exclusion area set by ATLAS [34], PandaX-4T experiment is more sensitive when  $m_{\chi}$ is above several hundred  $\text{GeV}/c^2$ .

In conclusion, this letter presents the new limits on WIMP-nucleus SD interaction cross section from PandaX-4T commissioning data. The data analysis method, background models and statistical inference are identical to the PandaX-4T SI analysis [5]. The most stringent upper limit (90% C.L.) on WIMP-neutron cross section in direct search experiment is obtained, with the lowest value of  $5.8 \times 10^{-42}$  cm<sup>2</sup> at WIMP mass of 40 GeV/c<sup>2</sup>. The WIMP-proton interaction cross section

FIG. 5. The upper panel is the triangle diagram of scattering between dark matter in 2HDM+a model and nuclei [33].  $a_i, a_j$  represents the mediator a/A. The lower panel is the corresponding box diagrams in 2HDM+a model [33].  $a_i, a_j$ represents the mediator a/A.

FIG. 6. PandaX-4T 95% C.L. normalized exclusion limit (red solid) for pseudo-scalar mediator model as a function of WIMP mass. The green band shows the  $\pm 1\sigma$  sensitivity band. The normalized limit is expressed in terms of the ratio of the excluded cross section to the nominal cross section of the model. The 95% C.L. from ATLAS [34] (orange solid) is also shown for comparison. The relic density (blue dashed) for each WIMP mass [34] is overlaid and described by the right blue axis, based on the parameters shown in (5).

constraint at 90% C.L. is also obtained with the lowest value of  $1.7 \times 10^{-40}$  cm<sup>2</sup> at WIMP mass of 40 GeV/c<sup>2</sup>. In addition, the exclusion limits (95% C.L.) for two distinct simplified models are also calculated. Both the tree-level contribution and the loop-level contribution are considered. This result is complementary to that obtained from the collider experiment (ATLAS [27, 34] and CMS [28]) in the WIMP mass region above several hundred GeV/c<sup>2</sup>. The PandaX-4T experiment continues taking physics data and will scan unexplored parameter space further.

We would like to thank Tong Li and Wei Chao for helpful discussion. This project is supported in part by grants from National Science Foundation of China (Nos. 1209061, 12005131, 11905128, 11925502, 11735003, 11775141), a grant from the Ministry of Science and Technology of China (No. 2016YFA0400301), and by Office of Science and Technology, Shanghai Municipal Government (grant No. 18JC1410200). We thank supports from Double First Class Plan of the Shanghai Jiao Tong University. We also thank the sponsorship from the Chinese Academy of Sciences Center for Excellence in Particle Physics (CCEPP), Hongwen Foundation in Hong Kong, Tencent Foundation in China and Yangyang Development Fund. Finally, we thank the CJPL administration and the Yalong River Hydropower Development Company Ltd. for indispensable logistical support and other help.
