#### Abstract

In relation to oriented coloring and chromatic number, the parameter oriented relative clique number of an oriented graph $\vec{G}$, denoted by $\omega_{r o}(\vec{G})$, is the main focus of this work. We solve an open problem mentioned in the recent survey on oriented coloring by Sopena (Discrete Mathematics 2016), and positively settle a conjecture due to Sen ( PhD thesis 2014), by proving that the maximum value of $\omega_{r o}(\vec{G})$ is 10 when $\vec{G}$ is a planar graph.

Keywords: oriented graph • relative clique number • triangle-free planar graph.

## 1 Introduction and the main result

An oriented graph $\vec{G}$ is a directed graph without any directed cycle of length 1 or 2 . The set of vertices and arcs of $\vec{G}$ is denoted by $V(\vec{G})$ and $A(\vec{G})$, respectively. The oriented graph $\vec{G}$ can be obtained by assigning directions to every edge of a simple graph $G$. In such a case, $\vec{G}$ is called an orientation of $G$ and $G$ is called the underlying graph of $\vec{G}$.

The notion of oriented coloring and chromatic number was introduced by Courcelle [2] in 1994 and then, following the works of Raspaud and Sopena [11], the discipline gained popularity [1, 5, 6, 9, 13, 14, 15].

An oriented $k$-coloring of an oriented graph $\vec{G}$ is a mapping $\phi: V(\vec{G}) \rightarrow C$, where $C$ is a set of $k$ colors, such that:

1. $\phi(u) \neq \phi(v)$ for every arc $u v$ in $A(\vec{G})$,

[^0]2. for every two arcs $u v$ and $x y, \phi(v)=\phi(x)$ implies $\phi(u) \neq \phi(y)$.

The oriented chromatic number of $\vec{G}$, denoted by $\chi_{o}(\vec{G})$, is the smallest integer $k$ for which the oriented graph $\vec{G}$ is $k$-colorable. There are two closely associated parameters to $\chi_{o}(\cdot)$, namely, oriented relative clique number and oriented absolute clique number.

A vertex subset $R$ of an oriented graph $\vec{G}$ is an oriented relative clique if $|\phi(R)|=|R|$ for any homomorphism $\phi$ of $\vec{G}$ to any oriented graph. The oriented relative clique number $\omega_{r o}(\vec{G})$ of $\vec{G}$ is the maximum $|R|$ where $R$ is an oriented relative clique of $\vec{G}$. 9 .

The oriented absolute clique is an oriented graph $\vec{G}$ for which $\chi_{o}(V(\vec{G}))=|V(\vec{G})|$. The oriented absolute clique number of a graph $\vec{G}$, denoted by $\omega_{a o}(\vec{G})$, is the maximum order of an oriented absolute clique contained in $\vec{G}$ 4].

Let $p \in\left\{\chi_{o}, \omega_{r o}, \omega_{a o}\right\}$. For a simple graph $G$, the parameter $p(G)$ is given by

$$
p(G)=\max \{p(\vec{G}): \vec{G} \text { is an orientation of } G\}
$$

For a family $\mathcal{F}$ of graphs, the parameter $p(\mathcal{F})$ is given by

$$
p(\mathcal{F})=\max \{p(G) \mid G \in \mathcal{F}\}
$$

From the above definitions, the following relation between the parameters can be inferred [9],

$$
\chi_{o}(\vec{G}) \geq \omega_{r o}(\vec{G}) \geq \omega_{a o}(\vec{G})
$$

It is observed that the parameter oriented chromatic number is an analogue of the ordinary chromatic number, while the oriented analogue of the ordinary clique number ramifies into two parameters: oriented relative and absolute clique number.

The analogous problems to the Four Color Theorem and the Grötzsch's Theorem for oriented graphs, thus, is finding the values of $\chi_{o}\left(\mathcal{P}_{3}\right)$ and $\chi_{o}\left(\mathcal{P}_{4}\right)$, where $\mathcal{P}_{g}$ denotes family of planar graphs with girth at least $g$. Naturally, the associated parameters are also studied for similar graph families, that is, researchers have also shown interest in finding the exact values of $\omega_{r o}\left(\mathcal{P}_{3}\right), \omega_{r o}\left(\mathcal{P}_{4}\right), \omega_{a o}\left(\mathcal{P}_{3}\right), \omega_{a o}\left(\mathcal{P}_{4}\right)$. In fact, finding the exact values of $\chi_{o}\left(\mathcal{P}_{g}\right), \omega_{r o}\left(\mathcal{P}_{g}\right)$, and $\omega_{a o}\left(\mathcal{P}_{g}\right)$ for all values of $g \geq 3$ is an interesting study for the researchers.

