# ALGEBRAIC RESULTS ON SP NUMBERS ALONG WITH A GENERALIZATION 

RAGHAVENDRA N BHAT, SUNDARRAMAN MADHUSUDANAN

#### Abstract

We defined numbers of the form $p \cdot a^{2}$ as SP numbers (Square-Prime numbers) ( $a \neq 1, p$ prime) in 1 along with proofs on their distribution. Some examples of SP Numbers : $75=3 \cdot 25 ; 108=3 \cdot 36 ; 45=5 \cdot 9$. These numbers are listed in the OEIS as A228056 [2]. In this paper, we will prove a few algebraic theorems and generalize the definition of SP Numbers to allow factors of arbitrary natural number powers.

## 1. Introduction and Summary of Previous results

In our previous paper titled 'Distribution of square-prime numbers' [1] we introduced the notion of a product of a prime and a square, with the square not being 1 . We call these SP numbers.

Here are the first 25 SP numbers: $8,12,18,20,27,28,32,44,45,48,50,52,63,68,72,75$, $76,80,92,98,99,108,112,116,117$.

In the paper we mainly proved three results. Firstly, SP numbers have an asymptotic distribution similar to prime numbers, meaning, for a large natural number $n$, the number of SP numbers smaller than $n$ is asymptotic to $\frac{n}{\log n}$, as with the case of primes. We denote the number of SP numbers smaller than $n$ by $S P(n)$. The result derived in the paper is $S P(n)=(\zeta(2)-1) \cdot \frac{n}{\log n}+O\left(\frac{n}{\log n^{2}}\right)$. We see that although asymptotically similar to the distribution of primes, the actual value of $S P(n)$ is lower than $\pi(n)$ for large $n$, since $\zeta(2)-1<1$.

Secondly, there are infinitely many pairs of SP numbers that are consecutive natural numbers. We call these SP twins. An example is $(27,28)$. More generally, we showed that if $S P_{1}$ and $S P_{2}$ are SP Numbers, the equation $S P_{1}-S P_{2}=g$, where $g \in \mathbb{N}$ has infinite solutions if it has one solution. Here $g$ is the gap between the two SP Numbers.

Thirdly, we analyzed techniques to give asymptotic estimates for number of SP numbers having a certain last digit. For example, the number of SP numbers ending in 1 approaches $\frac{1}{400} \frac{n}{\log n}(\zeta(2,1 / 10)+\zeta(2,9 / 10)+\zeta(2,3 / 10)+\zeta(2,7 / 10)-4)$.

In this paper, our goal is to study algebraic properties of SP numbers, their gaps and also their structure with regard to square-free numbers. Analogies to famous prime number conjectures
like the $x^{2}+1$ conjecture and primes between squares are studied. We then generalize the idea of a square multiplied by a prime to any power of a natural number multiplied by a prime.

## 2. Algebraic SP Theorems

Theorem 2.1: For any positive integer $x$, there exist at least one pair of SP numbers $(a, b)$ such that $a-b=x$.

Proof. We will divide all positive integers into five groups. We will then prove the existence of one pair of $S P$ numbers with difference $x$ in each group.

- $\mathbf{x}=1: 28-27=1$. Thus, there exists an $S P$ pair with difference 1.
- x is prime: Consider the following Pell's equation

$$
\begin{equation*}
m^{2}-p x n^{2}=1 \tag{3}
\end{equation*}
$$

where $p \in \mathbf{P} \neq x$. We know from Chakravala that (3) has at least 1 positive integer solution. Let that solution be $(M, N)$. Thus,

$$
\begin{gather*}
M^{2}-p x N^{2}=1  \tag{4}\\
\Rightarrow x M^{2}-p x^{2} N^{2}=x \Rightarrow x M^{2}-p(x N)^{2}=x \tag{5}
\end{gather*}
$$

Thus, we have generated two $S P$ numbers, $x M^{2}$ and $p(x N)^{2}$ that differ by $x$. Since $x$ was an arbitrary prime, this case holds.

