#### Abstract

Hadwiger's Conjecture from 1943 states that every graph with no $K_{t}$ minor is $(t-1)$ colorable; it remains wide open for all $t \geq 7$. For positive integers $t$ and $s$, let $\mathcal{K}_{t}^{-s}$ denote the family of graphs obtained from the complete graph $K_{t}$ by removing $s$ edges. We say that a graph $G$ has no $\mathcal{K}_{t}^{-s}$ minor if it has no $H$ minor for every $H \in \mathcal{K}_{t}^{-s}$. Jakobsen in 1971 proved that every graph with no $\mathcal{K}_{7}^{-2}$ minor is 6 -colorable. In this paper we consider the next step and prove that every graph with no $\mathcal{K}_{8}^{-4}$ minor is 7 -colorable. Our result implies that $H$-Hadwiger's Conjecture, suggested by Paul Seymour in 2017, is true for every graph $H$ on eight vertices such that the complement of $H$ has maximum degree at least four, a perfect matching, a triangle and a cycle of length four. Our proof utilizes an extremal function for $\mathcal{K}_{8}^{-4}$ minors obtained in this paper, generalized Kempe chains of contraction-critical graphs by Rolek and the second author, and the method for finding $K_{7}$ minors from three different $K_{5}$ subgraphs by Kawarabayashi and Toft; this method was first developed by Robertson, Seymour and Thomas in 1993 to prove Hadwiger's Conjecture for $t=6$.

## 1 Introduction

All graphs in this paper are finite and simple. For a graph $G$ we use $|G|, e(G), \delta(G), \Delta(G)$, $\alpha(G), \chi(G)$ to denote the number of vertices, number of edges, minimum degree, maximum degree, independence number, and chromatic number of $G$, respectively. The complement of $G$ is denoted by $\bar{G}$. For any positive integer k, we write $[k]$ for the set $\{1, \ldots, k\}$. A graph $H$ is a minor of a graph $G$ if $H$ can be obtained from a subgraph of $G$ by contracting edges. We write $G \succcurlyeq H$ if $H$ is a minor of $G$. In those circumstances we also say that $G$ has an $H$ minor. For positive integers $t, s$, we use $\mathcal{K}_{t}^{-s}$ to denote the family of graphs obtained from the complete graph $K_{t}$ by deleting $s$ edges. When $s \leq 2$, we use $K_{t}^{-}$to denote the unique graph in $\mathcal{K}_{t}^{-1}$; and $K_{t}^{=}$and $K_{t}^{<}$to denote the graphs obtained from $K_{t}$ by deleting two independent edges and two adjacent edges, respectively. Note that $\mathcal{K}_{t}^{-2}=\left\{K_{t}^{=}, K_{t}^{<}\right\}$. We say that a graph $G$ has no $\mathcal{K}_{t}^{-s}$ minor if it has no $H$ minor for every $H \in \mathcal{K}_{t}^{-s}$; and $G$ has a $\mathcal{K}_{t}^{-s}$ minor, otherwise. We write $G \succcurlyeq \mathcal{K}_{t}^{-s}$ if $G$ has a $\mathcal{K}_{t}^{-s}$ minor.

[^0]Our work is motivated by Hadwiger's Conjecture [11], which is perhaps the most famous conjecture in graph theory.

Conjecture 1.1 (Hadwiger's Conjecture [11). Every graph with no $K_{t}$ minor is $(t-1)$-colorable.
Conjecture 1.1 is trivially true for $t \leq 3$, and reasonably easy for $t=4$, as shown independently by Hadwiger [11] and Dirac [6]. However, for $t \geq 5$, Hadwiger's Conjecture implies the Four Color Theorem [2, 3]. Wagner [35] proved that the case $t=5$ of Hadwiger's Conjecture is, in fact, equivalent to the Four Color Theorem, and the same was shown for $t=6$ by Robertson, Seymour and Thomas [31]. Despite receiving considerable attention over the years, Hadwiger's Conjecture remains wide open for all $t \geq 7$, and is considered among the most important problems in graph theory and has motivated numerous developments in graph coloring and graph minor theory. Proving that graphs with no $K_{7}$ minor are 6 -colorable is thus the first case of Hadwiger's Conjecture that is still open. It is not even known yet whether every graph with no $K_{7}$ minor is 7 colorable; Rolek, Thomas and the second author [30] proved that every 8-contraction-critical graph with no $K_{7}$ minor has at most one vertex of degree eight. Jakobsen [13] in 1971 proved that every graph with no $K_{7}$ minor is 9-colorable. Kawarabayashi and Toft [15] in 2005 proved that every graph with no $K_{7}$ or $K_{4,4}$ minor is 6-colorable. Recently, Albar and Gonçalves [1] proved that every graph with no $K_{7}$ minor is 8 -colorable, and every graph with no $K_{8}$ minor is 10 -colorable. Their proofs are computer-assisted; Rolek and the second author [29] then gave computer-free proofs of their results, and further proved that every graph with no $K_{9}$ minor is 12 -colorable, and every graph with no $K_{t}$ minor is $(2 t-6)$-colorable for all $t \geq 10$ if Conjecture 5.1 in 29 holds.

Until very recently the best known upper bound on the chromatic number of graphs with no $K_{t}$ minor is $O\left(t(\log t)^{1 / 2}\right)$, obtained independently by Kostochka [17, 18] and Thomason [34], while Norin, Postle and the second author [26] improved the frightening $(\log t)^{1 / 2}$ term to $(\log t)^{1 / 4}$. The current record is $O(t \log \log t)$ due to Delcourt and Postle [10]. Kühn and Osthus [22] proved that Hadwiger's Conjecture is true for $C_{4}$-free graphs of sufficiently large chromatic number, and for all graphs of girth at least 19. We refer the reader to recent surveys [5, 16, 32] for further background on Hadwiger's Conjecture.

Given the difficulty of Hadwiger's Conjecture, Paul Seymour in 2017 suggested the study of the following $H$-Hadwiger's Conjecture.

Conjecture 1.2 (H-Hadwiger's Conjecture). For every graph $H$ on $t$ vertices, every graph with no $H$ minor is $(t-1)$-colorable.

It is worth noting that Wagner [36] in 1960 initiated the study of this type of problem and proved that every graph with no $K_{5}^{-}$minor is 4-colorable; Dirac [9] in 1964 proved that every graph with no $K_{6}^{-}$minor is 5-colorable; and Jakobsen [13] in 1971 proved that every graph with no $K_{7}^{-}$minor is 7 -colorable. Thus proving graphs with no $K_{7}^{-}$minor is 6 -colorable remains open. Rolek and the second author [29] in 2017 proved that every graph with no $K_{8}^{-}$minor is 9 -colorable. Very recently, Norin and Seymour [27] proved that every graph on $n$ vertices with independence number two has an $H$ minor, where $H$ is a graph with $\lceil n / 2\rceil$ vertices and at least $0.98688 \cdot\binom{|H|}{2}-o\left(n^{2}\right)$ edges.

Woodall [37] studied a special case of $H$-Hadwiger's Conjecture in 2001 by excluding the complete bipartite graph $K_{s, t}$ minor and made the following conjecture.

Conjecture 1.3 (Woodall [37]). Every graph with no $K_{s, t}$ minor is $(s+t-1)$-colorable.
In the same paper Woodall confirmed Conjecture 1.3 for $s \in\{1,2\}$ without using the extremal function for $K_{s, t}$ minors. The $s=2$ case also follows from the extremal function for $K_{2, t}$ minors by Myers [25], and Chudnovsky, Reed and Seymour [4]; the $s=3$ case when $t \geq 6300$ follows from the extremal function for $K_{3, t}$ minors by Kostochka and Prince [20]. Asymptomatic bounds for the chromatic number of graphs with no $K_{s, t}$ minor, when $t$ is sufficiently larger than $s$, follow from the extremal functions for $K_{s, t}$ minors by Kühn and Osthus [23], and Kostochka and Prince [19]; in particular, the extremal function by Kostochka and Prince implies that every graph with no $K_{s, t}$ minor is $(3 s+t-1)$-colorable when $t$ is sufficiently larger than $s$. Years later Kostochka [21] proved that Conjecture 1.3 is true for $t>C(s \log s)^{3}$.

Dirac in 1964 began the study of a variation of $H$-Hadwiger's Conjecture in [8] by excluding more than one forbidden minor simultaneously; he proved that every graph with no $\mathcal{K}_{t}^{-2}$ minor is $(t-1)$-colorable for each $t \in\{5,6\}$. Jakobsen [12] in 1971 proved that every graph with no $\mathcal{K}_{7}^{-2}$ minor is 6 -colorable; this implies that $H$-Hadwiger's Conjecture is true for all graphs $H$ on seven vertices such that $\Delta(\bar{H}) \geq 2$ and $\bar{H}$ has a matching of size two. Recently, Rolek and the second author [29] proved that every graph with no $\mathcal{K}_{8}^{-2}$ minor is 8-colorable, and Rolek [28] later proved that every graph with no $\mathcal{K}_{9}^{-2}$ minor is 10 -colorable. Proving that every graph with no $\mathcal{K}_{8}^{-2}$ minor is 7 -colorable is still open. We state the result of Jakobsen [12] below.

Theorem 1.4 (Jakobsen [12]). Every graph with no $\mathcal{K}_{7}^{-2}$ minor is 6 -colorable. In particular, $H$ Hadwiger's Conjecture is true for all graphs $H$ on seven vertices such that $\Delta(\bar{H}) \geq 2$ and $\bar{H}$ has a matching of size two.

The purpose of this paper is to consider the next step and prove the following main result.
Theorem 1.5. Every graph with no $\mathcal{K}_{8}^{-4}$ minor is 7 -colorable.
There are 11 ways to delete four edges from $K_{8}$, including four edges that form a perfect matching and four edges that are incident with the same vertex. Let $H$ be a graph on eight vertices such that $\Delta(\bar{H}) \geq 4$, and $\bar{H}$ has a perfect matching, a triangle and a cycle of length four. It is simple to check that every graph with no $H$ minor has no $\mathcal{K}_{8}^{-4}$ minor. Combining this with Theorem 1.5 leads to the observation that $H$-Hadwiger's Conjecture is true for all such graphs $H$. In particular, $H$-Hadwiger's Conjecture is true for five graphs $H$ obtained from $K_{8}$ by deleting eight edges, where $\bar{H}$ is given in Figure 1 .

Corollary 1.6. H-Hadwiger's Conjecture is true for all graphs $H$ on eight vertices such that $\Delta(\bar{H}) \geq 4$, and $\bar{H}$ has a perfect matching, a triangle and a cycle of length four.

Our proof of Theorem 1.5 utilizes an extremal function for $\mathcal{K}_{8}^{-4}$ minors (see Theorem 1.7), generalized Kempe chains of contraction-critical graphs obtained by Rolek and the second author [29]

Figure 1: Five non-isomorphic $\bar{H}$.
(see Lemma 2.4), and the method for finding $K_{7}$ minors from three different $K_{5}$ subgraphs by Kawarabayashi and Toft [15] (see Theorem 2.7).

Theorem 1.7. Every graph on $n \geq 8$ vertices with at least $4.5 n-12$ edges has a $\mathcal{K}_{8}^{-4}$ minor.
Theorem 1.7 is best possible in the sense that every ( $K_{2,2,2,2}, 4$ )-cockade (see the definition of an ( $H, k$ )-cockade in [33]) on $n$ vertices has $4.5 n-12$ edges but no $\mathcal{K}_{8}^{-3}$ minor.

This paper is organized as follows. In the next section, we introduce the necessary definitions and collect several tools which we will need later on. In Section 3, we prove Theorem 1.5. In Section 4, we prove Theorem 1.7 using more involved arguments.