Let us briefly discuss the state of the art for these problems. The best known bounds for the oriented chromatic numbers of the above mentioned are $18 \leq \chi_{o}\left(\mathcal{P}_{3}\right) \leq 80$ [7, 8] and $11 \leq \chi_{o}\left(\mathcal{P}_{4}\right) \leq 40$ [10], respectively. The exact values of $\chi_{o}\left(\mathcal{P}_{g}\right)$ for $g \geq 12$ is known to be 5 , however it is open for $g \in\{5,6, \cdots, 11\}$ to date [15]. The oriented relative clique numbers where shown to have the bounds $15 \leq \omega_{\text {ro }}\left(\mathcal{P}_{3}\right) \leq 32$ [3] and $10 \leq \omega_{r o}\left(\mathcal{P}_{4}\right) \leq 14$ [3] respectively, while tight bounds of $\omega_{a o}\left(\mathcal{P}_{3}\right)=15$ [9] and $\omega_{a o}\left(\mathcal{P}_{4}\right)=6$ [9] have been found for the absolute clique numbers. It is worth mentioning that the exact values of $\omega_{r o}\left(\mathcal{P}_{g}\right)$ and $\omega_{a o}\left(\mathcal{P}_{g}\right)$ is known for all $g \geq 5$ [3, 9].

Moreover, the tight bounds for the relative clique numbers is mentioned in the list of open problems in the recent survey on oriented coloring by Sopena [15] while Sen [12] in his thesis has conjectured the values as $\omega_{\text {ro }}\left(\mathcal{P}_{3}\right)=15$ and $\omega_{\text {ro }}\left(\mathcal{P}_{4}\right)=10$, respectively.

In this article, we settle the second open problem and its corresponding conjecture by showing $\omega_{r o}\left(\mathcal{P}_{4}\right)=10$.

Theorem 1.1. For the family $\mathcal{P}_{4}$ of triangle-free planar graphs, we have $\omega_{\text {ro }}\left(\mathcal{P}_{4}\right)=10$.
Organization of the article: we present the preliminaries in Section 2, the proof of the main result in Section 3, and finally conclude the work in Section 4.

## 2 Preliminaries

We follow West [16] for standard graph theory notation. Some useful, but non-standard notation are presented below.

The set of neighbors $N(v)$ of a vertex $v$ is the set of all adjacent vertices of $v$. Given an arc $u v \in A(\vec{G}), u$ is an in-neighbor of $v$ and $v$ is an out-neighbor of $u$. The set of all in-neighbors and out-neighbors of $v$ is denoted by $N^{-}(v)$ and $N^{+}(v)$, respectively. Moreover the degree, in-degree and out-degree of a vertex $v$ is given by $d(v)=|N(v)|$, $d^{-}(v)=\left|N^{-}(v)\right|$ and $d^{+}(v)=\left|N^{+}(v)\right|$, respectively.

Two vertices $u, v$ agree on a third vertex $w$ if $w \in N^{\alpha}(u) \cap N^{\alpha}(v)$ for some $\alpha \in\{+,-\}$. Also $u, v$ disagree on $w$ if $w \in N^{\alpha}(u) \cap N^{\beta}(v)$ for some $\{\alpha, \beta\}=\{+,-\} \mathbb{1}$. A vertex $v$ sees a vertex $u$ if they are adjacent, or they are connected by a directed 2-path. If $u, v$ are connected by a directed 2-path with the third vertex of the directed 2-path being $w$, we say that $u$ sees $v$ via $w$.

Furthermore, given a planar graph and its embedding we will denote the region of the plane corresponding to a face $f$ of the graph by $R_{f}$. The notation is unambiguous always but for some exceptions. In those exceptional cases, we will use a different way to describe a face/region. Thus, there is no scope of ambiguity.

