Abstract

In an isolated quantum many-body system undergoing unitary evolution, we study the thermalization of a subsystem, treating the rest of the system as a bath. In this setting, the eigenstate thermalization hypothesis (ETH) was proposed to explain thermalization. Consider a nearly integrable Sachdev-Ye-Kitaev model obtained by adding random all-to-all 4-body interactions as a perturbation to a random free-fermion model. When the subsystem size is larger than the square root of but is still a vanishing fraction of the system size, we prove thermalization if the system is initialized in a random product state, while almost all eigenstates violate the ETH. In this sense, the ETH is not a necessary condition for thermalization.

1 Introduction

1.1 Background

Thermalization is a fundamental concept in statistical mechanics. It says that a system in contact with a bath tends to evolve to a Gibbs state described by the canonical ensemble. Suppose an isolated quantum many-body system is initialized in a pure state. Under unitary evolution the system stays in a pure state and never thermalizes. To study thermalization, we divide the system into two parts A and \bar{A} such that subsystem A is much smaller than \bar{A} . We view \bar{A} as a bath of A and consider the thermalization of A , i.e., whether physical properties measured on A evolve to those of a Gibbs state.

It is important to understand the mechanism of thermalization. A proposal is the eigenstate thermalization hypothesis (ETH) [1–4].

^{*}aram@mit.edu

[†]yichenhuang@fas.harvard.edu

Definition 1. A state is A -thermal if its reduced density matrix for subsystem A is approximately equal to¹ that of a Gibbs state with the same energy.

Definition 2 (eigenstate thermalization hypothesis). An eigenstate obeys the ETH with respect to subsystem A if it is A -thermal.

An important feature of this definition is the size of subsystem A . This will be discussed in Subsection 1.3.

Definition 2 refers only to individual eigenstates, but one might also want to discuss the ETH for systems (i.e., Hamiltonians). In the literature, the term “strong ETH” or “weak ETH” [5–7], respectively, refers to systems where all or almost all eigenstates (possibly within some energy interval) obey the ETH. In this paper, unless otherwise noted, statements about the ETH refer to individual eigenstates.

For a Hamiltonian H , let $|\Psi_0\rangle$ and $|\Psi_t\rangle := e^{-iHt}|\Psi_0\rangle$ be the initial and time-evolved states, respectively.

Definition 3 (thermalization). Thermalization means that $|\Psi_t\rangle$ becomes A -thermal as t grows.

We present a well-known argument [8–10] for “ETH implies thermalization” based on two assumptions.

Assumption 1. The spectrum of H is non-degenerate (all eigenvalues are distinct).

Remark. Intuitively, this assumption is usually valid if H does not have any symmetry. Rigorously, it holds with probability 1 if H is a random Hamiltonian from the Gaussian unitary ensemble. It also holds for almost every local Hamiltonian on a lattice [6].

Let $|1\rangle, |2\rangle, \dots$ be a complete set of eigenstates of H with corresponding energies E_1, E_2, \dots .

Assumption 2. The energy distribution of $|\Psi_0\rangle$ is sharply peaked around the mean $E := \langle \Psi_0 | H | \Psi_0 \rangle$ in the sense that

$$\sum_{j: E_j \approx E} p_j \approx 1, \quad p_j := |\langle j | \Psi_0 \rangle|^2. \quad (1)$$

Remark. If H is a local Hamiltonian on a lattice, (1) with explicit error bounds was proved for any $|\Psi_0\rangle$ with exponential decay of correlations [11].

Assumption 1 implies that the time-averaged state

$$\bar{\rho} := \lim_{\tau \rightarrow +\infty} \frac{1}{\tau} \int_0^\tau |\Psi_t\rangle \langle \Psi_t| dt = \sum_j p_j |j\rangle \langle j| \quad (2)$$

is obtained by dephasing $|\Psi_0\rangle$ in the energy eigenbasis. Then, Assumption 2 implies that

$$\bar{\rho} \approx \sum_{j: E_j \approx E} p_j |j\rangle \langle j|. \quad (3)$$

¹More precisely, “approximately equal to” means that the trace distance between the two reduced density matrices vanishes in the thermodynamic limit.

If every $|j\rangle$ in the sum on the right-hand side is A -thermal, then $\bar{\rho}$ is A -thermal.

To establish thermalization, it is necessary that $\bar{\rho}$ is A -thermal. Furthermore, one needs to prove equilibration, i.e., the temporal fluctuation of the reduced density matrix of $|\Psi_t\rangle$ for subsystem A is small. This can be done under mild additional assumptions [12–14].

Question 1. Is the ETH a necessary condition for thermalization?

A positive answer to this question would further justify the essence of the ETH as an explanation for the emergence of the canonical ensemble from unitary evolution. If the answer is negative, then it is time to call for other mechanisms of thermalization. Either way Question 1 is illuminating.

The answer to Question 1 depends on the set of initial states under consideration. If the initial state is an eigenstate, then the system does not evolve and thus thermalization trivially implies the ETH.

