# SMOOTH NUMBERS AND THE DICKMAN $\rho$ FUNCTION 

OFIR GORODETSKY

To Professor Peter Sarnak on his 70th birthday

#### Abstract

We establish an asymptotic formula for $\Psi(x, y)$ whose shape is $x \rho(\log x / \log y)$ times correction factors. These factors take into account the contributions of zeta zeros and prime powers and the formula can be regarded as an (approximate) explicit formula for $\Psi(x, y)$. With this formula at hand we prove oscillation results for $\Psi(x, y)$, which resolve a question of Hildebrand on the range of validity of $\Psi(x, y) \asymp x \rho(\log x / \log y)$. We also address a question of Pomerance on the range of validity of $\Psi(x, y) \geq x \rho(\log x / \log y)$.

Along the way we improve classical estimates for $\Psi(x, y)$ and, on the Riemann Hypothesis, uncover an unexpected phase transition of $\Psi(x, y)$ at $y=(\log x)^{3 / 2+o(1)}$.

## 1. Introduction

A positive integer is called $y$-smooth if each of its prime factors does not exceed $y$. We denote the number of $y$-smooth integers not exceeding $x$ by $\Psi(x, y)$. We assume throughout $x \geq y \geq 2$. Let $\rho:[0, \infty) \rightarrow(0, \infty)$ be the Dickman function, defined as $\rho(t)=1$ for $t \leq 1$ and via the delay differential equation $t \rho^{\prime}(t)=-\rho(t-1)$ for $t>1$. Dickman [8] showed that

$$
\begin{equation*}
\Psi(x, y) \sim x \rho(\log x / \log y) \quad(x \rightarrow \infty) \tag{1.1}
\end{equation*}
$$

holds when $y \geq x^{\varepsilon}$. For this reason, it is useful to introduce the parameter

$$
u:=\log x / \log y
$$

The range of validity of (1.1) was considerably improved by de Bruijn [5] and H. Maier (unpublished), and the state of the art is due to Hildebrand who showed that [19]

$$
\begin{equation*}
\Psi(x, y)=x \rho(u)\left(1+O_{\varepsilon}\left(\frac{\log (u+1)}{\log y}\right)\right) \tag{1.2}
\end{equation*}
$$

holds when $\log y \geq(\log \log x)^{\frac{5}{3}+\varepsilon}$. In [17], Hildebrand showed that the Riemann Hypothesis (RH) implies that (1.2) holds in

$$
\begin{equation*}
y \geq(\log x)^{2+\varepsilon} . \tag{1.3}
\end{equation*}
$$

In fact, in this range he proves the slightly stronger estimate

$$
\Psi(x, y)=x \rho(u) \exp \left(O_{\varepsilon}\left(\frac{\log (u+1)}{\log y}\right)\right) .
$$

The reverse implication is also true: if even the weaker estimate $\Psi(x, y)=x \rho(u) \exp \left(O_{\varepsilon}\left(y^{\varepsilon}\right)\right)$ holds in the range (1.3) for every $\varepsilon>0$ then RH must be true. In [19, p. 290], Hildebrand speculates that $\Psi(x, y) \asymp x \rho(u)$ does not hold for $y \leq(\log x)^{2-\varepsilon}$. He writes

[^0]If the Riemann hypothesis is assumed, the range for $u$ can be further extended to $1 \leq u \leq \log x /(2+\varepsilon) \log \log x$, but it seems likely that then the critical limit is attained: it may be conjectured that for $u>\log x /(2-\varepsilon) \log \log x$, the relation $\Psi\left(x, x^{1 / u}\right) \sim x \rho(u)$ no longer holds.
This conjecture is repeated in [18] and by Granville in [14, 15]. We confirm it in stronger form. To state our result we recall the function

$$
K:(-1,0] \rightarrow \mathbb{R}, \quad K(t)=t \zeta(t+1) /(t+1), \quad K(0)=1,
$$

was introduced by de Bruijn [5, Eq. (2.8)]. Evidently $\lim _{t \rightarrow-1^{+}} K(t)=\infty$. It is strictly decreasing: the identity $\zeta(s)=s /(s-1)-s \int_{1}^{\infty}\{x\} x^{-1-s} d x$ for $s>0$ [23, Eq. (1.24)] implies $K(t)=1-t \int_{1}^{\infty}\{x\} x^{-2-t} d x$ and $K^{\prime}(t)=-\int_{1}^{\infty}\{x\}(1-t \log x) x^{-2-t} d x<0$.

Theorem 1.1. Let $\vartheta:=\sup _{\zeta(\rho)=0} \Re \rho \in[1 / 2,1]$ be supremum of the real parts of the zeros of the Riemann zeta function. Fix $\varepsilon>0$.
(1) Suppose $\vartheta \neq 1$. If $x \geq y \geq(\log x)^{1 /(1-\vartheta)+\varepsilon}$ then

$$
\Psi(x, y) \sim x \rho(u) K(-\log \log x / \log y), \quad x \rightarrow \infty
$$

(2) Given $A \in(1 / \vartheta, 1 /(1-\vartheta))^{1}$ and $\operatorname{sgn} \in\{+,-\}$ there exists an explicit function $x=x(y)$ of $y$ satisfying $y=(\log x)^{A+o(1)}$ and

$$
\begin{equation*}
\Psi(x, y)=x \rho(u) \exp \left(\Omega_{\operatorname{sgn}}\left(y^{\vartheta+A^{-1}-1-\varepsilon}\right)\right) \tag{1.4}
\end{equation*}
$$

(3) Suppose $\vartheta \neq 1$. If $2 \log x \leq y \leq(\log x)^{1 / \vartheta-\varepsilon}$ and $x \geq C_{\varepsilon}$ then

$$
\Psi(x, y)=x \rho(u) \exp \left(\Theta_{\varepsilon}\left(\frac{\log ^{2} x}{y \log y}\right)\right) .
$$

The key input to (1.4) is Landau's Oscillation Theorem. See Remark 2 for a refinement.
In [16, 22], Pomerance asked whether $\Psi(x, y) \geq x \rho(u)$ holds for all $x / 2 \geq y \geq 1$. In [16, p. 274], Granville proved that $\Psi(x, y)>2 x \rho(u)$ holds for $y \leq c(\log x)(\log \log x) / \log \log \log x$ if $x \geq C$. Below we extend Granville's range considerably. Moreover, if RH is true, we show $\Psi(x, y) \geq x \rho(u)$ holds when $y \notin\left[(\log x)^{2-\varepsilon},(\log x)^{2+\varepsilon}\right]$. For $y$ near $(\log x)^{2}$, the question lies beyond RH in a precise sense, but we indicate that a positive answer follows from a conjecture of Montgomery and Vaughan on the size of the remainder term in the PNT. If RH is false, the $\Omega_{-}$result in (1.4) already implies the inequality fails infinitely often.

Let

$$
L:=\max _{v \in \mathbb{R}} e^{v}\left(-\log (-\zeta(1 / 2))-\frac{1}{2} \int_{v}^{2 v} e^{-r} r^{-1} d r\right) \approx-0.666217
$$

Theorem 1.2. Fix $\varepsilon>0$ and suppose $x \geq C_{\varepsilon}$.
(1) For $y \in\left[\exp \left((\log \log x)^{5 / 3+\varepsilon}\right),(1-\varepsilon) x\right]$ we have

$$
\begin{equation*}
\Psi(x, y)=x \rho(u)\left(1+\Theta_{\varepsilon}(\log (u+1) / \log y)\right) \geq x \rho(u) \tag{1.5}
\end{equation*}
$$

and for $y \in\left[\varepsilon \log x, \exp \left((\log \log x)^{3 / 5-\varepsilon}\right) \log x\right]$

$$
\Psi(x, y)=x \rho(u) \exp \left(\Theta_{\varepsilon}\left(\frac{\log ^{2} x}{y \log y}\right)\right) \geq x \rho(u)
$$

[^1](2) Suppose RH is true. Then (1.5) holds for $y \in\left[(\log x)^{2+\varepsilon},(1-\varepsilon) x\right]$ and (1.6) holds for $y \in\left[\varepsilon \log x,(\log x)^{2-\varepsilon}\right]$. If $\Psi(x, y) \geq x \rho(u)$ holds for $y \in\left[(\log x)^{3 / 2},(\log x)^{3}\right]$ then
\[

$$
\begin{equation*}
\liminf _{y \rightarrow \infty} \frac{\psi(y)-y}{\sqrt{y} \log y} \geq L \tag{1.7}
\end{equation*}
$$

\]

If (1.7) holds with strict inequality then $\Psi(x, y) \geq x \rho(u)$ holds for $y \in[2,(1-\varepsilon) x]$.
RH implies $\psi(y)-y \ll \sqrt{y}(\log y)^{2}$ [23, Thm. 13.1]. It is believed that

$$
\begin{equation*}
\liminf _{y \rightarrow \infty} \frac{\psi(y)-y}{\sqrt{y}(\log \log \log y)^{2}}=-\frac{1}{2 \pi}, \tag{1.8}
\end{equation*}
$$

see [23, p. 484]; (1.8) implies that the limit considered in (1.7) is 0 .
Conventions and notation. The letters $C, c$ denote absolute positive constants that may change between different occurrences. The notation $A \ll B$ means $|A| \leq C B$ for some absolute constant $C$, and $A \ll_{a, b, \ldots} B$ means $|A| \leq C_{a, b, \ldots} B$ for $C_{a, b, \ldots}$ that may depend on the subscripts. We write $A \asymp B$ to mean $C_{1} B \leq A \leq C_{2} B$ for some absolute positive constants $C_{i}$, and $A \asymp_{a, b, \ldots} B$ means $C_{i}$ may depend on $a, b, \ldots$ We write $\Theta(B)$ and $\Theta_{a, b, \ldots}(B)$ to indicate a quantity $A$ with $A \asymp B$ and $A \asymp_{a, b, \ldots} B$, respectively. We write $\Omega_{+}(g(x))$ (resp. $\left.\Omega_{-}(g(x))\right)$ to indicate a function $f(x)$ with $\lim \sup _{x \rightarrow \infty} f(x) / g(x)>0\left(\right.$ resp. $\left.\liminf _{x \rightarrow \infty} f(x) / g(x)<0\right)$. A function $f$ is $\Omega_{ \pm}(g(x))$ if $\lim \sup f / g>0>\liminf f / g$. Throughout

$$
L(x)=\exp \left((\log x)^{\frac{3}{5}}(\log \log (x+1))^{-\frac{1}{5}}\right)
$$

We denote

$$
\vartheta=\sup _{\zeta(\rho)=0} \Re \rho \in[1 / 2,1] .
$$

For $y \geq 2$ and $\Re s>0$ we define the partial zeta function

$$
\zeta(s, y)=\prod_{p \leq y}\left(1-p^{-s}\right)^{-1}=\sum_{n \text { is } y \text {-smooth }} n^{-s} .
$$

We define $\xi:[1, \infty) \rightarrow[0, \infty)$ via

$$
e^{\xi(v)}=1+v \xi(v)
$$

We define the entire function

$$
I(s)=\int_{0}^{s} \frac{e^{v}-1}{v} d v=\sum_{i \geq 1} \frac{s^{i}}{i!i}
$$

We denote the Euler-Mascheroni constant by $\gamma$. The Laplace transform of $\rho$ is given by [4, Eq. (1.9)]

$$
\hat{\rho}(s):=\int_{0}^{\infty} \rho(v) e^{-s v} d v=\exp (\gamma+I(-s))
$$

for $s \in \mathbb{C}$. We define

$$
F(s, y)=\zeta(s)(s-1) F_{2}(s, y)
$$

for $s \in \mathbb{C}$ where

$$
F_{2}(s, y)=\hat{\rho}((s-1) \log y) \log y
$$

We write $\psi(x)=\sum_{n \leq x} \Lambda(n)$ for the Chebyshev function. We set

$$
\bar{u}=\min \{y / \log y, u\}
$$

If a meromorphic function has a removable singularity (e.g. $\zeta(s)(s-1)$ at $s=1$ ), we identify its value there with its limit. When we differentiate a bivariate function (e.g. $\zeta(s, y)$ ) we always do so with respect to the first variable. In sums and products over $p, p$ is understood to be prime. Throughout, $\varepsilon>0$ is an arbitrary fixed constant.