## 3 Proof of Theorem 1.1

The proof implies from the observations and lemmata proved in this section.
Let $\vec{H}$ be a minimal counter example of Theorem [1.1, with respect to lexicographic ordering of $(|V(H)|,|E(H)|)$. Let $R$ be a maximum oriented relative clique of $\vec{H}$. Also let $S=V(H) \backslash R$. The vertices of $R$ are good vertices while that of $S$ are helpers. Notice that, $|R| \geq 11$. Moreover, assume a particular planar embedding of $\vec{H}$ for the rest of this article unless otherwise stated.

The set $S$ of vertices is an independent set, as otherwise we can remove an edge with both end points in $S$ in order to obtain a smaller counter example contradicting the minimality of $\vec{H}$.

We want to show that any helper $h$ in $\vec{H}$ has $d(h)=2$. To begin with, note that $\vec{H}$ is connected due to its minimality. Moreover if $d(h)=1$, then even after deleting the vertex $h$ the set $R$ remains a oriented relative clique. Thus $d(h) \geq 2$. To begin with, we will improve the above result.

The proof of the following result was implicit inside the proof of Theorem 11 in the paper by Klostermeyer and MacGillivray [4]. However, we reprove it for the sake of completeness.

[^1]

Figure 1: Five good vertices $v_{1}, v_{2}, \cdots, v_{5}$ agreeing on a vertex $v$

Lemma 3.1. Five good vertices $v_{1}, v_{2}, \cdots, v_{5}$ cannot agree on a vertex $v$.
Proof. As $H$ is triangle-free, $v_{1}, v_{2}, \cdots, v_{5}$ are independent vertices. Assume that $v_{1}, v_{2}, \cdots, v_{5}$ are arranged in a clockwise order around $v$ in the planar embedding of $H$ and that the five vertices agree with each other on $v$. Note that $v_{2}$ must see $v_{4}$ via some vertex $h_{1}$. Observe that $R_{v v_{2} h_{1} v_{4} v}$ will contain $v_{3}$, but not $v_{1}$ and $v_{5}$ (see Fig. (1). Therefore, $v_{3}$ is forced to see $v_{1}$ and $v_{5}$ via $h_{1}$. This implies that either $v_{1}$ does not see $v_{4}$ or $v_{2}$ does not see $v_{5}$.

Using triangle-freeness of the planar graph, we can do a bit better than above.

Figure 2: Four good vertices $v_{1}, v_{2}, v_{3}, v_{4}$ agreeing with each other on a vertex $v$.

Lemma 3.2. Four good vertices $v_{1}, v_{2}, v_{3}, v_{4}$ cannot agree with each other on a vertex $v$.
Proof. Without loss of generality, assume that $v_{1}, v_{2}, v_{3}, v_{4}$ are arranged in a clockwise order around $v$ in the planar embedding of $H$ and that they are out-neighbors of $v$. Note

[^2]that $v_{2}$ must see $v_{4}$ via some $h_{1}$ as $H$ is triangle-free. Observe that $R_{v v_{2} h_{1} v_{4} v}$ will contain $v_{3}$, but not $v_{1}$. Therefore, $v_{1}$ is forced to see $v_{3}$ via $h_{1}$. Without loss of generality we may assume that $v_{1}, v_{2} \in N^{-}\left(h_{1}\right)$ and that $v_{3}, v_{4} \in N^{+}\left(h_{1}\right)$.

Observe that $v_{1}$ must see $v_{2}$ via some $h_{2}$ and $v_{3}$ must see $v_{4}$ via some $h_{3}$. As $h_{2}$ cannot see $v_{4}, h_{2}$, it is a helper. Similarly, as $h_{3}$ cannot see $v_{2}, h_{2}$, it is a helper (see Fig. (2).

Any good vertex containing in $R_{v_{1} h_{2} v_{2} h_{1} v_{1}}$ (resp., in $R_{v_{3} h_{3} v_{4} h_{1} v_{3}}$ ) must see $v_{3}$ (resp., $v_{2}$ ) via $h_{1}$ as that is the only option. Thus, it cannot see $v$ as it will force a triangle. On the other hand, for similar reasons, any good vertex contained in $R_{v v_{1} h_{2} v_{2} v}$ or in $R_{v v_{3} h_{3} v_{4} v}$ is an in-neighbor of $v$ in order for seeing $v_{3}$ or $v_{2}$ via $v$. However, if each of $R_{v v_{1} h_{2} v_{2} v}$ and $R_{v v_{3} h_{3} v_{4} v}$ contains at least one good vertex, they cannot see each other. Therefore, without loss of generality $R_{v v_{3} h_{3} v_{4} v}$ does not contain any good vertex.