## 2 Notation and tools

Let $G$ be a graph. If $x, y$ are adjacent vertices of $G$, then we denote by $G / x y$ the graph obtained from $G$ by contracting the edge $x y$ and deleting all resulting parallel edges. We simply write $G / e$ if $e=x y$. If $u, v$ are distinct nonadjacent vertices of $G$, then by $G+u v$ we denote the graph obtained from $G$ by adding an edge with ends $u$ and $v$. If $u, v$ are adjacent or equal, then we define $G+u v$ to be $G$. Similarly, if $M \subseteq E(G) \cup E(\bar{G})$, then by $G+M$ we denote the graph obtained from $G$ by adding all the edges of $M$ to $G$. Every edge in $\bar{G}$ is called a missing edge of $G$. For a vertex $x \in V(G)$, we will use $N(x)$ to denote the set of vertices in $G$ which are adjacent to $x$. We define $N[x]=N(x) \cup\{x\}$. The degree of $x$ is denoted by $d_{G}(x)$ or simply $d(x)$. If $A, B \subseteq V(G)$ are disjoint, we say that $A$ is complete to $B$ if each vertex in $A$ is adjacent to all vertices in $B$, and $A$ is anticomplete to $B$ if no vertex in $A$ is adjacent to any vertex in $B$. If $A=\{a\}$, we simply say $a$ is complete to $B$ or $a$ is anticomplete to $B$. We use $e(A, B)$ to denote the number of edges between $A$ and $B$ in $G$. The subgraph of $G$ induced by $A$, denoted by $G[A]$, is the graph with vertex set $A$ and edge set $\{x y \in E(G) \mid x, y \in A\}$. We denote by $B \backslash A$ the set $B-A$, and $G \backslash A$ the subgraph of $G$ induced on $V(G) \backslash A$, respectively. If $A=\{a\}$, we simply write $B \backslash a$ and $G \backslash a$, respectively. An $(A, B)$-path in $G$, when $A$ and $B$ are not necessarily disjoint, is a path with one end in $A$ and the other in $B$ such that all its internal vertices lie in $G \backslash(A \cup B)$. We simply say an ( $a, B$ )-path if $A=\{a\}$. It is worth noting that each vertex in $A \cap B$ is an $(A, B)$-path. For a positive integer $k$, a $k$-vertex is a vertex of degree $k$, and a $k$-clique is a set of $k$ pairwise adjacent vertices. Let $\mathcal{F}$ be a family of graphs. A graph $G$ is $\mathcal{F}$-free if it has no subgraph isomorphic to $H$ for every $H \in \mathcal{F}$. We simply say $G$ is $H$-free if $\mathcal{F}=\{H\}$. The join $G+H$ (resp. union $G \cup H$ )
of two vertex-disjoint graphs $G$ and $H$ is the graph having vertex set $V(G) \cup V(H)$ and edge set $E(G) \cup E(H) \cup\{x y \mid x \in V(G), y \in V(H)\}$ (resp. $E(G) \cup E(H)$ ). We use the convention "A :=" to mean that $A$ is defined to be the right-hand side of the relation. Finally, if $H$ is a connected subgraph of a graph $G$ and $y \in V(H)$, we simply say that we contract $H \backslash y$ onto $y$ when we contract $H$ to a single vertex, that is, contract all the edges of $H$.

To prove Theorem 1.5, we need to investigate the basic properties of contraction-critical graphs. For a positive integer $k$, a graph $G$ is $k$-contraction-critical if $\chi(G)=k$ and every proper minor of $G$ is $(k-1)$-colorable. Lemma 2.1 is a result of Dirac [7].

Lemma 2.1 (Dirac [7). Let $G$ be a $k$-contraction-critical graph. Then for each $v \in V(G)$,

$$
\alpha(G[N(v)]) \leq d(v)-k+2 .
$$

We will make use of the following results of Mader [24]. It seems very difficult to improve Theorem 2.3; it remains open whether every $k$-contraction-critical graph is 8 -connected for all $k \geq 8$. Let $z_{1}, z_{2}, z_{3}, z_{4}$ be four vertices in a graph $G$. We say that $G$ contains a $K_{4}$ minor rooted at $z_{1}, z_{2}, z_{3}, z_{4}$ if there exist $Z_{1}, Z_{2}, Z_{3}, Z_{4} \subseteq V(G)$ such that $z_{i} \in Z_{i}$ and $G\left[Z_{i}\right]$ is connected for all $i \in[4]$, and $Z_{i}$ and $Z_{j}$ are disjoint and there is an edge between $Z_{i}$ and $Z_{j}$ in $G$ for $1 \leq i<j \leq 4$.

Theorem 2.2 (Mader [24]). For all $i \in[4]$, let $Z_{i} \subseteq V(G)$ with $z_{i} \in Z_{i}$ such that $Z_{i} \cap Z_{j}=\emptyset$ for $1 \leq i<j \leq 4$, and $\alpha\left(G\left[\left\{z_{1}, z_{2}, z_{3}, z_{4}\right\}\right] \leq 2\right.$. If there exists a $\left(z_{i}, z_{j}\right)$-path consisting only of vertices from $Z_{i} \cup Z_{j}$ for $1 \leq i<j \leq 4$, then $G$ has a $K_{4}$ minor rooted at $\left\{z_{1}, z_{2}, z_{3}, z_{4}\right\}$.

Theorem 2.3 (Mader [24]). For all $k \geq 7$, every $k$-contraction-critical graph is 7 -connected.
Lemma 2.4 on contraction-critical graphs turns out to be very powerful, as the existence of pairwise vertex-disjoint paths is guaranteed without using the connectivity of such graphs. The proof of Lemma 2.4 uses Kempe chains. We recall the proof here as it will be needed in the proof of Lemma 2.5. Recall that every edge in $\bar{H}$ is a missing edge of a graph $H$.

Lemma 2.4 (Rolek and Song [29]). Let $G$ be any $k$-contraction-critical graph. Let $x \in V(G)$ be a vertex of degree $k+s$ with $\alpha(G[N(x)])=s+2$ and let $S \subset N(x)$ with $|S|=s+2$ be any independent set, where $k \geq 4$ and $s \geq 0$ are integers. Let $M$ be a set of missing edges of $G[N(x) \backslash S]$. Then there exists a collection $\left\{P_{u v} \mid u v \in M\right\}$ of paths in $G$ such that for each $u v \in M, P_{u v}$ has ends $u, v$ and all its internal vertices in $G \backslash N[x]$. Moreover, if vertices $u, v, w, z$ with $u v, w z \in M$ are distinct, then the paths $P_{u v}$ and $P_{w z}$ are vertex-disjoint.

Proof. Let $G, x, S$ and $M$ be given as in the statement. Let $H$ be obtained from $G$ by contracting $S \cup\{x\}$ to a single vertex, say $w$. Then $H$ is $(k-1)$-colorable. Let $c: V(H) \rightarrow\{1,2, \ldots, k-1\}$ be a proper $(k-1)$-coloring of $H$. We may assume that $c(w)=1$. Then each of the colors $2, \ldots, k-1$ must appear in $G[N(x) \backslash S]$, else we could assign $x$ the missing color and all vertices in $S$ the color 1 to obtain a proper $(k-1)$-coloring of $G$, a contradiction. Since $|N(x) \backslash S|=k-2$, we have $c(u) \neq c(v)$ for any two distinct vertices $u, v$ in $G[N(x) \backslash S]$. We next claim that for each $u v \in M$ there must exist a path between $u$ and $v$ with its internal vertices in $G \backslash N[x]$. Suppose not. Let
$H^{*}$ be the subgraph of $H$ induced by the vertices colored $c(u)$ or $c(v)$ under the coloring $c$. Then $V\left(H^{*}\right) \cap N(x)=\{u, v\}$. Notice that $u$ and $v$ must belong to different components of $H^{*}$ as there is no path between $u$ and $v$ with its internal vertices in $G \backslash N[x]$. By switching the colors on the component of $H^{*}$ containing $u$, we obtain a $(k-1)$-coloring of $H$ with the color $c(u)$ missing on $G[N(x) \backslash S]$, a contradiction. This proves that there must exist a path $P_{u v}$ in $H^{*}$ with ends $u, v$ and all its internal vertices in $H^{*} \backslash N[x]$ for each $u v \in M$. Clearly, for any $u v, w z \in M$ with $u, v, w, z$ distinct, the paths $P_{u v}, P_{w z}$ are vertex-disjoint, because no two vertices of $u, v, w, z$ are colored the same under the coloring $c$.

We shall make frequent use of the following lemma in the proof of Theorem 1.5.
Lemma 2.5. Let $G$ be any $k$-contraction-critical graph. Let $x \in V(G)$ be a vertex of degree $k+s$ with $\alpha(G[N(x)])=s+2$ and let $S \subset N(x)$ with $|S|=s+2$ be any independent set, where $k \geq 4$ and $s \geq 0$ are integers. If $M=\left\{x_{1} y_{1}, x_{1} y_{2}, x_{2} y_{1}, x_{2} y_{2}, a_{1} b_{11}, \ldots, a_{1} b_{1 r_{1}}, \ldots, a_{m} b_{m 1}, \ldots, a_{m} b_{m r_{m}}\right\}$ is $a$ set of missing edges of $G[N(x) \backslash S]$, where the vertices $x_{1}, x_{2}, y_{1}, y_{2}, a_{1}, \ldots, a_{m}, b_{11}, \ldots, b_{m r_{m}} \in N(x) \backslash S$ are all distinct, and for all $1 \leq i \leq m, a_{i} b_{i 1}, \ldots, a_{i} b_{i r_{i}}$ are $r_{i}$ missing edges with $a_{i}$ as a common end, and $x_{1} x_{2}, y_{1} y_{2} \in E(G)$, then $G \succcurlyeq G[N[x]]+M$.

Proof. By Lemma 2.4 there exists a collection $\left\{P_{u v} \mid u v \in M\right\}$ of paths in $G$ such that for each $u v \in M, P_{u v}$ has ends $u, v$ and all its internal vertices in $G \backslash N[x]$. In particular, for any $1 \leq i<j \leq m$, the paths $P_{a_{i} b_{i 1}}, \ldots, P_{a_{i} b_{i r_{i}}}$ are vertex-disjoint from the paths $P_{a_{j} b_{j 1}}, \ldots, P_{a_{j} b_{j r_{j}}}$ and $P_{x_{1} y_{1}}, P_{x_{1} y_{2}}, P_{x_{2} y_{1}}, P_{x_{2} y_{2}} ; P_{x_{1} y_{1}}$ and $P_{x_{2} y_{2}}$ are vertex-disjoint; $P_{x_{1} y_{2}}$ and $P_{x_{2} y_{1}}$ are vertex-disjoint but each of $P_{x_{1} y_{2}}$ and $P_{x_{2} y_{1}}$ is not necessarily vertex-disjoint from $P_{x_{1} y_{1}}$ and $P_{x_{2} y_{2}}$. By contracting each of $P_{a_{i} b_{i \ell}} \backslash b_{i \ell}$ onto $a_{i}$ for all $i \in[m]$ and $\ell \in\left[r_{i}\right]$, we see that $G \succcurlyeq G[N[x]]+(M \backslash$ $\left.\left\{x_{1} y_{1}, x_{1} y_{2}, x_{2} y_{1}, x_{2} y_{2}\right\}\right)$. We next apply Theorem 2.2 to show that $G \succcurlyeq G[N[x]]+M$.