De Palma et al. [15] considered initial states of the form $|\Psi_A\rangle \otimes |\Psi_{\bar{A}}\rangle$, where $|\Psi_A\rangle$ is an arbitrary pure state of subsystem A ; $|\Psi_{\bar{A}}\rangle$ has a sharply peaked energy distribution but is otherwise arbitrary. If all such initial states lead to thermalization, the ETH was proved under some assumptions, one of which is that the Hilbert space dimension of A is much smaller than the heat capacity of \bar{A} . In a system of N qubits, if the heat capacity is extensive, this assumption implies that $L \lesssim \ln N$, where L is the number of qubits in A .

However, eigenstates of local Hamiltonians and $|\Psi_{\bar{A}}\rangle$ typically have high complexity and cannot be efficiently prepared. We will focus on initial states of low complexity because they are more relevant to experiments and are more plausible models of naturally occurring states.

1.2 Results (informal)

In this paper, we consider a nearly integrable complex Sachdev-Ye-Kitaev (SYK) model in a system of N (Dirac) fermionic modes. The model has fermion number conservation and is obtained by adding random all-to-all 4-body interactions as a perturbation to a random free-fermion model. If the perturbation is sufficiently small, the eigenstates are close to random Gaussian states with definite fermion number. We prove that they obey and violate the ETH with overwhelming probability for $L \ll \sqrt{N}$ and $L \gtrsim \sqrt{N}$, respectively, where L is the number of fermionic modes in subsystem A . (We write $x \ll y$ if $x/y \rightarrow 0$ as $N \rightarrow \infty$; $x \gtrsim y$ if $x/y \geq c$ for some constant $c > 0$.) Previously, Magán [16] showed that random Gaussian states with definite fermion number obey the ETH in an average sense for $L \leq 2$.

Let the initial state $|\Psi_0\rangle$ be a (random) product state, where each fermionic mode is either vacant or occupied. No matter how small the perturbation is, the effect of the perturbation becomes crucial at sufficiently long times. Previously, we proved entanglement thermalization with high probability [17].

Definition 4 (entanglement thermalization [18]). For $L \leq N/2$ and to leading order in L , the entanglement entropy of subsystem A evolves to the thermodynamic entropy of A at the same energy.

Here we prove thermalization (Definition 3) with high probability when $L \ll N/\ln N$. However, thermalization never occurs when $L \geq cN$ for an arbitrarily small constant $c > 0$.

Table 1: Summary of results in the thermodynamic limit $N \rightarrow \infty$. L is the subsystem size. While eigenstate thermalization is a static property of the Hamiltonian, thermalization and entanglement thermalization are dynamic processes, in which the initial state is a (random) product state. Smiley (frown) means that the phenomenon in the column occurs (does not occur) when N and L satisfy the relation in the row. “Thermalization without eigenstate thermalization” is proved for $\sqrt{N} \lesssim L \ll N/\ln N$.

	eigenstate thermalization (Definition 2)	thermalization (Definition 3)	entanglement thermalization (Definition 4)
$L \ll \sqrt{N}$	☹ Theorem 1	☺ Theorem 4	☺ [17]
$\sqrt{N} \lesssim L \ll N/\ln N$	☹ Theorems 2, 3		
$cN < L \leq N/2$ for arbitrarily small constant $c > 0$		☹ Theorem 5	

Table 1 summarizes our results. “Thermalization without eigenstate thermalization” (the title of this paper) is proved for $\sqrt{N} \lesssim L \ll N/\ln N$. Although the subsystem size L is not upper bounded by a constant, it is still a vanishing fraction of the system size N .

“Thermalization without eigenstate thermalization” can be understood as follows. $\bar{\rho}$ is A -thermal if every $|j\rangle$ in the sum on the right-hand side of (3) is A -thermal. However, this gives only a sufficient condition for $\bar{\rho}$ being A -thermal. It could be possible that while most $|j\rangle$ ’s are not A -thermal, $\bar{\rho}$ (a mixture of many $|j\rangle$ ’s) is A -thermal because the deviations of different $|j\rangle$ ’s from A -thermality cancel. This possibility provably occurs in our model.

1.3 Eigenstate thermalization hypothesis

ETH for systems. Definition 2 is the definition of the ETH for individual eigenstates. Previous work has also defined the ETH for systems: A Hamiltonian obeys the strong or weak ETH (in an energy interval) if all or almost all² eigenstates (in the energy interval) obey the ETH, respectively.

Our results on the ETH (summarized in the second column of Table 1) apply to random eigenstates of random Hamiltonians. If we view them as statements about Hamiltonians, they imply that the weak ETH holds and fails with overwhelming probability for $L \ll \sqrt{N}$ and $L \gtrsim \sqrt{N}$, respectively.

Previous work by Mori and Shiraishi [19] showed evidence of thermalization in a model that obeys the weak ETH but not the strong ETH.³ In their model, for a generic initial state, the total weight of ETH-violating eigenstates in the sum on the right-hand side of (3) is negligible. Thus, the thermalization observed in Ref. [19] could be explained by the weak ETH. By contrast, in our model, for $\sqrt{N} \lesssim L \ll N/\ln N$, we observe thermalization without even the weak ETH, so $\bar{\rho}$ is A -thermal even though most eigenstates on the right-hand side

²“Almost all” means that the fraction of ETH-violating eigenstates (in the energy interval) vanishes in the thermodynamic limit.