## 2. A FORMULA AND ITS INVESTIGATION

2.1. On two saddle points. Let $f: \mathbb{R} \rightarrow \mathbb{R}$ be given by

$$
f(t):=t \log x+\log \left(F_{2}(t, y)\right)
$$

It satisfies

$$
f^{\prime}(t)=\log x-(\log y) I^{\prime}((1-t) \log y), \quad f^{\prime \prime}(t)=(\log y)^{2} I^{\prime \prime}((1-t) \log y)
$$

The function $f$ is convex since $I^{\prime \prime}(-r)=r^{-2} e^{-r}\left(e^{r}-(r+1)\right)>0$. We define

$$
\beta=\beta(x, y)=1-\frac{\xi(u)}{\log y}
$$

for $u=\log x / \log y$. We often shorten $\xi(u)$ to $\xi$ when no confusion may arise. The function $f$ attains its global minimum at $\beta$ because it is readily verified that

$$
\begin{equation*}
f^{\prime}(\beta)=0 . \tag{2.1}
\end{equation*}
$$

The asymptotics of $\beta$ are well understood thanks to the next lemma.
Lemma 2.1. [20, Lem. 1][26, Lem. 4.5] For $v \geq 3$ we have

$$
\begin{align*}
\xi(v) & =\log v+\log \log v+O(\log \log v / \log v)  \tag{2.2}\\
I^{\prime \prime}(\xi(v)) & =v(1+O(1 / \log v)) \tag{2.3}
\end{align*}
$$

Corollary 2.2. Fix $\varepsilon>0$.
(1) If $x \geq y \geq(1+\varepsilon) \log x$ then

$$
\begin{equation*}
\beta=\frac{\log \left(\frac{y}{\log x}\right)}{\log y}\left(1+O_{\varepsilon}\left(\frac{\log \log (y+1)}{\log y}\right)\right) \tag{2.4}
\end{equation*}
$$

(2) If $2 \log x \geq y \geq \varepsilon \log x$ then $\beta=O_{\varepsilon}(1 / \log y)$.
(3) We have $\beta \leq 1$. Equality occurs if and only if $y=x$.
(4) We have $\beta \geq 0$ if and only if $y \geq 1+\log x$, and $\beta=0$ if and only if $y=1+\log x$.

Proof. If $u<3$ then (2.4) means $\beta=1+O(\log \log (x+1) / \log x)$ which follows from $\xi(u)=$ $O(1)$. If $u \geq 3$ we use (2.2) to write

$$
\beta=\frac{\log (y /(u \log u))+O(\log \log (u+1) / \log u)}{\log y}
$$

and reduce (2.4) to

$$
\begin{equation*}
\log \left(\frac{\log y}{\log u}\right)+O\left(\frac{\log \log (u+1)}{\log u}\right) \ll \varepsilon^{\log \left(\frac{y}{\log x}\right) \frac{\log \log (y+1)}{\log y} . . . ~} \tag{2.5}
\end{equation*}
$$

If $x<_{\varepsilon} 1$ then $y \ll_{\varepsilon} 1$ and (2.4) is trivial, so we may assume $x \geq C_{\varepsilon}$. If $y \geq \log ^{3 / 2} x$ then the right-hand side of (2.5) is $\gg \log \log (y+1)$ and it suffices to show $\log \log u \ll_{\varepsilon} \log \log (y+1)$, which is clear. If $(1+\varepsilon) \log x \leq y<\log ^{3 / 2} x$, the right-hand side of (2.5) is

$$
\gg \varepsilon \log \left(\frac{y}{\log x}\right) \frac{\log \log \log x}{\log \log x} .
$$

Since $\log \log (u+1) / \log u<_{\varepsilon} \log \log \log x / \log \log x$, (2.5) reduces further to

$$
\begin{equation*}
\log \left(\frac{\log y}{\log u}\right)<_{\varepsilon} \log \left(\frac{y}{\log x}\right) \frac{\log \log \log x}{\log \log x} . \tag{2.6}
\end{equation*}
$$

We write

$$
\frac{\log y}{\log u}=\frac{\log y}{\log \log x}\left(1-\frac{\log \log y}{\log \log x}\right)^{-1}=\left(1+\frac{\log (y / \log x)}{\log \log x}\right)\left(1-\frac{\log \log y}{\log \log x}\right)^{-1}
$$

and (2.6) follows by using $\log (1+t) \ll|t|$ for $|t| \leq 1 / 2$. The second part of the lemma is similar to the first and is left to the reader. The third part follows from $\xi$ being 0 at $v=1$ and being strictly increasing. For the last part we need to solve $\beta \geq 0$, or $\log y \geq \xi(u)$. Since $\xi$ is strictly increasing, it suffices to solve $\log y=\xi(u)$. Exponentiating, this implies $y=e^{\xi(u)}=1+u \xi(u)=1+\log x$.

Let $g:(0, \infty) \rightarrow \mathbb{R}$ be given by

$$
g(t):=t \log x+\log \zeta(t, y)
$$

It satisfies

$$
g^{\prime}(t)=\log x-\sum_{p \leq y} \frac{\log p}{p^{t}-1}, \quad g^{\prime \prime}(t)=\sum_{p \leq y} \frac{p^{t}(\log p)^{2}}{\left(p^{t}-1\right)^{2}}
$$

The function $g$ is convex because $g^{\prime \prime}(t)>0$ for $t>0$. Since $\lim _{t \rightarrow 0^{+}} g(t)=\lim _{t \rightarrow \infty} g(t)=\infty$ it follows that $g$ has a global minimum, attained at a point

$$
\alpha=\alpha(x, y)
$$

which must satisfy

$$
\begin{equation*}
g^{\prime}(\alpha)=0 \tag{2.7}
\end{equation*}
$$

The following theorem of Hildebrand and Tenenbaum expresses the asymptotics of $\Psi(x, y)$ in terms of $\alpha$.

Theorem 2.3. [20, Thms. 1, 2] For $x \geq y \geq 2$ we have

$$
\begin{equation*}
\Psi(x, y)=\frac{x^{\alpha} \zeta(\alpha, y)}{\alpha \sqrt{2 \pi \phi_{2}(\alpha, y)}}\left(1+O\left(\bar{u}^{-1}\right)\right) \tag{2.8}
\end{equation*}
$$

where

$$
\begin{equation*}
\phi_{2}(\alpha, y):=\sum_{p \leq y} \frac{p^{\alpha}(\log p)^{2}}{\left(p^{\alpha}-1\right)^{2}}=\left(1+\frac{\log x}{y}\right)(\log x)(\log y)\left(1+O\left(\log (1+\bar{u})^{-1}\right)\right) \tag{2.9}
\end{equation*}
$$

Additionally,

$$
\begin{equation*}
\alpha=\frac{\log \left(1+\frac{y}{\log x}\right)}{\log y}\left(1+O\left(\frac{\log \log (y+1)}{\log y}\right)\right) \tag{2.10}
\end{equation*}
$$

The points $\alpha$ and $\beta$ are known to be close:

Lemma 2.4. For $x \geq y \geq \varepsilon \log x$ we have $\beta-\alpha=O_{\varepsilon}(1 / \log y)$.
Proof. If $x \geq y>\log x$ this is in [20, Eq. (3.5)]. If $\log x \geq y \geq \varepsilon \log x$ both $\beta$ and $\alpha$ are $O_{\varepsilon}(1 / \log y)$ by Corollary 2.2 and (2.10).

The following lemma is useful in simplifying the order of magnitude of $y^{\alpha}$ and $y^{\beta}$.
Lemma 2.5. For $x \geq y \geq 2$ we have $y^{1-\beta} \asymp u \log (u+1)$. For $x \geq y \geq \varepsilon \log x$ we have $y^{1-\alpha} \asymp{ }_{\varepsilon} u \log (u+1)$.
Proof. The estimate for $y^{1-\beta}$ follows from the definition of $\beta$ and Lemma 2.1. The estimate for $y^{1-\alpha}$ follows from the estimate for $y^{1-\beta}$ by Lemma 2.4.
2.2. The function $G$. We introduce

$$
G(s, y):=\frac{\zeta(s, y)}{F(s, y)}
$$

The following identities are tautological in their domain of definition:

$$
\begin{align*}
\frac{x^{\alpha} \zeta(\alpha, y)}{x^{\beta} F_{2}(\beta, y)} & =\zeta(\alpha)(\alpha-1) G(\alpha, y) \exp (f(\alpha)-f(\beta))  \tag{2.11}\\
& =\zeta(\beta)(\beta-1) G(\beta, y) \exp (g(\alpha)-g(\beta))
\end{align*}
$$

Let

$$
B(x, y):=\sqrt{\frac{(\log y)^{2} I^{\prime \prime}(\xi(u))}{\phi_{2}(\alpha, y)}}
$$

Alladi proved [2, Eq. (3.9)]

$$
\rho(u)=\frac{e^{-u \xi} \hat{\rho}(-\xi)}{\sqrt{2 \pi I^{\prime \prime}(\xi(u))}}\left(1+O\left(u^{-1}\right)\right)
$$

which can be phrased as

$$
\begin{equation*}
x \rho(u)=\frac{x^{\beta} F_{2}(\beta, y)}{\sqrt{2 \pi(\log y)^{2} I^{\prime \prime}(\xi(u))}}\left(1+O\left(u^{-1}\right)\right) \tag{2.12}
\end{equation*}
$$

Dividing (2.8) by (2.12) and employing (2.11) we obtain
Lemma 2.6 (Asymptotic formula). If $x \geq y \geq 2$ then $f(\alpha) \geq f(\beta)$ and

$$
\frac{\Psi(x, y)}{x \rho(u)}=K(\alpha-1) G(\alpha, y) \exp (f(\alpha)-f(\beta)) B(x, y)\left(1+O\left(\bar{u}^{-1}\right)\right)
$$

If $x \geq y>1+\log x$ then $g(\beta) \geq g(\alpha)$ and

$$
\frac{\Psi(x, y)}{x \rho(u)}=K(\beta-1) G(\beta, y) \exp (g(\alpha)-g(\beta)) \frac{\beta}{\alpha} B(x, y)\left(1+O\left(u^{-1}\right)\right)
$$

When $y / \log x \rightarrow \infty$, (2.4) and (2.10) show $\alpha / \beta \sim 1$ and $K(\alpha-1) \sim K(\beta-1) \sim$ $K(-\log \log x / \log y)$. If further $u \rightarrow \infty$ then $B(x, y) \sim 1$ by (2.9) and (2.3). Lemma 2.6 then implies

$$
\begin{equation*}
G(\alpha, y)(1+o(1)) \leq \Psi(x, y) /(x \rho(u) K(-\log \log x / \log y)) \leq G(\beta, y)(1+o(1)) \tag{2.13}
\end{equation*}
$$

as long as $u$ and $y / \log x$ both tend to $\infty$.
The savings in (2.8) and (2.12) are sharp. We can show that the lower order terms within the error terms are close, which allows us to prove in $\$ 7.4$ the following

Proposition 2.7. If $y>1+\log x$ then the error terms in Lemma 2.6 are $O(1 /(\alpha \log x))$.
Remark 1. With more work, $O(1 /(\alpha \log x))$ may be improved to an explicit term of size $\asymp 1 /(\alpha \log x)$ and an error of size $O\left(1 /\left(\alpha^{2}(\log x)(\log y)\right)\right)$.

Working in a zero-free region of $\zeta$ we choose the following logarithms of $\zeta(s, y)$ and $F(s, y)$ :

$$
\begin{aligned}
\log \zeta(s, y) & =\sum_{p \leq y}-\log \left(1-p^{-s}\right)=\sum_{n \text { is } y \text {-smooth }} \Lambda(n) /\left(n^{s} \log n\right) \\
\log F(s, y) & =\log \log y+\gamma+I((1-s) \log y)+\log (\zeta(s)(s-1))
\end{aligned}
$$

where $\log (\zeta(s)(s-1))$ is chosen to be real-valued for $s>1$. In further using Lemma 2.6 it will be of crucial importance to split $G$ as $G_{1} G_{2}$ where

$$
\begin{aligned}
& \log G_{1}(s, y)=\sum_{n \leq y} \frac{\Lambda(n)}{n^{s} \log n}-(\log (\zeta(s)(s-1))+\log \log y+\gamma+I((1-s) \log y)), \\
& \log G_{2}(s, y)=\sum_{k \geq 2} \sum_{y^{1 / k}<p \leq y} \frac{p^{-k s}}{k} .
\end{aligned}
$$

We compute the Mellin transform of $\log G_{1}(s, y)$ (Proposition 5.1) and then, via Landau's Oscillation Theorem, obtain the following lemma, essential to the proof of Theorem 1.1.

Lemma 2.8. Fix $s>-2$. Then, as $x \rightarrow \infty, \log G_{1}(s, x)=\Omega_{ \pm}\left(x^{\vartheta-s-\varepsilon}\right)$.
Lemma 2.8 is proved in $\$ 5.1$. For $s=0$ it goes back to Landau. For $s=1$ it is due to Diamond and Pintz [7] and our standard proof follows theirs.