- $\mathbf{x}$ is an odd composite square free number : Thus we have $x=p_{1} \cdot p_{2} \cdot \ldots \cdot p_{n}$, where $p_{1}, p_{2} \ldots, p_{n}$ are all odd prime numbers. Let $p_{1}$ be the smallest prime factor of $x$. Thus $p_{1} \geq 3$ and $p_{2}, p_{3}, \ldots p_{n}>3$. Thus we can write

$$
x=p_{1} \cdot y
$$

where $y=p_{2} \times p_{3} \times \ldots \times p_{n}$. And since $p_{2}, p_{3}, \ldots p_{n}>3, y>3$. Furthermore, since $y$ is a product of odd prime numbers, $y$ has to be odd. Thus, we can also write the above equation as

$$
x=p_{1} \cdot(2 k+1)
$$

And again, since $y>3$, we have $k>1$.

$$
x=p_{1} \cdot\left[(k+1)^{2}-k^{2}\right] \Rightarrow x=p_{1} \cdot(k+1)^{2}-p_{1} \cdot k^{2}
$$

And since $k>1$ and $p_{1}$ is prime, by definition $p_{1} \cdot(k+1)^{2}$ and $p_{1} \cdot k^{2}$ are both $S P$ numbers with difference $x$. This case holds.

- $\mathbf{x}$ is an even composite square free number : This means $x=p_{1} \cdot p_{2} \cdot \ldots \cdot p_{n}$, where $p_{1}=2$ and $p_{2}, p_{3} \ldots p_{n}$ are all odd prime numbers. Thus $p_{2}, p_{3}, \ldots p_{n} \geq 3$. Thus, as previously written,

$$
x=2 \times y
$$

where $y=p_{2} \times p_{3} \times \ldots \times p_{n}$. And since $p_{2}, p_{3}, \ldots p_{n} \geq 3, y \geq 3$. Furthermore, since $y$ is a product of odd prime numbers, $y$ is odd. Thus, we can also write the above equation as

$$
x=2 \cdot(2 k+1)
$$

And again, since $y \geq 3$, we have $k \geq 1$. The above equation simplifies to

$$
x=2 \cdot\left[(k+1)^{2}-k^{2}\right] \Rightarrow x=2 \cdot(k+1)^{2}-2 \cdot k^{2}
$$

Note that in the previous case we had $k>1$ and here, we have $k \geq 1$. This is an issue because, when $k=1,2 \cdot k^{2}$ will be 2 which is not an $S P$ number. Note that

$$
k=1 \Rightarrow y=3 \Rightarrow p_{2} \cdot p_{3} \cdot \ldots \cdot p_{n}=3 \Rightarrow p_{2}=3
$$

since 3 is prime and has only 1 factor. Thus, except in the case where $p_{1}=2, p_{2}=3$, this proof works exactly like the previous case.
Now, let us look at $p_{1}=2, p_{2}=3$, or in other words, $x=p_{1} \cdot p_{2}=6.18-12=6$ and $18=2 \cdot 3^{2}, 12=3 \cdot 2^{2}$.
Since 6 was the only integer in this group for which the general method did not work, we can combine the previous 2 paragraphs to jointly say that for every even composite square free integer $x$, there exists a pair of SP numbers $(a, b)$ such that $a-b=x$.

- $\mathbf{x}$ is a non square free number : By the property of non square free numbers, we can write $x=t^{2} \cdot s$ where $s$ is a square free number. Now, using the result from the four cases above, we can say that for all $s$, there exists a pair of $S P$ numbers $(j, k)$ such that

$$
s=j-k \Rightarrow t^{2} \cdot s=t^{2} \cdot j-t^{2} \cdot k \Rightarrow x=t^{2} \cdot j-t^{2} \cdot k
$$

Since $(j, k)$ are $S P$ numbers, $\left(t^{2} \cdot j\right.$ and $\left.t^{2} \cdot k\right)$ are both $S P$ numbers having difference $x$. Thus, for every non square free integer $x$, there exists a pair of $S P$ numbers $(a, b)$ such that $a-b=x$.
Combining all the groups above, we can say that for any positive integer $x$, there exist at least one pair of SP numbers $(a, b)$ such that $a-b=x$.