³Using a combination of analytical and numerical methods, it was shown [20] that an exponentially small (in the system size) fraction of the eigenstates of the model violate the ETH.

of (3) are not.

Subsystem size in ETH. The idea behind the ETH is that eigenstates should look thermal with respect to “simple” observables. Since we lack a general proof of when the ETH holds, we cannot precisely determine which observables should be included here. One plausible approach is to consider all observables that act non-trivially only on a sufficiently small subsystem. Indeed, Ref. [21] provided evidence that in systems with spatially local interactions, the ETH fails if the subsystem size is a constant fraction of the system size.

In our model, we observe a sharp threshold in the subsystem size L : If $L \ll \sqrt{N}$ then the ETH holds for most eigenstates and if $L \gtrsim \sqrt{N}$ then it fails for most eigenstates. Our model (9) has non-local interactions and has the same set of eigenstates as an integrable Hamiltonian. In the future, it would be interesting to study the validity of the ETH with respect to the subsystem size in systems that are non-integrable and/or have spatially local interactions.

2 Results (formal)

2.1 Model and definitions

The real (complex) SYK q model [22–26] is a quantum mechanical model of Majorana (Dirac) fermions with random all-to-all q -body interactions (“ q -body” means that each term in the Hamiltonian acts non-trivially only on q fermionic modes).

Consider an N -mode (Dirac) fermionic system with creation and annihilation operators a_j^\dagger, a_j indexed by $j = 1, 2, \dots, N$. Let A be an arbitrary subsystem of L fermionic modes and \bar{A} be the complement of A (rest of the system).

Definition 5 (complex SYK2 model). Let h be a random matrix of order N from the Gaussian unitary ensemble. The Hamiltonian of the complex SYK2 model is

$$H_{\text{SYK2}} = a^\dagger h a, \quad (4)$$

where $a := (a_1, a_2, \dots, a_N)^T$ is a column vector of N annihilation operators.

Definition 6 (complex SYK4 model [24, 26]). Let

$$\mathcal{I} := \{(j, k, l, m) \in \{1, 2, \dots, N\}^{\times 4} : (j < k) \text{ and } (l < m) \text{ and } (jN + k \leq lN + m)\} \quad (5)$$

and $J := \{J_{jklm}\}_{(j,k,l,m) \in \mathcal{I}}$ be a collection of $|\mathcal{I}|$ independent complex Gaussian random variables with zero mean $\overline{J_{jklm}} = 0$ and unit variance $\overline{|J_{jklm}|^2} = 1$. The Hamiltonian of the complex SYK4 model is

$$H_{\text{SYK4}} = \sum_{(j,k,l,m) \in \mathcal{I}} J_{jklm} a_j^\dagger a_k^\dagger a_l a_m + \text{H.c.}, \quad (6)$$

where “H.c.” means Hermitian conjugate.

Let

$$Q := \sum_{j=1}^N a_j^\dagger a_j \quad (7)$$

be the fermion number operator. Let ϵ_1, ϵ_2 be infinitesimal and

$$H_{\text{SYK}} := H_{\text{SYK2}} + \epsilon_2 H_{\text{SYK4}}. \quad (8)$$

Our model is

$$H = Q + \epsilon_1 H_{\text{SYK}} = Q + \epsilon_1 H_{\text{SYK2}} + \epsilon_1 \epsilon_2 H_{\text{SYK4}}. \quad (9)$$

Both H_{SYK} and H are nearly integrable as both H_{SYK2} and $Q + \epsilon_1 H_{\text{SYK2}}$ are integrable models of free fermions. By definition, the complex SYK2 and SYK4 models and hence H_{SYK} and H conserve fermion number in that

$$[H_{\text{SYK2}}, Q] = [H_{\text{SYK4}}, Q] = [H_{\text{SYK}}, Q] = [H, Q] = 0. \quad (10)$$

Let

$$\sigma_\beta := e^{-\beta H} / \text{tr}(e^{-\beta H}) \quad (11)$$

be a thermal state at inverse temperature β . Neglecting infinitesimal quantities, the reduced density matrix of subsystem A is

$$\sigma_{\beta,A} := \text{tr}_{\bar{A}} \sigma_\beta = e^{-\beta Q_A} / \text{tr}(e^{-\beta Q_A}), \quad (12)$$

where

$$Q_A := \sum_{j \in A} a_j^\dagger a_j \quad (13)$$

is the restriction of Q to A . Let $|\phi\rangle$ be such that that $Q|\phi\rangle = n|\phi\rangle$. If σ_β and $|\phi\rangle$ have the same energy, then

$$\text{tr}(\sigma_\beta H) = \langle \phi | H | \phi \rangle = n \implies \beta = \ln(N/n - 1). \quad (14)$$