Any good vertex contained in $R_{v v_{2} h_{1} v_{3} v}$ (resp., in $R_{v v_{1} h_{1} v_{4} v}$ ) cannot, respectively, see $v_{1}, v_{4}$ (resp., $v_{2}, v_{3}$ ) via $h_{1}$ alone. Thus they must see some of them via $v$. Hence any good vertex contained in $R_{v v_{2} h_{1} v_{3} v}$ or in $R_{v v_{1} h_{1} v_{4} v}$ is also an in-neighbor of $v$. As

$$
\left.\mid R \backslash\left\{v, v_{1}, v_{2}, v_{3}, v_{4}, h_{1}\right\}\right) \mid \geq 5
$$

we have at least five good vertices agreeing on $v$. This contradicts Lemma 3.1,
Using the above result, we prove the following.

Figure 3: Three good vertices $v_{1}, v_{2}, v_{3}$ disagree with a fourth good vertex $v_{4}$ on a vertex $v$.

Lemma 3.3. It is not possible to have three good vertices $v_{1}, v_{2}, v_{3}$ disagree with a fourth good vertex $v_{4}$ on a vertex $v$.

Proof. Assume that $v_{1}, v_{2}, v_{3}, v_{4}$ are arranged in a clockwise order around $v$ in the planar embedding of $H$ and that $v_{1}, v_{2}, v_{3} \in N^{-}(v)$ while $v_{4} \in N^{+}(v)$.

Note that $v_{1}$ must see $v_{3}$ via some $h_{1}$. Without loss of generality assume that $v_{1} \in$ $N^{-}\left(h_{1}\right)$ and $v_{3} \in N^{+}\left(h_{1}\right)$. Let the face $v v_{1} h_{1} v_{3} v$ divides the plane into two connected regions: $A$ is the one containing $v_{2}$ and $B$ is the one containing $v_{4}$. Assume that each of
$A$ and $B$ contains a good vertex. Suppose a good vertex $w_{1}$ is contained in $A$ and another good vertex $w_{2}$ is contained in $B$ (see Fig. (3)).

Observe that $w_{1}$ cannot see $w_{2}$ or $v_{4}$ via $v$, as otherwise four vertices will agree on $v$ contradicting Lemma 3.2. Hence, $w_{1}$ must see $v_{4}$ via $h_{1}$. This forces $w_{1}$ to see $w_{2}$ also via $h_{1}$ to avoid creating a triangle. Thus each vertex of $R \backslash\left\{v, v_{1}, v_{2}, v_{3}, v_{4}, h_{1}\right\}$ must be adjacent to $h_{1}$. However as

$$
\left|R \backslash\left\{v, v_{1}, v_{2}, v_{3}, v_{4}, h_{1}\right\}\right| \geq 5
$$

the vertex $h_{1}$ has at least seven good neighbors. Hence by pigeonhole principle at least four good vertices agree on $h_{1}$, a contradiction to Lemma 3.2.

Therefore, all the vertices of $R \backslash\left(N(v) \cup\left\{v, h_{1}\right\}\right)$ must be contained either in $A$ or in $B$. If they are all inside $A$, then they have to see $v_{4}$. The only options are via $v$ or $h_{1}$. If one of them sees $v_{4}$ via $v$, then $v$ agrees on at least four good vertices contradicting Lemma 3.2. Thus all the vertices of $R \backslash\left(N(v) \cup\left\{v, h_{1}\right\}\right)$ sees $v_{4}$ via $h_{1}$, again contradicting Lemma 3.2 as

$$
\left|R \backslash\left\{v, v_{1}, v_{2}, v_{3}, v_{4}, h_{1}\right\}\right| \geq 5
$$

On the other hand, if they are all inside $B$, then they have to see $v_{2}$. The only options are via $v$ or $h_{1}$. If three of them sees $v_{2}$ via $v$, then $v$ agrees on at least four good vertices contradicting Lemma 3.2. Thus at most two of the vertices can see $v_{2}$ via $v$. As

$$
\left|R \backslash\left\{v, v_{1}, v_{2}, v_{3}, v_{4}, h_{1}\right\}\right| \geq 5
$$

at least three vertices of $R \backslash\left\{v, v_{1}, v_{2}, v_{3}, v_{4}, h_{1}\right\}$ sees $v_{2}$ via $h_{1}$, yet again contradicting Lemma 3.2.