Theorem 2.2: There are infinitely many SP Numbers of the form $x^{2}+1$.
Proof. Our goal is to show that the equation $x^{2}+1=p a^{2}$ has infinitely many solutions where $a, x \in \mathbb{N}$ and $p$ is prime. We start the proof with the knowledge that at least one solution already exists (we have 50,325 and 1025 as the first 3 SP Numbers of the form $x^{2}+1$ ).

$$
m^{2}-2 n^{2}=-1
$$

has a solution, namely $(7,5)$. Let $(A, B)=(7,5)$. Now, consider the equation

$$
m^{2}-2 n^{2}=1
$$

We know the above Pell's equation has infinitely many solutions. Let $(X, Y)$ be an arbitrary solution to the above equation. Thus, we have the following 2 equations:

$$
\begin{equation*}
A^{2}-2 B^{2}=-1 \tag{1}
\end{equation*}
$$

$$
\begin{equation*}
X^{2}-2 Y^{2}=1 \tag{2}
\end{equation*}
$$

Multiplying (1) and (2), we get

$$
\left(A^{2}-2 B^{2}\right)\left(X^{2}-2 Y^{2}\right)=-1 \Rightarrow(A X+2 B Y)^{2}-2(A Y+B X)^{2}=-1
$$

Thus, for every one of the infinite solutions of the Pell's equation $(X, Y)$, we have a new solution for the equation:

$$
m^{2}-2 n^{2}=-1 \Rightarrow 2 n^{2}=m^{2}+1
$$

Thus, there are infinitely many SP numbers of the form $x^{2}+1$.

Theorem 2.3 : For any positive integer $x$, there exists at least one $S P$ number between $x^{2}$ and $(x+2)^{2}$.

Proof. Consider the sub-sequence of $S P$ numbers $8,18,32,50,72,98,128,162, \ldots$. All of them are of the form $2 n^{2}$. Notice that $2 n^{2}$ lies between $x^{2}$ and $(x+2)^{2}$ if and only if $n \sqrt{2}$ lies between $x$ and $x+2$.

Thus, we now need to prove that for any positive integer $x$, there exists at least one positive integer $n$ such that $n \sqrt{2}$ lies between $x$ and $(x+2)$. We will prove this using contradiction.

Assume that there exists a positive integer $x$ such that the smallest multiple of $\sqrt{2}$ greater than $x$ is greater than $x+2$. Let this multiple be $a \sqrt{2}$ This means there is no multiple of $\sqrt{2}$ in $[x, x+2]$. But then,

$$
(a-1) \sqrt{2}<x<x+2<a \sqrt{2} \Rightarrow a \sqrt{2}-(a-1) \sqrt{2}>x+2-x \Rightarrow \sqrt{2}>2
$$

which is a contradiction.

Theorem 2.4 : All $S P$ numbers of the form $p a^{2}$, where $p$ is a prime and $a$ has at least one prime factor of the form $4 k+1$ can be written as a sum of $2 S P$ numbers.

Proof. By the 2 squares theorem, if $4 k+1$ is a prime, $(4 k+1)^{2}$ can be written as $x^{2}+y^{2}$, where $x, y>1$. Now, since $4 k+1$ is a factor of $a$, we can write

$$
\begin{gathered}
a=n \cdot(4 k+1) \Rightarrow p a^{2}=p n^{2} \cdot(4 k+1)^{2} \\
\Rightarrow p a^{2}=p n^{2} \cdot\left(x^{2}+y^{2}\right) \Rightarrow p a^{2}=p \cdot(n x)^{2}+p \cdot(n y)^{2}
\end{gathered}
$$

We now have our original $S P$ number $p a^{2}$ as a sum of two $S P$ numbers $p \cdot(n x)^{2}$ and $p \cdot(n y)^{2}$

## 3. SP Numbers of the form $x^{3}+1$

Conjecture 3.1: There are infinitely many SP Numbers of the form $x^{3}+1$, if the Bunyakovsky [3] conjecture is true.

Proof. Let $x=t^{2}-1$ for $t \in \mathbb{N}$.
We have $x^{3}+1=(x+1)\left(x^{2}-x+1\right) \Rightarrow x^{3}+1=t^{2} \cdot\left(t^{4}-3 t^{2}+3\right)$
Consider $f(t)=t^{4}-3 t^{2}+1$. It satisfies the following 3 properties of the Bunyakovsky conjecture:

1) The leading coefficient is positive.
2) The polynomial is irreducible over integers.
3) $G C D(f(2), f(3))$ is 1 and the coefficients of $f(x)$ are relatively prime.

Using the above three conditions, it follows from the Bunyakovsky conjecture that $f(t)$ is prime for infinitely many positive integers $t$. This implies $t^{2} \cdot\left(t^{4}-3 t^{2}+3\right)$ is of the form prime $\cdot t^{2}$ for infinitely many $t$ which further implies there exists infinitely many $x=t^{2}-1$ such that $x^{3}+1$ is an SP number.