Let $z_{1}=x_{1}, z_{2}=x_{2}, z_{3}=y_{1}, z_{4}=y_{2}$. From the proof of Lemma 2.4, each of $P_{x_{1} y_{1}}, P_{x_{1} y_{2}}$, $P_{x_{2} y_{1}}, P_{x_{2} y_{2}}$ is a Kempe chain, and vertices of $z_{1}, z_{2}, z_{3}, z_{4}$ are colored differently under the coloring $c$, where $c$ is given in the proof of Lemma 2.4. For each $i \in[4]$, let $Z_{i}$ be the set of vertices $v$ of $G\left[V\left(P_{x_{1} y_{1}}\right) \cup V\left(P_{x_{1} y_{2}}\right) \cup V\left(P_{x_{2} y_{1}}\right) \cup V\left(P_{x_{2} y_{2}}\right)\right]$ such that $c(v)=c\left(z_{i}\right)$. Then $z_{i} \in Z_{i}$ and $Z_{i} \cap Z_{j}=\emptyset$ for $1 \leq i<j \leq 4$. Note that $\alpha\left(G\left[\left\{z_{1}, z_{2}, z_{3}, z_{4}\right\}\right] \leq 2\right.$ because $z_{1} z_{2}, z_{3} z_{4} \in E(G)$; the $\left(z_{1}, z_{2}\right)$-path has only one edge $z_{1} z_{2}$, the $\left(z_{3}, z_{4}\right)$-path has only one edge $z_{3} z_{4}$, and the $\left(z_{i}, z_{j}\right)$-path for each $i \in[2]$ and $j \in\{3,4\}$ is $P_{x_{i} y_{j}}$. By Theorem 2.2, we see that $G\left[V\left(P_{x_{1} y_{1}}\right) \cup V\left(P_{x_{1} y_{2}}\right) \cup V\left(P_{x_{2} y_{1}}\right) \cup V\left(P_{x_{2} y_{2}}\right)\right]$ has a $K_{4}$ minor rooted at $z_{1}, z_{2}, z_{3}, z_{4}$. It follows that $G \succcurlyeq G[N[x]]+M$, as desired.

Remark 2.6. Lemma 2.5 can be applied when

$$
M=\left\{x_{1} y_{1}, x_{1} y_{2}, x_{2} y_{1}, x_{2} y_{2}, a_{1} b_{11}, \ldots, a_{1} b_{1 r_{1}}, \ldots, a_{m} b_{m 1}, \ldots, a_{m} b_{m r_{m}}\right\}
$$

is a subset of edges and missing edges of $G[N(x) \backslash S]$, where $x_{1}, x_{2}, y_{1}, y_{2}, a_{1}, \ldots, a_{m}, b_{11}, \ldots, b_{m r_{m}} \in$ $N(x) \backslash S$ are all distinct, and $x_{1} x_{2}, y_{1} y_{2} \in E(G)$. Under those circumstances, it suffices to apply Lemma 2.5 to $M^{*}$, where $M^{*}=\{e \in M \mid e$ is a missing edge of $\left.G[N(x) \backslash S])\right\}$. It is straightforward to see that $G \succcurlyeq G[N[x]]+M$.

Figure 2: The nine possibilities for three 5-cliques in Theorem 2.7.
Finally we need a tool to find a desired $\mathcal{K}_{8}^{-4}$ minor through three different 5 -cliques in 7 connected graphs. This method was first introduced by Robertson, Seymour and Thomas [31 to prove Hadwiger's Conjecture for $t=6$ : they found a desired $K_{6}$ minor via three different 4-cliques in 6 -connected non-apex graphs. This method was later extended by Kawarabayashi and Toft [15] to find a desired $K_{7}$ minor via three different 5 -cliques in 7 -connected graphs.

Theorem 2.7 (Kawarabayashi and Toft [15]). Let $G$ be a 7 -connected graph such that $|G| \geq 19$. If $G$ contains three different 5 -cliques, say $L_{1}, L_{2}, L_{3}$, such that $\left|L_{1} \cup L_{2} \cup L_{3}\right| \geq 12$, that is, they fit into one of the nine configurations depicted in Figure 园, then $G \succcurlyeq K_{7}$. In particular, $G$ has seven pairwise vertex-disjoint "good paths", where a "good path" is an ( $L_{i}, L_{j}$ )-path in $G$ with $i \neq j$.

It is worth noting that Theorem 2.7 corresponds to [15, Lemma 5], where the existence of such seven "good paths" follows from the proof of [15, Lemma 5]. Theorem 2.7 implies the following:

Corollary 2.8. Let $G$ be a 7 -connected graph such that $|G| \geq 19$. If $G$ contains three different 5-cliques, say $L_{1}, L_{2}, L_{3}$, such that $\left|L_{1} \cup L_{2} \cup L_{3}\right| \geq 12$, that is, they fit into one of the nine configurations depicted in Figure 2, then $G \succcurlyeq \mathcal{K}_{8}^{-4}$. Moreover, if $L_{1} \cap L_{2} \cap L_{3}=\emptyset$, then $G \succcurlyeq \mathcal{K}_{8}^{-3}$. Proof. By Theorem [2.7, $G$ has seven pairwise vertex-disjoint "good paths". By choosing such seven
"good paths", say $Q_{1}, \ldots, Q_{7}$, with $\left|V\left(Q_{1}\right) \cup \ldots \cup V\left(Q_{7}\right)\right|$ minimum, we may assume that no internal vertex of each $Q_{i}$ lies in $L_{1} \cup L_{2} \cup L_{3}$. Moreover, if $v \in L_{i} \cap L_{j}$ for some $i \neq j$, then $v$ does not belong to any "good path" on at least two vertices. It is then straightforward to verify that each possibility of $L_{1}, L_{2}, L_{3}$, given in Figure $2(\mathrm{a}-\mathrm{g})$, together with $Q_{1}, \ldots, Q_{7}$, yields a $\mathcal{K}_{8}^{-3}$ minor; and each possibility of $L_{1}, L_{2}, L_{3}$, given in Figure $2(\mathrm{~h}, \mathrm{i})$, together with $Q_{1}, \ldots, Q_{7}$, yields a $\mathcal{K}_{8}^{-4}$ minor, as desired.

Figure 3: The graph $H_{8}$.

Finally we need a lemma of Rolek, Thomas and the second author.
Lemma 2.9 (Rolek, Song and Thomas [30]). Let $H$ be a graph with $|H|=8$ and $\alpha(H)=2$. Then $H$ contains $K_{4}$ or $H_{8}$ as a subgraph, where $H_{8}$ is depicted in Figure 3.

## 3 Coloring graphs with no $\mathcal{K}_{8}^{-4}$ minor

We begin this section with two lemmas. Lemma 3.1 below follows directly from Lemma 2.5 . We give a proof here without using Theorem 2.2 (its proof was written in German).

Figure 4: Applying Lemma 2.4 to $N(x)$ with $S=\left\{w_{1}, w_{6}\right\}$ and $M=\left\{w_{2} w_{5}, w_{3} w_{8}, w_{4} w_{7}, w_{3} w_{7}\right\}$.

Lemma 3.1. Let $G$ be an 8 -contraction-critical graph. If there exists $x \in V(G)$ such that $G[N(x)]$ is isomorphic to $H_{8}$, then $G \succcurlyeq \mathcal{K}_{8}^{-3}$.

Proof. Suppose $G[N(x)]=H_{8}$ for some $x \in V(G)$. Let $w_{1}, \ldots, w_{8}$ be the vertices of $N(x)$ as depicted in Figure 4. Note that $\left|H_{8}\right|=8$ and $\alpha\left(H_{8}\right)=2$. By Lemma 2.4 applied to $N(x)$ with $S=\left\{w_{1}, w_{6}\right\}$ and $M=\left\{w_{2} w_{5}, w_{3} w_{8}, w_{4} w_{7}, w_{3} w_{7}\right\}$, there exist pairwise vertex-disjoint paths $Q_{1}, Q_{2}, Q_{3}$ and another path $Q_{4}$ such that $Q_{1}, Q_{2}, Q_{3}, Q_{4}$ have ends in $\left\{w_{2}, w_{5}\right\},\left\{w_{3}, w_{8}\right\},\left\{w_{4}, w_{7}\right\}$ and $\left\{w_{3}, w_{7}\right\}$, respectively, and all their internal vertices are in $G \backslash N[x]$. Note that $Q_{4}$ and $Q_{2}$ may have more than $w_{3}$ in common, and $Q_{4}$ and $Q_{3}$ may have more than $w_{7}$ in common; see Figure 4 Let $u \in V\left(Q_{4}\right) \cap V\left(Q_{2}\right)$ such that the $\left(w_{7}, u\right)$-subpath $Q_{4}^{\prime}$ of $Q_{4}$ and $Q_{2}$ have exactly $u$ in common; and let $v \in V\left(Q_{4}^{\prime}\right) \cap V\left(Q_{3}\right)$ such that the $(u, v)$-subpath $Q_{4}^{\prime \prime}$ of $Q_{4}^{\prime}$ and $Q_{3}$ have exactly $v$ in common. Let $Q_{4}^{\prime \prime \prime}$ denote the $\left(w_{7}, v\right)$-subpath of $Q_{4}^{\prime}$. By contracting $Q_{1} \backslash w_{5}$ onto $w_{2}$, both $Q_{2} \backslash w_{8}$ and $Q_{4}^{\prime \prime} \backslash v$ onto $w_{3}$, and both $Q_{3} \backslash w_{4}$ and $Q_{4}^{\prime \prime \prime}$ onto $w_{7}$, we see that $H_{8}+M$ has a $\mathcal{K}_{7}^{-3}$ minor after contracting the edge $w_{6} w_{8}$. Hence $G \succcurlyeq G[N[x]]+M \succcurlyeq \mathcal{K}_{8}^{-3}$, as desired.

Lemma 3.2. Let $G$ be an 8-contraction-critical graph. If $G$ has $a$-clique $A$ and a-clique $B$ such that $B \nsubseteq A$, then $G \succcurlyeq \mathcal{K}_{8}^{-3}$.

Proof. Let $A:=\left\{a_{1}, \ldots, a_{6}\right\}$ and $B:=\left\{b_{1}, \ldots, b_{5}\right\}$. Let $t:=|A \cap B|$. Then $0 \leq t \leq 4$ because $B \nsubseteq A$. We may further assume that $b_{i}=a_{i}$ for each $i \in[t]$ when $t \neq 0$. Assume first $t=4$. Then $G[A \cup B]$ contains $K_{7}^{<}$as a subgraph. By Theorem 2.3, $G$ is 7 -connected. We obtain a $K_{8}^{<}$ minor by contracting a component of $G \backslash(A \cup B)$ to a single vertex, as desired. We may assume that $0 \leq t \leq 3$. Then there exist $5-t$ pairwise vertex-disjoint paths $Q_{t+1}, \ldots, Q_{5}$ between $A \backslash B$ and $B \backslash A$ in $G \backslash(A \cap B)$. We may assume that $Q_{i}$ has ends $a_{i}, b_{i}$ for each $i \in\{t+1, \ldots, 5\}$. Then $G \backslash\left\{a_{1}, \ldots, a_{5}\right\}$ is connected, so there must exist a path $Q$ with one end $a_{6}$ and the other in $V\left(Q_{t+1} \backslash a_{t+1}\right) \cup \cdots \cup V\left(Q_{5} \backslash a_{5}\right)$, say in $V\left(Q_{5} \backslash a_{5}\right)$. We may assume that $Q$ is vertex-disjoint from $Q_{t+1}, \ldots, Q_{4}$ by choosing $Q$ to be a shortest such path. Now contracting both $Q_{5} \backslash a_{5}$ and $Q \backslash a_{6}$ onto $b_{5}, Q_{4} \backslash a_{4}$ onto $b_{4}$, and all the edges of $Q_{j}$ for each $j \in\{t+1, \ldots, 3\}$ when $t \leq 2$, we see that $G \succcurlyeq G[A \cup B]+\left\{a_{t+1} b_{t+1}, \ldots, a_{5} b_{5}, a_{6} b_{5}\right\} \succcurlyeq \mathcal{K}_{8}^{-3}$.