The function $\log G_{1}(s, y)$ and its derivatives with respect to $s$ can be expressed as sums over zeros of $\zeta$ (Corollaries 5.4 5.5). This allows us to prove in 55.3 the following

Lemma 2.9. Fix $i \geq 0$. For $\varepsilon-2 \leq s \leq 1 / \varepsilon$ and $x \geq 4$ we have

$$
\begin{align*}
& \left(\log G_{1}\right)^{(i)}(s, x)<_{i, \varepsilon}(\log x)^{i} x^{1-s} L(x)^{-c}<_{i, \varepsilon} x^{1-s} L(x)^{-c_{i}}  \tag{2.14}\\
& \left(\log G_{1}\right)^{(i)}(s, x)=(-1)^{i}(\log x)^{i-1} \frac{\psi(x)-x+O_{i, \varepsilon}\left(x^{\vartheta}\right)}{x^{s}}<_{i, \varepsilon} x^{\vartheta-s}(\log x)^{i+1} \tag{2.15}
\end{align*}
$$

Littlewood proved that $\psi(x)-x=\Omega_{ \pm}(\sqrt{x} \log \log \log x)$ [23, Thm. 15.11]. Applying (2.15) if $\vartheta=1 / 2$ and Lemma [2.8] otherwise, we get

Corollary 2.10. Fix $s>-2$. Then, as $x \rightarrow \infty, \log G_{1}(s, x)=\Omega_{ \pm}\left(x^{\frac{1}{2}-s} \log \log x / \log x\right)$.
In 5.4 we prove the following illuminating representations of $\log G_{1}$.
Lemma 2.11. For $x>2$ and $s>\vartheta$,

$$
\begin{equation*}
\log G_{1}(s, x)=-\int_{x}^{\infty} \frac{d(\psi(t)-t)}{t^{s} \log t} \tag{2.16}
\end{equation*}
$$

For $x>2$ and $s>-2$,

$$
\log G_{1}(s, x)=\int_{2^{-}}^{x} \frac{d(\psi(t)-t)}{t^{s} \log t}+\int_{1}^{2} \frac{t^{-2}-t^{-s}}{\log t} d t+\int_{2}^{\infty} \frac{d t}{t^{2} \log t}-\log (\zeta(s)(s-1))
$$

One can show $\log G_{2}(s, x) \rightarrow 0$ when $s-1 / 2 \geq \varepsilon$ and $x \rightarrow \infty$. In $\S 6$ we prove more:

Proposition 2.12. Fix $i \geq 0$. For $x \geq 2$ and $1 \geq s \geq \varepsilon / \log x$ we have

$$
\begin{align*}
\left(\log G_{2}\right)^{(i)}(s, x) & =\left(1+O_{\varepsilon, i}\left(L(x)^{-c}+x^{-s}\right)\right) \frac{(-2)^{i}}{2} \int_{\sqrt{x}}^{x}(\log t)^{i-1} t^{-2 s} d t  \tag{2.17}\\
& \asymp_{\varepsilon, i} \frac{(-\log x)^{i} x^{\max \left\{1-2 s, \frac{1}{2}-s\right\}}}{\max \{1,|s-1 / 2| \log x\}} .
\end{align*}
$$

For $1 / 4 \geq s \geq \varepsilon / \log x$ we have

$$
\begin{equation*}
\log G_{2}(s, x)=\left(1+O_{\varepsilon}\left(L(x)^{-c}\right)\right) \int_{\sqrt{x}}^{x}\left(-\log \left(1-t^{-s}\right)-t^{-s}\right) \frac{d t}{\log t} \tag{2.18}
\end{equation*}
$$

### 2.3. Proof of Theorem 1.1.

2.3.1. First part. We may assume $u \rightarrow \infty$ due to (1.1). By (2.13) it suffices to show $G(\alpha, y), G(\beta, y) \sim 1$. When $y \geq(\log x)^{1 /(1-\vartheta)+\varepsilon}$, the bounds for $\log G_{1}$ and $\log G_{2}$ given in (2.15) and (2.17) imply this (we simplify $y^{-\alpha}$ and $y^{-\beta}$ using Lemma 2.5).
2.3.2. Second part. Fix $\beta_{0} \in(0,1)$. Given $y \geq 2$ there is a unique $x=x(y)$ with $\beta(x, y)=\beta_{0}$. Using (2.1) we see that $x$ is determined by

$$
\left(y^{1-\beta_{0}}-1\right) /\left(1-\beta_{0}\right)=\log x
$$

and in particular $y=(\log x)^{1 /\left(1-\beta_{0}\right)+o(1)}$. Applying (2.13) with our $x=x(y)\left(\right.$ so that $\left.\beta=\beta_{0}\right)$,

$$
\begin{equation*}
\Psi(x, y) \ll x \rho(u) \exp \left(\log G_{1}\left(\beta_{0}, y\right)+\log G_{2}\left(\beta_{0}, y\right)\right) \tag{2.19}
\end{equation*}
$$

For our fixed $\beta_{0}$,

$$
\begin{equation*}
\log G_{1}\left(\beta_{0}, y\right)=\Omega_{-}\left(y^{\vartheta-\beta_{0}-\varepsilon}\right) \tag{2.20}
\end{equation*}
$$

by Lemma 2.8. If $\beta_{0} \in(1-\vartheta, \vartheta)$, the $\Omega_{-}$result follows from (2.19), (2.20) and the bound for $\log G_{2}$ given in (2.17). We now prove the $\Omega_{+}$result. Given $y \geq 2$ and fixed $\alpha_{0} \in(0,1)$ there is a unique $x=x(y)$ with $\alpha(x, y)=\alpha_{0}$. Using (2.7) we see that $x$ is determined by

$$
-\zeta^{\prime}\left(\alpha_{0}, y\right) / \zeta\left(\alpha_{0}, y\right)=\sum_{p \leq y} \log p /\left(p^{\alpha_{0}}-1\right)=\log x
$$

By (2.10),$y=(\log x)^{1 /\left(1-\alpha_{0}\right)+o(1)}$. Applying (2.13) with our $x=x(y)\left(\right.$ so that $\left.\alpha=\alpha_{0}\right)$,

$$
\begin{equation*}
\Psi(x, y) \gg x \rho(u) \exp \left(\log G_{1}\left(\alpha_{0}, y\right)+\log G_{2}\left(\alpha_{0}, y\right)\right) \geq \exp \left(\log G_{1}\left(\alpha_{0}, y\right)\right) \tag{2.21}
\end{equation*}
$$

For our fixed $\alpha_{0}$,

$$
\begin{equation*}
\log G_{1}\left(\alpha_{0}, y\right)=\Omega_{+}\left(y^{\vartheta-\alpha_{0}-\varepsilon}\right) \tag{2.22}
\end{equation*}
$$

by Lemma [2.8, If $\alpha_{0} \in(0, \vartheta)$, the $\Omega_{+}$result follows from (2.21) and (2.22).
2.3.3. Third part. Let $s \in\{\alpha, \beta\}$. We use (2.15) and (2.17) to see that $\log G_{1}(s, y) \ll$ $y^{\vartheta-s} \log y$ and $\log G_{2}(s, y) \asymp_{\varepsilon} y^{1-2 s} / \log y \asymp_{\varepsilon} \log ^{2} x /(y \log y)$ whenever $(\log x)^{1 / \vartheta-\varepsilon} \geq y \geq$ $2 \log x$ and $x \geq C$. We apply these estimates to

$$
(1+o(1)) K(\alpha-1) G(\alpha, y) B(x, y) \leq \frac{\Psi(x, y)}{x \rho(u)} \leq(1+o(1)) K(\beta-1) G(\beta, y) B(x, y) \frac{\beta}{\alpha}
$$

which follows from Lemma 2.6. The logarithms of $B(x, y), K(s-1)$ and $\beta / \alpha$ are negligible: they are $<_{\varepsilon} \log \log y$ as seen from (2.9), (2.3) (for $B$ ) and (2.10), (2.4) (for $K$ and $\beta / \alpha$ ).

Remark 2. Estimates (2.21) and (2.22) show that the $\Omega_{+}$case of (1.4) can be replaced with

$$
\Psi(x, y) \gg x \rho(u) \exp \left(\Omega_{+}\left(y^{\vartheta+A^{-1}-1-\varepsilon}\right)+\log G_{2}\left(1-A^{-1}, y\right)\right)
$$

which holds for any $A \in(1,1 /(1-\vartheta))$. In proving the $\Omega_{-}$case of (1.4) one may avoid using (2.8) by utilizing Rankin's bound $\Psi(x, y) \leq x^{\alpha} \zeta(\alpha, y)$.

## 3. New estimates and their proofs

Corollary 3.1. Suppose $\vartheta<1$. If $x \geq y \geq(\log x)^{\frac{1}{2} \max \left\{3,(1-\vartheta)^{-1}\right\}+\varepsilon}$ then, as $x \rightarrow \infty$,

$$
\begin{equation*}
\Psi(x, y) \sim x \rho(u) K(\beta-1) G(\beta, y) \sim x \rho(u) K(\alpha-1) G(\alpha, y) \tag{3.1}
\end{equation*}
$$

If $\vartheta=3 / 4$ then Corollary 3.1 implies that, as $x \rightarrow \infty$, (3.1) holds for $y \geq(\log x)^{2+\varepsilon}$. Under RH, (3.1) holds for $x \geq y \geq(\log x)^{3 / 2+\varepsilon}$. A different behavior emerges once $y \asymp$ $(\log x)^{3 / 2}(\log \log x)^{-1 / 2}$ :
Corollary 3.2. Assume RH. Suppose $x \geq C_{\varepsilon}$. If $\varepsilon \log x \leq y \leq(\log x)^{2-\varepsilon}$ then

$$
\Psi(x, y)=x \rho(u) K(\alpha-1) G(\alpha, y) \exp \left(\Theta_{\varepsilon}\left(\frac{\log ^{3} x}{y^{2} \log y}\right)\right)
$$

If $(1+\varepsilon) \log x \leq y \leq(\log x)^{2-\varepsilon}$ then

$$
\Psi(x, y)=x \rho(u) K(\beta-1) G(\beta, y) \exp \left(-\Theta_{\varepsilon}\left(\frac{\log ^{3} x}{y^{2} \log y}\right)\right)
$$

We do not explore this, but the contribution of the $k=3$ term (i.e. cubes) to $\log G_{2}(\alpha, y)$ and $\log G_{2}(\beta, y)$ also undergoes a phase transition and is of size $\asymp_{\varepsilon} \log ^{3} x /\left(y^{2} \log y\right)$ once $y \leq(\log x)^{3 / 2-\varepsilon}$.

A classical estimate of Hildebrand and Tenenbaum [20, Thm. 2] states that

$$
\log \left(\frac{\Psi(x, y)}{x}\right)=\left(1+O_{\varepsilon}\left(\exp \left(-(\log y)^{\frac{3}{5}-\varepsilon}\right)\right)\right) \log \rho(u)+O_{\varepsilon}\left(\frac{\log (u+1)}{\log y}\right)
$$

holds for $x \geq y \geq(\log x)^{1+\varepsilon}$ (cf. [27, Thm. III.5.21]). We offer an improvement in terms of range and error.
Corollary 3.3. Suppose $x \geq C_{\varepsilon}$. For $x \geq y \geq \log x \cdot L(\log x)^{\varepsilon}$,

$$
\begin{equation*}
\log \left(\frac{\Psi(x, y)}{x K(\alpha-1)}\right)=\left(1+O_{\varepsilon}\left(L(y)^{-c_{\varepsilon}}\right)\right) \log \rho(u)+O_{\varepsilon}\left(\frac{1}{\log x}\right) \tag{3.2}
\end{equation*}
$$

and the same holds with $K(\alpha-1)$ replaced by $K(\beta-1)$. For $\log x \cdot L(\log x)^{c} \geq y \geq \varepsilon \log x$,

$$
\begin{equation*}
\log \left(\frac{\Psi(x, y)}{x \rho(u)}\right)=\left(1+\Theta_{\varepsilon}\left(\frac{\log x}{y}\right)\right) \log G_{2}(\alpha, y) \tag{3.3}
\end{equation*}
$$

We zoom in on the behavior at $y \asymp \log x$, which was considered by Erdős [9] (who studied $y=\log x$ ), Erdős and van Lint [10], de Bruijn [6] and Granville [14]. In [14] it is explained why "the real difficulty lies in this range".