Now we focus on proving that a vertex $v$ cannot have two good in-neighbors and two good out-neighbors. The proof is divided into two cases. The first case is as follows.

Lemma 3.4. Let $v_{1}, v_{2}, v_{3}, v_{4}$ be good neighbors of a vertex $v$ arranged in a clockwise order around $v$. It is not possible to have $v_{1}, v_{3} \in N^{+}(v)$ and $v_{2}, v_{4} \in N^{-}(v)$.

Proof. Assume that $v_{1}$ sees $v_{3}$ via some $h_{1}$. Then $v_{2}$ is forced to see $v_{4}$ via $h_{1}$ as well. Let $w_{1}$ be a good vertex contained inside $R_{v v_{i} h_{1} v_{i+1} v}$, where $i \in\{1,2,3,4\}$ and + operation is taken modulo 4 . Note that $w_{1}$ have to see $v_{i+2}$ ( + is taken modulo 4) via $v$ or $h_{1}$. In either case, $v$ or $h_{1}$ becomes adjacent to four good vertices among which three disagree with the fourth one on $v$ or $h_{1}$, respectively. This is a contradiction to Lemma 3.3.

Now we present the second case.
Lemma 3.5. Let $v_{1}, v_{2}, v_{3}, v_{4}$ be good neighbors of a vertex $v$ arranged in a clockwise order around $v$. It is not possible to have $v_{1}, v_{2} \in N^{+}(v)$ and $v_{3}, v_{4} \in N^{-}(v)$.

Proof. Assume that $v_{1}$ sees $v_{2}$ via some $h_{1}$. Also suppose that $v_{3}$ sees $v_{4}$ via the same $h_{1}$. Let $w_{1}$ be a good vertex contained inside $R_{v v_{i} h_{1} v_{i+1} v}$, where $i \in\{1,2,3,4\}$ and + operation is taken modulo 4 . Note that $w_{1}$ have to see $v_{i+2}$ ( + is taken modulo 4) via $v$ or $h_{1}$. In either case, $v$ or $h_{1}$ becomes adjacent to four good vertices among which three disagree with the fourth one on $v$ or $h_{1}$, respectively. This is a contradiction to Lemma 3.3.

Figure 4: $v_{1}, v_{2} \in N^{+}(v)$ and $v_{3}, v_{4} \in N^{-}(v)$

Thus $v_{3}$ must see $v_{4}$ via a different vertex $h_{2}$ (see Fig. (4). If the region $R_{v v_{1} h_{1} v_{2} v}$ contain a vertex $w$, then $w$ must see $v_{3}, v_{4}$ via $h_{1}$ contradicting Lemma 3.3. Thus $R_{v v_{1} h_{1} v_{2} v}$ does not contain a good vertex. Similarly, $R_{v v_{3} h_{1} v_{4} v}$ also does not contain a good vertex.

Let $W=R \backslash\left\{v_{1}, v_{2}, v_{3}, v_{4}, v, h_{1}, h_{2}\right\}=\left\{w_{1}, w_{2}, \cdots, w_{t}\right\}$. Observe that $|W|=t \geq 4$. Note that a $w_{i}$ must be contained in $R_{v v_{1} h_{1} v_{2} v v_{3} h_{2} v_{4} v}$ and can see at most two of the four good vertices $v_{1}, v_{2}, v_{3}, v_{4}$ via a particular vertex due to Lemma 3.3. Now let us consider some cases.