We are now ready to prove Theorem 1.5, which we restate for convenience.
Theorem 1.5. Every graph with no $\mathcal{K}_{8}^{-4}$ minor is 7 -colorable.
Proof. Suppose the assertion is false. Let $G$ be a graph with no $\mathcal{K}_{8}^{-4}$ minor such that $\chi(G) \geq 8$. We may choose such a graph $G$ so that it is 8 -contraction-critical. Then $\delta(G) \geq 7, G$ is 7 -connected by Theorem 2.3, and $\delta(G) \leq 8$ by Theorem 1.7. Let $x \in V(G)$ be of minimum degree. Since $G$ is 8 -contraction-critical and has no $\mathcal{K}_{8}^{-4}$ minor, by Lemma 2.1 applied to $G[N(x)]$, we see that
(1) $\delta(G)=8$ and $\alpha(G[N(x)])=2$.
(2) $G$ is $\mathcal{K}_{7}^{-4}$-free.

Proof. Suppose $G$ contains an $H \in \mathcal{K}_{7}^{-4}$ as a subgraph. Since $G$ is 7 -connected, we obtain a $\mathcal{K}_{8}^{-4}$ minor of $G$ by contracting a component of $G \backslash V(H)$ to a single vertex, a contradiction.
(3) $G[N(x)]$ contains a 4-clique.

Proof. Suppose $G[N(x)]$ is $K_{4}$-free. By Lemma 2.9, $G[N(x)]$ contains $H_{8}$ as a subgraph. Let the vertices of $H_{8}$ be labeled as in Figure 4. Then $w_{1} w_{6} \notin E(G)$ because $G[N(x)]$ is $K_{4}$-free. We consider the worst scenario that $G[N(x)]=H_{8}$. By Lemma 3.1, $G \succcurlyeq \mathcal{K}_{8}^{-3}$, a contradiction.
(4) $n_{8} \geq 25$, where $n_{8}$ denotes the number of vertices of degree eight in $G$.

Proof. Suppose $\left|n_{8}\right| \leq 24$. Then $e(G) \geq\left(8 n_{8}+9\left(|G|-n_{8}\right)\right) / 2 \geq(9|G|-24) / 2$. By Theorem 1.7, $G \succcurlyeq \mathcal{K}_{8}^{-4}$, a contradiction.
(5) $G$ is $K_{6}$-free.

Proof. Suppose $G$ has a 6 -clique $A$. By (4), $n_{8} \geq 25$. Let $y \in V(G) \backslash A$ be an 8 -vertex in $G$. By (3), $N[y]$ has a 5 -clique $B$ such that $y \in B$. Then $B \nsubseteq A$. By Lemma $3.2, G \succcurlyeq \mathcal{K}_{8}^{-3}$, a contradiction.
(6) $G[N(x)]$ has two disjoint 4-cliques.

Proof. Suppose $G[N(x)]$ does not have two disjoint 4-cliques. By (5), $G[N(x)]$ is $K_{5}$-free. Then $\delta(G[N(x)]) \geq 3$ because $\alpha(G[N(x)])=2$. We claim that $\delta(G[N(x)]) \geq 4$. Suppose not. Let $y \in N(x)$ such that $y$ has exactly three neighbors $y_{1}, y_{2}, y_{3} \in N(x)$. Let $Y:=\left\{y, y_{1}, y_{2}, y_{3}\right\}$ and $Z:=\left\{z_{1}, z_{2}, z_{3}, z_{4}\right\}=N(x) \backslash Y$. Then $Z$ is a 4 -clique in $G$ and $Y$ is not a clique. We may assume that $y_{1} y_{2} \notin E(G)$. Note that $e\left(y_{i}, Z\right) \geq 1$ for each $i \in[2]$. We may assume that $y_{1} z_{1} \in E(G)$. Suppose $y_{1}$ is anticomplete to $\left\{z_{2}, z_{3}, z_{4}\right\}$. Then $y_{1} y_{3} \in E(G)$ and $y_{2}$ must be complete to $\left\{z_{2}, z_{3}, z_{4}\right\}$. By Lemma 2.5 applied to $N(x)$ with $S=\left\{y, z_{4}\right\}$ and $M=\left\{y_{1} z_{2}, y_{1} z_{3}, y_{3} z_{2}, y_{3} z_{3}, y_{2} z_{1}\right\}$, we obtain a $\mathcal{K}_{8}^{-3}$ minor from $G[N[x]]+M$ after contracting the edge $y y_{2}$, a contradiction. Thus $e\left(y_{1}, Z\right) \geq 2$. Similarly, $e\left(y_{2}, Z\right) \geq 2$. Note that $e\left(\left\{y_{1}, y_{2}\right\}, Z\right) \leq 5$, else $G\left[Z \cup\left\{x, y_{1}, y_{2}\right\}\right]$ is not $\mathcal{K}_{7}^{-3}$-free, contrary to (2). We may assume that $e\left(y_{1}, Z\right)=2$ and $y_{1} z_{2} \in E(G)$. Then $y_{1}$ is anticomplete to $\left\{z_{3}, z_{4}\right\}$ and so $y_{2}$ must be complete to $\left\{z_{3}, z_{4}\right\}$. By Lemma 2.5 applied to $N(x)$ with $S=\left\{y, z_{1}\right\}$ and $M=\left\{y_{1} z_{3}, y_{1} z_{4}, y_{3} z_{3}, y_{3} z_{4}, y_{2} z_{2}\right\}$, we obtain a $\mathcal{K}_{8}^{-4}$ minor from $G[N[x]]+M$ after contracting the edge $y y_{1}$, a contradiction. This proves that $\delta(G[N(x)]) \geq 4$, as claimed.

By (3), $G[N(x)]$ has a 4-clique $A$. Let $N(x)=\left\{a_{1}, \ldots, a_{4}, b_{1}, \ldots, b_{4}\right\}$, where $A=\left\{a_{1}, \ldots, a_{4}\right\}$ is a 4 -clique and $B:=\left\{b_{1}, \ldots, b_{4}\right\}$ is not. We may assume that $b_{1} b_{2} \notin E(G)$. Since $G[N(x)]$ is $K_{5}$-free and $\alpha(G[N(x)])=2$, we may further assume that $b_{1} a_{1}, b_{2} a_{2} \notin E(G)$. Then $b_{1} a_{2}, b_{2} a_{1} \in E(G)$. Note that $e\left(b_{i}, A\right) \geq 2$ for each $i \in[2]$ because $\delta(G[N(x)]) \geq 4$. On the other hand, $e\left(\left\{b_{1}, b_{2}\right\}, A\right) \leq 5$, else $G\left[A \cup\left\{x, b_{1}, b_{2}\right\}\right]$ is not $\mathcal{K}_{7}^{-3}$-free, contrary to (2). We may assume that $e\left(b_{1}, A\right)=2$ and $2 \leq e\left(b_{2}, A\right) \leq 3$. We may further assume that $b_{1} a_{3}, b_{2} b_{3} \in E(G)$. Then $b_{1} a_{4} \notin E(G)$. It follows that $b_{2} a_{4} \in E(G)$ and $b_{1}$ is complete to $\left\{b_{3}, b_{4}\right\}$. By Lemma 2.5 applied to $N(x)$ with $S=\left\{b_{1}, a_{4}\right\}$ and $M=\left\{b_{2} a_{2}, b_{2} a_{3}, b_{3} a_{2}, b_{3} a_{3}, b_{4} a_{1}\right\}$, we obtain a $\mathcal{K}_{8}^{-4}$ minor from $G[N[x]]+M$ after contracting the edge $b_{1} b_{4}$, a contradiction.

To complete the proof, recall that $x$ is an 8-vertex in $G$. Since $n_{8} \geq 25$ by (4), let $y \in V(G) \backslash N[x]$ such that $y$ is an 8 -vertex in $G$. By (6), let $A, B$ be disjoint 4 -cliques of $G[N(x)]$ and let $C$ be a 4-clique of $G[N(y)]$. Let $L_{1}:=A \cup\{x\}, L_{2}:=B \cup\{x\}$ and $L_{3}:=C \cup\{y\}$. Then $L_{1} \cap L_{2}=\{x\}$ and
$L_{1} \cap L_{2} \cap L_{3}=\emptyset$. By Corollary 2.8, $L_{1}, L_{2}, L_{3}$ are not as depicted in Figure 2(c,d,f,g) because $G$ has no $\mathcal{K}_{8}^{-4}$ minor. We may assume that $\left|L_{1} \cap L_{3}\right| \geq\left|L_{2} \cap L_{3}\right|$. Then $\left|L_{1} \cap L_{3}\right| \geq 2$, else $L_{1}, L_{2}, L_{3}$ are as depicted in Figure $2(\mathrm{c}, \mathrm{d}, \mathrm{g})$.

Let $L_{1}:=\left\{x, x_{1}, \ldots, x_{4}\right\}, L_{2}:=\left\{x, y_{1}, \ldots, y_{4}\right\}$ and $L_{3}:=\left\{y, z_{1}, \ldots z_{4}\right\}$. Suppose first $\left|L_{1} \cap L_{3}\right|=$ 4. We may assume that $x_{i}=z_{i}$ for each $i \in[4]$. Note that $G\left[L_{1} \cup L_{3}\right]=K_{6}^{-}$. By Menger's Theorem, there exist four pairwise vertex-disjoint $\left(\left\{z_{1}, \ldots, z_{4}\right\},\left\{y_{1}, \ldots, y_{4}\right\}\right)$-paths, say $Q_{1}, \ldots, Q_{4}$, in $G \backslash\{x, y\}$. We may assume that $Q_{j}$ has ends $y_{j}, z_{j}$ for each $j \in[4]$. Let $Q$ be a shortest path in $G \backslash\left\{x, y, y_{1}, y_{2}, y_{3}, z_{4}\right\}$ with one end $y_{4}$ and the other in $V\left(Q_{1} \backslash y_{1}\right) \cup V\left(Q_{2} \backslash y_{2}\right) \cup V\left(Q_{3} \backslash y_{3}\right)$. We may assume that $Q$ is vertex-disjoint from $Q_{1}$ and $Q_{2}$ but contains a vertex on $Q_{3} \backslash y_{3}$. Let $u \in V(Q) \cap V\left(Q_{3}\right)$ and $v \in V(Q) \cap V\left(Q_{4}\right)$ such that the $(u, v)$-subpath of $Q$ has no internal vertex in $V\left(Q_{3}\right) \cup V\left(Q_{4}\right)$. Let $Q_{3}^{*}$ be the $\left(u, y_{3}\right)$-subpath of $Q_{3}$ and $Q_{4}^{*}$ be the $\left(v, z_{4}\right)$-subpath of $Q_{4}$. Then $G \succcurlyeq G\left[L_{1} \cup L_{2} \cup L_{3}\right]+\left\{y_{1} z_{1}, y_{2} z_{2}, y_{3} z_{3}, y_{4} z_{3}, y_{4} z_{4}\right\} \succcurlyeq \mathcal{K}_{8}^{-4}$ by first contracting all the edges of $Q_{1}, Q_{2}$, then the $\left(y_{4}, v\right)$-subpath of $Q_{4}$ onto $y_{4}, Q_{4}^{*} \backslash v$ onto $z_{4}, Q_{3}^{*} \backslash u$ onto $y_{3}$, and both $Q \backslash v$ and the ( $u, z_{3}$ )-subpath of $Q_{3}$ onto $z_{3}$, a contradiction. Suppose next $\left|L_{1} \cap L_{3}\right|=3$. Then $G\left[L_{1} \cup L_{3}\right]$ is not $\mathcal{K}_{7}^{-4}$-free, contrary to (22. Thus $\left|L_{1} \cap L_{3}\right| \leq 2$. Since $\left|L_{1} \cap L_{3}\right| \geq 2$ and $\left|L_{1} \cap L_{3}\right| \geq\left|L_{2} \cap L_{3}\right|$, we see that $\left|L_{1} \cap L_{3}\right|=2$ and $0 \leq\left|L_{2} \cap L_{3}\right| \leq 2$. Note that $\left|L_{2} \cap L_{3}\right| \neq 0$, else $L_{1}, L_{2}, L_{3}$ are as depicted in Figure $2(\mathrm{f})$. Thus $\left|L_{1} \cap L_{3}\right|=2$ and $1 \leq\left|L_{2} \cap L_{3}\right| \leq 2$. We may assume that $x_{3}=z_{1}, x_{4}=z_{2}$.