Corollary 3.4. Suppose $x \geq C_{\varepsilon}$. For $\varepsilon \log x \leq y \leq \varepsilon^{-1} \log x$ we have

$$
\begin{equation*}
\log \left(\frac{\Psi(x, y)}{x \rho(u)}\right)=\left(1+O_{\varepsilon}\left(L(y)^{-c}\right)\right) \int_{\sqrt{y}}^{y}\left(-\log \left(1-v^{-\alpha}\right)-v^{-\alpha}\right) \frac{d v}{\log v}+f(\alpha)-f(\beta) . \tag{3.4}
\end{equation*}
$$

Setting $t:=y / \log x$,

$$
\begin{aligned}
& 0<f(\alpha)-f(\beta)=u\left(\log \left(1+t^{-1}\right)-\left(1+t^{-1}\right)^{-1}\right)+O_{\varepsilon}\left(\frac{y}{\log ^{2} y}\right) \\
& 0<\int_{\sqrt{y}}^{y}\left(-\log \left(1-v^{-\alpha}\right)-v^{-\alpha}\right) \frac{d v}{\log v}=\frac{y}{\log y}\left(\log \left(1+t^{-1}\right)-(1+t)^{-1}\right)+O_{\varepsilon}\left(\frac{y}{\log ^{2} y}\right)
\end{aligned}
$$

For example, if $y=\log x$ then both $f(\alpha)-f(\beta)$ and the integral in (3.4) are $\sim u\left(\log (2)-\frac{1}{2}\right)$.
Remark 3. If $y \leq \log x$ then $\Psi(x, y) \leq x^{1 / \log y} \zeta(1 / \log y, y)=e^{O(u)}$. Since de Bruijn showed $\rho(u)=e^{-u \log (u \log u)+O(u)}$ [4], it follows that

$$
\log (\Psi(x, y) /(x \rho(u)))=u(\log (u(\log u) / y)+O(1))
$$

for $y \leq \log x$. In particular $\log (\Psi(x, y) /(x \rho(u)) \sim u \log ((\log x) / y)$ as $y / \log x \rightarrow 0$.
Let

$$
A(s):=(\log (\zeta(s)(s-1)))^{\prime} \asymp 1
$$

for $s \in[0,1]$. Recall $f^{\prime \prime}(\beta)=(\log y)^{2} I^{\prime \prime}(\xi(u))$ and $g^{\prime \prime}(\alpha)=\phi_{2}(\alpha, y)$ are estimated in (2.3) and (2.9), respectively, and are $\asymp_{\varepsilon}(\log x)(\log y)$ when $y \geq \varepsilon \log x$. The following technical lemma is proved in $\$ 7$ and is used in the proofs of Corollaries 3.1] 3.4.
Lemma 3.5. Suppose $x \geq C_{\varepsilon}$.
(1) Define quantities $E$ and $E^{\prime}$ via

$$
\begin{equation*}
\beta-\alpha=\frac{\frac{G^{\prime}}{G}(\alpha, y)+A(\alpha)}{f^{\prime \prime}(\beta)}(1+E)=\frac{\frac{G^{\prime}}{G}(\beta, y)+A(\beta)}{g^{\prime \prime}(\alpha)}\left(1+E^{\prime}\right) . \tag{3.5}
\end{equation*}
$$

When $x \geq y \geq \varepsilon \log x$ we have $E<_{\varepsilon}\left(\left|\frac{G^{\prime}}{G}(\alpha, y)\right|+1\right) / \log x$ and $1+E \asymp_{\varepsilon} 1$. When $x \geq y \geq(1+\varepsilon) \log x$ we have $E^{\prime} \ll_{\varepsilon}\left(\left|\frac{G^{\prime}}{G}(\beta, y)\right|+1\right) / \log x$ and $1+E^{\prime} \asymp_{\varepsilon} 1$.
(2) Define quantities $E_{1}$ and $E_{2}$ via

$$
\begin{aligned}
& g(\beta)-g(\alpha)=g^{\prime \prime}(\alpha)(\beta-\alpha)^{2}\left(1+E_{1}\right) / 2 \text { if } x \geq y \geq(1+\varepsilon) \log x \\
& f(\alpha)-f(\beta)=f^{\prime \prime}(\beta)(\beta-\alpha)^{2}\left(1+E_{2}\right) / 2 \text { if } x \geq y \geq \varepsilon \log x
\end{aligned}
$$

Then $E_{1}, E_{2}<_{\varepsilon}\left(\left|\frac{G^{\prime}}{G}(\alpha, y)\right|+1\right) / \log x$ and $1+E_{1}, 1+E_{2} \asymp_{\varepsilon} 1$.
(3) If $x \geq y \geq \varepsilon \log x$ then

$$
\begin{equation*}
B(x, y)=1+O_{\varepsilon}\left(\frac{\left|\frac{G^{\prime}}{G}(\alpha, y)\right|+\left|(\log G)^{(2)}(\alpha, y)\right|(\log y)^{-1}+1}{\log x}\right) \tag{3.6}
\end{equation*}
$$

Let $h(t):=\left(1+t^{-1}\right)^{-1 / 2}$. For $x \geq y \geq 2$,

$$
\begin{equation*}
B(x, y)=h(y / \log x)\left(1+O\left((\log (1+\bar{u}))^{-1}\right)\right) \tag{3.7}
\end{equation*}
$$

Remark 4. Suppose $x \geq y \geq(\log x)^{1 /(1-\vartheta)+\varepsilon}$ and $x \geq C_{\varepsilon}$. From Lemma 3.5, (2.15) and (2.17), the logarithms of $G(\alpha, y), G(\beta, y), B(x, y)$ and $\beta / \alpha$ are

$$
<_{\varepsilon} \frac{1}{\log x}+\frac{(\log x)(\log \log x)}{y^{1-\vartheta}} .
$$

Thus, from Lemma 2.6 with the error term supplied by Proposition 2.7,

$$
\begin{equation*}
\Psi(x, y)=x \rho(u) K(s-1)\left(1+O_{\varepsilon}\left(\frac{1}{\log x}+\frac{(\log x)(\log \log x)}{y^{1-\vartheta}}\right)\right) \tag{3.8}
\end{equation*}
$$

for $s \in\{\alpha, \beta\}$. This gives a stronger version of the first part of Theorem 1.1.
3.1. Proof of Corollary 3.1. Our starting point is Lemma 2.6 with the error term supplied by Proposition 2.7. Since $B(x, y) \sim 1$ (by (3.6)) and $\beta / \alpha \sim 1$ when $y \geq(\log x)^{1+\varepsilon}$, it suffices to show that $g(\alpha)-g(\beta)$ and $f(\alpha)-f(\beta)$ are $o(1)$ as $x \rightarrow \infty$ in the considered range. By Lemma 3.5,

$$
\begin{equation*}
g(\beta)-g(\alpha), f(\alpha)-f(\beta) \asymp_{\varepsilon}(\log x)^{-1}(\log y)^{-1}\left(\frac{G^{\prime}}{G}(\alpha, y)+A(\alpha)\right)^{2} \tag{3.9}
\end{equation*}
$$

By (2.15) and (2.17) with $i=1$,

$$
\begin{align*}
G_{1}^{\prime}(\alpha, y) / G_{1}(\alpha, y) & \ll y^{\vartheta-\alpha}(\log y)^{2} \\
-G_{2}^{\prime}(\alpha, y) / G_{2}(\alpha, y) & \asymp_{\varepsilon} \int_{\sqrt{y}}^{y} t^{-2 \alpha} d t \asymp \frac{y^{\max \left\{1-2 \alpha, \frac{1}{2}-\alpha\right\}} \log y}{\max \{1,|\alpha-1 / 2| \log y\}} \ll\left(y^{1-2 \alpha}+1\right) \log y \tag{3.10}
\end{align*}
$$

By Lemma [2.5, these estimates give the result. The exponents $(1-\vartheta)^{-1} / 2$ and $3 / 2$ in the corollary arise from our bounds for $G_{1}^{\prime} / G_{1}$ and $G_{2}^{\prime} / G_{2}$, respectively.
3.2. Proof of Corollary 3.2. Our starting point is Lemma 2.6. In the considered ranges, $\alpha, \beta \leq 1 / 2-c_{\varepsilon}$ by (2.10) and Lemma 2.4. According to Lemma 3.5, and (2.15) and (2.17) with $i=1,2$, RH implies in our range that

$$
\frac{\beta}{\alpha}-1, B(x, y)-1 \ll_{\varepsilon} \frac{\log ^{2} y}{\sqrt{y}}+\frac{\log x}{y}=o\left(\frac{\log ^{3} x}{y^{2} \log y}\right) .
$$

By (3.9) and (3.10), $g(\beta)-g(\alpha)$ and $f(\alpha)-f(\beta)$ are $\asymp_{\varepsilon} \log ^{3} x /\left(y^{2} \log y\right)$.
3.3. Proof of Corollary 3.3. Suppose $y \geq \varepsilon \log x$. Taking logarithms in the first part of Lemma 2.6 and using the error term supplied by Proposition 2.7 we see

$$
\log \left(\frac{\Psi(x, y)}{x \rho(u) K(\alpha-1)}\right)=\log G(\alpha, y)+f(\alpha)-f(\beta)+\log B(x, y)+O\left(\frac{1}{\alpha \log x}\right)
$$

Recall $G=G_{1} G_{2}$. By (2.14) with $i=0$ and Lemma 2.5,

$$
\log G_{1}(\alpha, y) \ll y^{1-\alpha} L(y)^{-c} \asymp_{\varepsilon} u \log (u+1) L(y)^{-c}
$$

The term $\log G_{2}(\alpha, y)$ is studied in (2.17). The terms $\log B(x, y)$ and $f(\alpha)-f(\beta)$ are estimated in Lemma 3.5 in terms of $G$. By (2.14) and (2.17) we find

$$
\begin{aligned}
\log B(x, y) & \lll \frac{\log G_{2}(\alpha, y)}{u}+L(y)^{-c}+\frac{1}{\log x} \\
f(\alpha)-f(\beta) & =\Theta_{\varepsilon}\left(\frac{\log ^{2} G_{2}(\alpha, y)}{u}\right)+O_{\varepsilon}\left(\frac{\log G_{2}(\alpha, y)}{\min \left\{\log x, L(y)^{c}\right\}}+\frac{\log x}{L(y)^{c}}+\frac{1}{(\log x)(\log y)}\right)
\end{aligned}
$$

Using (2.17) this gives (3.2) and (3.3). By (3.5), (3.2) holds with $\beta$ instead of $\alpha$ too.
3.4. Proof of Corollary 3.4. We take logarithms in the first part of Lemma 2.6. We have

$$
K(\alpha-1) \asymp \alpha^{-1} \asymp_{\varepsilon} \log y
$$

by (2.10) and $\log B(x, y)=O_{\varepsilon}(1)$ by (3.7). Hence

$$
\log \left(\frac{\Psi(x, y)}{x \rho(u)}\right)=\log G_{1}(\alpha, y)+\log G_{2}(\alpha, y)+f(\alpha)-f(\beta)+O_{\varepsilon}(\log \log y)
$$

By (2.14) we have

$$
\log G_{1}(\alpha, y) \ll y^{1-\alpha} L(y)^{-c} \asymp_{\varepsilon} y L(y)^{-c}
$$

By (2.18), the quantity $\log G_{2}(\alpha, y)$ is equal to the integral in (3.4), finishing the proof of (3.4). To study $f(\alpha)-f(\beta)$ we use [20, Eq. (7.6)] and [3, p. 88], which say

$$
\begin{equation*}
\alpha=\frac{\log \left(1+\frac{y}{\log x}\right)}{\log y}\left(1+O\left(\frac{1}{\log y}\right)\right), \quad \xi=\log (u \log u)+\frac{\log \log u}{\log u}+O\left(\frac{1}{\log u}\right) \tag{3.11}
\end{equation*}
$$

to deduce that

$$
\begin{equation*}
\alpha-\beta=\frac{\log \left(1+\frac{\log x}{y}\right)}{\log y}+O_{\varepsilon}\left(\frac{1}{\log ^{2} y}\right)>0 . \tag{3.12}
\end{equation*}
$$

By the definition of $f$,

$$
\begin{equation*}
f(\alpha)-f(\beta)=(\alpha-\beta) \log x+\int_{\xi}^{(1-\alpha) \log y} \frac{e^{t}-1}{t} d t . \tag{3.13}
\end{equation*}
$$

The term $\alpha-\beta$ was just estimated. We estimate the integral in (3.13) using (3.11) $-(3.12)$ :

$$
\begin{aligned}
\int_{\xi}^{(1-\alpha) \log y} \frac{e^{t}-1}{t} d t & =\frac{1}{(1-\alpha) \log y}\left(1+O_{\varepsilon}\left(\frac{1}{\log y}\right)\right) \int_{\xi}^{(1-\alpha) \log y}\left(e^{t}-1\right) d t \\
& =\left.\frac{1}{\log y}\left(1+O_{\varepsilon}\left(\frac{1}{\log y}\right)\right)\left(e^{t}-t\right)\right|_{t=\xi} ^{t=(1-\alpha) \log y} \\
& =\frac{y^{1-\alpha}-e^{\xi}}{\log y}\left(1+O_{\varepsilon}\left(\frac{1}{\log y}\right)\right)
\end{aligned}
$$

and

$$
\begin{aligned}
y^{1-\alpha}-e^{\xi} & =e^{\xi}\left(e^{\log y(\beta-\alpha)}-1\right)=-e^{\xi}\left(1+\frac{\log x}{y}\right)^{-1}\left(1+O_{\varepsilon}\left(\frac{1}{\log y}\right)\right) \\
& =-\log x\left(1+\frac{\log x}{y}\right)^{-1}\left(1+O_{\varepsilon}\left(\frac{1}{\log y}\right)\right)
\end{aligned}
$$

To estimate the integral in (3.4) we integrate by parts, obtaining it equals

$$
\frac{y}{\log y}\left(-\log \left(1-y^{-\alpha}\right)-y^{-\alpha}\right)\left(1+O_{\varepsilon}\left(\frac{1}{\log y}\right)\right)
$$

We use (3.11) to write

$$
y^{-\alpha}=\left(1+\frac{y}{\log x}\right)^{-1}\left(1+O_{\varepsilon}\left(\frac{1}{\log y}\right)\right)
$$

which gives the desired approximation for the integral.

