#### ABSTRACT

Various elastic coefficients of Au<sub>2</sub>O<sub>3</sub> doped PbO-B<sub>2</sub>O<sub>3</sub>-SeO<sub>2</sub>:Er<sub>2</sub>O<sub>3</sub> (PBSE) glass ceramics were evaluated as functions of Au<sub>2</sub>O<sub>3</sub> content using ultrasonic velocity measurements. The elastic coefficients and micro-hardness showed a decreasing tendency with the concentration of Au<sub>2</sub>O<sub>3</sub>. Such decrease is attributed to the increasing concentration of gold metallic particles and [SeO<sub>3</sub>]<sup>2-</sup>groups that acted as modifiers and induced imperfections in these samples. Obtained results were observed to be consistent with the conclusions drawn from spectroscopic studies that include X-ray photoelectron spectroscopy (XPS), infrared (IR), photoluminescence (PL) and positron annihilation (PAL) spectroscopy studies. Overall, these studies have revealed that even though, the presence of gold metallic particles is preferable for achieving superior luminescence and electrical properties, presence of such particles caused to decrease the elastic coefficients and micro-hardness of these glass ceramics. However, when the concentration of Au<sub>2</sub>O<sub>3</sub> is increased beyond 0.075 mol%, we have observed a slight increase of elastic coefficients and micro-hardness.

### 1. Introduction

Various elastic coefficients like Young's modulus (*Y*), shear modulus (*G*), Poisson's ratio ( $\sigma$ ), micro- hardness (*H*) and various other parameters like Debye temperature ( $\theta_D$ ) etc., can be evaluated by determining sound velocities in glasses and glass ceramics. Knowledge of such parameters not only helps in assessing their elastic behavior but also throw useful information on structural variations occurring in the glasses and glass ceramics. In the recent past, a large number of studies on elastic properties of different glasses and glass ceramics were investigated by measuring ultrasonic velocities in them [1-5].

Among various glass systems, selenium oxide (SeO<sub>2</sub>) is a rare glass system. As such it is a feeble glass forming oxide and forms the glass when the modifying oxides like PbO and different traditional glass formers like borate, silicate, etc. are added. Interestingly, in the process of glass forming, the coordination number of Se ions with oxygen varies from 4 to 3 and the oxide of selenium transforms from [SeO<sub>4</sub>]<sup>2-</sup> (selenate) structural units to isolated [SeO<sub>4</sub>]<sup>2-</sup> (selenite) pyramidal units [6, 7]. Among these two groups, the [SeO<sub>4</sub>]<sup>2-</sup> do participate in the glass

formation, whereas [SeO<sub>3</sub>]<sup>2-</sup> act as modifying ions and generate different imperfections and cause to decrease elastic coefficients of the samples. Hence, the elastic parameters of these samples depend on relative proportions of these two groups. Quite recently, we have reported the luminescence properties of  $Er^{3+}$  doped lead boroselenate glass ceramics admixed with Au<sub>2</sub>O<sub>3</sub> [8]. Au<sub>2</sub>O<sub>3</sub> is added with a view to enhance PL efficiency of rare earth dopant ions since the gold particles emit PL in the visible region and also bring important changes in the elastic properties of the host glass ceramic. The studies further suggested that higher the fraction of [SeO<sub>3</sub>]<sup>2-</sup> units (determined by XPS studies) larger is the PL efficiency of erbium ions. Such higher efficiency was attributed to the decreased phonon losses because of higher concentration of structural defects induced by [SeO<sub>3</sub>]<sup>2-</sup> units. We have added about 40 mol% of PbO to the glass system to enhance the density, refractive index (which cause to increase PL efficiency) and also to minimize the sublimity and hygroscopic nature of SeO2. We have also added a minimal concentration of B<sub>2</sub>O<sub>3</sub> (10 mol%) to this glass system in order to ensure good glass formation. Further, it may be noted that the physical characteristics of amorphous systems containing SeO<sub>2</sub> are very

\* Corresponding authors. *E-mail addresses*: jaroslaw.jedryka@o2.pl (J. Jedryka), nvr8@rediffmail.com (N. Veeraiah). limitedly investigated and in most of such systems small concentration of SeO<sub>2</sub> was added as a dopant. Such studies as on the glasses or glass ceramics mixed with relatively large concentration of SeO<sub>2</sub> are very rare in spite of their high suitability for the several applications for example, in electrical and optical devices as sensors and various non-linear optical (NLO) devices etc. [9-13].