## 4. A generalization of SP Numbers

SP Numbers are those numbers that are of the form $p a^{2}$. We could extend the definition to numbers of the form $p a^{k}$ and get asymptotic estimates on their distribution. Let us call these numbers $\mathrm{KP}_{k}$ Numbers. SP Numbers are a special case of KP numbers and can be defined to be $\mathrm{KP}_{2}$. Trivially, the prime numbers and semi-prime numbers are $\mathrm{KP}_{0}$ and $\mathrm{KP}_{1}$ respectively. Let $K P_{k}(n)$ denotes the number of $\mathrm{KP}_{k}$ Numbers smaller than $n$. As proved in [1],

$$
K P_{2}(n)=(\zeta(2)-1) \frac{n}{\log n}+O\left(\frac{n}{\log ^{2} n}\right)
$$

Theorem 4.1 : For any $k$ greater than 1 ,

$$
K P_{k}(n)=(\zeta(k)-1) \frac{n}{\log n}+O\left(\frac{n}{\log ^{2} n}\right)
$$

Proof.

$$
K P_{k}(n)=\sum_{a=2}^{\sqrt{n / 2}} \pi\left(\frac{n}{a^{k}}\right)
$$

The error term remains to be $O\left(\frac{n}{\log ^{2} n}\right)$, as in [1]. The main term simplifies to

$$
\begin{gathered}
n \sum_{a=2}^{\log ^{2} n} \frac{1}{a^{k}\left(\log n-\log \left(a^{k}\right)\right)}=\frac{n}{\log n} \sum_{a=2}^{\log ^{2} n} \frac{1}{a^{k}\left(1-\frac{k \log a}{\log n}\right)} \\
\Rightarrow \frac{n}{\log n} \sum_{a=2}^{\log ^{2} n} \frac{1}{a^{k}}\left(1+O\left(\frac{\log a}{\log n}\right)\right) \\
=\frac{n}{\log n} \sum_{a=2}^{\log ^{2} n} \frac{1}{a^{k}}+O\left(\frac{n}{\log ^{2} n}\right) \leq \frac{n}{\log n} \sum_{a=2}^{\infty} \frac{1}{a^{k}}+O\left(\frac{n}{\log ^{2} n}\right)
\end{gathered}
$$

$$
=(\zeta(k)-1) \frac{n}{\log n}+O\left(\frac{n}{\log ^{2} n}\right)
$$

## 5. PSP Numbers

A special type of SP Numbers can be defined to be the product of a prime and a square such that the square is a prime square. An approach similar to the proof of Theorem 4.1 can be employed to get the asymptotic estimate of the count of PSP Numbers.

Theorem 5.1 : The number of PSP numbers smaller than $n$ is

$$
P(2) \frac{n}{\log n}+O\left(\frac{n}{\log ^{2} n}\right)
$$

where $P(2)$ is the prime zeta function of 2 .
Proof.

$$
\begin{gathered}
P S P(n)=\sum_{p=2}^{\sqrt{n / 2}} \pi\left(\frac{n}{p^{2}}\right), \text { where } p \text { is prime. } \\
\leq \frac{n}{\log n} \sum_{p=2}^{\infty} \frac{1}{p^{2}}+O\left(\frac{n}{\log ^{2} n}\right)=P(2) \frac{n}{\log n}+O\left(\frac{n}{\log ^{2} n}\right) .
\end{gathered}
$$

As a corollary (owing to Theorem 4.1), we have

$$
P K P_{k}(n)=P(k) \frac{n}{\log n}+O\left(\frac{n}{\log ^{2} n}\right)
$$

where PKP Numbers are numbers of the form $p_{1} p_{2}^{k}$, where $p_{1}$ and $p_{2}$ are arbitrary prime numbers and $P(k)$ is the prime zeta function of $k$.

## 6. Future work and Concluding Remarks

Conjecture 3.1 can be explored further via the use of elliptic curves. Trying to find an SP Number of the form $x^{3}+1$ is analogous to finding integer solutions to

$$
x^{3}+1=p a^{2} \Rightarrow p x^{3}+p=(p a)^{2}
$$

Letting $y=p a$, we have the elliptic curve equation

$$
y^{2}=p x^{3}+p
$$

Computational experiments have given us over 25 integer solutions to this equation. Potential future work can involve proving the existence of infinite integer solutions to the same.