## 4. Pomerance's question

4.1. Proof of first part of Theorem 1.2. Estimate (1.6) follows from (3.3) upon simplifying $\log G_{2}$ using (2.17). Estimate (1.5) is in (3.2) if $x \geq C$ and $x^{c} \geq y$ since, by Taylor-approximating $K$ at 0 ,

$$
\begin{equation*}
K(\beta-1)=1+\Theta\left(\frac{\log (u+1)}{\log y}\right) \tag{4.1}
\end{equation*}
$$

for $x^{c} \geq y \geq(\log x)^{2}$. For $x^{c} \leq y \leq(1-\varepsilon) x$, we recall de Bruijn's approximation $\Lambda(x, y)$ [5], defined as

$$
\Lambda(x, y):=x \int_{\mathbb{R}} \rho(u-v) d\left(\left\lfloor y^{v}\right\rfloor / y^{v}\right)
$$

for $x \notin \mathbb{Z}$. Integrating the definition by parts gives

$$
\begin{equation*}
\Lambda(x, y)=x \rho(u)-\{x\}+x \int_{0}^{u-1}\left(-\rho^{\prime}(u-v)\right)\left\{y^{v}\right\} y^{-v} d v \tag{4.2}
\end{equation*}
$$

De Bruijn 5 proved $\Psi(x, y)=\Lambda(x, y)+O\left(x \exp \left(-C \log ^{1 / 2} x\right)\right)$ for $u=O(1)$. Suppose $x^{c} \leq y \leq(1-\varepsilon) x$. Then the contribution of $0 \leq v \leq c_{\varepsilon} / \log y$ to the integral in the right-hand side of (4.2) is $\geq c_{\varepsilon} / \log x$, which yields (1.5) in the remaining range.
4.2. Proof of second part of Theorem 1.2. We assume RH holds. Estimate (1.6) in $2 \log x \leq y \leq(\log x)^{2-\varepsilon}$ follows from the third part of Theorem 1.1 and for $\varepsilon \log x \leq y<$ $2 \log x$ it is in the first part of Theorem 1.2. In $x(1-\varepsilon) \geq y \geq x^{c}$, (1.5) holds by the first part of Theorem 1.2. In $x^{c} \geq y \geq(\log x)^{2+\varepsilon}$, (1.5) follows from (4.1) and (3.8) since $K$ is strictly decreasing. It remains to deal with $(\log x)^{2-\varepsilon} \leq y \leq(\log x)^{2+\varepsilon}$. In this range, Corollary 3.1 tells us

$$
\Psi(x, y)=(1+o(1)) x \rho(u) K(\beta-1) G(\beta, y), \quad x \rightarrow \infty
$$

The asymptotic estimates for $\log G_{1}$ and $\log G_{2}$ given in (2.15) and (2.17) respectively, yield

$$
\log G(\beta, y)=\frac{1+o(1)}{2} \int_{\sqrt{y}}^{y} \frac{d t}{t^{2 \beta} \log t} d t+\frac{\psi(y)-y}{y^{\beta} \log y}+O\left(\frac{y^{\frac{1}{2}-\beta}}{\log y}\right)
$$

We want

$$
\begin{equation*}
\log K(\beta-1)+\frac{y^{\frac{1}{2}-\beta}}{\log y}\left(\frac{\psi(y)-y}{\sqrt{y}}+O(1)\right)+\frac{1+o(1)}{2} \int_{\sqrt{y}}^{y} \frac{d t}{t^{2 \beta} \log t} d t+o(1) \tag{4.3}
\end{equation*}
$$

to be non-negative. We show that if

$$
\begin{equation*}
\liminf _{y \rightarrow \infty} \frac{\psi(y)-y}{\sqrt{y} \log y}>L \tag{4.4}
\end{equation*}
$$

holds and $x \geq C$ then (4.3) is non-negative for $(\log x)^{3 / 2} \leq y \leq(\log x)^{3}$. We consider three cases. If $(2 \beta-1) \log y \geq C$ then (4.4) implies that (4.3) is positive if $x \geq C$. If $(2 \beta-1) \log y \leq-C$ then (4.3) is positive by (4.4) and additionally invoking (2.17) to estimate the integral in (4.3). The most delicate range is $(2 \beta-1) \log y=O(1)$. Here $K(\beta-1) \sim K(-1 / 2)$. Set

$$
\beta=\frac{1}{2}+\frac{v}{\log y}
$$

so that $v$ is bounded. We express $\log (\Psi(x, y) /(x \rho(u))$ as a function of $y$ and $v$ :

$$
\begin{equation*}
\log \left(\frac{\Psi(x, y)}{x \rho(u)}\right)=\log K(-1 / 2)+e^{-v} \frac{\psi(y)-y}{\sqrt{y} \log y}+\frac{1}{2} \int_{v}^{2 v} \frac{e^{-r}}{r} d r+o(1) \tag{4.5}
\end{equation*}
$$

If (4.4) holds, we find by the definition of $L$ that the right-hand side of (4.5) is $>c$ for some $c>0$, if $y$ is sufficiently large. If instead

$$
\liminf _{y \rightarrow \infty} \frac{\psi(y)-y}{\sqrt{y} \log y}<L
$$

then, by definition, we can find $v \in \mathbb{R}$ such that if $\beta=1 / 2+v / \log y$ then the right-hand side of (4.5) is $<-c$ for some $c>0$, if $y$ is sufficiently large. This finishes the proof.

## 5. Study of $G_{1}$

5.1. Proof of Lemma 2.8. For our purposes, given a function $A$ its Mellin transform is

$$
\{\mathcal{M} A\}(s)=\int_{1}^{\infty} A(x) x^{-s-1} d x
$$

Proposition 5.1. Let $T(x):=\int_{x}^{\infty} d t /\left(t^{2} \log t\right)$, which decays like $(x \log x)^{-1}$ as $x \rightarrow \infty$ and blows up as $x \rightarrow 1^{+}$. Fix $s_{0}>-2$ and $a>0$. The function $\log G_{1}\left(s_{0}, x\right)+T\left(x^{a}\right)$ is defined at $x=1^{+}$and

$$
\left\{\mathcal{M}\left(\log G_{1}\left(s_{0}, x\right)-T\left(x^{a}\right)\right)\right\}(s)=\frac{1}{s} \log \frac{\zeta\left(s+s_{0}\right)\left(s+s_{0}-1\right)}{\zeta\left(s_{0}\right)\left(s_{0}-1\right)(1+s / a)}
$$

holds for $\Re s>\max \left\{1-s_{0}, 0\right\}$. This transform has analytic continuation to $\Re s>\max \{\vartheta-$ $\left.s_{0},-a\right\}$.

Proof. We require the following identity [7, Lem. 2.2]:

$$
\begin{equation*}
\log \log x+\gamma=\int_{1}^{x} \frac{1-v^{-1}}{v \log v} d v-\int_{x}^{\infty} \frac{d v}{v^{2} \log v}, \quad x>1 \tag{5.1}
\end{equation*}
$$

Write $\log G_{1}\left(s_{0}, x\right)$ as $A_{1}(x)-\left(A_{2}(x)+A_{3}(x)+A_{4}(x)\right)$ where

$$
\begin{array}{lr}
A_{1}(x)=\sum_{n \leq x} \frac{\Lambda(n)}{n^{s_{0}} \log n}, & A_{2}(x)=\log \log x+\gamma \\
A_{3}(x)=I\left(\left(1-s_{0}\right) \log x\right), & A_{4}(x)=\log \left(\zeta\left(s_{0}\right)\left(s_{0}-1\right)\right)
\end{array}
$$

By [23, Thm. 1.3], the Mellin transform of $x \mapsto \sum_{m \leq x} h(m)$ is $s^{-1} \sum_{n=1}^{\infty} h(n) n^{-s}$, so

$$
\left\{\mathcal{M} A_{1}\right\}(s)=s^{-1} \log \zeta\left(s+s_{0}\right)
$$

for $\Re s>\max \left\{1-s_{0}, 0\right\}$. For any constant $b$ we have $\{\mathcal{M} b\}(s)=s^{-1} b$ and so

$$
\left\{\mathcal{M} A_{4}\right\}(s)=s^{-1} \log \left(\zeta\left(s_{0}\right)\left(s_{0}-1\right)\right)
$$

For $A_{3}$ first suppose $s_{0}<1$. We shall use the identity [7, Eq. (2.3)]

$$
\begin{equation*}
\log \frac{z+1}{z}=\int_{1}^{\infty} t^{-z} \frac{1-t^{-1}}{t \log t} d t, \quad \Re z>0 . \tag{5.2}
\end{equation*}
$$

To verify (5.2) we check that both sides have the same derivative and tend to 0 when $\Re z \rightarrow \infty$. Applying (5.2) with $z=\left(s_{0}+s-1\right) /\left(1-s_{0}\right)$ and substituting $t=x^{1-s_{0}}$ we obtain

$$
\begin{equation*}
\log \frac{s}{s+s_{0}-1}=\int_{1}^{\infty} x^{-s} \frac{x^{1-s_{0}}-1}{x \log x} d x=s \int_{1}^{\infty} x^{-s-1} \int_{1}^{x} \frac{v^{1-s_{0}}-1}{v \log v} d v d x \tag{5.3}
\end{equation*}
$$

for $\Re s>\max \left\{1-s_{0}, 0\right\}$, where in the last equality we integrated by parts. Substituting $v=e^{u /\left(1-s_{0}\right)}$ we find

$$
\begin{equation*}
\left\{\mathcal{M} A_{3}\right\}(s)=s^{-1} \log \frac{s}{s+s_{0}-1} \tag{5.4}
\end{equation*}
$$

If $s_{0}=1$ then $A_{3} \equiv 0$ and (5.4) still holds. If $s_{0}>1$, the left-hand side of (5.3) still agrees with its right-hand side by the uniqueness principle and so (5.4) persists. For $A_{2}$, we apply (5.1) with $x^{a}$ in place of $x$, obtaining

$$
A_{2}(x)=\int_{1}^{x^{a}} \frac{1-t^{-1}}{t \log t} d t-\int_{x^{a}}^{\infty} \frac{d t}{t^{2} \log t}-\log a=: \widetilde{A_{2}}(x)-T\left(x^{a}\right)-\log a
$$

where $T$ is as in the statement of the proposition. We have $\{\mathcal{M} \log a\}(s)=s^{-1} \log a$. By (5.3) with $s_{0}=2, s / a$ in place of $s$ and the substitution $x=u^{a}$, we find

$$
\left\{\mathcal{M} \widetilde{A_{2}}\right\}(s)=s^{-1} \log \frac{s+a}{s} .
$$

We now sum the Mellin transforms of $A_{1},-A_{2}-T\left(x^{a}\right)=\log a-\widetilde{A_{2}},-A_{3}$ and $-A_{4}$.
To establish Lemma 2.8 fix $\varepsilon>0$ and $s>-2$. Suppose that $\log G_{1}(s, x)<x^{\vartheta-s-\varepsilon}$ (resp. $\log G_{1}(s, x)>-x^{\vartheta-s-\varepsilon}$ ) for $x \geq C_{\varepsilon, s}$. Reach contradiction by applying Landau's Oscillation Theorem [23, Lem. 15.1] to $A(x)=2 x^{\vartheta-s-\varepsilon}-\left(\log G_{1}(s, x)-T\left(x^{s+2}\right)\right)($ resp. $A(x)=$ $\left.2 x^{\vartheta-s-\varepsilon}+\log G_{1}(s, x)-T\left(x^{s+2}\right)\right)$, an eventually positive function.
5.2. Explicit formulas for $G_{1}$. Given $x>0$ and $s \in \mathbb{C}$ we let $S_{1}(x, s):=\sum_{n \leq x}{ }^{\prime} \Lambda(n) n^{-s}$, where the prime on the summation indicates that if $x$ is a prime power, the last term of the sum should be multiplied by $1 / 2$. Landau [21] established an explicit formula for $S_{1}(x, s)$ when $\zeta(s) \neq 0$. In $\S \in$ we establish a truncated version of it, stated in the lemma below. We denote by $x^{\prime}$ the prime power closest to $x$ not equal to $x$, and set $\langle x\rangle=\left|x-x^{\prime}\right|$.
Lemma 5.2. Suppose $\zeta(s) \neq 0$. For $x \geq 4$ and $T \geq 2+|\Im s|$ we define $R_{1}(x, T, s)$ by

$$
\begin{equation*}
S_{1}(x, s)=\frac{x^{1-s}}{1-s}-\frac{\zeta^{\prime}(s)}{\zeta(s)}-\sum_{|\Im(\rho-s)| \leq T} \frac{x^{\rho-s}}{\rho-s}+\sum_{k=1}^{\infty} \frac{x^{-2 k-s}}{2 k+s}+R_{1}(x, T, s) \tag{5.5}
\end{equation*}
$$

where the first sum is over non-trivial zeros $\rho$ of $\zeta$. Then

$$
\begin{equation*}
R_{1}(x, T, s) \ll(\log x) x^{\prime-\Re s} \min \left\{1, \frac{x}{T\langle x\rangle}\right\}+\frac{\log ^{2}(x T)}{T}\left(2^{|\Re s|} x^{1-\Re s}+\frac{2^{-\Re s}}{\log x}\right) . \tag{5.6}
\end{equation*}
$$