- If $w_{1}$ sees $v_{1}, v_{2}$ via $h_{3}$ and $v_{3}, v_{4}$ via $h_{4}$, then both $w_{2}$ and $w_{3}$ (irrespective of their placement) is forced to see $v_{1}$ or $v_{2}$ via $h_{3}$ and $v_{3}$ or $v_{4}$ via $h_{4}$ creating a vertex with three good neighbor disagreeing on it with a fourth one. This is a contradiction to Lemma 3.3.
- If $w_{1}$ sees $v_{1}, v_{3}$ via $h_{3}$ and $v_{2}, v_{4}$ via $h_{4}$, then the graph $H$ no longer remains planar.
- If $w_{1}$ sees $v_{1}, v_{2}$ via $h_{3}$ and $v_{3}$ via $h_{4}$ (or by being adjacent to it) and $v_{4}$ via $h_{5}$ (or by being adjacent to it), then $w_{2}$ is not able to see at least one of $v_{1}, v_{2}, v_{3}, v_{4}$ irrespective of its placement.
- If $w_{1}$ sees $v_{1}$ via $h_{3}$ (or by being adjacent to it) and $v_{2}$ via $h_{4}$ (or by being adjacent to it) and $v_{3}$ via $h_{5}$ (or by being adjacent to it) and $v_{4}$ via $h_{6}$ (or by being adjacent to it), then $w_{2}$ is not able to see at least two of $v_{1}, v_{2}, v_{3}, v_{4}$ irrespective of its placement.

Thus we are done.
Therefore, we can conclude that the graph $\vec{H}$ does not have any vertex $v$ with at least four good neighbors. However, we want to improve this and show that $|N(v) \cap R| \leq 2$ for any $v \in V(\vec{H})$. Indeed, the previous results will be used to prove so.

Lemma 3.6. Three good vertices $v_{1}, v_{2}, v_{3}$ cannot agree with each other on a vertex $v$.
Proof. Let $v_{1}$ see $v_{2}$ via some $h_{1}$. Let $v_{3}$ also see $v_{2}$ via $h_{1}$.
Let $w_{1}$ be a good vertex contained inside $R_{v v_{i} h_{1} v_{i+1} v}$, where $i \in\{1,2,3\}$ and + operation is taken modulo 3. Note that $w_{1}$ have to see $v_{i+2}\left(+\right.$ is taken modulo 3) via $v$ or $h_{1}$. In either case, $v$ (or $h_{1}$ ) becomes adjacent to four good vertices contradicting Lemma 3.3, 3.4 or 3.5.

Hence $v_{2}$ must see $v_{3}$ via $h_{2}$ and $v_{3}$ must see $v_{1}$ via $h_{3}$. Let $w_{1}$ be a good vertex contained inside $R_{v v_{i} h_{i} v_{i+1} v}$, where $i \in\{1,2,3\}$ and + operation is taken modulo 3 . Note that $w_{1}$ have to see $v_{i+2}$ ( + is taken modulo 3 ) via $v$ or $h_{i}$. In either case, $v$ (or $h_{i}$ ) becomes adjacent to four good vertices contradicting Lemma 3.3, 3.4 or 3.5,

Therefore, every vertex of $W=R \backslash\left\{v, v_{1}, v_{2}, v_{3}, h_{1}, h_{2}, h_{3}\right\}$ must be contained in $R_{v_{1} h_{1} v_{2} h_{2} v_{3} h_{3} v_{1}}$ and $|W| \geq 4$.

Note that a $w_{i}$ must be contained in $R_{v_{1} h_{1} v_{2} h_{2} v_{3} h_{3} v_{1}}$ and can see at most two of the three good vertices $v_{1}, v_{2}, v_{3}$ via a particular vertex due to Lemma 3.3. Now let us consider some cases.

- If $w_{1}$ sees $v_{1}, v_{2}$ via $h_{4}$ and $v_{3}$ via $h_{5}$, then $w_{2}$ (irrespective of their placement) is forced to see $v_{1}$ or $v_{2}$ via $h_{4}$ creating a vertex with four good neighbors, a contradiction.
- If $w_{1}$ sees $v_{1}$ via $h_{4}$ (or by being adjacent to it) and $v_{2}$ via $h_{5}$ (or by being adjacent to it) and $v_{3}$ via $h_{6}$ (or by being adjacent to it), then $w_{2}$ is not able to see at least one of $v_{1}, v_{2}, v_{3}$ irrespective of its placement.