We first consider the case $\left|L_{2} \cap L_{3}\right|=2$. We may assume that $y_{3}=z_{3}, y_{4}=z_{4}$. Then there exist two vertex-disjoint $\left(\left\{x_{1}, x_{2}\right\},\left\{y_{1}, y_{2}\right\}\right)$-paths, say $Q_{1}, Q_{2}$, in $G \backslash\left\{x, x_{3}, x_{4}, y_{3}, y_{4}\right\}$. We may assume that $Q_{j}$ has ends $x_{j}, y_{j}$ for each $j \in[2]$. We may further assume $y \notin V\left(Q_{1}\right)$. Let $Q_{2}^{*}$ be the $\left(y_{2}, y\right)-$ subpath of $Q_{2}$ when $y \in V\left(Q_{2}\right)$. Then $G \succcurlyeq G\left[L_{1} \cup L_{2} \cup L_{3}\right]+\left\{x_{1} y_{1}, x_{2} y_{2}\right\} \succcurlyeq \mathcal{K}_{8}^{-3}$ by contracting all the edges of $Q_{1}$ and $Q_{2}$ when $y \notin V\left(Q_{2}\right)$; and $G \succcurlyeq G\left[L_{1} \cup L_{2} \cup L_{3}\right]+\left\{x_{1} y_{1}, x_{2} y, y_{2} y\right\} \succcurlyeq \mathcal{K}_{8}^{-2}$ by first contracting all the edges of $Q_{1}$, then $Q_{2}^{*} \backslash y$ onto $y_{2}$, and the $\left(y, x_{2}\right)$-subpath of $Q_{2}$ onto $x_{2}$ when $y \in V\left(Q_{2}\right)$, a contradiction.

It remains to consider the case $\left|L_{2} \cap L_{3}\right|=1$. We may assume that $z_{3}=y_{4}$. Then there exist three vertex-disjoint $\left(\left\{x_{1}, x_{2}, z_{4}, y\right\},\left\{y_{1}, y_{2}, y_{3}\right\}\right)$-paths, say $Q_{1}, Q_{2}, Q_{3}$, in $G \backslash\left\{x, x_{3}, x_{4}, y_{4}\right\}$. We may assume that $Q_{1}$ has ends $\left\{x_{1}, y_{1}\right\}$. Note that $L_{3} \backslash\left(L_{1} \cup L_{2}\right)=\left\{y, z_{4}\right\}$. By symmetry, we may further assume that $Q_{3}$ has ends $y_{3}, z_{4}$. Then $Q_{2}$ has ends $y_{2}, x_{2}$, or $y_{2}, y$. By contracting all the edges of $Q_{1}, Q_{2}$ and $Q_{3}$, we see that $G \succcurlyeq G\left[L_{1} \cup L_{2} \cup L_{3}\right]+\left\{x_{1} y_{1}, x_{2} y_{2}, y_{3} z_{4}\right\} \succcurlyeq \mathcal{K}_{8}^{-3}$ in the former case, and $G \succcurlyeq G\left[L_{1} \cup L_{2} \cup L_{3}\right]+\left\{x_{1} y_{1}, y_{2} y, y_{3} z_{4}\right\} \succcurlyeq \mathcal{K}_{8}^{-3}$ in the latter case, a contradiction.

This completes the proof of Theorem 1.5.

## 4 An extremal function for $\mathcal{K}_{8}^{-4}$ minors

Throughout this section, if $G$ is a graph and $K$ is a subgraph of $G$, then by $N(K)$ we denote the set of vertices of $V(G) \backslash V(K)$ that are adjacent to a vertex of $K$. If $V(K)=\{x\}$, then $N(K)=N(x)$. It can be easily checked that for each vertex $x \in V(G)$, if $K$ is a component of $G \backslash N[x]$, then $N(K)$ is a minimal separating set of $G$.

We first give a brief outline of the proof of Theorem 1.7. We follow the main ideas in [33].

Suppose for a contradiction that $G$ is a counterexample to Theorem 1.7 with as few vertices as possible. Since deletion or contraction of edges does not produce smaller counterexamples, it follows easily that $G$ has minimum degree at least five, and every edge of $G$ belongs to at least four triangles. With some effort it can be shown that $G$ is 5 -connected, and has at most one 5 -vertex but no 6 -vertex and no 7 -vertex. As $e(G)=4.5|G|-12$, we see that $G$ has an 8 -vertex. Fix such a vertex $x$. We then show that $x$ is not adjacent to a 5 -vertex in $G$. If $G \backslash N[x]$ has a a component $K$ such that $M \subseteq N(K)$, where $M$ is the set of all vertices of $N(x)$ that are not adjacent to every other vertex of $N(x)$, then we can find a vertex $y \in N(x)$ such that $G[N(x) \backslash y] \succcurlyeq \mathcal{K}_{6}^{-4}$, and so $G \succcurlyeq \mathcal{K}_{8}^{-4}$ by contracting the connected graph $G[V(K) \cup\{y\}]$ to a single vertex. Thus we may assume that for no 8 -vertex $x$ such a component exists. In particular, $G \backslash N[x]$ is disconnected. In the next step we prove that there is no component $K$ of $G \backslash N[x]$ with $|K| \geq 2$ such that $d_{G}(v) \geq 9$ for all vertices $v \in V(K)$, except possibly one. In the last step, we select an 8 -vertex $x \in V(G)$ to minimize the size of a component $K$ of $G \backslash N[x]$ with $|K| \geq 2$. It follows easily that $K$ does not have a vertex that is an 8 -vertex in $G$.

We next prove two lemmas that will be needed in the proof of Theorem 1.7 .
Lemma 4.1. Let $H$ be a graph with $|H|=8$ and $\delta(H) \geq 4$. Then there exists $x \in V(H)$ such that $H \backslash x$ has a $\mathcal{K}_{6}^{-4}$ minor.

Proof. We may assume that $\delta(H)=4$ and every edge is incident with a 4 -vertex in $H$. Suppose $H \backslash x$ has no $\mathcal{K}_{6}^{-4}$ minor for every $x$ in $H$. Suppose first that $H$ has a 4-clique, say $A:=\left\{a_{1}, \ldots, a_{4}\right\}$. Let $B:=V(H) \backslash A$. By the minimality of $e(H)$, we may assume that $a_{i}$ is a 4 -vertex in $H$ for each $i \in[3]$. Let $b_{i} \in B$ be the unique neighbor of $a_{i}$ in $B$ for each $i \in[3]$. Note that $b_{1}, b_{2}, b_{3}$ are not necessarily distinct. We claim that for all $a \in A$ and $b \in B$, if $a b \in E(H)$, then $a$ and $b$ have at least one common neighbor. Suppose not. We may assume that $a \neq a_{1}$. Let $H^{*}:=H \backslash a_{1}$. Then $e\left(H^{*} / a b\right)=e\left(H^{*}\right)-1=(e(H)-4)-1 \geq(16-4)-1=11=e\left(K_{6}\right)-4$. Thus $H \backslash a_{1}$ has a $\mathcal{K}_{6}^{-4}$ minor, a contradiction. This implies that $b_{i} a_{4} \in E(H)$ for each $i \in[3]$. Note that $e(b, A) \geq 1$ for each $b \in B$. It follows that $a_{4}$ is complete to $B$ and so $d\left(a_{4}\right)=7$. By the minimality of $e(H)$, we see that each vertex in $B$ is a 4 -vertex in $H$, which is impossible. This proves that $H$ is $K_{4}$-free. Suppose next $\alpha(H)=2$. By Lemma 2.9, $H$ contains $H_{8}$ as a subgraph. Let the vertices of $H$ be labeled as in Figure 3. It is simple to check that $H_{8} \backslash w_{2}$ has a $\mathcal{K}_{6}^{-4}$ minor after contracting the edge $w_{1} w_{3}$. Thus $H$ is $K_{4}$-free and $\alpha(H) \geq 3$.

It is straightforward to check that $H=K_{4,4}$ when $\alpha(H)=4$; and $K_{4,4} \backslash x$ has a $\mathcal{K}_{6}^{-4}$ minor for every $x$ in $K_{4,4}$. Thus $\alpha(H)=3$. Let $S:=\left\{x_{1}, x_{2}, x_{3}\right\}$ be an independent set of $H$ and let $V(H) \backslash S:=\left\{y_{1}, \ldots, y_{5}\right\}$. Since $d\left(x_{i}\right) \geq 4$ for each $i \in[3]$, we may assume that $\left\{y_{1}, y_{2}\right\}$ is complete to $S$. Suppose $y_{3}$ is complete to $S$. Since $K_{3,4}$ has a $\mathcal{K}_{6}^{-4}$ minor, we see that $y_{4}$ is neither complete to $S$ nor complete to $\left\{y_{1}, y_{2}, y_{3}\right\}$. We may assume that $y_{4} x_{1} \notin E(H)$ and $y_{4} y_{1} \notin E(H)$. Then $H \backslash y_{5}$ has a $\mathcal{K}_{6}^{-4}$ minor after contracting the edge $x_{1} y_{1}$, a contradiction. This proves that no $y_{j}$ is complete to $S$ for each $j \in\{3,4,5\}$. It follows that $d\left(x_{i}\right)=4$, and $e\left(y_{j}, S\right)=2$ for each $i \in[3]$ and $j \in\{3,4,5\}$; in addition, we may assume that $y_{3}$ is complete to $\left\{x_{1}, x_{2}\right\}, y_{4}$ is complete to $\left\{x_{2}, x_{3}\right\}$ and $y_{5}$ is complete to $\left\{x_{1}, x_{3}\right\}$. If $H\left[\left\{y_{3}, y_{4}, y_{5}\right\}\right]=K_{3}$, then $H \backslash y_{2}$ has a $\mathcal{K}_{6}^{-4}$ minor after contracting
the edge $x_{1} y_{1}$, a contradiction. Thus we may assume that $y_{3} y_{5} \notin E(G)$ and $y_{3} y_{2} \in E(G)$. Then either $y_{3} y_{4} \in E(G)$ or $y_{3} y_{1} \in E(G)$. Thus $H \backslash y_{5}$ has a $\mathcal{K}_{6}^{-4}$ minor after contracting the edge $x_{3} y_{4}$, a contradiction.

Lemma 4.2 follows from the proof of Lemma 16 of Jørgensen [14]. We recall the proof here for convenience.

Lemma 4.2 (Jørgensen [14]). Let $G$ be a 4-connected graph and let $S \subseteq V(G)$ be a separating set of four vertices. Let $G_{1}$ and $G_{2}$ be proper subgraphs of $G$ so that $G_{1} \cup G_{2}=G$ and $G_{1} \cap G_{2}=G[S]$. Let $d_{1}$ be the maximum number of edges that can be added to $G_{2}$ by contracting edges of $G$ with at least one end in $G_{1}$. If $\left|G_{1}\right| \geq 6$, then

$$
e(G[S])+d_{1} \geq 5
$$

Proof. Let $x \in V\left(G_{1}\right) \backslash S$. Then there exist four pairwise internally vertex-disjoint $(x, S)$-paths, say $Q_{1}, \ldots, Q_{4}$, in $G_{1}$. For each $i \in[4]$, let $s_{i}$ be the vertex in $V\left(Q_{i}\right) \cap S$. If all four of these paths have length one, then, since $\left|G_{1}\right| \geq 6$, we may choose a vertex $y \in V\left(G_{1}\right) \backslash(S \cup\{x\})$. Then there are at least three internally vertex-disjoint $(y, S)$-paths in $G_{1} \backslash\{x\}$. Contracting some of these paths results in $S$ having at least five edges, as desired.