The current investigation is aimed to investigate the influence of Au<sub>2</sub>O<sub>3</sub> on elastic characteristics of PbO-B<sub>2</sub>O<sub>3</sub>-SeO<sub>2</sub>:Er<sub>2</sub>O<sub>3</sub> glass ceramics. As mentioned earlier, addition of traces of Au<sub>2</sub>O<sub>3</sub> to these makes them useful for the designing of miniature (nanosized) optoelectronic circuits and memory devices with large data storage capacity [14]. Owing these reasons the knowledge of elastic properties of SeO<sub>2</sub> based glass system doped with Au<sub>2</sub>O<sub>3</sub> is highly helpful. In general, Au<sub>2</sub>O<sub>3</sub> is a volatile oxide and breaks into AuO, Au<sub>2</sub>O and Au<sup>0</sup> metallic particles (MPs) during the synthesis of the glasses. The presence of larger content of Au<sup>0</sup> MPs will have a strong bearing on elastic properties as well as other physical characteristics of the glasses. For obtaining the glass samples with larger fraction of Au<sup>0</sup> MPs (possible by reducing trivalent gold ions), in this study the synthesized glasses were heated for a time interval of 24 h at the crystallization temperature. Such treatment reduces Au<sup>3+</sup> ions into Au<sup>0</sup> particles; in addition, it is guite likely for the formation of anisotropic crystalline phases e.g., Au<sub>2</sub>(Se<sup>(IV)</sup>O<sub>3</sub>)<sub>3</sub> and Au<sub>2</sub>(Se<sup>(IV)</sup>O<sub>3</sub>)<sub>2</sub>(Se<sup>(-</sup> VI)O<sub>4</sub>) of selenium ions [15,16] in the samples. Glasses with such crystallites are useful for NLO devices [16]. Further, the development of such crystalline phases along with Au<sup>0</sup> MPs in the glasses causes to entrench several nanosized free volume defects in the material which alter the elastic properties. We propose to determine the concentration of such defects by means of positron annihilation lifetime(PAL) spectroscopy in this study [17,18].

Thus, in continuation to our earlier investigations on the impact of Au<sub>2</sub>O<sub>3</sub> on photoluminescence features of PbO-B<sub>2</sub>O<sub>3</sub>-SeO<sub>2</sub>:Er<sub>2</sub>O<sub>3</sub> glass ceramics, the current investigation is devoted to study the elastic properties (in combination with PAL characteristics in detail) as a function of Au<sub>2</sub>O<sub>3</sub> content and to correlate these results with those of luminescence characteristics

## 2. Experimental

The chemical composition chosen for the present is: 40PbO-10B<sub>2</sub>O<sub>3</sub>-(50-x)SeO<sub>2</sub>-0.5Er<sub>2</sub>O<sub>3</sub>:xAu<sub>2</sub>O<sub>3</sub> (where x = 0, 0.025, 0.050, 0.075 and 0.1, all in mol%) and the samples are labeled as EA<sub>0</sub>, EA<sub>25</sub>, EA<sub>50</sub>, EA<sub>75</sub> and EA100. PbO, H3BO3, SeO2, Au2O3 and Er2O3 compounds were mixed thoroughly and melted in Pt crucibles in the range of temperature 1000-1050 °C (for about 40 min) in a thermally controlled furnace. The resultant molten liquid was casted in to slabs of rectangular shape and were annealed at 350 °C. For crystallization, the samples were held at 630 °C (crystallization temperature-onset, identified from DSC studies) for 24 h and then chilled to room temperature. The densities of the samples were measured by Archimedes' principle (using o-xylene as the buoyant liquid) to an accuracy of ±0.001.The other details of the preparation of the samples and characterization techniques e.g., X-ray diffraction (XRD), IR and XPS spectra etc. were reported in our earlier communication [8]. Transmission electron microscopy (TEM) images of the prepared samples were recorded on a JEOL 2200FS instrument with FE gun operated at 200 kV. XPS measurements were performed on PHI 5000 Versa Probe ULVAC instrument with a monochromatic AI K $\alpha$  (h $\nu$  = 1486.6 eV) as the source. Spectra were registered with respect to C 1s peak. Positron annihilation spectra were recorded on "Ortec" positron lifetime system with a <sup>22</sup>Na isotope (100 kBq) source. Lifetime T of the positroniums (from which the size of the free volume space defects is determined) is evaluated to a precision of 230 ps at 18 °C in the atmosphere of RH = 35%.