Let $\|B\|_1 := \text{tr} \sqrt{B^\dagger B}$ denote the trace norm of a linear operator B . The trace distance

$$T(\rho_1, \rho_2) := \|\rho_1 - \rho_2\|_1 / 2 = \max_{\|B\| \leq 1} |\text{tr}(\rho_1 B) - \text{tr}(\rho_2 B)| / 2, \quad 0 \leq T(\rho_1, \rho_2) \leq 1 \quad (15)$$

and the fidelity

$$F(\rho_1, \rho_2) := \text{tr}^2 \sqrt{\sqrt{\rho_1} \rho_2 \sqrt{\rho_1}}, \quad 0 \leq F(\rho_1, \rho_2) \leq 1 \quad (16)$$

are measures of distinguishability between two density operators. It is well known that

$$1 - \sqrt{F(\rho_1, \rho_2)} \leq T(\rho_1, \rho_2) \leq \sqrt{1 - F(\rho_1, \rho_2)}. \quad (17)$$

We use standard asymptotic notations. Let $f, g : \mathbb{R}^+ \rightarrow \mathbb{R}^+$ be two functions. One writes $f(x) = O(g(x))$ if and only if there exist constants $M, x_0 > 0$ such that $f(x) \leq M g(x)$ for all $x > x_0$; $f(x) = \Omega(g(x))$ if and only if there exist constants $M, x_0 > 0$ such that $f(x) \geq M g(x)$ for all $x > x_0$; $f(x) = \Theta(g(x))$ if and only if there exist constants $M_1, M_2, x_0 > 0$ such that $M_1 g(x) \leq f(x) \leq M_2 g(x)$ for all $x > x_0$; $f(x) = o(g(x))$ if and only if for any constant $M > 0$ there exists a constant $x_0 > 0$ such that $f(x) < M g(x)$ for all $x > x_0$.

2.2 Eigenstate thermalization

The spectrum of H_{SYK2} is non-degenerate with probability 1 [17]. Then, due to fermion number conservation (10) and since the perturbation $\epsilon_2 H_{\text{SYK4}}$ is infinitesimal, H , H_{SYK} , H_{SYK2} , and $Q + \epsilon_1 H_{\text{SYK2}}$ have the same set of eigenstates (up to an infinitesimal error), each of which has a definite fermion number.

Let $|\psi\rangle$ be an eigenstate of H_{SYK2} with fermion number n and $\nu := n/N$ be the filling fraction. We write $|\psi\rangle \sim \mathcal{P}_{N,n}$ if $|\psi\rangle$ is randomly sampled using the following procedure:

1. Let h be a random matrix of order N from the Gaussian unitary ensemble.
2. $|\psi\rangle$ is chosen uniformly at random from the $\binom{N}{n}$ eigenstates of $a^\dagger h a$ with fermion number n .

Let $\rho_A := \text{tr}_{\bar{A}} |\psi\rangle\langle\psi|$ be the reduced density matrix. Recall the definition (12) of $\sigma_{\beta,A}$, where β is given by (14).

Theorem 1 (eigenstate thermalization). *Suppose that $1/2 \geq \nu = \Omega(1)$. For $L = o(\sqrt{N})$ and any Δ such that $\Omega(L^2) = \Delta = o(N)$,*

$$\Pr_{|\psi\rangle \sim \mathcal{P}_{N,n}} (F(\rho_A, \sigma_{\beta,A}) = 1 - O(\Delta/N)) = 1 - O(e^{-\Delta}), \quad (18)$$

$$\Pr_{|\psi\rangle \sim \mathcal{P}_{N,n}} (T(\rho_A, \sigma_{\beta,A}) = O(\sqrt{\Delta/N})) = 1 - O(e^{-\Delta}). \quad (19)$$

Theorem 2 (failure of ETH). *Suppose that $1/2 \geq \nu = \Omega(1)$. For $L = \Omega(\sqrt{N})$,*

$$\Pr_{|\psi\rangle \sim \mathcal{P}_{N,n}} (F(\rho_A, \sigma_{\beta,A}) = e^{-\Omega(L^2/N)}) = 1 - e^{-\Omega(L^2)}, \quad (20)$$

$$\Pr_{|\psi\rangle \sim \mathcal{P}_{N,n}} (T(\rho_A, \sigma_{\beta,A}) = 1 - e^{-\Omega(L^2/N)}) = 1 - e^{-\Omega(L^2)}. \quad (21)$$

Theorem 3 (failure of ETH). *Suppose that $\nu \leq 1/2$. For $L > n$,*

$$F(\rho_A, \sigma_{\beta,A}) \leq (1 - \nu)^{L-n}, \quad T(\rho_A, \sigma_{\beta,A}) \geq 1 - (1 - \nu)^{L-n}. \quad (22)$$

These results on the ETH are for individual eigenstates. To interpret Theorems 1, 2 as statements about Hamiltonians, recall the definition of the weak ETH in an energy interval in Subsection 1.3.

