THE ALGEBRAIC BRAUER GROUP OF A REDUCTIVE GROUP OVER A NONARCHIMEDEAN LOCAL FIELD

DYLON CHOW

ABSTRACT. We show that for nonarchimedean local fields F, the pairing from the algebraic part of the Brauer group of a reductive group G characterizes all continuous homomorphisms from G(F) into \mathbb{Q}/\mathbb{Z} . This generalizes results of Loughran and Loughran-Tanimoto-Takloo-Bighash.

INTRODUCTION

Let F be a non-Archimedean local field of characteristic 0 and X an algebraic variety defined over F. The set X(F) of F-rational points on X acquires a natural analytic topology from F. Each element of the Brauer group Br(X) of X defines a locally constant map from X(F) into \mathbb{Q}/\mathbb{Z} .

Let X be a F-variety and let BrX denote the Brauer group of X. If L is a k-algebra and $x \in X(L)$, then $x : \text{Spec } L \to X$ induces a homomorphism Br $X \to \text{Br } L$. By composition with the invariant map $\text{Br}(F) \to \mathbb{Q}/\mathbb{Z}$ of local class field theory, each element $x \in X(F)$ defines a homomorphism Br $X \to \mathbb{Q}/\mathbb{Z}$. Similarly, each element of Br X defines a map $X(F) \to \mathbb{Q}/\mathbb{Z}$.

Let F be any field and let \overline{F} be a separable closure of F. Let $\operatorname{Br}_1 X$ be the kernel of the homomorphism $\operatorname{Br} X \to \operatorname{Br} X_{\overline{F}}$, and let $\operatorname{Br}_0 X$ denote the image of $\operatorname{Br} F \to \operatorname{Br} X$. The *algebraic part* of $\operatorname{Br}(X)$ is defined to be the quotient $\operatorname{Br}_a X = \operatorname{Br}_1 X/\operatorname{Br}_0 X$. For an algebraic group G over F, the morphism $e : \operatorname{Spec} F \to G$ associated with the identity element $e \in G(F)$ induces a homomorphism $\operatorname{Br} G \to \operatorname{Br} F$. Let $\operatorname{Br}_e G$ be the intersection of $\operatorname{Br}_1 G$ with the kernel of $\operatorname{Br} G \to \operatorname{Br} F$. The quotient homomorphism $\operatorname{Br}_1 G \to \operatorname{Br}_a G$ restricts to an isomorphism $\operatorname{Br}_e G \cong \operatorname{Br}_a G$. Elements of $\operatorname{Br}_e G$ define continuous homomorphisms from G(F) into $\operatorname{Br}(F)$ [San81, Lemme 6.9].

We consider the algebraic part $\operatorname{Br}_a(G)$ of the Brauer group of a connected reductive Fgroup G. To state our main result, let G^{sc} be the simply connected cover of the derived group G^{der} of G and let

$$\rho: G^{sc} \to G$$

be the natural morphism $G^{sc} \to G^{der} \hookrightarrow G$. The main purpose of this paper is to prove the following:

Theorem 0.1. Let F be a non-archimedean local field of characteristic 0. Let G be a connected reductive group defined over F and let $\rho : G^{sc} \to G$ be the natural map. The pairing

$$\operatorname{Br}_e G \times G(F) \to \mathbb{Q}/\mathbb{Z}$$

induces an isomorphism

$$\operatorname{Br}_e G \cong \operatorname{Hom}_{\operatorname{cont}}(G(F)/\rho(G^{sc}(F)), \mathbb{Q}/\mathbb{Z}).$$

This generalizes a theorem of Loughran [Lou18], who proved it for tori, and Loughran, Takloo-Bighash, and Tanimoto [LTBT20], who proved it for semisimple groups. We will address the situation of a number field in future work.

1. NOTATION AND CONVENTIONS

1.1. We use F to denote a field. Let \overline{F} be an algebraic closure of F and write F^s for the separable closure of F in \overline{F} . We let $\Gamma = \Gamma_F$ denote the Galois group of F^s over F; it is a profinite topological group with the Krull topology.

1.2. If G is a connected reductive group defined over a field F and K is a field extension of F, we write G_K for the K-group obtained from G by extension of scalars. Let \mathbb{G}_m be the multiplicative group scheme GL_1 . For an algebraic group G, let X(G) denote the group of characters of G, i.e. the group of algebraic group homomorphisms $G \to \mathbb{G}_m$. We let $X^*(G) = X(G_{F^s})$. In other words, $X^*(G)$ consists of the characters of G defined over F^s . The group Γ acts continuously on $X^*(G)$.