If $s=1$ then the term $x^{1-s} /(1-s)-\zeta^{\prime}(s) / \zeta(s)$ should be interpreted as $\log x-\gamma$.
Next we need the identity [1, p. 228]

$$
\begin{equation*}
I(-z)+\int_{0}^{\infty} \frac{e^{-z-t}}{z+t} d t+\gamma+\log z=0, \quad z \in \mathbb{C} \backslash(-\infty, 0] \tag{5.7}
\end{equation*}
$$

where $\log z$ is chosen to be real-valued for $z>0$ (it is in fact equivalent to (5.1)).
Corollary 5.3. Let $S_{0}(x, s):=\sum_{n \leq x}{ }^{\prime} \Lambda(n) n^{-s} / \log n$. Suppose $s \in \mathbb{C}$ has $\zeta(s+t) \neq 0$ for $t \geq 0$. For $x \geq 4$ and $T \geq 2+|\Im s|$ we define $R_{0}(x, T, s)$ by

$$
\begin{aligned}
S_{0}(x, s)= & I((1-s) \log x)+\gamma+\log \log x+\log (\zeta(s)(s-1)) \\
& -\sum_{|\Im(\rho-s)| \leq T} \int_{0}^{\infty} \frac{x^{\rho-s-t}}{\rho-s-t} d t+\sum_{k=1}^{\infty} \int_{0}^{\infty} \frac{x^{-2 k-s-t}}{2 k+s+t} d t+R_{0}(x, T, s)
\end{aligned}
$$

where $\log (\zeta(z)(z-1))$ is real-valued for $z>1$ and defined on $\{s+t: t \geq 0\}$. Then

$$
\begin{equation*}
R_{0}(x, T, s) \ll x^{\prime-\Re s} \min \left\{1, \frac{x}{T\langle x\rangle}\right\}+\frac{\log ^{2}(x T)}{T \log x}\left(2^{|\Re s|} x^{1-\Re s}+2^{-\Re s}\right) . \tag{5.8}
\end{equation*}
$$

Proof. We start with an integral identity (cf. [25, Prop. 1]):

$$
S_{0}(x, s)=\int_{0}^{\infty} \sum_{n \leq x}^{\prime} \frac{\Lambda(n)}{n^{s+t}} d t=\int_{0}^{\infty} S_{1}(x, s+t) d t
$$

We integrate both sides of (5.5) along $\{s+t: t \geq 0\}$. We may interchange sum and integral because the sum over $\rho$ is finite, while the integral of the $k$-sum converges absolutely. It remains to show
$\lim _{A \rightarrow \infty} \int_{0}^{A}\left(\frac{x^{1-s-t}-1}{1-s-t}-\frac{(\zeta(s+t)(s+t-1))^{\prime}}{\zeta(s+t)(s+t-1)}\right) d t=I((1-s) \log x)+\gamma+\log (\zeta(s)(s-1) \log x)$.
The substitution $(1-s-t) \log x=v$ allows us to evaluate the integral as

$$
I((1-s) \log x)-I((1-s-A) \log x)-\log (\zeta(s+A)(s+A-1))+\log (\zeta(s)(s-1))
$$

The required limit follows from (5.7) with $z=(s+A-1) \log x(A \rightarrow \infty)$.
From the definition of $\log G_{1}$, Lemma 5.2 and Corollary 5.3 we get
Corollary 5.4. Suppose $\zeta(s) \neq 0$. For $x \geq 4$ and $T \geq 2+|\Im s|$ we have, for $R_{1}$ estimated in (5.6),

$$
-\left(\log G_{1}\right)^{\prime}(s, x)=\frac{\mathbf{1}_{x \in \mathbb{N}} \Lambda(x)}{2 x^{s}}-\sum_{|\Im(\rho-s)| \leq T} \frac{x^{\rho-s}}{\rho-s}+\sum_{k=1}^{\infty} \frac{x^{-2 k-s}}{2 k+s}+R_{1}(x, T, s) .
$$

Suppose further that $\zeta(s+t) \neq 0$ for $t \geq 0$. We have, for $R_{0}$ estimated in (5.8),

$$
\log G_{1}(s, x)=\frac{\mathbf{1}_{x \in \mathbb{N}} \Lambda(x)}{2 x^{s} \log x}-\sum_{|\Im(\rho-s)| \leq T} \int_{0}^{\infty} \frac{x^{\rho-s-t}}{\rho-s-t} d t+\sum_{k=1}^{\infty} \int_{0}^{\infty} \frac{x^{-2 k-s-t}}{2 k+s+t} d t+R_{0}(x, T, s)
$$

Applying Cauchy's integral formula to the first part of Corollary 5.4 we get
Corollary 5.5. Fix $i \geq 2$ and $a>0$. Let $x \geq 4$. Suppose that $\zeta(z) \neq 0$ for $|z-s| \leq a / \log x$. Then for $T \geq 2+|\Im s|+a / \log x$ we have

$$
-\left(\log G_{1}\right)^{(i)}(s, x)=\frac{\mathbf{1}_{x \in \mathbb{N}} \Lambda(x)(-\log x)^{i-1}}{2 x^{s}}-\sum_{|\Im(\rho-s)| \leq T} \frac{\partial^{i-1}}{\partial s^{i-1}} \frac{x^{\rho-s}}{\rho-s}+\frac{\partial^{i-1}}{\partial s^{i-1}} \sum_{k=1}^{\infty} \frac{x^{-2 k-s}}{2 k+s}+R_{i}
$$

for $R_{i}=R_{i}(x, T, s)$ satisfying

$$
R_{i}(x, T, s)<_{i, a}(\log x)^{i} x^{\prime \Re s} \min \left\{1, \frac{x}{T\langle x\rangle}\right\}+\frac{\log ^{2}(x T)(\log x)^{i-1}}{T}\left(2^{\Re s \mid} x^{1-\Re s}+\frac{2^{-\Re s}}{\log x}\right)
$$

5.3. Proof of Lemma 2.9. We explain $i=0$; general $i$ is similar. Under our assumptions,

$$
-\int_{0}^{\infty} \frac{x^{\rho-s-t}}{\rho-s-t} d t=-\frac{1}{\log x} \frac{x^{\rho-s}}{\rho-s}\left(1+O_{\varepsilon}\left(\frac{1}{|\rho| \log x}\right)\right)
$$

for every zero of $\zeta$. For the first estimate we apply Corollary 5.4 with $T=L(x)^{c}$ and use the Vinogradov-Korobov zero-free region to bound the sum over the zeros. For the second estimate we apply Corollary 5.4 with $T=x$ and write the sum over zeros as

$$
-\sum_{|\Im \rho| \leq x} \int_{0}^{\infty} \frac{x^{\rho-s-t}}{\rho-s-t} d t=-\frac{x^{-s}}{\log x} \sum_{|\rho| \leq x} \frac{x^{\rho}}{\rho}\left(1+O_{\varepsilon}\left(|\rho|^{-1}\right)\right)
$$

Since $\sum_{\rho} 1 /|\rho|^{2}$ converges [23, Thm. 10.13], $\sum_{\rho \mid \leq x}\left|x^{\rho} / \rho^{2}\right| \ll x^{\vartheta}$. By Lemma 5.2 with $s=0$, $-\sum_{|\rho| \leq x} x^{\rho} / \rho=\psi(x)-x+O\left(\log ^{2} x\right)$ and so

$$
-\sum_{|\Im \rho| \leq x} \int_{0}^{\infty} \frac{x^{\rho-s-t}}{\rho-s-t} d t=x^{-s}\left(\psi(x)-x+O_{\varepsilon}\left(x^{\vartheta}\right)\right)<_{\varepsilon} x^{-s} x^{\vartheta} \log ^{2} x
$$

where the last inequality is Exercise 1 in [23, p. 430].
5.4. Proof of Lemma 2.11. By definition,

$$
\begin{equation*}
\sum_{n \leq x} \frac{\Lambda(n)}{n^{s} \log n}=\int_{2^{-}}^{x} \frac{d \psi(t)}{t^{s} \log t} \tag{5.9}
\end{equation*}
$$

Through the change of variables $v \mapsto(1-s) \log t(s \neq 0$ fixed $)$,

$$
\begin{equation*}
I((1-s) \log x)=\int_{1}^{x} \frac{t^{1-s}-1}{t \log t} d t \tag{5.10}
\end{equation*}
$$

which is also true for $s=1$. The second part follows from (5.9), (5.10) and (5.1). For (2.16) observe that both sides of are real-analytic functions for $s>\vartheta\left(\right.$ since $\psi(x)=x+O\left(x^{\vartheta} \log ^{2} x\right)$ [23, p. 430]) so by the uniqueness principle it suffices to consider $s>1$. We use (5.9), (5.10) and

$$
\log \zeta(s)=\sum_{n \geq 1} \frac{\Lambda(n)}{n^{s} \log n}=\int_{2^{-}}^{\infty} \frac{d \psi(t)}{t^{s} \log t}
$$

to find that

$$
\begin{aligned}
\log G_{1}(s, x) & =-\int_{x}^{\infty} \frac{d(\psi(t)-t)}{t^{s} \log y}+H(s, x) \\
H(s, x) & :=\int_{1}^{x} \frac{1-t^{1-s}}{t \log t} d t-\int_{x}^{\infty} \frac{1}{t^{s} \log t}-\log ((s-1) \log x)-\gamma
\end{aligned}
$$

The derivative of $H$ with respect to $s$ is 0 and $H(2, x) \equiv 0$ by (5.1), so $H \equiv 0$.

## 6. Study of $G_{2}$ : proof of Proposition 2.12

We have $\log G_{2}=\log G_{2,1}+\log G_{2,2}$ for

$$
\log G_{2,1}(s, x)=\sum_{\sqrt{x}<p \leq x} \frac{p^{-2 s}}{2}, \quad \log G_{2,2}(s, x)=\sum_{k \geq 3} \sum_{x^{1 / k}<p \leq x} \frac{p^{-k s}}{k}
$$

The PNT with error term shows, via integration by parts, that for $s \in[0,1]$ we have

$$
\begin{equation*}
\log G_{2,1}(s, x)=\frac{1+O\left(L(x)^{-c}\right)}{2} \int_{\sqrt{x}}^{x} \frac{d t}{t^{2 s} \log t} \tag{6.1}
\end{equation*}
$$

For $x \neq 0$ let $\operatorname{Ei}(x)$ be the exponential integral, to be understood in principal value sense:

$$
\operatorname{Ei}(x)=-\int_{-x}^{\infty} e^{-t} t^{-1} d t=\int_{-\infty}^{x} e^{t} t^{-1} d t=e^{x} x^{-1}\left(1+O\left(x^{-1}\right)\right)
$$

By performing the change of variables $v=(1-2 s) \log t$ in (6.1) we see that

$$
\begin{aligned}
\int_{\sqrt{x}}^{x} \frac{d t}{t^{2 s} \log t} & =\operatorname{Ei}((1-2 s) \log x)-\operatorname{Ei}\left(\left(\frac{1}{2}-s\right) \log x\right) \\
& \sim\left\{\begin{array}{ll}
\frac{x^{\frac{1}{2}-s}}{\left(s-\frac{1}{2}\right) \log x} & \text { if }(2 s-1) \log x \rightarrow \infty \\
\frac{x^{1-2 s}}{(1-2 s) \log x} & \text { if }(2 s-1) \log x \rightarrow-\infty
\end{array} \asymp \frac{x^{\max \left\{1-2 s, \frac{1}{2}-s\right\}}}{\max \{1,|s-1 / 2| \log x\}}\right.
\end{aligned}
$$

for $s \in[0,1] \backslash\{1 / 2\}$. When $s=1 / 2$ the integral is $\log 2$ since $(\log \log t)^{\prime}=1 /(t \log t)$.
Lemma 6.1. For $1 \geq s \geq \varepsilon / \log x$ we have

$$
\log G_{2,2}(s, x)<_{\varepsilon} \frac{x^{\max \left\{1-3 s, \frac{1}{3}-s\right\}}}{\max \{1,|s-1 / 3| \log x\}} .
$$

