

# The q-Binomial Coefficient for Negative Arguments and Some q-Binomial Summation Identities

M.J. Kronenburg

## Abstract

Using a property of the q-shifted factorial, an identity for q-binomial coefficients is proved, which is used to derive the formulas for the q-binomial coefficient for negative arguments. The result is in agreement with an earlier paper about the normal binomial coefficient for negative arguments. Some new q-binomial summation identities are derived, and the formulas for negative arguments transform some of these summation identities into each other. One q-binomial summation identity is transformed into a new q-binomial summation identity.

**Keywords:** q-binomial coefficient.

**MSC 2010:** 11B65

## 1 Definitions and Basic Identities

Let the following definition of the q-binomial coefficient, also called the Gaussian polynomial, be given.

$$\binom{m+p}{m}_q = \prod_{j=1}^m \frac{1-q^{p+j}}{1-q^j} \quad (1.1)$$

Let the q-shifted factorial, also called the q-Pochhammer symbol, be given by [7]:

$$(a; q)_k = \prod_{j=0}^{k-1} (1 - aq^j) \quad (1.2)$$

Then the q-binomial coefficient for integer  $k \geq 0$  is:

$$\binom{n}{k}_q = \prod_{j=1}^k \frac{1-q^{n-k+j}}{1-q^j} = \frac{(q^{n-k+1}; q)_k}{(q; q)_k} \quad (1.3)$$

Let  $\Gamma_q(x)$  be the q-gamma function [2].

For complex  $x, y$ :

$$\binom{x}{y}_q = \frac{\Gamma_q(x+1)}{\Gamma_q(y+1)\Gamma_q(x-y+1)} \quad (1.4)$$

From this follows the symmetry identity:  
For complex  $x, y$ :

$$\binom{x}{y}_q = \binom{x}{x-y}_q \quad (1.5)$$

The functional equation of the  $\Gamma_q(x)$  function is [2]:

$$\Gamma_q(x+1) = \frac{1-q^x}{1-q} \Gamma_q(x) \quad (1.6)$$

Combination of (1.4) and (1.6) gives the absorption identity:  
For complex  $x, y$ :

$$\binom{x}{y}_q = \frac{1-q^x}{1-q^y} \binom{x-1}{y-1}_q \quad (1.7)$$

From definition (1.3) follows:  
For integer  $n \geq 0$  and integer  $k$ :

$$\binom{n}{k}_q = 0 \text{ if } k > n \quad (1.8)$$

From this and (1.5) follows:  
For integer  $n \geq 0$  and integer  $k$ :

$$\binom{n}{k}_q = 0 \text{ if } k < 0 \quad (1.9)$$

## 2 The q-Binomial Coefficient for Negative Arguments

For deriving the q-binomial coefficient for negative arguments, the following theorem [4, 7] is needed.

**Theorem 2.1.** *For integer  $k \geq 0$ :*

$$(a; q)_k = (-a)^k q^{k(k-1)/2} \left( \frac{q^{1-k}}{a}; q \right)_k \quad (2.1)$$

*Proof.* From:

$$k(k-1)/2 = \sum_{j=0}^{k-1} j = \sum_{j=0}^{k-1} (k-j-1) \quad (2.2)$$

follows:

$$q^{k(k-1)/2} = \prod_{j=0}^{k-1} q^j = \prod_{j=0}^{k-1} q^{k-j-1} \quad (2.3)$$

This is used in:

$$(-a)^k q^{k(k-1)/2} \prod_{j=0}^{k-1} \left( 1 - \frac{q^{1-k}}{a} q^j \right) = q^{k(k-1)/2} \prod_{j=0}^{k-1} (q^{1-k+j} - a) = \prod_{j=0}^{k-1} (1 - a q^{k-j-1}) = \prod_{j=0}^{k-1} (1 - a q^j) \quad (2.4)$$

□

**Theorem 2.2.** For integer  $k \geq 0$ :

$$\binom{n}{k}_q = (-1)^k q^{nk-k(k-1)/2} \binom{-n+k-1}{k}_q \quad (2.5)$$

*Proof.* Using (1.3) and the previous theorem and  $-n = (-n+k-1) - k + 1$ :

$$\begin{aligned} \binom{n}{k}_q &= \frac{(q^{n-k+1}; q)_k}{(q; q)_k} = (-1)^k q^{k(n-k+1)+k(k-1)/2} \frac{(q^{-n}; q)_k}{(q; q)_k} \\ &= (-1)^k q^{nk-k(k-1)/2} \binom{-n+k-1}{k}_q \end{aligned} \quad (2.6)$$