For measuring the longitudinal velocity in the samples, the OPBOX 2.1 measuring device with software was used. This device controls the operation of ultrasonic heads (transmitting and receiving). The frequency of the transmitted signal was 20 MHZ. The speed of the sound is

determined by measuring the passage time of the ultrasonic impulse and its echo through the glass ceramic. Shear velocities were measured with a piezoelectric composite oscillator technique [19,20] using an X-cut (0.13 MHz) cylindrical quartz transducer (2.0 cm long and 0.25 cm diameter). The dimensions of the glass ceramics used for these measurements are approximately the same as those of quartz transducer.

# 3. Results and discussion

X-ray diffractogram of the glass ceramic EA<sub>25</sub> is presented in Fig. 1. The diffractogram exhibited two diffraction peaks at  $2\theta = 29.9^{\circ}$  and  $44.0^{\circ}$  due to the reflections from Au<sub>2</sub>(SeO<sub>3</sub>)<sub>3</sub> crystal phase and Au<sup>0</sup> MPs, respectively [14,16,21]. The diffractograms of all the other samples have exhibited similar peaks. Out of these two peaks, the peak due to Au<sup>0</sup> MPs exhibited a gradual growth up to 0.075 mol% of Au<sub>2</sub>O<sub>3</sub> (inset of Fig. 1); such growth of the peak suggests an increase in the concentration of Au<sup>0</sup> metallic particles. It may be noted here that in the diffractogram of the as-prepared sample no peaks were noticed and indicated the amorphous character of such samples.

In order to prove, further, the crystallinity in the samples, we have recorded TEM images and presented in Fig.2, for the samples  $EA_{50}$  and  $EA_{75}$  with different magnifications. The pictures indicated a large number segregated crystal grains of nanosize embedded in the glass samples.

Further, we have recorded positron annihilation decay profiles in these glass ceramics in order to estimate the free volume defects/free volume space entrenched in the glass ceramics. Fig. 3(a) represents the positron decay profiles of one of the glass ceramic samples viz., EA<sub>100</sub>. The decay curve is deconvoluted in to I<sub>1</sub>, I<sub>2</sub> and I<sub>3</sub> components. By using the lifetime ( $\tau_3$ ) of the third component (long lived component), we have estimated radius R of free cavities in the glass ceramics with the standard expression [22,23]:

$$\tau_{3} = \frac{1}{2} \left[ 1 - \frac{R}{R_{0}} + \frac{1}{2\pi} sin\left(\frac{2\pi R}{R_{0}}\right) \right]^{-1}$$
(1)

Using the value of  $I_3$  (the intensity of the 3<sup>rd</sup> component of the decay profiles) and the radius R of free cavities (found to be in the range of 2.6 to 2.8 Å), the free volume space fraction  $f_V$  trapped in the sample is determined with the equation:

**Fig. 1.** X-ray diffractogram of EA<sub>25</sub> sample [Ref. 8]. Inset represents the variation of the intensity of the diffraction peak related to  $Au^0$  metallic particles and  $Au_2(SeO_3)_3$  crystalline phase with the concentration of  $Au_2O_3$ . The patterns were recorded in continuous scan mode with a scan speed of 2 deg/min.

EA75

Fig. 2. TEM images of  $\mathsf{EA}_{50}$  and  $\mathsf{EA}_{75}$  glass ceramic samples recorded with different magnifications.

$$f_{\nu} = AI_3(\%) \left(\frac{4}{3}\pi R^3\right) \tag{2}$$

In Eq. (2), relative fraction of the  $f_{\rm v}$  in the titled samples (without using the value of A whose value is predicted for polymers as  $0.0018/{\rm \AA^3}$ ) is estimated with respect to that of the pure glass, using following equation

$$\frac{\Delta f}{f} = \left(\frac{fv_i - fv_0}{fv_0}\right) \cdot 100\% \tag{3}$$

In Eq. (3),  $f_{\nu i}$  represents free volume of the titled glass ceramics mixed with different contents of gold oxide and  $f_{\nu 0}$  denotes free volume in the pure glass ceramic.