Corollary 1. *Let n be a positive integer such that $N/2 \geq n = \Omega(N)$. For $L = o(\sqrt{N})$, the probability (with respect to the randomness of h) that $Q + \epsilon_1 a^\dagger h a$ obeys the weak ETH in the energy interval $(n - 1/2, n + 1/2)$ is $1 - e^{-\Delta}$ for any $\Delta = o(N)$. For $L = \Omega(\sqrt{N})$, the probability that $Q + \epsilon_1 a^\dagger h a$ obeys the weak ETH in the energy interval $(n - 1/2, n + 1/2)$ is $e^{-\Omega(L^2)}$.*

2.3 Thermalization

We initialize the system in a product state with fermion number n and let $\nu = n/N$. Since the ensemble of SYK q Hamiltonians is invariant with respect to permutations of indices, we may assume without loss of generality that the initial state is

$$|\Psi_0\rangle = a_1^\dagger a_2^\dagger \cdots a_n^\dagger |0\rangle, \quad (23)$$

where $|0\rangle$ is the vacuum state with no fermions. Since $|\Psi_0\rangle$ has a definite fermion number, H and H_{SYK} generate the same dynamics in the sense that

$$e^{-iHt}|\Psi_0\rangle = e^{-int}e^{-iH_{\text{SYK}}\epsilon_1 t}|\Psi_0\rangle. \quad (24)$$

Let L, m be positive integers such that Lm is a multiple of N . Let A_1, A_2, \dots, A_m be m possibly overlapping subsystems, each of which has exactly L fermionic modes. Suppose that each fermionic mode in the system is in exactly Lm/N out of these m subsystems. Let

$$\rho(t) := e^{-iHt}|\Psi_0\rangle\langle\Psi_0|e^{iHt}, \quad \rho_{A_j}(t) := \text{tr}_{\bar{A}_j} \rho(t) \quad (25)$$

be the state and its reduced density matrix at time t , respectively.

Let τ be sufficiently large and t be uniformly distributed in the interval $[0, \tau]$. Recall the definition (12) of $\sigma_{\beta, A}$, where β is given by (14).

Theorem 4 (thermalization). *For $1/2 \geq \nu = \Omega(1)$, subsystems of size*

$$L = o(N/\ln N) \quad (26)$$

thermalize in the sense that $(\text{poly}(N))$ denotes a polynomial of sufficiently high degree in N)

$$\Pr_h \left(\Pr_J \left(\Pr_{t \in [0, \tau]} \left(\frac{1}{m} \sum_{j=1}^m \|\rho_{A_j}(t) - \sigma_{\beta, A_j}\|_1^2 = \frac{O(L \ln N)}{N} \right) = 1 - e^{-\Omega(N)} \right) = 1 \right) \geq 1 - 1/\text{poly}(N). \quad (27)$$

For any linear operator B_j on subsystem A_j with $\|B_j\| \leq 1$, Eq. (15) implies that

$$|\text{tr}(\rho(t)B_j) - \text{tr}(\sigma_{\beta}B_j)| \leq \|\rho_{A_j}(t) - \sigma_{\beta, A_j}\|_1. \quad (28)$$

Thus, (27) implies thermalization of physical properties measured on $o(N/\ln N)$ fermionic modes.

In contrast to Eq. (26), reduced density matrices do not thermalize if the subsystem size is a constant fraction of the system size. Let $\mathbb{E}_{|A|=L}$ denote averaging over all subsystems of L fermionic modes. There are $\binom{N}{L}$ such subsystems.

Theorem 5 (failure of thermalization). *Suppose that $1/2 \geq \nu = \Omega(1)$. For $L = \Omega(N)$ and any h, J, t ,*

$$\mathbb{E}_{|A|=L} \|\rho_A(t) - \sigma_{\beta, A}\|_1 = \Omega(1). \quad (29)$$

3 Methods

In this section, we give intuitive sketches of the proofs of our results. Full calculations are deferred to Appendix A.

3.1 Eigenstate thermalization

For a density operator ρ , let $\langle B \rangle := \text{tr}(\rho B)$ denote the expectation value of an operator B . Let \mathbf{C} be the correlation matrix with its elements given by

$$\mathbf{C}_{jk} := \langle a_j^\dagger a_k \rangle. \quad (30)$$

It is easy to see that \mathbf{C} is a Hermitian matrix of order N .

Lemma 1 ([17, 27]). $|\psi\rangle \sim \mathcal{P}_{N,n}$ means that $|\psi\rangle$ is a uniformly random Gaussian state with fermion number n in the sense of Definition 7.

Definition 7 (uniformly random pure Gaussian state with definite fermion number). A pure Gaussian state with fermion number n is uniformly random if its correlation matrix is given by

$$\mathbf{C} = U^\dagger \text{diag}(\underbrace{1, 1, \dots, 1}_{n \text{ ones}}, \underbrace{0, 0, \dots, 0}_{N-n \text{ zeros}})U, \quad (31)$$

where U is a unitary matrix chosen uniformly at random with respect to the Haar measure.

Assume without loss of generality that the indices of the L fermionic modes in subsystem A are $1, 2, \dots, L$. Let $\mathbf{C}_A = (U_{n \times L})^\dagger U_{n \times L}$ be the $L \times L$ upper left submatrix of \mathbf{C} , where $U_{n \times L}$ is the $n \times L$ upper left submatrix of U .

We can interpret \mathbf{C}_A as the overlap of two projectors, as follows. Let P_n and P_L be projectors of ranks n and L , respectively, such that $U_{n \times L} = P_n U P_L$. Then, $\mathbf{C}_A = P_L (U^\dagger P_n U) P_L$. We can view this as the overlap between a fixed projector P_L and a random projector $U^\dagger P_n U$.