We may now assume that $Q_{1}$ has length at least two. Since $\left\{x, s_{1}\right\}$ is not a separating set, there is a path $Q$ from a vertex on $Q_{1} \backslash\left\{x, s_{1}\right\}$ to a vertex on $Q_{j} \backslash x$ for some $j \in\{2,3,4\}$, so that only the ends of $Q$ belong to $V\left(Q_{1}\right) \cup V\left(Q_{2}\right) \cup V\left(Q_{3}\right) \cup V\left(Q_{4}\right)$. We may assume that $j=2$. Since $\left\{x, s_{1}, s_{2}\right\}$ does not separate the graph, there is a path $R$ from $V\left(Q_{1} \backslash\left\{x, s_{1}\right\}\right) \cup V\left(Q_{2} \backslash s_{2}\right) \cup V(Q)$ to $Q_{\ell} \backslash x$ for some $\ell \in\{3,4\}$, so that only the ends of $R$ belong to $V\left(Q_{1}\right) \cup V\left(Q_{2}\right) \cup V\left(Q_{3}\right) \cup V\left(Q_{4}\right) \cup V(Q)$. The result follows from the existence of these paths.

We are now ready to prove Theorem 1.7, which we restate for convenience.
Theorem 1.7. Every graph on $n \geq 8$ vertices with at least $4.5 n-12$ edges has a $\mathcal{K}_{8}^{-4}$ minor.
Proof. Suppose the assertion is false. Let $G$ be a graph on $n \geq 8$ vertices with $e(G) \geq 4.5 n-12$ and, subject to this, $n$ is minimum. We may assume that $e(G)=\lceil 4.5 n-12\rceil$. It is simple to check that $G \succcurlyeq \mathcal{K}_{8}^{-4}$ for each $n \in\{8,9\}$. Thus $n \geq 10$. We next prove several claims.

Claim 1. $\delta(G) \geq 5$.
Proof. Suppose $\delta(G) \leq 4$. Let $x \in V(G)$ with $d(x) \leq 4$. Then

$$
e(G \backslash x)=e(G)-d(x) \geq\lceil 4.5 n-12\rceil-4>\lceil 4.5|G \backslash x|-12\rceil .
$$

Thus $G \backslash x$ has a $\mathcal{K}_{8}^{-4}$ minor by the minimality of $G$, a contradiction.
Claim 2. Every edge in $G$ belongs to at least 4 triangles. Moreover, if $x \in V(G)$ is a 5 -vertex, then $G[N[x]]=K_{6}$.

Proof. Suppose there exists $e \in E(G)$ such that $e$ belongs to at most three triangles. Then

$$
e(G / e) \geq\lceil 4.5 n-12\rceil-4>\lceil 4.5|G / e|-12\rceil .
$$

Thus $G / e \succcurlyeq \mathcal{K}_{8}^{-4}$ by the minimality of $G$, a contradiction. This implies that $G[N[x]]=K_{6}$ for each 5 -vertex $x$ in $G$.

Claim 3. No two 5 -vertices in $G$ are adjacent.
Proof. Suppose there exist two distinct 5 vertices, say $x, y$, in $G$ such that $x y \in E(G)$. Then $|G \backslash\{x, y\}|=n-2 \geq 8$ and

$$
e(G \backslash\{x, y\})=e(G)-9=\lceil 4.5(n-2)-12\rceil .
$$

Thus $G \backslash\{x, y\}$ has a $\mathcal{K}_{8}^{-4}$ by the minimality of $G$, a contradiction.
Let $S$ be a minimal separating set of vertices in $G$, and let $G_{1}$ and $G_{2}$ be proper subgraphs of $G$ so that $G=G_{1} \cup G_{2}$ and $G_{1} \cap G_{2}=G[S]$. For each $i \in[2]$, let $d_{i}$ be the maximum number of edges that can be added to $G_{3-i}$ by contracting edges of $G$ with at least one end in $G_{i}$. More precisely, let $d_{i}$ be the largest integer so that $G_{i}$ contains pairwise disjoint sets of vertices $V_{1}, \ldots, V_{p}$ so that $G_{i}\left[V_{j}\right]$ is connected, $\left|S \cap V_{j}\right|=1$ for $1 \leq j \leq p:=|S|$, and so that the graph obtained from $G_{i}$ by contracting each of $G_{i}\left[V_{1}\right], \ldots, G_{i}\left[V_{p}\right]$ to a single vertex and deleting $V(G) \backslash \bigcup_{j=1}^{p} V_{j}$ has $e(G[S])+d_{i}$ edges. It follows from the minimality of $G$ that for each $i \in[2]$,

$$
\begin{equation*}
e\left(G_{i}\right)+d_{3-i}<4.5\left|G_{1}\right|-12 \text { if }\left|G_{i}\right| \geq 8 . \tag{*}
\end{equation*}
$$

Claim 4. If $\left|G_{i}\right|=7$ for some $i \in[2]$, then $|S| \leq 5, G_{i}$ contains $K_{7}^{-}$or $K_{7}^{\overline{=}}$ as a spanning subgraph, and each missing edge of $G_{i}$ lies in $G[S]$.

Proof. Suppose, say, $\left|G_{1}\right|=7$. Let $C$ be a component of $G_{2} \backslash S$. We first prove that $G_{1} \backslash S$ is connected. Suppose not. By Claims 1, 2 and 3, $G_{1} \backslash S$ must contain two nonadjacent 5 -vertices in $G$ with $G[S]=K_{5}$. Thus $G_{1}=K_{7}^{-}$and so $G \succcurlyeq \mathcal{K}_{8}^{-3}$ by contracting $C$ to a single vertex, a contradiction. Thus $G_{1} \backslash S$ is connected, and so $G_{1} \backslash S$ has least one 6 -vertex, say $x$, in $G$. Suppose next $|S|=6$. Then $G[S]=G[N(x)]$ contains $K_{2,2,2}$ as a spanning subgraph by Claim 2, But then $G \succcurlyeq \mathcal{K}_{8}^{-4}$ by contracting $C$ to a single vertex, a contradiction. This proves that $|S| \leq 5$ and so $\left|G_{1} \backslash S\right| \geq 2$.

We next show that no vertex in $G_{1} \backslash S$ is a 5 -vertex in $G$. Suppose not. Let $y \in V\left(G_{1} \backslash S\right)$ be a 5-vertex in $G$. Then $x y \in E(G)$ and $G_{1}=K_{7}^{-}$by Claim 2 . Note that $G[S]$ is a complete subgraph because $G[N(y)]=K_{5}$ and $G[N(x)]$ contains $K_{2,2,2}$ as a subgraph by Claim 2. Then $|S| \leq 3$, else $G \succcurlyeq \mathcal{K}_{8}^{-4}$ by contracting $C$ to a single vertex. Suppose $\left|G_{2}\right| \geq 8$. Then

$$
\begin{aligned}
e\left(G_{2}\right) & =e(G)-e\left(G_{1}\right)+e(G[S]) \\
& =\lceil 4.5 n-12\rceil-20+\binom{|S|}{2} \\
& =\lceil(4.5 \times(n-(7-|S|))-12)+4.5 \times(7-|S|)\rceil-20+\binom{|S|}{2} \\
& \geq\left\lceil 4.5\left|G_{2}\right|-12\right\rceil
\end{aligned}
$$

because $|S| \leq 3$. By the minimality of $G$, we see that $G_{2} \succcurlyeq \mathcal{K}_{8}^{-4}$, a contradiction. Thus $\left|G_{2}\right| \leq 7$. If $\left|G_{2}\right|=6$, then $G_{2}=K_{6}$ and $n=7+6-|S|=13-|S|$; but then

$$
\lceil 4.5 \times(13-|S|)-12\rceil=e(G)=e\left(G_{1}\right)+e\left(G_{2}\right)-e(G[S])=20+15-\binom{|S|}{2},
$$

which is impossible because $|S| \leq 3$. Thus $\left|G_{2}\right|=7$ and so $n=7+7-|S|=14-|S|$. Using a similar argument for $G_{1}$, we see that $G_{2} \backslash S$ is connected and so $G_{2}=K_{7}$ or $K_{7}^{-}$. Note that $G_{2}=K_{7}^{-}$when $|S|=3$, else $G \succcurlyeq \mathcal{K}_{8}^{-4}$ by contracting $G_{1} \backslash S$ to a single vertex. But then
$\lceil 4.5 \times(14-|S|)-12\rceil=e(G)=e\left(G_{1}\right)+e\left(G_{2}\right)-e(G[S]) \leq 20+(21-\max \{0,|S|-2\})-\binom{|S|}{2}$,
which is impossible because $|S| \leq 3$. This proves that no vertex in $G_{1} \backslash S$ is a 5 -vertex in $G$. It then follows that each vertex in $G_{1} \backslash S$ is a 6 -vertex in $G$. By Claim 2 and the fact that $|S| \leq 5$, we see that $G[S]$ is isomorphic to $K_{|S|}, K_{|S|}^{-}$, or $K_{|S|}^{=}$, and every vertex in $V\left(G_{1} \backslash S\right)$ is adjacent to all the other vertices in $G_{1}$. Thus $G_{1}$ contains $K_{7}^{-}$or $K_{7}^{=}$as a spanning subgraph such that all its missing edges lie in $G[S]$.

Claim 5. Neither $G_{1}$ nor $G_{2}$ has exactly seven vertices.
Proof. Suppose not, say $\left|G_{1}\right|=7$. By Claim $4,|S| \leq 5, G_{1}$ contains $K_{7}^{-}$or $K_{7}^{\overline{=}}$ as a spanning subgraph, and each missing edge of $G_{1}$ lies in $G[S]$. We next prove that $\left|G_{2}\right| \geq 8$. Suppose $\left|G_{2}\right| \leq 7$. Note that $\left|G_{2}\right| \geq 6$ by Claim 1. Suppose $\left|G_{2}\right|=6$. Then $G_{2}=K_{6}$ and $G[S]=K_{5}$. But then $n=\left|G_{1}\right|+\left|G_{2}\right|-|S|=7+6-5<10$, a contradiction. Thus $\left|G_{2}\right|=7$ and so $n=14-|S|$. Since $n \geq 10$, we see that $|S| \leq 4$. By Claim $4, G_{2}$ contains $K_{7}^{-}$or $K_{7}^{\overline{7}}$ as a spanning subgraph, and each missing edge of $G_{2}$ lies in $G[S]$. Suppose $|S|=4$. Then $G[S]=K_{4}^{=}$, else $G \succcurlyeq \mathcal{K}_{8}^{-4}$ by contracting $G_{2} \backslash S$ to a single vertex. Let $y \in V\left(G_{2}\right) \backslash S$ and $z \in S$ such that $z$ is incident with a missing edge in $G[S]$. It is simple to check that $G \succcurlyeq \mathcal{K}_{8}^{-4}$ by contracting the edge $y z$ and $G_{2} \backslash(S \cup\{y\})$ to a single vertex, a contradiction. Thus $|S| \leq 3$. As noted in the proof of Claim 4, we see that $G_{1}=G_{2}=K_{7}^{-}$when $|S|=3$. But then

$$
\lceil 4.5 \times(14-|S|)-12\rceil=e(G)=e\left(G_{1}\right)+e\left(G_{2}\right)-e(G[S]) \leq 2 \times(21-\max \{0,|S|-2\})-\binom{|S|}{2}
$$