The free volume fraction of the free space ( $\Delta f/f_0$ ) obtained relative to that of the un-doped samples is plotted against Au<sub>2</sub>O<sub>3</sub> concentration in Fig. 3(b). The plot showed a gradual increase of the free space fraction in the samples up to 0.075 mol% of Au<sub>2</sub>O<sub>3</sub>. Such increase of magnitude of free space obviously causes to enhance the acoustic impedance of the

glass ceramics leading to decrease the values of elastic parameters.

In order to have additional confirmation of the presence of  $Au^0$  MPs (which act as modifiers) and to have an idea over their variation with the concentration of  $Au_2O_3$  in these samples we have recorded XPS spectra. Fig. 4 represents such spectrum for the sample  $EA_{100}$ . The spectrum exhibited the peaks corresponding to the binding energy (BE) of 4f  $Au^{3+}$ ions at 85.8 eV and 89.6 eV and two more peaks at 84.0 eV and 87.6 eV connected with the BE of  $Au^0$  MPs [24,25]. Fig.4 (inset) represents variation of concentration of  $Au^{3+}$  ions and  $Au^0$  MPs with the content of  $Au_2O_3$ . The figure showed an increase of  $Au^0$  MPs (at the expense of  $Au^{3+}$ ions) up to 0.075 mol% of  $Au_2O_3$ . These gold MPs behave as modifiers and produce structural imperfections as mentioned earlier [8,17].

infrared Fig.5, represents the (IR) spectrum of PbO-B2O3-SeO2-Er2O3 glass ceramic containing 0.05 mol% of Au2O3. Spectrum exhibited the vibrational bands due to [SeO<sub>4</sub>]<sup>2-</sup> units (at nearly 950 cm<sup>-1</sup>) and stretching (symmetrical) vibrational band of quarantined selenite [SeO<sub>3</sub>]<sup>2-</sup> pyramidal groups in the wavenumber range 850-900 cm<sup>-1</sup> [11]. In addition, the spectrum also exhibited the conventional vibrational bands of BO3 and BO4 units as shown in the figure. With increase of Au<sub>2</sub>O<sub>3</sub> content up to 0.075 mol%, the vibrational band of  $[SeO_3]^{2-}$  groups exhibited a gradual growth, whereas that of [SeO<sub>4</sub>]<sup>2-</sup> groups showed a decaying trend (inset of Fig. 5). The selenite [SeO<sub>3</sub>]<sup>2-</sup> groups mainly act as modifiers [12] and induce structural defects in the glass ceramic. In support of this argument, we have observed the growth of BO<sub>3</sub> vibrational band, whereas that of BO<sub>4</sub> units exhibited a decreasing trend

Fig. 6(a) and (b) represent propagation of longitudinal waves (by which the velocity  $v_1$  is determined) in the samples EA<sub>0</sub> and EA<sub>50</sub>. In these figures, measuring gates are represented by the two arrows. Such arrows in fact, indicate the starting and end point of the measuremen

between two consecutive reflected pulse

Using the values of  $v_1$  and  $v_s$ , various elastic coefficients of PBSE glass ceramics doped with different concentrations of Au<sub>2</sub>O<sub>3</sub> are estimated with the standard expressions and tabulated in Table 1. Their variations with the concentration of Au<sub>2</sub>O<sub>3</sub> are presented in Fig. 7.

All these parameters showed a decreasing trend with the content of  $Au_2O_3$  up to 0.075 mol%. In Fig. 8(a) and (b), Young's and shear moduli variations with the content of  $Au_2O_3$  are presented. The variations showed the gradual decrement of these parameters (and also the microhardness H of the samples (Table 1)) with the content of  $Au_2O_3$ .

Zhang et al. [26] have established a general empirical relation between Vickers hardness  $H_v$  and yield strength  $\sigma_v$  as

$$H_y \approx 3\sigma_y$$
 (4)

The obtained vales of  $\sigma_v$  evaluated based on this relation are presented

Fig. 3. (a) Positron annihilation lifetime decay profiles of the glass ceramics  $EA_{100}$ . Fig. 3(b) Variations of free volume fraction  $\Delta f/f_0$  with concentrations of  $Au_2O_3$  doped PBSE glass ceramics.