Let $\lambda_1 \leq \lambda_2 \leq \dots \leq \lambda_L$ be the eigenvalues of \mathbf{C}_A . Since the reduced density matrix ρ_A is a Gaussian state,

$$\rho_A = \bigotimes_{j=1}^L \text{diag}(\lambda_j, 1 - \lambda_j) \quad (32)$$

is a product state in a basis. In the same basis,

$$\sigma_{\beta,A} = \bigotimes_{j=1}^L \text{diag}(\nu, 1 - \nu) \quad (33)$$

is also a product state. Since the fidelity is multiplicative,

$$F(\rho_A, \sigma_{\beta,A}) = \prod_{j=1}^L \left(\sqrt{\nu \lambda_j} + \sqrt{(1 - \nu)(1 - \lambda_j)} \right)^2. \quad (34)$$

Proof of Theorem 3. For $L > n$, \mathbf{C}_A is singular, and the multiplicity of the eigenvalue 0 is at least $L - n$. Using Eqs. (32), (33) and since the fidelity (trace distance) is non-decreasing (non-increasing) under partial trace,

$$F(\rho_A, \sigma_{\beta,A}) \leq F \left(\bigotimes_{j=1}^{L-n} \text{diag}(0, 1), \bigotimes_{j=1}^{L-n} \text{diag}(\nu, 1 - \nu) \right) = (1 - \nu)^{L-n}, \quad (35)$$

$$T(\rho_A, \sigma_{\beta,A}) \geq T \left(\bigotimes_{j=1}^{L-n} \text{diag}(0, 1), \bigotimes_{j=1}^{L-n} \text{diag}(\nu, 1 - \nu) \right) = 1 - (1 - \nu)^{L-n}. \quad (36)$$

□

For $L \leq \min\{n, N - n\}$, the joint probability distribution of $\lambda_1, \lambda_2, \dots, \lambda_L$ is the Jacobi unitary ensemble with parameters $r = N - n - L$ and $s = n - L$ [27–29].

Definition 8 (Jacobi unitary ensemble). The probability density function of the Jacobi unitary ensemble with parameters $r, s > -1$ is

$$\mathcal{J}(\lambda_1, \lambda_2, \dots, \lambda_L) \propto \prod_{1 \leq j < k \leq L} (\lambda_j - \lambda_k)^2 \prod_{j=1}^L (1 - \lambda_j)^r \lambda_j^s, \quad 0 \leq \lambda_j \leq 1. \quad (37)$$

We explain why the ETH holds and fails with high probability for $L = o(\sqrt{N})$ and $L = \Omega(\sqrt{N})$, respectively. To this end, consider the limit $L \rightarrow \infty$ with $L = o(N)$. In this case, Theorem 2.1 in Ref. [30] says that the empirical distribution of

$$\sqrt{\frac{N}{\nu(1-\nu)L}}(\lambda_j - \nu) \quad (38)$$

converges weakly to the semicircle distribution with radius 2 almost surely. Thus,

$$\lambda_j = \nu \pm \Theta(\sqrt{L/N}) \quad (39)$$

for almost all j with high probability. Since $L = o(N)$, by Taylor expansion,

$$\sqrt{\nu\lambda_j} + \sqrt{(1-\nu)(1-\lambda_j)} = 1 - \Theta(\lambda_j - \nu)^2. \quad (40)$$

Substituting this into Eq. (34),

$$F(\rho_A, \sigma_{\beta,A}) = \prod_{j=1}^L (1 - \Theta(L/N)) = \begin{cases} 1 - o(1), & L = o(\sqrt{N}), \\ 1 - \Omega(1), & L = \Omega(\sqrt{N}). \end{cases} \quad (41)$$

Proofs of the probabilistic bounds in Theorems 1, 2 without assuming $L \rightarrow \infty$ or $L = o(N)$ are given in Appendix A.1. There we do not use Theorem 2.1 in Ref. [30] but instead rely on a recent concentration result [31] for the second moment of the Jacobi ensemble.

3.2 Thermalization

Proof sketch of Theorem 4. In a previous paper [17], we proved entanglement thermalization: With high probability, the von Neumann entropies of $\rho_{A_j}(t)$ and σ_{β,A_j} are equal to leading order in L . So are the free energies of $\rho_{A_j}(t)$ and σ_{β,A_j} . Since the thermal state minimizes the free energy [32], the free energy of $\rho_{A_j}(t)$ is only slightly higher than the minimum. Pinsker’s inequality [33] implies that any state of low free energy is close to a thermal state in trace distance.

Condition (26) ensures that with high probability, the free energy of $\rho_{A_j}(t)$ is sufficiently low so that the trace distance between $\rho_{A_j}(t)$ and σ_{β,A_j} from the above analysis is $o(1)$.

Proof sketch of Theorem 5. $\rho(t)$ for any $t \in \mathbb{R}$ has a definite fermion number, but σ_β does not. This difference has its footprint in the reduced density matrices. If the fermion number operator (13) is measured on a random subsystem A of L fermionic modes, we obtain a probability distribution on the integers $0, 1, 2, \dots, L$. For $\rho(t)$, the distribution is hypergeometric corresponding to drawing L balls without replacement from a pool of n white and $N - n$ black balls. For σ_β , the distribution is binomial corresponding to drawing L balls with replacement from the same pool.