Proof. If $x<_{\varepsilon} 1$ then $\log G_{2,2}(s, x)<_{\varepsilon} 1$ so we may assume $x \geq C_{\varepsilon}$. In the same way we showed (6.1), we find that the contribution of $k=3$ to $\log G_{2,2}(s, x)$ is acceptable, so we omit this case. We consider the contribution of $k \geq \max \left\{2 / s, \log _{2} x\right\}$ (base-2 logarithm) to $\log G_{2,2}$. For such $k$,

$$
\sum_{x^{1 / k}<p \leq x} p^{-k s} \leq 2^{-k s}+\sum_{p \geq 3} p^{-k s} \ll 2^{-k s}+\int_{2}^{\infty} t^{-k s} d t \ll 2^{-k s}
$$

Hence

$$
\begin{equation*}
\sum_{k \geq \max \left\{2 / s, \log _{2} x\right\}} \sum_{x^{1 / k}<p \leq x} p^{-k s} / k \ll \sum_{k \geq \max \left\{2 / s, \log _{2} x\right\}} 2^{-k s} / k \ll x^{-s} \tag{6.2}
\end{equation*}
$$

which is negligible. It remains to consider the contribution of $4 \leq k<\max \left\{2 / s, \log _{2} x\right\}$ to $\log G_{2,2}$. We show that primes $p \in\left(x^{1 / 4}, x\right]$ have an acceptable contribution. The assumption $s \geq \varepsilon / \log x$ implies $1 /\left(1-t^{-s}\right)<_{\varepsilon} 1$ when $t \geq x^{1 / 4} / 2$, and so

$$
\sum_{\max \left\{2 / s, \log _{2} x\right\}>k \geq 4} \sum_{x^{1 / 4}<p \leq x} p^{-k s} / k \ll \sum_{k \geq 4} \int_{x^{1 / 4} / 2}^{x} \frac{d t}{t^{k s} k \log t} \ll_{\varepsilon} \int_{x^{1 / 4} / 2}^{x} \frac{d t}{t^{4 s} \log t}
$$

which is acceptable. For the primes $p \in\left(x^{1 / k}, x^{1 / 4}\right]$, the bound $\pi(y) \ll y / \log y$ shows

$$
\begin{equation*}
\sum_{\max \left\{2 / s, \log _{2} x\right\}>k \geq 4} \sum_{x^{1 / k}<p \leq x^{1 / 4}} p^{-k s} / k \ll \sum_{\max \left\{2 / s, \log _{2} x\right\}>k \geq 4} x^{\frac{1}{4}-s} / \log x \lll x^{\frac{1}{4}-s}, \tag{6.3}
\end{equation*}
$$

where in the last inequality we used $s \geq \varepsilon / \log x$. This is an acceptable bound.
Estimate (2.17) when $i=0$ is a direct consequence of (6.1) and Lemma 6.1; $i>0$ is similar and so is omitted. We now assume $1 / 4 \geq s \geq \varepsilon / \log x$ and establish (2.18). The contribution of $k \geq \max \left\{2 / s, \log _{2} x\right\}$ to $\log G_{2}$ is $\ll x^{-s}$ as in (6.2). We now consider $2 \leq k<\max \left\{2 / s, \log _{2} x\right\}$. If $x^{1 / k}<p \leq \sqrt{x}$ we get a contribution of $<_{\varepsilon} x^{1 / 2-s}$ similarly to (6.3). We handle $2 \leq k<\max \left\{2 / s, \log _{2} x\right\}$ and $\sqrt{x}<p \leq x$ by the PNT and integration by parts, obtaining a contribution of

$$
\left(1+O_{\varepsilon}\left(L(x)^{-c}\right)\right) \int_{\sqrt{x}}^{x} \sum_{2 \leq k<\max \left\{2 / s, \log _{2} x\right\}} \frac{t^{-k s}}{k} \frac{d t}{\log t} .
$$

Since $t^{s}-1>_{\varepsilon} 1$ when $t \in[\sqrt{x}, x]$ we may extend the $k$-sum within the integral to the range $k \geq 2$ at a cost of $<_{\varepsilon} \int_{\sqrt{x}}^{x} t^{-2} d t \ll 1$.

## 7. Proofs of Lemma 3.5] and Proposition 2.7

Lemma 7.1. Fix $2 \leq k \leq 5$. Suppose $x \geq C_{\varepsilon}$. Let I be the closed interval with endpoints $\alpha$ and $\beta$. For $t \in I$,

$$
\begin{align*}
& g^{(k)}(t) \asymp_{\varepsilon}(-1)^{k}(\log x)(\log y)^{k-1} \text { if } x \geq y \geq(1+\varepsilon) \log x,  \tag{7.1}\\
& f^{(k)}(t) \asymp_{\varepsilon}(-1)^{k}(\log x)(\log y)^{k-1} \text { if } x \geq y \geq \varepsilon \log x . \tag{7.2}
\end{align*}
$$

Proof. Suppose $x \geq y \geq(1+\varepsilon) \log x$. As shown in Lemma 4 of [20],

$$
g^{(k)}(t)=(-1)^{k} \sum_{p \leq y}(\log p)\left(p^{t}-1\right)^{-k} Q_{k-1}\left(p^{t} \log p\right)
$$

for a polynomial $Q_{k-1}$ of degree $k-1$ and non-negative coefficients, so $(-1)^{k} g^{(k)}(t)$ is positive and monotone for $t>0$. By the same lemma, $g^{(k)}(\alpha) \asymp(-1)^{k}(\log x)(\log y)^{k-1}$ for $x \geq y \geq$ $\log x$. It remains to show $g^{(k)}(\beta)$ is also of order $(-1)^{k}(\log x)(\log y)^{k-1}$. Since $\beta \geq c_{\varepsilon} / \log y$ by Corollary 2.2, the same lemma shows that

$$
(\log y)^{k-1} \frac{y^{1-\beta}-1}{1-\beta} \lll \varepsilon(-1)^{k} g^{(k)}(\beta) \ll_{\varepsilon}(\log y)^{k-1} \sum_{p \leq y} \frac{\log p}{p^{\beta}-1} .
$$

By definition of $\beta$, the left-hand side is $(\log x)(\log y)^{k-1}$. The sum in the right-hand side is upper bounded in [20, Eq. (7.1)] by

$$
\sum_{p \leq y} \frac{\log p}{p^{\beta}-1} \ll \frac{1}{1-y^{-\beta}} \int_{1}^{y} t^{-\beta} d t+O(1)
$$

which is $<_{\varepsilon} \log x$ by definition of $\beta$. This finishes the proof of (7.1). For $f^{(k)}$,

$$
f^{(k)}(t)=(-\log y)^{k} I^{(k)}((1-t) \log y)
$$

Observe $I^{(k)}(v) \asymp e^{v} /(v+1)$ uniformly for $v \geq 0$ [26, Lem. 4.5] and $e^{v} /(v+1) \asymp u$ as long as $0 \leq v=\xi(u)+O(1)$. Hence, by monotonicity of $I^{(k)}$, it suffices to show $0 \leq(1-t) \log y=$ $\xi(u)+O_{\varepsilon}(1)$ holds for $t \in\{\alpha, \beta\}$. For $t=\beta$ it is trivial. For $t=\alpha,(1-\alpha) \log y=\xi(u)+O_{\varepsilon}(1)$ follows from Lemma 2.4 so it is left to show $\alpha<1$. By definition $\sum_{p \leq y} \log p /\left(p^{\alpha}-1\right)=\log x$, and at $\alpha=1$ the sum is $\log y-\gamma+o(1)$ [23, p. 182] which is $<\log x$ when $x \geq C$, so $\alpha<1$.

Corollary 7.2. Suppose $x \geq C_{\varepsilon}$. Let $I$ be the closed interval with endpoints $\alpha$ and $\beta$. For $t \in I$,

$$
\begin{align*}
& g^{\prime \prime}(t)=g^{\prime \prime}(\alpha)\left(1+O_{\varepsilon}(|\alpha-\beta| \log y)\right) \text { if } x \geq y \geq(1+\varepsilon) \log x, \\
& f^{\prime \prime}(t)=f^{\prime \prime}(\beta)\left(1+O_{\varepsilon}(|\alpha-\beta| \log y)\right) \text { if } x \geq y \geq \varepsilon \log x . \tag{7.3}
\end{align*}
$$

Proof. For any $t \in I, g^{\prime \prime}(t)=g^{\prime \prime}(\alpha)+(t-\alpha) g^{(3)}\left(t_{2}\right)$ for some $t_{2} \in I$. The estimates for $g^{\prime \prime}$ and $g^{(3)}$ in Lemma 7.1 imply the result for $g^{\prime \prime}$. The proof of (7.3) is similar.

Lemma 7.3. Suppose $x \geq C_{\varepsilon}$. Let $2 \leq k \leq 4$ and $s \in\{\alpha, \beta\}$. We have

$$
g^{(k)}(\alpha)-f^{(k)}(\beta)=A^{(k-1)}(s)+O_{\varepsilon}\left(\left|(\log G)^{(k)}(s, y)\right|+|\alpha-\beta|(\log x)(\log y)^{k}\right)
$$

in the range $x \geq y \geq(1+\varepsilon) \log x$ if $s=\beta$ and in $x \geq y \geq \varepsilon \log x$ if $s=\alpha$.
Proof. When $s=\alpha$ we write $g^{(k)}(\alpha)-f^{(k)}(\beta)=f^{(k)}(\alpha)-f^{(k)}(\beta)+(\log G)^{(k)}(\alpha, y)+A^{(k-1)}(\alpha)$ and replace $f^{(k)}(\alpha)-f^{(k)}(\beta)$ by $(\alpha-\beta) f^{(k+1)}(t)$ for $t$ between $\alpha$ and $\beta$. Lemma 7.1 bounds $f^{(k+1)}(t)$. The case $s=\beta$ is similar.
7.1. Proof of Lemma 3.5- first part. The relations $g^{\prime}(\alpha)=f^{\prime}(\beta)=0$ can be written as

$$
\begin{equation*}
\left(-\zeta^{\prime} / \zeta\right)(\alpha, y)=\left(-F_{2}^{\prime} / F_{2}\right)(\beta, y)=\log x \tag{7.4}
\end{equation*}
$$

Writing $\zeta(s, y)$ as $F_{2}(s, y) G(s, y) \zeta(s)(s-1)$, (7.4) implies

$$
\begin{equation*}
\left(-F_{2}^{\prime} / F_{2}\right)(\alpha, y)+\left(F_{2}^{\prime} / F_{2}\right)(\beta, y)=\left(G^{\prime} / G\right)(\alpha, y)+A(\alpha) \tag{7.5}
\end{equation*}
$$

By the mean value theorem, for some $t$ between $\alpha$ and $\beta$ we have

$$
\begin{equation*}
\left(-F_{2}^{\prime} / F_{2}\right)(\alpha, y)+\left(F_{2}^{\prime} / F_{2}\right)(\beta, y)=(\beta-\alpha) f^{\prime \prime}(t) \tag{7.6}
\end{equation*}
$$

We compare (7.6) with (7.5) to find $1+E=f^{\prime \prime}(\beta) / f^{\prime \prime}(t)$ where $E$ is defined in (3.5). By (7.2), $1+E \asymp_{\varepsilon} 1$. To upper bound $|E|$ we use the estimate in Corollary 7.2 to find $E \ll_{\varepsilon}|\alpha-\beta| \log y$. We simplify this using the bound for $|\alpha-\beta|$ we just derived: $1+E \asymp_{\varepsilon} 1$ implies $|\alpha-\beta|<_{\varepsilon}\left(\left|\frac{G^{\prime}}{G}(\alpha, y)\right|+1\right) /((\log x)(\log y))$. To study $E^{\prime}$ we argue similarly using the relation

$$
(\beta-\alpha) g^{\prime \prime}\left(t^{\prime}\right)=-\left(\zeta^{\prime} / \zeta\right)(\alpha, y)+\left(\zeta^{\prime} / \zeta\right)(\beta, y)=\left(G^{\prime} / G\right)(\beta, y)+A(\beta)
$$

for some $t^{\prime}$ between $\alpha$ and $\beta$. This shows $1+E^{\prime}=g^{\prime \prime}(\alpha) / g^{\prime \prime}\left(t^{\prime}\right)$.
7.2. Proof of Lemma 3.5 - second part. We approximate $g$ at $\alpha$ using a quadratic Taylor polynomial:

$$
g(\beta)-g(\alpha)=\frac{g^{\prime \prime}(\alpha)(\beta-\alpha)^{2}}{2}\left(1+O_{\varepsilon}\left(\frac{\left|g^{(3)}(t)\right||\alpha-\beta|}{(\log x)(\log y)}\right)\right)
$$

for some $t$ between $\alpha$ and $\beta$. By Lemma 7.1, $g^{(3)}(t)<_{\varepsilon}(\log x)(\log y)^{2}$ and we bound $|\alpha-\beta|$ using (3.5). Alternatively, $g(\beta)-g(\alpha)=g^{\prime \prime}(t)(\beta-\alpha)^{2} / 2$ for some $t$ between $\alpha$ and $\beta$, and we appeal to Lemma 7.1 with $k=2$. The same arguments work for $f(\alpha)-f(\beta)$.
7.3. Proof of Lemma 3.5 - third part. The square of $B$ can be written as

$$
B^{2}(x, y)=\frac{f^{\prime \prime}(\beta)}{g^{\prime \prime}(\alpha)}=1+\frac{f^{\prime \prime}(\beta)-g^{\prime \prime}(\alpha)}{g^{\prime \prime}(\alpha)} .
$$