Fig. 4. XPS spectrum of EA\_{100} sample. Inset shows the relative variations of intensities of the peaks of  $Au^0$  and  $Au^{3+}$  ions with content of  $Au_2O_3$ .

in Table 1. The value of  $\sigma_y$  exhibited a decreasing trend with the concentration of Au<sub>2</sub>O<sub>3</sub> up to 0.075 mol% similar to Vickers hardness H<sub>v</sub> and subsequently, Alao and Yin [27] have applied this relation to evaluate the dependence of contact hardness, H<sub>c</sub>, on the yield strength,  $\sigma_y$ , for lithium metasilicate glass–ceramics. According to these people the value of H<sub>c</sub> is given by

$$H_c = C\sigma_y \tag{5}$$

In Eq. (5), C is a constraint factor which is found to be 3 for materials that exhibit a combination of piling-up and shear-banding phenomenon such as lithium metasilicate glass–ceramics [26]. In the present case for PBSE glass ceramics the evaluated value of H<sub>v</sub> gives an approximate idea over the dependence of yield strength  $\sigma_y$  on the concentration of Au<sub>2</sub>O<sub>3</sub>. In other words it can be said that the yield strength is minimal for the

glass ceramic EA75.

The IR spectra have clearly suggested that an increasing concentration of  $[SeO_3]^{2-}$  structural groups with increase of Au<sub>2</sub>O<sub>3</sub>. XPS spectra have demonstrated a steady growth in the concentration of Au<sup>0</sup> metallic particles.

Both of these acted as modifiers and de-augment Se-O-Se linkages in the glass network and also introduce free volume defects in the glass ceramics. Such enhanced degree of de-fragmentation in the glass network facilitated a decrease of ultrasonic speed and caused to decrease elastic parameters and micro-hardness.

Our earlier results on photoluminescence studies of these glass ceramics have also indicated an increase in the luminescence efficiency of green emission ( ${}^4S_{3/2} \rightarrow {}^4I_{15/2}$ ) and orange emission ( ${}^4F_{9/2} \rightarrow {}^4I_{15/2}$ ) of erbium ions, as mentioned earlier, with increase of Au<sub>2</sub>O<sub>3</sub> content [8] and patterns of PL emission and band positions obtained were found to be in accordance with the reported data in the literature [28–30]. Such enhancement was attributed to the decrease of phonon losses or due to the rise in the degree of internal structural chaos in the glass ceramic network. In conclusion even though, the introduction of Au<sub>2</sub>O<sub>3</sub> is proved to improve the optical properties and also the electrical characteristics in various glasses and glass ceramics, it caused to decrease the elastic coefficients and micro-hardness of PbO-B<sub>2</sub>O<sub>3</sub>-SeO<sub>2</sub>:Er<sub>2</sub>O<sub>3</sub> glass ceramics.

#### 4. Conclusions

Different elastic coefficients and micro-hardness H/yield strength  $\sigma_v$ of Au<sub>2</sub>O<sub>3</sub> mixed PbO-B<sub>2</sub>O<sub>3</sub>-SeO<sub>2</sub>:Er<sub>2</sub>O<sub>3</sub> glass ceramics were estimated using ultrasonic velocities. The coefficients were found to decrease with Au<sub>2</sub>O<sub>3</sub> concentration up to 0.075 mol%. Such decrease was ascribed to growing presence of [SeO<sub>3</sub>]<sup>2-</sup> structural groups and also Au<sup>0</sup> metallic particles that produce structural imperfections like free volume defects by acting as modifiers. This argument was further supported by XPS, IR and positron annihilation spectroscopy studies. Such increased degree of disorder or increased magnitude of free volume space with increase of Au<sub>2</sub>O<sub>3</sub> content was projected to be an obstruction for the passage of ultrasonic waves in the samples and hence responsible for the decrement in the elastic coefficients and micro-hardness of the studied glass ceramics. Finally, it is concluded that even though, the Au<sub>2</sub>O<sub>3</sub> is a favorable dopant for superior optical and electrical properties of the studied glass ceramics it caused to have an adverse effect on the elastic coefficients. However, when the concentration of Au<sub>2</sub>O<sub>3</sub> is increased beyond 0.075 mol%, we have observed a slight increase of elastic coefficients and micro-hardness.