□

**Theorem 2.3.** For integer  $k \leq n$ :

$$\binom{n}{k}_q = (-1)^{n-k} q^{(n-k)(n+k+1)/2} \binom{-k-1}{n-k}_q \quad (2.7)$$

*Proof.* In the previous theorem replacing  $k$  with  $n-k$ , which makes it valid when  $n-k \geq 0$  which is when  $k \leq n$ , and then applying (1.5) to the left side:

$$\binom{n}{n-k}_q = \binom{n}{k}_q \quad (2.8)$$

and using  $n(n-k) - (n-k)(n-k-1)/2 = (n-k)(n+k+1)/2$  gives this theorem. □

These two transformations can be used to transform one q-binomial summation identity into another, and can be used to express the q-binomial coefficient for negative integer  $n$  and integer  $k$  into the q-binomial coefficient for nonnegative integer  $n$  and  $k$ .

**Theorem 2.4.** For negative integer  $n$  and integer  $k$ :

$$\binom{n}{k}_q = \begin{cases} (-1)^k q^{nk-k(k-1)/2} \binom{-n+k-1}{k}_q & \text{if } k \geq 0 \\ (-1)^{n-k} q^{(n-k)(n+k+1)/2} \binom{-k-1}{n-k}_q & \text{if } k \leq n \\ 0 & \text{otherwise} \end{cases} \quad (2.9)$$

*Proof.* The first two cases are identical to theorems 2.2 and 2.3.

For the third case, from (1.7) follows for integer  $n, k$ :

$$\binom{n-1}{k-1}_q = \frac{1-q^k}{1-q^n} \binom{n}{k}_q \quad (2.10)$$

When  $k = 0$  the right side is zero, so when  $n < 0$  and  $k = 0$  this identity produces zeros for  $n < k < 0$ , which is the third case. This identity does not produce zeros for all  $k < 0$  because when  $n > 0$  a point will be reached where  $n = 0$  and this expression becomes  $(1-q^k)0/0$  which is undefined. □

The normal binomial coefficients are the  $q$ -binomial coefficients with  $q = 1$ , in which case this theorem reduces to theorem 2.1 in [5].

For  $n = -1$  this theorem results in:

$$\binom{-1}{k}_q = \begin{cases} (-1)^k q^{-k(k+1)/2} & \text{if } k \geq 0 \\ (-1)^{k+1} q^{-k(k+1)/2} & \text{if } k \leq -1 \end{cases} \quad (2.11)$$

which is in agreement with example 1.4 in [3].

As an example of the second case of this theorem:

$$\binom{-3}{-5}_q = q^{-7} \binom{4}{2}_q = q^{-7} (1 + q^2)(1 + q + q^2) \quad (2.12)$$

which is in agreement with example 1.2 in [3].

The  $q$ -binomial coefficient polynomial is palindromic, which means that  $a_j = a_{k(n-k)-j}$ , from which follows that it is self-reciprocal, where  $j$  is replaced by  $k(n-k) - j$ :

$$\begin{aligned} \binom{n}{k}_q &= \sum_{j=0}^{k(n-k)} a_j q^j = \sum_{j=0}^{k(n-k)} a_{k(n-k)-j} q^j = \sum_{j=0}^{k(n-k)} a_j q^{k(n-k)-j} \\ &= q^{k(n-k)} \sum_{j=0}^{k(n-k)} a_j q^{-j} = q^{k(n-k)} \binom{n}{k}_{q^{-1}} \end{aligned} \quad (2.13)$$

The theorems above leave all  $q$ -binomial coefficients self-reciprocal.

For theorem 2.2:

$$q^{k(n-k)} \binom{n}{k}_{q^{-1}} = (-1)^k q^{nk-k(k-1)/2} q^{-k(n+1)} \binom{-n+k-1}{k}_{q^{-1}} \quad (2.14)$$

and because  $-k(n-k) + nk - k(k-1)/2 - k(n+1) = -(nk - k(k-1)/2)$ :

$$\binom{n}{k}_{q^{-1}} = (-1)^k q^{-(nk-k(k-1)/2)} \binom{-n+k-1}{k}_{q^{-1}} \quad (2.15)$$

For theorem 2.3:

$$q^{k(n-k)} \binom{n}{k}_{q^{-1}} = (-1)^{n-k} q^{(n-k)(n+k+1)/2} q^{-(n-k)(n+1)} \binom{-k-1}{n-k}_{q^{-1}} \quad (2.16)$$

and because  $-k(n-k) + (n-k)(n+k+1)/2 - (n-k)(n+1) = -(n-k)(n+k+1)/2$ :

$$\binom{n}{k}_{q^{-1}} = (-1)^{n-k} q^{-(n-k)(n+k+1)/2} \binom{-k-1}{n-k}_{q^{-1}} \quad (2.17)$$