1.3. If A is an abelian group with the discrete topology on which a profinite group Γ acts as a group of automorphisms, then A is called a Γ -module if the action map $\Gamma \times A \rightarrow A, (\sigma, a) \mapsto \sigma a$ is continuous. Equivalently, A is a Γ -module if for all $a \in A$ the stabilizer $\{\sigma \in \Gamma | \sigma a = a\}$ of a is open in Γ .

1.4. Let k be a field, k_s a separable closure of k and G an algebraic k-group. Then $H^i(k, H)$ denotes the *i*-th cohomology set of the Galois group $\operatorname{Gal}(k_s/k)$ of k_s over k, with coefficients in $H(k_s)$ (i = 0, 1) and, if G is commutative, the *i*-th cohomology group of $\operatorname{Gal}(k_s/k)$ in $G(k_s)$ for all $i \in \mathbb{N}$.

1.5. If F' is a finite field extension of F and G is an algebraic group over F', the Weil restriction of G is the algebraic group $G_{F'/k}$ over k such that for all k-algebras R, $G_{F'/F}(R) = G(F' \otimes R)$. By an induced Γ -module we mean a Γ -module that has a finite Γ -stable \mathbb{Z} -basis. We say than an F-torus T is induced if $X^*(T)$ is an induced Γ -module. Equivalently, an F-torus T is induced if it is a finite product of tori of the form $(\mathbb{G}_m)_{k'/F}$ with k' a finite separable extension of F.

1.6. As usual, \mathbb{Q} , \mathbb{R} , and \mathbb{C} will denote respectively the fields of rational, real, and complex numbers; \mathbb{Z} denotes the ring of rational integers.

1.7. Sometimes our characters have values in \mathbb{Q}/\mathbb{Z} , in which case we use the exponential mapping $x \mapsto \exp(2\pi i x)$ from \mathbb{Q}/\mathbb{Z} to \mathbb{C}^{\times} to view them as complex-valued characters.

1.8. Let G_{der} denote the derived group of G, G_{sc} the simply connected cover of G_{der} , and G_{ad} the adjoint group of G, i.e., $G_{ad} = G/Z_G$ where Z_G is the center of G. Let $\rho : G^{sc} \to G$ be the natural morphism. Given a maximal F-torus T of G, let $T_{sc} = \rho^{-1}(T)$.

2. Preliminaries

2.1. Let F be a local field or a number field and let X be a F-variety. Let $\operatorname{Br} X$ be the Brauer group of X. If L is a k-algebra and $x \in X(L)$, then $x : \operatorname{Spec} L \to X$ induces a homomorphism $\operatorname{Br} X \to \operatorname{Br} L$. By composition with the invariant map $\operatorname{Br}(F) \to \mathbb{Q}/\mathbb{Z}$ of local class field theory, each element $x \in X(F)$ defines a homomorphism $\operatorname{Br} X \to \mathbb{Q}/\mathbb{Z}$. Similarly, each element of $\operatorname{Br} X$ defines a map $X(F) \to \mathbb{Q}/\mathbb{Z}$.

2.2. Let F be any field and let \overline{F} be a separable closure of F. Let $\operatorname{Br}_1 X$ be the kernel of the homomorphism $\operatorname{Br} X \to \operatorname{Br} X_{\overline{F}}$, and let $\operatorname{Br}_0 X$ denote the image of $\operatorname{Br} F \to \operatorname{Br} X$. The algebraic part of $\operatorname{Br}(X)$ is defined to be the quotient $\operatorname{Br}_a X = \operatorname{Br}_1 X/\operatorname{Br}_0 X$. For an algebraic group G over F, the morphism $e: \operatorname{Spec} F \to G$ associated with the identity element $e \in G(F)$ induces a homomorphism $\operatorname{Br} G \to \operatorname{Br} F$. Let $\operatorname{Br}_e G$ be the intersection of $\operatorname{Br}_1 G$ with the kernel of $\operatorname{Br} G \to \operatorname{Br} F$. The quotient homomorphism $\operatorname{Br}_1 G \to \operatorname{Br}_a G$ restricts to an isomorphism $\operatorname{Br}_e G \cong \operatorname{Br}_a G$. Elements of $\operatorname{Br}_e G$ define continuous homomorphisms from G(F) into $\operatorname{Br}(F)$ [San81, Lemme 6.9].

2.3. A morphism $f: T \to U$ of tori is defined over F is a crossed module in a natural way and we can consider its cohomology groups $H^i(F, T \to U)$. We refer the reader to [Bor98] for the definition and properties of crossed modules and their cohomology.

3. Non-Archimedean local fields

We prove the theorem in two stages. In the first stage we start from the case of tori and generalize the result for only those G whose derived group is simply connected.