To prove (3.7) we estimate the numerator and denominator using (2.3) and (2.9), respectively. This also shows $B(x, y)$ is bounded when $y \geq \varepsilon \log x$. We turn to (3.6). The denominator is $\asymp_{\varepsilon}(\log x)(\log y)$ by Lemma 7.1 and the numerator is estimated in Lemma 7.3 in terms of $\alpha-\beta$ and $(\log G)^{(2)}$. Estimating $\alpha-\beta$ using (3.5) gives (3.6).
7.4. Proof of Proposition [2.7. The range $2 \log x \geq y>1+\log x$ is already in Lemma 2.6 because $\alpha \asymp 1 / \log y$ in this range by (2.10). If $\log y \leq \sqrt{\log x}$ and $y \geq 2 \log x$, we make use of the Main Theorem of Saha, Sankaranarayanan and Suzuki [24], which in the current range gives

$$
\Psi(x, y)=\frac{x^{\alpha} \zeta(\alpha, y)}{\alpha \sqrt{2 \pi \phi_{2}(\alpha, y)}}\left(1+\frac{g^{(4)}(\alpha)}{8 g^{(2)}(\alpha)^{2}}-\frac{5 g^{(3)}(\alpha)^{2}}{24 g^{(2)}(\alpha)^{3}}+O\left(\frac{1}{\alpha \log x}\right)\right)
$$

We also use Smida's result [26, Thm. 1]

$$
\rho(u)=\frac{e^{\gamma-u \xi+I(\xi)}}{\sqrt{2 \pi I^{\prime \prime}(\xi(u))}}\left(1+\frac{f^{(4)}(\beta)}{8 f^{(2)}(\beta)^{2}}-\frac{5 f^{(3)}(\beta)^{2}}{24 f^{(2)}(\beta)^{3}}+O\left(u^{-2}\right)\right)
$$

We divide these two estimates to get the formulas in Lemma [2.6, with the term $1+O\left(u^{-1}\right)$ replaced by

$$
1+\frac{1}{8}\left(\frac{g^{(4)}(\alpha)}{g^{(2)}(\alpha)^{2}}-\frac{f^{(4)}(\beta)}{f^{(2)}(\beta)^{2}}\right)-\frac{5}{24}\left(\frac{g^{(3)}(\alpha)^{2}}{g^{(2)}(\alpha)^{3}}-\frac{f^{(3)}(\beta)^{2}}{f^{(2)}(\beta)^{3}}\right)+O\left(\frac{1}{\alpha \log x}\right)
$$

This is estimated in Lemma 7.3 as $1+O(1 /(\alpha \log x))$ once we invoke (3.5), (2.14) and (2.17).
It remains to consider $\log y>\sqrt{\log x}$. By Lemma 3.5, (2.14) and (2.17), the quantities $g(\alpha)-g(\beta), f(\alpha)-f(\beta), B(x, y)-1$ and $(\beta-\alpha) / \alpha$ are $O(1 / \log x)$, so we need to show

$$
\begin{equation*}
\Psi(x, y)=x \rho(u) K(\beta-1)(1+O(1 / \log x))=x \rho(u) K(\alpha-1)(1+O(1 / \log x)) \tag{7.7}
\end{equation*}
$$

By [12, Prop. A.5],

$$
\Psi(x, y)=x \rho(u) K(\widetilde{\beta}-1)\left(1+O\left(\frac{1}{(\log x)(\log y)}+\frac{y}{x \log x}\right)\right)
$$

for $\widetilde{\beta}:=1+\rho^{\prime}(u) /(\rho(u) \log y)$. This implies the first equality in (7.7) since $-\rho^{\prime}(u) / \rho(u) \in$ $[\xi(u), \xi(u+1)]=[\xi(u), \xi(u)+O(1 / u)][11$, Lem. 2] [17, Lem. 1] and so $\widetilde{\beta}=\beta+O(1 / \log x)$. By (3.5), the first equality in (7.7) implies the second.

Acknowledgements. We are grateful to Sacha Mangerel for asking us about the integer analogue of [13], sparking this work, and to Andrew Granville for discussions on exposition. We thank the referees for a careful reading of the manuscript and useful suggestions.

## Appendix A. Proof of Lemma 5.2

We follow the proof of [23, Thm. 12.5]. We apply [23, Cor. 5.3] with $\sigma_{0}=\max \{0,1-$ $\Re s\}+1 / \log x$ and $a_{n}=\Lambda(n) n^{-s}$ to obtain

$$
\begin{align*}
S_{1}(x, s) & =\frac{1}{2 \pi i} \int_{\sigma_{0}-i T}^{\sigma_{0}+i T}-\frac{\zeta^{\prime}(s+w)}{\zeta(s+w)} x^{w} \frac{d w}{w}+E_{s}  \tag{A.1}\\
E_{s} & \ll \sum_{\substack{x / 2<n<2 x \\
n \neq x}} \frac{\Lambda(n)}{n^{\Re s}} \min \left\{1, \frac{x}{T|x-n|}\right\}+\frac{x^{\sigma_{0}}}{T}\left(-\frac{\zeta^{\prime}}{\zeta}\right)\left(\sigma_{0}+\Re s\right) .
\end{align*}
$$

In the sum over $(x / 2,2 x)$ we consider separately $n=x^{\prime}$ and $n \neq x^{\prime}$. We find

$$
E_{s} \ll(\log x) x^{\prime \Re s} \min \left\{1, \frac{x}{T\langle x\rangle}\right\}+\frac{2^{|\Re s|} x^{1-\Re s} \log ^{2} x}{T}+\frac{x^{\sigma_{0}}}{T}\left(-\frac{\zeta^{\prime}}{\zeta}\right)\left(\sigma_{0}+\Re s\right) .
$$

We use $-(\zeta / \zeta)^{\prime}(t) \asymp(t-1)^{-1}$ for $t \in(1,2]$ and $-\left(\zeta^{\prime} / \zeta\right)(t) \asymp 2^{-t}$ for $t \geq 2$ to find that $E_{s}$ can be absorbed in $R_{1}(x, T, s)$. Recall $T \geq 2+|\Im s|$. By [23, Lem. 12.2], there are $T_{1}, T_{2} \in[T, T+1]$ such that

$$
\begin{equation*}
\frac{\zeta^{\prime}}{\zeta}\left(\sigma+i \Im s-i T_{2}\right), \frac{\zeta^{\prime}}{\zeta}\left(\sigma+i \Im s+i T_{1}\right) \ll \log ^{2} T \tag{A.2}
\end{equation*}
$$

uniformly for $-1 \leq \sigma \leq 2$. We extend the range of integration in (A.1) from $|\Im w| \leq T$ to $-T_{2} \leq \Im w \leq T_{1}$. The error we incur is at most

$$
\ll \frac{x^{\sigma_{0}}}{T}\left(-\frac{\zeta^{\prime}}{\zeta}\right)\left(\sigma_{0}+\Re s\right)
$$

which can be absorbed in our bound for $E_{s}$. Let $K>-\Re s$ denote an odd positive integer which will be taken to $\infty$, and let $\mathcal{C}$ denote the contour consisting of three line segments,
connecting $\sigma_{0}-i T_{2},-K-\Re s-i T_{2},-K-\Re s+i T_{1}, \sigma_{0}+i T_{1}$, in this order. Cauchy's residue theorem shows that

$$
\begin{aligned}
& \frac{1}{2 \pi i} \int_{\sigma_{0}-i T_{2}}^{\sigma_{0}+i T_{1}}-\frac{\zeta^{\prime}(s+w)}{\zeta(s+w)} x^{w} \frac{d w}{w}=\frac{x^{1-s}}{1-s}-\frac{\zeta^{\prime}(s)}{\zeta(s)} \\
&-\sum_{-T_{2}<\Im(\rho-s)<T_{1}} \frac{x^{\rho-s}}{\rho-s}+\sum_{1 \leq k<K / 2} \frac{x^{-2 k-s}}{2 k+s}+\frac{1}{2 \pi i} \int_{\mathcal{C}}-\frac{\zeta^{\prime}(s+w)}{\zeta(s+w)} x^{w} \frac{d w}{w}
\end{aligned}
$$

if $s \neq 1$. If $s=1$, the integrand has a double pole at $w=0$ and $x^{1-s} /(1-s)-\zeta^{\prime}(s) / \zeta(s)$ should be replaced with the residue $\log x-\gamma$. We shorten the sum over $-T_{2}<\Im(\rho-s)<T_{1}$ to one over $-T \leq \Im(\rho-s) \leq T$, and the incurred error is

$$
\ll \sum_{\Im(\rho-s) \in\left(T, T_{1}\right) \cup\left(-T_{2},-T\right)} \frac{x^{1-\Re s}}{|\rho-s|} \ll \frac{x^{1-\Re s} \log T}{T}
$$

which is acceptable. It remains to bound the integral over $\mathcal{C}$. To bound its horizontal parts, we consider separately three ranges of $\Re w \in\left[-K-\Re s, \sigma_{0}\right]$. The contribution of $\Re w \in\left[-1-\Re s, \min \left\{2-\Re s, \sigma_{0}\right\}\right]$ can be bounded using (A.2):

$$
\frac{1}{2 \pi i} \int_{-1-\Re s+i T_{1}}^{\min \left\{2-\Re s, \sigma_{0}\right\}+i T_{1}}-\frac{\zeta^{\prime}(s+w)}{\zeta(s+w)} x^{w} \frac{d w}{w} \ll \frac{\log ^{2} T}{T} \frac{x^{\min \left\{2-\Re s, \sigma_{0}\right\}}}{\log x}
$$

and the same bound holds if $T_{1}$ is replaced with $-T_{2}$. This error is acceptable.
Next, the contribution of $\Re w \in\left(2-\Re s, \sigma_{0}\right]$ should only be considered if this is a nonempty interval, i.e. when $\Re s>2-1 / \log x$. In this case, we use $-\zeta^{\prime}(t) / \zeta(t) \ll 2^{-t}(t \geq 2)$ to estimate the integral as

$$
\frac{1}{2 \pi i} \int_{2-\Re s+i T_{1}}^{\sigma_{0}+i T_{1}}-\frac{\zeta^{\prime}(s+w)}{\zeta(s+w)} x^{w} \frac{d w}{w} \ll \frac{2^{-\Re s}}{T} \frac{(x / 2)^{\sigma_{0}}}{\log x} \ll \frac{2^{-\Re s}}{T}
$$

which is acceptable. The same bound holds if $T_{1}$ is replaced with $-T_{2}$. To bound the contribution of $\Re w \in[-K-\Re s,-1-\Re s]$ we make use of [23, Lem. 12.4] which says that $\left(\zeta^{\prime} / \zeta\right)(z) \ll \log (|z|+1)$ holds for all $z$ with $\Re z \leq-1$ and $\min _{k \geq 1}|z+2 k| \geq 1 / 4$, and so

$$
\frac{1}{2 \pi i} \int_{-K-\Re s+i T_{1}}^{-1-\Re s+i T_{1}}-\frac{\zeta^{\prime}(s+w)}{\zeta(s+w)} x^{w} \frac{d w}{w} \ll \int_{-K}^{-1} \log (T+|a|) \frac{x^{a-\Re s}}{T} d a \ll \frac{\log T}{T} \frac{x^{-1-\Re s}}{\log x}
$$

which is acceptable. The same bound holds if $T_{1}$ is replaced with $-T_{2}$. The integral over the vertical part of $\mathcal{C}$ is bounded using $\left(\zeta^{\prime} / \zeta\right)(z) \ll \log (|z|+1)$ again:

$$
\frac{1}{2 \pi i} \int_{-K-\Re s-i T_{2}}^{-K-\Re s+i T_{1}}-\frac{\zeta^{\prime}(s+w)}{\zeta(s+w)} x^{w} \frac{d w}{w} \ll \frac{\log (K T)}{K+\Re s} x^{-K-\Re s} \int_{-T_{2}}^{T_{1}} d t \ll \frac{T \log (K T) x^{-K-\Re s}}{K+\Re s} .
$$

When we let $K$ tend to $\infty$, this bound tends to 0 .