### 3 Some q-Binomial Summation Identities

Some q-binomial summation identities are derived and it is shown how q-binomial coefficients with negative arguments transform one summation identity into another. The following identities are the q-binomial theorem and the q-binomial theorem for negative powers [10]:

$$\prod_{k=0}^{n-1} (1 + xq^k) = \sum_{k=0}^n q^{\binom{k}{2}} \binom{n}{k}_q x^k \quad (3.1)$$

$$\frac{1}{\prod_{k=0}^{n-1} (1 - xq^k)} = \sum_{k=0}^{\infty} \binom{n+k-1}{n-1}_q x^k \quad (3.2)$$

The following is an obvious product rule:

$$\prod_{k=0}^{a-1} (1 + xq^k) \prod_{k=0}^{b-1} (1 + xq^{a+k}) = \prod_{k=0}^{a+b-1} (1 + xq^k) \quad (3.3)$$

With these three identities some q-binomial summation identities are derived, using that the coefficients of a product of two polynomials are the convolutions of the coefficients of the two polynomials.

**Theorem 3.1.** *The q-analog of the Chu-Vandermonde identity [1]:*

$$\sum_{k=0}^n q^{(a-k)(n-k)} \binom{a}{k}_q \binom{b}{n-k}_q = \binom{a+b}{n}_q \quad (3.4)$$

*Proof.* Using (3.1) with (3.3):

$$\left( \sum_{k=0}^a q^{\binom{k}{2}} \binom{a}{k}_q x^k \right) \left( \sum_{k=0}^b q^{\binom{k}{2}} \binom{b}{k}_q q^{ak} x^k \right) = \sum_{k=0}^{a+b} q^{\binom{k}{2}} \binom{a+b}{k}_q x^k \quad (3.5)$$

The coefficients of both sides must be equal:

$$\sum_{k=0}^n q^{\binom{k}{2}} \binom{a}{k}_q q^{\binom{n-k}{2}} \binom{b}{n-k}_q q^{a(n-k)} = q^{\binom{n}{2}} \binom{a+b}{n}_q \quad (3.6)$$

Because:

$$\binom{k}{2} + \binom{n-k}{2} + a(n-k) - \binom{n}{2} = (a-k)(n-k) \quad (3.7)$$

the theorem is proved. By replacing  $k$  with  $n-k$  and interchanging  $a$  and  $b$ , the power of  $q$  in the summand can be replaced by  $q^{(b-n+k)k}$ .  $\square$

**Theorem 3.2.**

$$\sum_{k=0}^n q^{(b+1)k} \binom{a+k}{a}_q \binom{b+n-k}{b}_q = \binom{n+a+b+1}{n}_q \quad (3.8)$$

*Proof.* Using the reciprocal of (3.3) with  $-x$ :

$$\frac{1}{\prod_{k=0}^{a-1}(1-xq^k)} \frac{1}{\prod_{k=0}^{b-1}(1-xq^{a+k})} = \frac{1}{\prod_{k=0}^{a+b-1}(1-xq^k)} \quad (3.9)$$

which with (3.2) becomes:

$$\left(\sum_{k=0}^{\infty} \binom{a+k-1}{a-1}_q x^k\right) \left(\sum_{k=0}^{\infty} \binom{b+k-1}{b-1}_q q^{ak} x^k\right) = \sum_{k=0}^{\infty} \binom{a+b+k-1}{a+b-1}_q x^k \quad (3.10)$$

The coefficients of both sides must be equal:

$$\sum_{k=0}^n \binom{a+k-1}{a-1}_q \binom{b+n-k-1}{b-1}_q q^{a(n-k)} = \binom{a+b+n-1}{a+b-1}_q = \binom{n+a+b-1}{n}_q \quad (3.11)$$

Replacing  $a$  by  $a+1$  and  $b$  by  $b+1$ , and then replacing  $k$  by  $n-k$  and interchanging  $a$  and  $b$  gives the theorem. By replacing  $k$  with  $n-k$  and interchanging  $a$  and  $b$ , the power of  $q$  in the summand can be replaced by  $q^{(a+1)(n-k)}$ .  $\square$