which is impossible because $|S| \leq 3$. This proves that $\left|G_{2}\right| \geq 8$.
Recall that $G_{1}$ contains $K_{7}^{-}$or $K_{7}^{\overline{7}}$ as a spanning subgraph, and each missing edge of $G_{1}$ lies in $G[S]$. It follows that $e(G[S])+d_{1}=\binom{|S|}{2}$. Suppose $G_{1}=K_{7}^{\overline{7}}$. Then $4 \leq|S| \leq 5$. But then

$$
\begin{aligned}
e\left(G_{2}\right)+d_{1} & =e(G)-e\left(G_{1}\right)+e(G[S])+d_{1} \\
& =\lceil 4.5 n-12\rceil-19+\binom{|S|}{2} \\
& =\lceil(4.5 \times(n-(7-|S|))-12)+4.5 \times(7-|S|)\rceil-19+\binom{|S|}{2} \\
& \geq\left\lceil 4.5\left|G_{2}\right|-12\right\rceil,
\end{aligned}
$$

contrary to $(*)$ because $4 \leq|S| \leq 5$ and $\left|G_{2}\right| \geq 8$. Thus $G_{1}=K_{7}^{-}$or $K_{7}$. Note that $|S| \leq 3$, else $G \succcurlyeq \mathcal{K}_{8}^{-4}$ by contracting a component of $G_{2} \backslash S$ to a single vertex. But then

$$
\begin{aligned}
e\left(G_{2}\right)+d_{1} & =e(G)-e\left(G_{1}\right)+e(G[S])+d_{1} \\
& \geq\lceil 4.5 n-12\rceil-21+\binom{|S|}{2} \\
& =\lceil(4.5 \times(n-(7-|S|))-12)+4.5 \times(7-|S|)\rceil-21+\binom{|S|}{2} \\
& \geq\left\lceil 4.5\left|G_{2}\right|-12\right\rceil
\end{aligned}
$$

contrary to $(*)$ because $|S| \leq 3$ and $\left|G_{2}\right| \geq 8$. This proves Claim 5 .
Observe that, if $\left|G_{1}\right| \geq 8$ and $\left|G_{2}\right| \geq 8$, then by $(*)$, we have

$$
\begin{aligned}
4.5 n-12 \leq e(G) & =e\left(G_{1}\right)+e\left(G_{2}\right)-e(G[S]) \\
& <\left(4.5\left|G_{1}\right|-12-d_{2}\right)+\left(4.5\left|G_{2}\right|-12-d_{1}\right)-e(G[S]) \\
& =4.5(n+|S|)-24-d_{1}-d_{2}-e(G[S])
\end{aligned}
$$

It follows that

$$
\begin{equation*}
9|S|>24+2\left(d_{1}+d_{2}+e(G[S])\right) \quad \text { if }\left|G_{1}\right| \geq 8 \text { and }\left|G_{2}\right| \geq 8 \tag{**}
\end{equation*}
$$

Claim 6. $G$ is 5-connected.

Proof. Suppose $G$ is not 5 -connected. Let $S$ be a minimal separating set of $G$, and $G_{1}, G_{2}, d_{1}, d_{2}$ be defined as above. Then $\left|G_{1}\right| \neq 6$, else by Claim 2 , we have $G_{1}=K_{6}$ and so $G[S]=K_{5}$, a contradiction. Similarly, $\left|G_{2}\right| \neq 6$. By Claim 5, $\left|G_{1}\right| \geq 8$ and $\left|G_{2}\right| \geq 8$. By ( $\left.* *\right)$, $|S| \geq 3$. If $|S|=3$, then either $e(G[S]) \geq 2$ or $\min \left\{d_{1}, d_{2}\right\} \geq 1$; in either case, $d_{1}+d_{2}+e(G[S]) \geq 2$, contrary to $(* *)$. Therefore, $|S|=4$ and $G$ is 4-connected. By Lemma 4.2, $e(G[S])+d_{1} \geq 5$. Note that $d_{2} \geq 1$ when $S$ is not a 4-clique, and $e(G[S])=6$ when $S$ is a 4-clique. In either case, we have $d_{1}+d_{2}+e(G[S]) \geq 6$, contrary to $(* *)$.

Claim 7. If there exists $x \in S$ such that $S \backslash x$ is a clique, then $G[S]=K_{5}$.
Proof. Suppose $S \backslash x$ is a clique but $G[S] \neq K_{5}$. Let $G_{1}$ and $G_{2}$ be as above. Then $\left|G_{1}\right| \neq 6$, else $G_{1}=K_{6}$ and $G[S]=K_{5}$. Similarly, $\left|G_{2}\right| \neq 6$. By Claim 5, $\left|G_{1}\right| \geq 8$ and $\left|G_{2}\right| \geq 8$. By Claim 6, $|S| \geq 5$. If $S$ contains a 6 -clique, then $G \succcurlyeq K_{8}^{-}$by contracting a component of $G_{1} \backslash S$ and a component of $G_{2} \backslash S$ to two distinct vertices, a contradiction. Thus $5 \leq|S| \leq 6$ and $S$ is not a clique. Then $\delta(G[S])=d_{G[S]}(x) \leq|S|-2$. Since $S \backslash x$ is a clique, we see that

$$
d_{1}=d_{2}=|S|-1-d_{G[S]}(x)=|S|-1-\delta(G[S])
$$

It follows that

$$
e(G[S])=\binom{|S|-1}{2}+d_{G[S]}(x)=\binom{|S|-1}{2}+\delta(G[S])
$$

This, together with $(* *)$, implies that

$$
\begin{aligned}
9|S| & >24+2\left(d_{1}+d_{2}\right)+2 e(G[S]) \\
& =24+4|S|-4-4 \delta(G[S])+(|S|-1)(|S|-2)+2 \delta(G[S]) \\
& =20+4|S|+|S|^{2}-3|S|+2-2 \delta(G[S]) \\
& \geq 20+|S|^{2}+|S|+2-2(|S|-2) \\
& =|S|^{2}-|S|+26,
\end{aligned}
$$

which is impossible because $5 \leq|S| \leq 6$.
Claim 8. No vertex in $G$ is a 6 -vertex.
Proof. Suppose to the contrary that $G$ has a 6 -vertex, say $x$. By Claim $2, G[N(x)]$ contains $K_{2,2,2}$ as a spanning subgraph. Let $C$ be a component of $G \backslash N[x]$. By Claim 6 , $|N(C)| \geq 5$. If $N(C)=N(x)$ or $G[N(x)]$ contains $K_{6}^{=}$as a spanning subgraph, then $G \succcurlyeq \mathcal{K}_{8}^{-4}$ by contracting $C$ to a single vertex. Thus $|N(C) \cap N(x)|=5$ for every component $C$ of $G \backslash N[x]$ and $G[N(x)]=K_{2,2,2}$. By Claim 2 , no vertex in $N(x)$ is a 5 -vertex in $G$. Thus $G \backslash N[x]$ is disconnected. Let $C^{\prime} \neq C$ be another component of $G \backslash N[x]$. By Claim $7, G[N(C)]=K_{5}^{=}$and $G\left[N\left(C^{\prime}\right)\right]=K_{5}^{=}$. Let $y \in N(x) \cap N(C)$ such that $y$ is incident with a missing edge of $G[N(C)]$. Then $G \succcurlyeq \mathcal{K}_{8}^{-4}$ by contracting $C$ onto $y$ and $C^{\prime}$ to a single vertex, a contradiction.

Claim 9. No vertex in $G$ is a 7 -vertex.
Proof. Suppose $G$ has a 7 -vertex, say $x$. By Claim 2, $\delta(G[N(x)]) \geq 4$, and so $\bar{G}[N(x)]$ is the disjoint union of paths and cycles. By Claim 9, no vertex in $N(x)$ is a 6 -vertex in $G$. Suppose there exists $y \in N(x)$ such that $y$ is a 5 -vertex in $G$. Then $N[y] \subseteq N[x]$ and $G[N[y]]=K_{6}$. Thus $G[N[x]] \succcurlyeq \mathcal{K}_{8}^{-4}$ because $\delta(G[N(x)]) \geq 4$, a contradiction. This proves that no vertex in $N(x)$ is a 5-vertex or 6-vertex in $G$. Let $\mathcal{F}:=\left\{C_{7}, C_{6} \cup K_{1}, C_{5} \cup K_{2}, C_{4} \cup K_{3}\right\}$. Then $\bar{G}[N(x)]$ is a spanning subgraph of some member in $\mathcal{F}$ because $\bar{G}[N(x)]$ is the disjoint union of paths and cycles. We only consider the worst scenario that $\bar{G}[N(x)]$ is isomorphic to some graph in $\mathcal{F}$. It is straightforward to check that every graph in $\mathcal{F}$ has a $\mathcal{K}_{6}^{-3}$ minor. Let $C$ be a component of $G \backslash N[x]$. By Claim 6, $|N(C)| \geq 5$. If $N(C)=N(x)$, then $G \succcurlyeq \mathcal{K}_{8}^{-4}$ by contracting $C$ to a single vertex. Thus $N(C) \neq N(x)$ for every component $C$ of $G \backslash N[x]$. We claim that $G \backslash N[x]$ is disconnected. Suppose not. Then $C=G \backslash N[x]$ and $\bar{G}[N(x)]=K_{1}+C_{6}$. Note that every vertex on $C_{6}$ belongs to $N(C)$. Thus $G \succcurlyeq \mathcal{K}_{8}^{-4}$ by contracting $G \backslash N[x]$ onto a vertex of $C_{6}$, a contradiction. This proves that $G \backslash N[x]$ is disconnected, as claimed. Let $C$ and $C^{\prime}$ be two distinct components of $G \backslash N[x]$ such that $N(C)$ contains the most number of missing edges of $G[N(x)]$. It is straightforward to check that either $G[N(C)]$ must contain two adjacent missing edges, say $x_{1} x_{2}, x_{1} x_{3}$, where $x_{1}, x_{2}, x_{3} \in N(x)$ are distinct, or $\bar{G}[N(x)] \in\left\{K_{1} \cup C_{6}, K_{2} \cup C_{5}\right\}$ and $G[N(C)]=G\left[N\left(C^{\prime}\right)\right]=K_{5}^{\bar{\prime}}$. In the former case, since $\left|N\left(C^{\prime}\right)\right| \geq 5$, by Claim 7 , we see that $G\left[N\left(C^{\prime}\right) \backslash x_{1}\right]$ must contain a missing edge, say $e$. By contracting $C$ onto $x_{1}$ and $C^{\prime}$ onto an end of the edge $e$, it is straightforward to check that $G[N[x]]+\left\{x_{1} x_{2}, x_{1} x_{3}, e\right\} \succcurlyeq \mathcal{K}_{8}^{-4}$, a contradiction. In the latter case, let $y_{1} y_{2}$ be a missing edge
in $G[N(C)]$ and $y_{3} y_{4}$ be a missing edge in $G\left[N\left(C^{\prime}\right)\right]$ such that $y_{1} y_{2}, y_{3} y_{4}$ are two different missing edges in $G[N[x]]$. We may assume that $y_{1} \neq y_{3}$. Then $G[N[x]]+\left\{y_{1} y_{2}, y_{3} y_{4}\right\} \succcurlyeq \mathcal{K}_{8}^{-4}$ by contracting $C$ onto $y_{1}$ and $C^{\prime}$ onto $y_{3}$, a contradiction.

Claim 10. $G$ is $\mathcal{K}_{7}^{-2}$-free.
Proof. Suppose $G$ has a subgraph $H$ such that $H \in \mathcal{K}_{7}^{-2}$. Since $G$ is 5-connected, we obtain a $\mathcal{K}_{8}^{-4}$ minor in $G$ by contracting a component of $G \backslash V(H)$ to a single vertex, a contradiction.