Note added. Very recently, we became aware of related work by Yu, Gong, and Cirac [34]. They studied the entanglement of random Gaussian states with definite fermion number. Their Theorem 1 is conceptually similar to our Lemma 3 but gives different bounds and is proved using different methods.

A Proofs

A.1 Eigenstate thermalization

Lemma 2. For any $x, y \in \mathbb{R}^+$ such that $x + y \leq 1$,

$$1 - (x - y)^2 / \max\{x, y\} \leq (\sqrt{xy} + \sqrt{(1-x)(1-y)})^2 \leq 1 - (x - y)^2. \quad (42)$$

Proof. Let

$$x = \cos^2 \frac{\theta + \alpha}{2}, \quad y = \cos^2 \frac{\theta - \alpha}{2}, \quad 0 \leq \theta \pm \alpha \leq \pi \quad (43)$$

so that

$$(\sqrt{xy} + \sqrt{(1-x)(1-y)})^2 = \cos^2 \alpha = 1 - \sin^2 \alpha, \quad (x - y)^2 = \sin^2 \theta \cdot \sin^2 \alpha. \quad (44)$$

The condition $x + y \leq 1$ implies that $\theta \geq \pi/2$ so that

$$\max\{x, y\} \leq \max_{\alpha \in [0, \pi - \theta]} \cos^2 \frac{\theta - \alpha}{2} = \sin^2 \theta \leq 1. \quad (45)$$

We complete the proof by combining (44), (45). \square

Let

$$M := \sum_{j=1}^L (\lambda_j - \nu)^2 \quad (46)$$

be the shifted second moment of the Jacobi ensemble.

Lemma 3 ([31]).

$$\Pr \left(\left| M - \nu(1 - \nu) \frac{L(L-1)}{N-1} \right| > \delta \right) = O(e^{-\Omega(N-2L)\delta \min\{N\delta/L^2, 1\}}). \quad (47)$$

Proof of Theorem 1. Using Eq. (34) and Lemma 2,

$$F(\rho_A, \sigma_{\beta, A}) \geq \prod_{j=1}^L (1 - (\lambda_j - \nu)^2 / \nu) \geq 1 - M/\nu. \quad (48)$$

Then, Eq. (18) follows from Lemma 3. Equation (19) follows from (17) and Eq. (18). \square

Proof of Theorem 2. Using Eq. (34) and Lemma 2,

$$F(\rho_A, \sigma_{\beta, A}) \leq \prod_{j=1}^L (1 - (\lambda_j - \nu)^2) \leq e^{-M}. \quad (49)$$

For $L \leq L' := \min\{n, N/3\}$, Eq. (20) follows from (49) and Lemma 3.

For $L > L' = \Omega(N)$, let A' be an (arbitrary) subsystem of L' fermionic modes in A . We have proved that

$$\Pr_{|\psi\rangle \sim \mathcal{P}_{N,n}} (F(\rho_{A'}, \sigma_{\beta, A'}) = e^{-\Omega(N)}) = 1 - e^{-\Omega(N^2)}. \quad (50)$$

Equation (20) follows the fact that the fidelity is non-decreasing under partial trace.

Equation (21) follows from (17) and Eq. (20). \square

A.2 Proof of Theorem 4

Let

$$S(\rho) := -\text{tr}(\rho \ln \rho) \quad (51)$$

be the von Neumann entropy of a density operator and

$$H_b(\nu) := -\nu \ln \nu - (1 - \nu) \ln(1 - \nu) \quad (52)$$

be the binary entropy function.

Theorem 6 ([17]). *Suppose that $1/2 \geq \nu = \Omega(1)$. For $L \leq N/10$,*

$$\Pr_h \left(\Pr_J \left(\Pr_{t \in [0, \tau]} \left(\frac{1}{m} \sum_{j=1}^m S(\rho_{A_j}(t)) \geq H_b(\nu)L - \frac{O(L \ln N)}{N} \right) = 1 - e^{-\Omega(N)} \right) = 1 \right) \geq 1 - 1/\text{poly}(N). \quad (53)$$

Recall the definition (13) of Q_A . It is easy to see that

$$\frac{1}{m} \sum_{j=1}^m Q_{A_j} = \frac{LQ}{N} \implies \frac{1}{m} \sum_{j=1}^m \text{tr}(\rho_{A_j}(t) Q_{A_j}) = \nu L. \quad (54)$$

Using Pinsker's inequality [33] between the trace distance and quantum relative entropy,

$$\begin{aligned} \frac{1}{2} \|\rho_A(t) - \sigma_{\beta,A}\|_1^2 &\leq S(\rho_A(t) \|\sigma_{\beta,A}) := -\text{tr}(\rho_A(t) \ln \sigma_{\beta,A}) - S(\rho_A(t)) \\ &= \beta \text{tr}(\rho_A(t) Q_A) + \ln \text{tr}(e^{-\beta Q_A}) - S(\rho_A(t)) \end{aligned} \quad (55)$$

so that

$$\frac{1}{2m} \sum_{j=1}^m \|\rho_{A_j}(t) - \sigma_{\beta,A_j}\|_1^2 \leq H_b(\nu)L - \frac{1}{m} \sum_{j=1}^m S(\rho_{A_j}(t)). \quad (56)$$

Theorem 4 follows from this inequality and Theorem 6.