**Theorem 3.3.**

$$\sum_{k=0}^n (-1)^k q^{\binom{k}{2}} \binom{a}{k}_q \binom{b+n-k}{b}_q = \begin{cases} q^{an} \binom{n-a+b}{n}_q & \text{if } a \leq b \\ (-1)^n q^{bn+n(n+1)/2} \binom{a-b-1}{n}_q & \text{if } a > b \end{cases} \quad (3.12)$$

*Proof.* From (3.3) replacing  $a$  with  $b$  and  $b$  with  $a-b$  gives:

$$\frac{\prod_{k=0}^{a-1}(1+xq^k)}{\prod_{k=0}^{b-1}(1-(-x)q^k)} = \prod_{k=0}^{a-b-1}(1+xq^{b+k}) \quad (3.13)$$

Therefore:

$$\left(\sum_{k=0}^a q^{\binom{k}{2}} \binom{a}{k}_q x^k\right) \left(\sum_{k=0}^{\infty} \binom{b+k-1}{b-1}_q (-1)^k x^k\right) = \sum_{k=0}^{a-b} q^{\binom{k}{2}} \binom{a-b}{k}_q q^{bk} x^k \quad (3.14)$$

The coefficients of both sides must be equal:

$$\sum_{k=0}^n q^{\binom{k}{2}} \binom{a}{k}_q \binom{b+n-k-1}{b-1}_q (-1)^{n-k} = q^{bn} \binom{n}{n}_q \binom{a-b}{n}_q \quad (3.15)$$

Replacing  $b$  by  $b+1$  gives the second case of the theorem. When  $a \leq b$  application of theorem 2.2 to the right side of the second case gives the first case of the theorem.  $\square$

The special cases  $b = a-1$  and  $a = n, b = 0$  of this theorem appear in exercise 3.9 in [7].

## 4 Transforming q-Binomial Summation Identities

From theorem 3.2 and theorem 2.3 the following theorem follows.

**Theorem 4.1.**

$$\sum_{k=0}^n (-1)^k q^{(a-b)(n-k)+k(k+1)/2} \binom{a}{k}_q \binom{b+n-k}{b}_q = \begin{cases} q^{(a-b)n} \binom{n-a+b}{n}_q & \text{if } a \leq b \\ (-1)^n q^{n(n+1)/2} \binom{a-b-1}{n}_q & \text{if } a > b \end{cases} \quad (4.1)$$

*Proof.* In theorem 3.2 replacing  $a$  by  $-a$  and using theorem 2.3:

$$\binom{-a+k}{-a}_q = (-1)^k q^{-ak+k(k+1)/2} \binom{a-1}{k}_q \quad (4.2)$$

and replacing  $a$  by  $a+1$  gives the first case of this theorem. For the second case of the theorem, using theorem 2.2 when  $a > b$ :

$$\binom{n-a+b}{n}_q = (-1)^n q^{(n-a+b)n-n(n-1)/2} \binom{a-b-1}{n}_q \quad (4.3)$$

gives the second case of the theorem. This theorem is identical to theorem 3.3 except for the power of  $q$  in the summand.  $\square$

Some summation identities from the previous section can be transformed into each other. Theorem 3.3 can be transformed into theorem 3.2 using theorem 2.2 by replacing  $a$  with  $-a$ :

$$\binom{-a}{k}_q = (-1)^k q^{-ak-k} \binom{k}{2} \binom{a+k-1}{a-1}_q \quad (4.4)$$

which with the first case of theorem 3.3 gives:

$$\sum_{k=0}^n q^{a(n-k)} \binom{a+k-1}{a-1}_q \binom{b+n-k}{b}_q = \binom{n+a+b}{n}_q \quad (4.5)$$

Replacing  $a$  with  $a+1$  and  $k$  with  $n-k$  and interchanging  $a$  and  $b$  gives theorem 3.2.

Theorem 3.3 can be transformed into theorem 3.1 using theorem 2.3 by replacing  $b$  with  $-b$ :

$$\binom{-b+n-k}{-b}_q = (-1)^{n-k} q^{(n-k)(-2b+n-k+1)/2} \binom{b-1}{n-k}_q \quad (4.6)$$

which with the second case of theorem 3.3 by replacing  $b$  by  $b+1$  and using  $k(k-1)/2 + (n-k)(-2(b+1)+n-k+1)/2 + bn - n(n-1)/2 = k(b-n+k)$  gives:

$$\sum_{k=0}^n q^{k(b-n+k)} \binom{a}{k}_q \binom{b}{n-k}_q = \binom{a+b}{n}_q \quad (4.7)$$

Replacing  $k$  by  $n-k$  and interchanging  $a$  and  $b$  gives theorem 3.1.