Claim 11. $G$ has at most one 5 -vertex.
Proof. Suppose to the contrary that $G$ has two distinct 5 -vertices, say $x$ and $y$. By Claims 2 and 3, $x y \notin E(G)$ and $N[x]$ and $N[y]$ are 6-cliques. Suppose $N(x) \neq N(y)$. By Claim 6 and Menger's Theorem, there exist five pairwise internally vertex-disjoint $(x, y)$-paths $Q_{1}, \ldots, Q_{5}$. We may assume that $Q_{1}$ has at least four vertices with $V\left(Q_{1}\right) \cap N(x)=\left\{x_{1}\right\}$ and $V\left(Q_{1}\right) \cap N(y)=\left\{y_{1}\right\}$. Let $Q_{1}^{*}$ be the $\left(x_{1}, y_{1}\right)$-subpath of $Q_{1}$. Then $G \succcurlyeq \mathcal{K}_{8}^{-4}$ by contracting all the edges of $Q_{1}^{*} \backslash y_{1}$, $Q_{2} \backslash\{x, y\}, \ldots, Q_{5} \backslash\{x, y\}$, a contradiction. Thus $N(x)=N(y)$. Then $G[N[x] \cup N[y]]=K_{7}^{-}$, contrary to Claim 10 .

Claim 12. No 8 -vertex is adjacent to a 5 -vertex in $G$.
Proof. Suppose to the contrary that there exists $x y \in E(G)$ such that $d(x)=8$ and $d(y)=5$. By Claim 2, $G[N[y]]=K_{6}, N[y] \subseteq N[x]$ and $\delta(G[(N(x)]) \geq 4$. Let $A:=N(x) \backslash N[y]$. Then $|A|=3$ because $x y \in E(G)$. Let $A:=\left\{a_{1}, a_{2}, a_{3}\right\}$. Suppose $G[A] \neq K_{3}$, say $a_{1} a_{2} \notin E(G)$. Then either $e\left(\left\{a_{1}, a_{2}\right\}, N(x) \backslash A\right) \geq 7$, or $e\left(\left\{a_{1}, a_{2}\right\}, N(x) \backslash A\right)=6$ and $a_{3}$ is complete to $\left\{a_{1}, a_{2}\right\}$, because $\delta\left(G[(N(x)]) \geq 4\right.$. Then $G\left[N[x] \backslash a_{3}\right] \succcurlyeq \mathcal{K}_{8}^{-4}$ in the former case, and $G[N[x]] / a_{1} a_{3} \succcurlyeq \mathcal{K}_{8}^{-4}$ in the latter case, a contradiction. This proves that $G[A]=K_{3}$. Then $e\left(a_{i}, N(x) \backslash A\right) \geq 2$ for each $i \in[3]$. If $e\left(a_{j}, N(x) \backslash A\right) \geq 3$ for some $j \in[3]$, then $G\left[N[y] \cup\left\{a_{j}\right\}\right]$ is not $\mathcal{K}_{7}^{-2}$-free, contrary to Claim 10. Thus $e\left(a_{i}, N(x) \backslash A\right)=2$ for each $i \in[3]$. Next if there exists $z \in N(x) \cap N(y)$ such that $z$ has exactly one neighbor, say $a_{1}$, in $A$, then $G[N[x]] / z a_{1} \succcurlyeq \mathcal{K}_{8}^{-4}$, a contradiction. Since $e(A, N(x) \backslash A)=6$ and $|N(x) \cap N(y)|=4$, it follows that there exists $z^{*} \in N(x) \cap N(y)$ such that $z^{*}$ is anticomplete to $A$ in $G$. By Claim 11, $z^{*}$ is not a 5 -vertex in $G$. Let $C$ be a component of $G \backslash N[x]$ such that $z^{*} \in N(C)$. Note that $y \notin N(C)$ and $N(x) \cap N(y)$ is a 4-clique. By Claim 7 , $N(C)$ must contain at least two vertices, say $a_{1}, a_{2}$, in $A$. By contracting $C$ onto $z^{*}$, we see that $G\left[N[x] \backslash a_{3}\right]+\left\{z^{*} a_{1}, z^{*} a_{2}\right\} \succcurlyeq \mathcal{K}_{8}^{-4}$, a contradiction.

Claim 13. Let $x \in V(G)$ be an 8 -vertex in $G$, and let $M$ be the set of vertices of $N(x)$ not adjacent to all other vertices of $N(x)$. Then there is no component $K$ of $G \backslash N[x]$ such that $M \subseteq N(K)$. In particular, $G \backslash N[x]$ is disconnected.

Proof. Suppose such a component $K$ exists. Then every vertex in $M$ has a neighbor in $K$ because $M \subseteq N(K)$. By Lemma 4.1, there exists $y \in N(x)$ such that $G[N(x)] \backslash y$ has a $\mathcal{K}_{6}^{-4}$ minor. If $N[y]=N[x]$, then $G[N[x]] \succcurlyeq \mathcal{K}_{8}^{-4}$, a contradiction. Thus $y \in M \subseteq N(K)$. By contracting $K$ onto $y$, we obtain a $\mathcal{K}_{8}^{-4}$ minor in $G$, a contradiction. This proves that no such component $K$ exists. By

Claims 8, 9 and 12, every vertex in $M$ has degree at least eight, and thus every vertex in $M$ has a neighbor in $G \backslash N[x]$. It follows that $G \backslash N[x]$ is disconnected.

Claim 14. Let $x \in V(G)$ be an 8-vertex in $G$. Then $G \backslash N[x]$ has at most one component $C$ with $|C|=1$. Moreover, if $C$ is a component of $G \backslash N[x]$ such that $|C|=1$, then the sole vertex in $C$ is a 5 -vertex in $G$.

Proof. Let $C$ be a component of $G \backslash N[x]$ with $|C|=1$. Let $y$ be the only vertex in $C$. Suppose $y$ is not a 5 -vertex in $G$. Then $d(y) \geq 8$ by Claims 8 and 9 , and so $N(C)=N(x)$, contrary to Claim 13 . Thus $y$ is a 5 -vertex in $G$. By Claim 11, $G \backslash N[x]$ has at most one such component $C$.

Claim 15. Let $x \in V(G)$ be an 8-vertex in $G$. Then there is no component $C$ of $G \backslash N[x]$ such that $|C| \geq 2$ and for every vertex $y \in V(C)$, either $d_{G}(y)=5$ or $d_{G}(y) \geq 9$.

Proof. Suppose such a component $C$ exists. By Claim 11, $C$ has at most one 5 -vertex in $G$. Let $y \in V(C)$ such that $d_{G}(y) \geq 9$. Then $|V(C) \cup N(C)| \geq 10$. By Claim $13, N(C) \neq N(x)$. Thus $|C| \geq|N[y] \backslash N(C)| \geq 10-7=3$. Let $G_{1}:=G \backslash C$ and $G_{2}:=G[C \cup N(C)]$. Note that $\left|G_{2}\right| \geq 10$ and $N(C)$ is a minimal separating set of $G$. Let $d_{1}$ be defined as in the paragraph prior to Claim 4 . Let $z \in N(C)$ such that $d_{G[N(C)]}(z)=\delta(G[N(C)])$. Let $d:=d_{G[N(C)]}(z)$. By contracting $G_{1} \backslash N(C)$ onto $z$, we see that $d_{1} \geq|N(C)|-d-1$. By $(*)$,

$$
\begin{equation*}
e\left(G_{2}\right)<4.5(|C|+|N(C)|)-12-(|N(C)|-d-1)=4.5|C|+3.5|N(C)|+d-11 \tag{a}
\end{equation*}
$$

Now let $t=e_{G}(C, N(C))$. Then $e\left(G_{2}\right)=e(C)+t+e(G[N(C)])$. Note that $2 e(C) \geq 9(|C|-1)+5-t$ and $2 e(G[N(C)]) \geq d|N(C)|$, so we have

$$
\begin{equation*}
2 e\left(G_{2}\right)=2 e(C)+2 t+2 e(G[N(C)]) \geq 9|C|-4+t+d|N(C)| \tag{b}
\end{equation*}
$$

Combining (a) and (b) yields

$$
9|C|+7|N(C)|+2 d-22>2 e\left(G_{2}\right) \geq 9|C|-4+t+d|N(C)|
$$

and so

$$
\begin{equation*}
-t>d(|N(C)|-2)-7|N(C)|+18 \tag{c}
\end{equation*}
$$

Note that $\delta(G[N(x)]) \geq 4$ by Claim 2, and $N(C)$ is a subset of $N(x)$, so

$$
d=\delta(G[N(C)]) \geq 4-(8-|N(C)|)=|N(C)|-4
$$

This, together with (c), implies that

$$
\begin{aligned}
-t & >(|N(C)|-4)(|N(C)|-2)-7|N(C)|+18 \\
& =|N(C)|^{2}-13|N(C)|+26 \\
& =\left(|N(C)|-\frac{13}{2}\right)^{2}-\frac{65}{4}
\end{aligned}
$$

so $-t \geq-16$. But then

$$
|C|(|C|-1) \geq 2 e(C) \geq 9(|C|-1)+5-t \geq 9|C|-20
$$

which implies that $|C| \geq 8$ because $|C| \geq 3$. Thus $G \succcurlyeq C \succcurlyeq \mathcal{K}_{8}^{-4}$, contrary to the choice of $G$.

To complete the proof, since $e(G)=\lceil 4.5 n-12\rceil$, we have $\delta(G) \leq 8$. By Claims 3,8 and 9 , let $x$ be an 8-vertex in $G$. By Claim 14, let $C$ be a component of $G \backslash N_{G}[x]$ with $|C| \geq 2$ and, subject to that, $x$ and $C$ are chosen so that $|C|$ is minimized. By Claims 11 and $15, C$ contains an 8 -vertex, say $y$, in $G$. Note that $N_{G}(x) \neq N_{G}(y)$ because $|C| \geq 2$. Let $K$ be the component of $G \backslash N_{G}[y]$ containing $x$. Then $|K| \geq 2$ because $N_{G}(x) \neq N_{G}(y)$. Note that $N_{G}(x) \cap N_{G}(y) \subseteq N(K)$, and every vertex in $N_{G}(x) \backslash N_{G}(y)$ belongs to $K$. Let $M$ be the set of vertices of $N_{G}(y)$ not adjacent to all other vertices of $N_{G}(y)$. We claim that $M \subseteq N(K)$. Suppose not. Let $z \in M \backslash N(K)$. Then $z \notin N_{G}(x)$, else $z \in N(K)$ because $x \in V(K)$. It follows that $z \in V(C)$. By Claim 12, we have $d_{G}(z) \geq 8$; in addition, $N_{G}(z)$ has no 5 -vertex in $G$ if $d_{G}(z)=8$, and at least one vertex in $N_{G}(z) \backslash N_{G}(y)$ is not a 5 -vertex in $G$ if $d_{G}(z) \geq 9$, due to Claim 11. In either case, let $z^{\prime}$ be a neighbor of $z$ in $G \backslash N_{G}[y]$ such that $d_{G}\left(z^{\prime}\right) \geq 8$. Note that $z^{\prime} \in\left(N_{G}(x) \backslash N_{G}(y)\right) \cup V(C)$. Suppose $z^{\prime} \notin V(K)$. Then $z^{\prime} \in V(C)$ because every vertex in $N_{G}(x) \backslash N_{G}(y)$ belongs to $K$. Let $C^{\prime}$ be the component of $G \backslash N_{G}[y]$ that contains $z^{\prime}$. Then $\left|C^{\prime}\right| \geq 2$ by Claim 14, and $C^{\prime}$ is a proper subset of $C$, contrary to our choice of $x$ and $C$. This proves that $z^{\prime} \in V(K)$, and so $z \in N(K)$, contrary to the choice of $z$. Thus $K$ is a component of $G \backslash N_{G}[y]$ such that $M \subseteq N(K)$, contrary to Claim 13.

This completes the proof of Theorem 1.7.