Thus, we are done.
The final lemma in the similar direction follows.
Lemma 3.7. It is not possible to have two good vertices $v_{1}, v_{2}$ disagree with a third good vertex $v_{3}$ on a vertex $v$.

Proof. Let $v_{1}$ see $v_{2}$ via some $h_{1}$. The cycle $v v_{1} h_{1} v_{2} v$ divides the plane into two connected regions: $A$ containing $v_{3}$ and $B$ not containing $v_{3}$.

Let $w_{1}$ be a good vertex contained inside $B$. Note that $w_{1}$ have to see $v_{3}$ via $v$ or $h_{1}$. In either case, $v$ (or $h_{1}$ ) becomes adjacent to four good vertices contradicting Lemma 3.3, 3.4 or 3.5. Therefore, every vertex of $W=R \backslash\left\{v, v_{1}, v_{2}, v_{3}, h_{1}\right\}=\left\{w_{1}, w_{2}, \cdots, w_{t}\right\}$ must be contained in $A$. Notice that $|W|=t \geq 6$.

Note that a $w_{i}$ must be contained in $A$ and can see at most two of the three good vertices $v_{1}, v_{2}, v_{3}$ via a particular vertex. Now let us consider some cases.

- If $w_{1}$ sees $v_{1}, v_{2}$ via $h_{2}$ and $v_{3}$ via $h_{3}$, then $w_{2}$ (irrespective of their placement) is forced to see $v_{1}$ or $v_{2}$ via $h_{2}$ creating a vertex with four good neighbors, a contradiction.
- If $w_{1}$ sees $v_{1}$ via $h_{2}$ (or by being adjacent to it) and $v_{2}$ via $h_{3}$ (or by being adjacent to it) and $v_{3}$ via $h_{4}$ (or by being adjacent to it), then $w_{2}$ is not able to see at least one of $v_{1}, v_{2}, v_{3}$ irrespective of its placement.

Thus we are done.
This implies that the graph $\vec{H}$ does not have any vertex $v$ with at least three good neighbors.

Lemma 3.8. It is not possible for a vertex to have at least three good neighbors.
Proof. Follows directly from Lemma 3.6 and 3.7 .

In particular, for any helper $h$ we have $d(h) \leq 2$. Thus, using our earlier observation that the degree of $h$ is at least 2 , we can conclude that $d(h)=2$.

Observe that two helpers $h_{1}$ and $h_{2}$ cannot have $N\left(h_{1}\right)=N\left(h_{2}\right)=\{u, v\}$. The reason is, both $h_{1}$ and $h_{2}$ contributes in $u$ seeing $v$. Therefore, even if we delete $h_{2}$, the set $R$ still remains an oriented relative clique contradicting the minimality of $\vec{H}$.

Now construct a graph $H^{*}$ from $H$ as follows: delete each helper and add an edge between its neighbors. Observe that $H^{*}$ is planar, not necessarily triangle-free, with $V\left(H^{*}\right)$ being the set of good neighbors of $\vec{H}$. Also the degree of a vertex $v$ in $H^{*}$ is greater than equal to the degree of $v$ in $H$. As $H^{*}$ is a planar graph, it must have a vertex $x$ with degree at most five. Therefore, we can say that there exists a good vertex $x$ in $\vec{H}$ having degree at most five. We fix the name of this vertex $x$ for the rest of this section.
Proof of Theorem 1.1. Let $x$ be a good vertex of $\vec{H}$ having degree at most five whose existence follows from the above paragraph. Let $X=R \backslash(N(x) \cup\{x\})$. We know due to Lemma 3.8 that $|R \cap N(x)| \leq 2$.

As $|R| \geq 11$, we have $|X| \geq 8$. Note that each vertex of $X$ must see $x$ via one of its neighbors. Therefore, by pigeonhole principle at least one of the neighbors $x_{1}$ (say) of $x$ will have two good neighbors from $X$. Thus $x_{1}$ has three good neighbors, contradicting Lemma 3.8.

## 4 Conclusions

Among the set of open problems concerning the analogue of clique numbers for oriented planar graphs having girth $g$, exact values were known for all cases except for $\omega_{r o}\left(\mathcal{P}_{3}\right)$ and $\omega_{r o}\left(\mathcal{P}_{4}\right)$. Here we find the exact value for the later, leaving only the former as an open problem.