A.3 Proof of Theorem 5

Let $i_1 < i_2 < \dots < i_L$ be the indices of the L fermionic modes in A . Define

$$P_A^{>l} = \sum_{\substack{(n_1, n_2, \dots, n_L) \in \{0,1\}^{\times L} \\ \sum_{j=1}^L n_j > l}} \prod_{j=1}^L (n_j + (1 - 2n_j) a_{i_j} a_{i_j}^\dagger). \quad (57)$$

Let $[N] := \{1, \dots, N\}$. Let $\binom{[N]}{n} := \{R \subseteq [N] : |R| = n\}$ be the set of size- n subsets of $[N]$. Let $\{|\psi_R\rangle\}_{R \in \binom{[N]}{n}}$ be the complete set of computational basis states with n fermions, where

$$|\psi_R\rangle := \left(\prod_{j \in R} a_j^\dagger \right) |0\rangle. \quad (58)$$

By construction, $P_A^{>l} = (P_A^{>l})^2$ is a projector such that

$$P_A^{>l} |\psi_R\rangle = |\psi_R\rangle \text{ or } 0 \quad (59)$$

if $|\psi_R\rangle$ contains $> l$ or $\leq l$ fermions in A , respectively. Hence,

$$\begin{aligned} \mathbb{E}_{|A|=L} \|P_A^{>l} |\psi_R\rangle\| &= \binom{N}{L}^{-1} |\{R' \subseteq [N] : |R'| = L \text{ and } |R \cap R'| > l\}| \\ &= \binom{N}{L}^{-1} \sum_{j>l} \binom{n}{j} \binom{N-n}{L-j}. \end{aligned} \quad (60)$$

The time-evolved state can be expanded as

$$e^{-iHt} |\Psi_0\rangle = \sum_{R \in \binom{[N]}{n}} c_R(t) |\psi_R\rangle \quad (61)$$

so that

$$\begin{aligned} \mathbb{E}_{|A|=L} \text{tr}(\rho_A(t) P_A^{>l}) &= \mathbb{E}_{|A|=L} \|P_A^{>l} e^{-iHt} |\Psi_0\rangle\|^2 = \mathbb{E}_{|A|=L} \sum_{R \in \binom{[N]}{n}} |c_R(t)|^2 \|P_A^{>l} |\psi_R\rangle\| \\ &= \sum_{R \in \binom{[N]}{n}} |c_R(t)|^2 \mathbb{E}_{|A|=L} \|P_A^{>l} |\psi_R\rangle\| = \binom{N}{L}^{-1} \sum_{j>l} \binom{n}{j} \binom{N-n}{L-j}, \quad \forall t \in \mathbb{R}. \end{aligned} \quad (62)$$

Equations (12), (14) imply that

$$\mathrm{tr}(\sigma_{\beta,A} P_A^{>l}) = \frac{1}{\mathrm{tr}(e^{-\beta Q_A})} \sum_{j>l} \binom{L}{j} e^{-\beta j} = \sum_{j>l} \binom{L}{j} \nu^j (1-\nu)^{L-j}. \quad (63)$$

Equations (62) and (63) are the tails of the hypergeometric and binomial distributions, respectively. The distributions have the same mean νL but different variances: $L\nu(1-\nu)\frac{N-L}{N-1}$ for the hypergeometric distribution and $L\nu(1-\nu)$ for the binomial distribution. Furthermore, both distributions are well approximated by Gaussians matching those moments. Thus, their tails are distinguishable in the sense of (64) for $l = \nu L + \Theta(\sqrt{L})$.

The total variation distance between the hypergeometric and binomial distributions has been studied in the context of de Finetti theorem. The theorem states that for a permutation-invariant probability distribution of N random variables, the marginal distribution of $L \ll N$ variables is close to a mixture of distributions, each of which represents L independent and identically distributed random variables [35]. From either the Gaussian approximation or (in the $\nu = 1/2$ case) Theorem 35 and Lemmas 45, 46 in Ref. [35], we have

$$0 < \mathbb{E}_{|A|=L} \mathrm{tr}(\sigma_{\beta,A} P_A^{>l}) - \mathbb{E}_{|A|=L} \mathrm{tr}(\rho_A(t) P_A^{>l}) = \Omega(1) \quad (64)$$

for $L = \Omega(N)$. We complete the proof by noting that

$$\mathbb{E}_{|A|=L} \|\rho_A(t) - \sigma_{\beta,A}\|_1 \geq \mathbb{E}_{|A|=L} \left| \mathrm{tr}(\rho_A(t) P_A^{>l} - \sigma_{\beta,A} P_A^{>l}) \right| \geq \left| \mathbb{E}_{|A|=L} \mathrm{tr}(\rho_A(t) P_A^{>l} - \sigma_{\beta,A} P_A^{>l}) \right|. \quad (65)$$