3.1. **Tori.**

Lemma 3.1. Let T be a torus over a local field F of characteristic 0. The bilinear pairing $Br_eT \times T(F) \to Br \ F \subset \mathbb{Q}/\mathbb{Z}$

is perfect, i.e., the induced map

$$Br_eT \to Hom(T(F), \mathbb{Q}/\mathbb{Z})$$

is an isomorphism of abelian groups.

Proof. See [Lou18, Theorem 4.3].

3.2. Groups with simply connected derived group. Let F be a p-adic field. Now assume that G is such that $G^{der} = G^{sc}$. Define $T = G/G^{der}$. We have an exact sequence

$$1 \to G^{der} \to G \to T \to 1.$$

We get an exact sequence

$$1 \to G^{der}(F) \to G(F) \to T(F) \to 1,$$

and thus an isomorphism

$$G(F)/j(G^{der}(F)) \cong T(F)$$

Since $\operatorname{Pic}(\overline{G}) = 0$, we have ([San81, Lemme 6.9 (i)]) canonical isomorphisms $H^2(F, \mathsf{X}^*(G)) \cong$ Br_aG and $H^2(F, \mathsf{X}^*(T)) \cong$ Br_aT. The projection $G \to T$ yields a commutative diagram

$$\begin{array}{c} \mathrm{Br}_{a}T & \longrightarrow & \mathrm{Br}_{a}G \\ \downarrow & & \downarrow \\ H^{2}(F,\mathsf{X}^{*}(T)) & \longrightarrow & H^{2}(F,\mathsf{X}^{*}(G)) \end{array}$$

The vertical arrows are isomorphisms. The first row is part of a long exact sequence coming from the exact sequence $1 \to G^{sc} \to G \to T \to 1$: ([San81, Corollaire 6.11])

$$\dots \to Pic(G^{sc}) \to \operatorname{Br}_a T \to \operatorname{Br}_a G \to \operatorname{Br}_a G^{sc}.$$

Since $Pic(G^{sc}) = 1$ and $Br_a(G^{sc}) = 1$ ([San81, Lemme 9.4 (iv)]), the horizontal arrow is an isomorphism. We get a commutative diagram

$$\begin{array}{ccc} H^{2}(F,\mathsf{X}^{*}(T)) & \longrightarrow & H^{2}(F,\mathsf{X}^{*}(G)) \\ & & & \downarrow \\ & & & \downarrow \\ Hom(G(F)/j(G^{der}(F)), \mathbb{Q}/\mathbb{Z}) & \longrightarrow & Hom(T(F), \mathbb{Q}/\mathbb{Z}) \end{array}$$

This proves the result for groups whose derived group is simply connected.

3.3. General reductive groups. In the second stage we use the following result, which allows one to reduce to the case where the derived group is simply connected.

Lemma 3.2. For any connected reductive F-group G split by K, there exists an extension

$$1 \to Z \to \widetilde{G} \to G \to 1$$

such that

- Z is a central torus in \tilde{G} ,
- Z is obtained from Weil restriction of scalars from a split K-torus, and
- \widetilde{G}^{der} is simply connected.

Such an extension is called a z-extension. We proceed with the proof of the general case. A similar result appears in [LM15, Lemma A.1, Appendix]. Consider a z-extension as above. We get two more exact sequences. First, since PicZ = 0, we get from [San81, Corollary 6.11] an exact sequence of abelian groups

$$1 \to \operatorname{Br}_e G \to \operatorname{Br}_e G \to \operatorname{Br}_e Z.$$

Since Z is an induced torus, $H^1(F, Z) = 0$, and so we get another exact sequence

$$1 \to Z(F) \to \widetilde{G}(F) \to G(F) \to 1.$$

Applying Hom $(-, \mathbb{Q}/\mathbb{Z})$ we get an exact sequence

$$1 \to \operatorname{Hom}(G(F), \mathbb{Q}/\mathbb{Z}) \to \operatorname{Hom}(\widetilde{G}(F), \mathbb{Q}/\mathbb{Z}) \to \operatorname{Hom}(Z(F), \mathbb{Q}/\mathbb{Z}) \to 1.$$

This induces an exact sequence

$$1 \to \operatorname{Hom}(G(F)/G^{der}(F), \mathbb{Q}/\mathbb{Z}) \to \operatorname{Hom}(\widetilde{G}(F)/\widetilde{G}^{der}(F), \mathbb{Q}/\mathbb{Z}) \to \operatorname{Hom}(Z(F), \mathbb{Q}/\mathbb{Z}).$$

We get the following commutative diagram with exact rows:

The two vertical arrows are the isomorphisms constructed above. We define a homomorphism $\operatorname{Br}_e G \to \operatorname{Hom}(G(F)/G^{der}(F), \mathbb{Q}/\mathbb{Z})$ to be the unique homomorphism that makes the diagram commute – it is an isomorphism, which can be seen to be induced from the Brauer pairing. This completes the proof.
